A person's attitude toward a computer is influenced by a variety of aspects, e.g., the social issues relating to computer use (Popovich et al., 1987), computer liking, computer confidence, computer anxiety or comfort (Delcourt & Kinzie, 1993; Loyd & Gressard, 1984a), achievement (Bandalos & Benson, 1990), usefulness, and value (Francis-Pelton & Pelton, 1996).

Computer Anxiety

According to Henderson et al. (1995) anxiety is viewed as "a drive that motivates the organism to avoid the stimulus for anxiety" (p. 24). This implies that an individual will avoid the use of a computer in the presence of computer anxiety and if possible.

Kaplan and Sadock (1998) referred to anxiety as "a diffuse, unpleasant, vague sense of apprehension, often accompanied by autonomic symptoms" (p. 581). Specifically, computer anxiety involves an array of emotional reactions, including fear, apprehension, uneasiness, and distrust of computer technology in general (Negron, 1995; Rohner & Simonson, 1981).

Computer anxiety is also influenced by a variety of aspects, e.g., general anxiety and confidence (Harrison & Rainer, 1992), computer liking (Chu & Spires, 1991; Loyd & Gressard, 1984b), impact of computers on society (Raub, 1981), equipment-related anxiety (Marcoulides, 1989), comfort and value (Violato et al., 1989), and corporate pressure.

The Relationship between Computer Attitude and Computer Anxiety

Computer anxiety is often included as a component of attitude (Delcourt & Kinzie, 1993; Loyd & Gressard, 1984a). Jawahar and Elango (2001) reported, however, that previous studies used the concepts of computer anxiety and negative attitudes toward computers interchangeably. Computer anxiety is, however, not solely responsible for a negative attitude. A person can have a negative attitude toward computers even though he or she is not overly anxious about using them. This may be because of a negative experience, e.g., an apologizing clerk blaming an erroneous account statement on the computer.

Furthermore, attitude allows for both a negative and a positive grading, whereas anxiety is, by definition, either negative or absent.

MAIN THRUST OF THE CHAPTER: A MODEL FOR INTERACTION

In order to indicate the various influences on the mental states of computer attitude and computer anxiety and the effect they have on a user's ability to execute computer-related tasks effectively, a model for interaction was developed (Figure 1).

The model shows interaction on three levels of abstraction. The right-hand column resembles a typical flow diagram but with an adapted convention. It shows the sequence of mental and operational events when a user is confronted with a task to be done on the computer. The diamond symbols do not represent conscious decisions but rather indicate general user behavior as determined by the user's current levels of computer attitude, computer anxiety, knowledge, and pressure experienced.

As an example of how to read the flow diagram, consider a user who has to perform a computer task. If his or her level of computer anxiety is not above a specific critical level (*D1*), he or she has a positive attitude toward computer tasks (*D2*). If he or she knows how to perform the task (*D4*), he or she will do the task (*P2*). If the user's knowledge is inadequate, this person will go through a process of learning (*P1*) until he or she can do the task. If the anxiety level is high (*D1*), the user will only use the computer if forced to do so (*D3*), or else he or she will opt out of the task or do it without a computer (*P3*).

The middle column in Figure 1 indicates the user's current levels of computer anxiety and computer attitude. The influence that computer anxiety and computer attitude have on each other as well as their influence on user behavior and the processes of learning and task execution is indicated with curved arrows (*E5–E11*). It is also clear that task execution (computer experience, *P2*) impacts computer attitude and anxiety in return (*E12–E13*).

The left-hand column shows the external processes and factors that influence a user's levels of computer attitude and anxiety.

Further discussion in this chapter serves to substantiate the claimed influences from the literature.

Factors that Determine Computer Attitude

Several studies have been undertaken to explore potential factors associated with a positive attitude toward computers (Brodt & Stronge, 1986; Scarpa et al., 1992; Sultana, 1990; Schwirian et al., 1989; Bongartz, 1988; Burkes, 1991). Some of the factors that were considered were level of education, years of experience in the work environment, computer experience, age, gender, and job title (*E3* and *E13*). The only factor that was repeatedly, although not consistently, found to have a positive effect on computer attitude, was computer experience (*E13*).

Causes of Computer Anxiety

According to Torkzadeh and Angulo (1992), there are three perspectives of computer anxiety: psychological (*E1*), sociological (*E1*), and operational (*E1* and *E12*). From a psychological perspective, users may fear that they will damage the computer, feel threatened when having to ask younger workers for help, or feel that they are losing control because computers are perceived as a threat to one's power and influence. From a sociological perspective, people have a need for social contact with other people, and because computers can change existing social patterns, they find the situation unbearable. People may also have a fear of computers replacing them. From an operational point of view, people want to avoid embarrassment connected with their inability to type or to use the keyboard. An initially confident user might be disillusioned with the complexity and sophistication of computer systems and procedures after a first experience (*E12*).

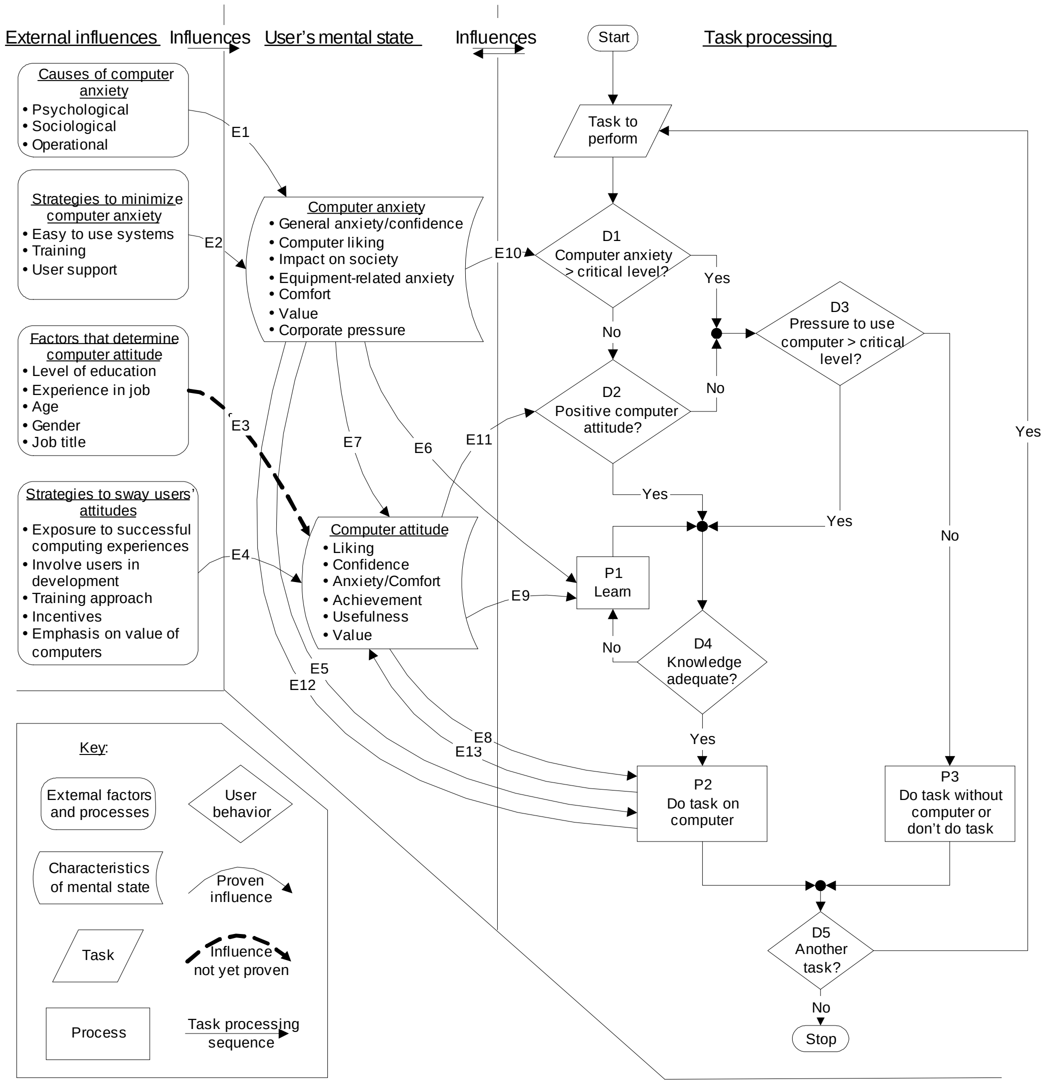
Effects of a Positive Attitude

According to Ngin et al. (1993), individuals with work excitement express creativity, receptivity to learning, and have the ability to see opportunity in everyday situations. Positive attitudes enhance the learning process (Shneiderman, 1980) (*E9*), specifically the motivation to learn and the ability to retain information in a given situation (Jawahar & Elango, 2001).

A negative attitude may lead to computer resistance (Sheiderman, 1980) (*D2*, *D3*, and *P3*), a phenomenon that can be found among experienced as well as inexperienced users (Negron, 1995). A negative attitude may even lead to defamation or sabotage of computer technology (Gibson & Rose, 1986).

A person's attitude toward computers and related technology could determine his or her performance with

Figure 1. Model for interaction



the technology and the satisfaction he or she draws from the experience (*E8*), although contradictory results are reported in the literature. Nickell and Pinto (1986) as well as Jawahar and Elango (2001) found a positive correlation between scores on a computer attitude scale and the final course grades of students enrolled in an introductory computer class. Other studies on students report an inverse relation between attitudes and performance (Hayek & Stephens, 1989; Marcoulides, 1988; Mawhinney & Saraswat, 1991), while still other researchers report no relationship between these two constructs (O'Quin et al., 1987; Kernan & Howard, 1990; Szajna & Mackay, 1995).

It was indicated above that scales to measure computer attitude differ with regard to the components they include. Jawahar and Elango (2001) also indicated that some tests measure attitudes toward working with computers, while others have components measuring general attitudes toward computers. These might be possible reasons for the contradictory results regarding the impact of computer attitude on computing performance. One cannot expect to obtain consistent results if the instruments used differ substantially from one another. This is one area in this field of research where agreement and subsequent standardization are yet to be achieved.

Impact of Computer Anxiety

Anxiety affects people's thinking, perception, and learning (Kaplan & Sadock, 1998). It also produces confusion and distortions of perception relating to time, space, people, and the meanings of events. These distortions usually have a negative effect on learning ability by lowering concentration, reducing recall ability, and impairing the ability to make associations (*E6*).

Specifically, computer anxiety can be recognized by a fear expressed regarding present or future interactions with computers or computer-related technology, negative global attitudes about computers (*E7*), or self-critical internal dialogues during computer interactions (Rosen & Weil, 1995).

People with computer anxiety experience the incidence of physical, phobic symptoms, such as stomach cramps and cold sweats, as well as psychological symptoms, such as a resistance to use and a negative attitude toward a system (Shneiderman, 1980).

Computer anxiety seems to be a good predictor of computer achievement (*E5*). Marcoulides (1988) found that computer anxiety influenced the effectiveness with which college students could utilize the computer. Rosen et al. (1987) also found that computer-anxious undergraduate students enrolled in computer-based courses were twice as likely to drop out of the course and received lower course grades than nonanxious students.

Although anxiety usually has a negative connotation, there appear to be optimal levels of anxiety that help people to function effectively (Higgins, 1989) and that make them more alert and aware of what is going on (Lugo & Hershey, 1981; Beck & Emery, 1985) (*E5*).

Strategies to Sway Users' Attitudes

Previously, it was indicated that a negative computer attitude might lead to computer resistance. It is, therefore, important to identify strategies to enhance or sway users' attitudes toward computer use. Possible strategies are as follows (*E4*):

- Expose the users to successful and positive computer experiences (Yaghmaie et al., 1998).
- Make users aware of the fact that their computer literacy would be an advantage in any future work environment (Emmet, 1988).
- Involve users actively in the implementation of computer systems (Barry & Gibbons, 1990).
- Emphasize the ease with which work can be accomplished using a computer function (Marasovic et al., 1997).
- In training, stress the fact that computer use leads to desired outcomes (Marasovic et al., 1997).
- Include in training programs activities aimed at increasing self-efficacy (Henderson et al., 1995).
- Introduce incentives in order to convince and motivate users (Sultana, 1990).
- Consider the user's attitude and motivation when system designers design the user interface (Galitz, 1997).

Strategies to Minimize Computer Anxiety

Computer anxiety is something that will not just disappear on its own, but it is something that has to be dealt with. It is considered to be a temporal emotional state rather than a permanent personality trait and, therefore, can be remedied through positive computing experiences (Cambre & Cook, 1987). Possible strategies are as follows (*E2*):

- Easy-to-use computer systems (Appelbaum & Primmer, 1990)
- Basic training for the most routine tasks (Cambre & Cook, 1987; Flaughler, 1986; Lewis, 1988)
- Advanced training, which is essential to keep users interested as they progress (Appelbaum & Primmer, 1990)
- User support in the form of manuals, consultants, user groups, and computer specialists (Appelbaum & Primmer, 1990)

FUTURE TRENDS

It was argued above that the variety with regard to components and focus of the scales used by researchers to measure computer attitudes might be responsible for the contradictory results regarding the impact of computer attitude on computing performance. If a measuring scale for both computer attitude and computer anxiety can be standardized, much of the current confusion that exists in the literature could be solved. For example, the definition of computer comfort as it is given under "Terms and Definitions" below is merely the opposite of that for computer anxiety. This means that a standardization of measuring scales would include a consolidation of terminology.

CONCLUSION

The use of a graphic model provides an efficient way of understanding the interaction between computer attitude and computer anxiety, together with their causes, indicators, impacts, and strategies to deal with them.

From this model, it can be deduced that there are two-way interactions between computer attitude and computer anxiety on the one hand and computer task execution on the other. A vicious circle can be established where anxiety inhibits performance (*E5*), which in turn, produces a negative attitude toward the system (*E13*) and further slows the process of learning to use the system (*E9*).

External strategies can be applied to reduce computer anxiety and sway users' attitudes toward the use of computers (*E1–E4*). This will then lead to better achievement (E5 and *E8*), which will, in turn, lead to self-confidence (*E12*) and appreciation of the value of computers in general (*E13*). Less anxiety and a positive attitude will support the learning process (*E6* and *E9*), which will eventually result in better achievement.

Because of the proven effect of computer experience on attitude, moderate pressure can be applied to ensure that users do not avoid the use of computers and, in this way, never get the opportunity to gain experience (*D3*). This pressure can be explicit by means of assignment or by applying measures to create intrinsic motivation so that the user drives him- or herself.

KEY TERMS

Computer Anxiety: A diffuse, unpleasant, and vague sense of discomfort and apprehension when confronted by computer technology or people who talk about computers.

Computer Attitude: A complex mental state that affects a human's choice of action or behavior toward computers and computer-related tasks.

Computer Comfort: The user does not experience any suffering, anxiety, pain, etc., when using a computer.

Computer Confidence: The user is confident that he or she would be able to master a required skill to solve a particular problem using a computer, e.g., learning how to use a specific facility of an application program or learning a programming language.

Computer Liking: The use of a computer to solve problems is enjoyable, stimulating, and even addictive.

Self-Efficacy: Measure of a person's belief and confidence that he or she can perform a certain task.

Usefulness: The user is convinced that the use of computers in the workplace is an efficient and effective means to solve problems.

Computer-Mediated Learning Groups

INTRODUCTION

Online learning has seen tremendous growth over the past decade in both the corporate and higher education sectors of society. This has been facilitated by rapid increases in the availability of computer- and network-based technologies for communication and sharing of information. The U.S. National Center for Educational Statistics (2003) recently reported that for the 2000-01 academic year, 2- and 4-year institutions offered over 127,000 different distance education (DE) courses and had over three million enrollments. Of the institutions offering DE courses, 90% reported using the Internet and asynchronous communication as an instructional delivery mode (National Center for Educational Statistics, 2003). In the corporate sector, the American Society for Training & Development reported record levels technology-mediated training (or e-learning) accompanied by slight decreases in face-to-face classroom training (Thompson, Koon, Woodwell, & Beauvais, 2002). At the same time, there has been an increased awareness among distance educators and researchers regarding the importance of human interaction in the learning process. These two trends have driven the study of computer-mediated communication (CMC) and computer support for collaborative learning (CSCL). Groupwork has long been an important instructional strategy used in face-to-face learning environments and is now being explored in computer-mediated environments. This article will define critical aspects of computer-mediated groupwork and outline benefits and challenges to using computer-mediated groups as an instructional strategy. Additional details for the research presented in this article can be found in full-length publications by the authors (Graham, 2002a, 2002b, 2003; Graham & Misanchuk, 2003).

BACKGROUND

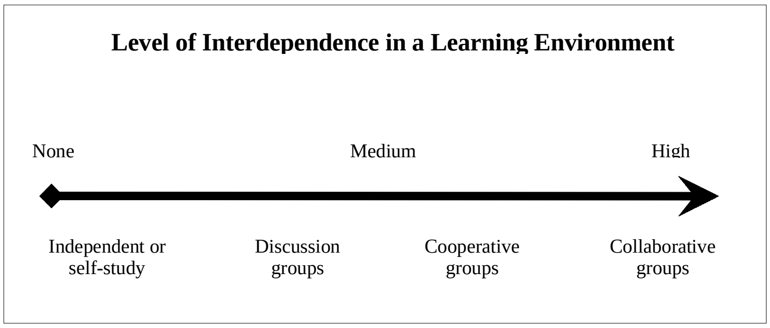
The first step to understanding the challenges and benefits of using computer-mediated learning groups is understanding the term itself. There are three important concepts embedded in the term *computer-mediated learning groups* that will be addressed in this section of the article. First is understanding what groups are and the role of interdependence in groupwork. Second is understanding the differences between *computer-mediated* groups and face-to-face groups. Lastly is the difference between *learning* groups and other types of groups such as *work* groups, an often overlooked distinction that has important implications for learning.

Interdependence in Groups

In a learning environment, there is a wide range of instructional strategies that emphasize interaction between individuals involved in the learning process. Interdependence can be defined *as the level of dependence between group members required to accomplish the desired learning outcome*, and is one of the most important characteristics defining the nature of the group interaction. Figure 1 depicts the spectrum of interdependence and some examples of different groups across that spectrum. At the low end of the spectrum, there is independent learning, which involves little or no interaction or dependence on others in the learning process. At the high end of the spectrum, instructional activities are highly dependent on collaborative interactions between group members.

Discussion groups appear at the lower end of the spectrum because participants are usually assessed based on their individual contributions and insights rather than the ability of the group to negotiate and come to a consensus or a common understanding of the discussion topic. Cooperative groups also have a lower level of interdependence than collaborative groups because they tend to divide the work into chunks that can be accomplished independently. There may be a high level of interaction at the administrative level in chunking and assigning tasks, but the majority of the work is done individually and then pieced together at the end, which also leads to a sense of individual accountability. Groups working collaboratively are more interdependent than cooperative groups. Rather than assigning individual tasks in a "divide and conquer" approach, they work through each of the tasks together as a group. Each

Figure 1. Different levels of interdependence in learning environments



participant's learning success depends on all other group members' efforts. Paulus (2004) asserts that students often default to a cooperative framework unless explicitly instructed to employ collaborative ways of working (Hathorn & Ingram, 2002; Kitchen & McDougall, 1999). This default behavior is mirrored in learning groups versus work groups, as explained in the following section.

Computer-Mediated vs. Face-to-Face Groups

The most common model of groupwork is in a face-to-face situation, whether it be in the workplace, classroom, committees, clubs, or other organizations. Indeed, many people have trouble envisioning successful interaction when group members are not co-located. However, the use of computer-mediated communication (CMC) tools to facilitate work has become more and more common in global business ventures, and is gaining acceptance in educational settings as well. Table 1 lists several of the most common tools used by distributed groups for communicating.

Groups may not necessarily need the most "enriched" mode of communication: often, a telephone conversation can accomplish as much as an elaborate videoconference.

Learning Groups vs. Work Groups

Much of the research literature related to computer-mediated groupwork looks at *work* groups as opposed to *learning* groups. There are important differences between the two that have an impact on how we understand

Table 1. Communication tools used by groups working at a distance

Synchronous	**Asynchronous**
• telephone (including multi-party calls) • instant messaging or other computer-mediated text (or voice) chat • two-way videoconferencing • electronic white-board tools	• email or listservs • voice mail messages • electronic bulletin boards/ discussion forums • commenting on documents using word processor tracking features • WebLogs (Blogs)

Table 2. Differences between typical work and learning groups

Work Group Characteristics	**Learning Group** Characteristics
• Hierarchical leadership structure • Clear role definitions • Cooperation maximizes productivity • Goals are product-oriented • Team members take on tasks that reflect skills and strengths already acquired • Focus is on the product or outcome	• Flat leadership structure • No role definitions • Collaboration maximizes learning • Goals are learning-oriented • Team members may accept tasks to gain skills they have not already acquired in order to learn • Focus is on the process or learning

this body of research. Table 2 outlines some common differences between *work* groups and *learning* groups.

For example, because the focus of a work group is typically product-oriented rather than learning-oriented, work groups often function more like cooperative groups (with the goal of maximizing productivity) than collaborative groups. Projects are often divided into tasks and assigned to the group members who already have the skills to accomplish the task. For example, a design group might have a project manager, an instructional designer, and a programmer, each with expertise and experience in their area. Learning teams, on the other hand, typically have a more process-oriented focus because they are interested in learning outcomes; indeed, in the ideal learning team, members who are inexperienced in a certain area will take on challenging tasks in order to improve their proficiency, which works directly against the productivity model. Work groups often have a hierarchical leadership structure with clear role definitions. In learning groups, leadership structures tend to be less hierarchical and formal because group members are peers with comparable levels of knowledge and expertise and roles may be arbitrarily assigned.

BENEFITS OF COMPUTER-MEDIATED LEARNING GROUPS

The use of learning groups has proven to be a powerful instructional tool in face-to-face contexts. There is an increasing awareness that learning groups can also have a positive impact on learning in a distributed, computer-mediated context. Table 3 summarizes three major benefits to using learning groups.

Challenges Associated with Computer-Mediated Learning Groups

There are three major areas that are important for successful implementation of groups in a computer-mediated environment (Graham, 2002a; Graham & Misanchuk, 2003):

1. Creating the groups
2. Structuring the learning activities
3. Facilitating group interactions

Table 4 identifies challenges associated with each of these major areas. This section will briefly address each of these challenges.

1. **Choosing Appropriate Group Size.** There is no ideal group size because appropriate group size is highly dependent on the learning context. Larger groups have a greater capacity for diversity of ideas and input at the increased cost of coordinating the group efforts. Prominent cooperative learning researchers have suggested that for learning effectiveness “the smaller [the group] the better” (Johnson, Johnson, & Holubec, 1994, p. 24). Size is a particularly important consideration in a computer-mediated environment where communication takes longer than in face-to-face environments (Bordia, 1997; Walther, 1996).
2. **Determining Group Composition.** Determining whether to create heterogeneous or homogeneous groups is an important consideration. Homogeneous groups tend to be more cohesive (Perrone & Sedlacek, 2000) while heterogeneous groups have the advantage of bringing different perspectives to the group discussion and work which can enrich

Table 3. Three major benefits for using computer-mediated learning groups

Benefits	Description
Learning Theory Perspective	Collaboration creates synergistic problem solving, making the group more than the sum of is parts (Brown et al., 1989) and requires students to present and defend their ideas, negotiating and constructing meaning.
Cooperative Learning Research	Johnson and Johnson (1996) found that group learning results in “significantly higher achievement and retention than does competitive and individualistic learning” (p.1022).
Learner Motivation	Cooperative experiences encourage more task orientation and personal social support than competitive or individualist environments and encourage students to monitor each others’ work (Johnson & Johnson, 1996).

Table 4. Six challenges to creating effective computer-mediated learning groups

Creating the Groups	Structuring Learning Activities	Facilitating Group Interactions
Choosing appropriate group size	Establishing an appropriate level of interdependence	Developing cooperative group skills
Determining group composition	Creating learner accountability	Establishing group norms

the learning experience (Cohen, 1994). Some differences that may be considered when forming groups are: demographic, content knowledge, technical skill level, location (time zones), and so forth. In a computer-mediated environment, spreading the individuals with high technical skills across groups can: (1) prevent the creation of some groups with all of the technical expertise and others with no technical expertise; and (2) allow skilled group members to mentor other group members in developing needed technology skills. Diversity of location (meaning different time zones) can present challenges for teams trying to coordinate work, especially if synchronous communication tools are used.

3. **Establishing an Appropriate Level of Interdependence.** One of the most difficult challenges with online learning groups is establishing an appropriate level of interdependence among group members. The tension that exists is between efficiency and learning. Higher levels of interdependence mean higher levels of collaboration (and thus communication) among learners. The learning task will dictate what portion of that communication will be directly related to learning and what portion will be required for task coordination and administration. The nature of the learning task will also determine whether interaction can be predominantly asynchronous or whether there needs to be a synchronous component. An appropriate goal would be to try to minimize time required for coordination efforts and maximize time spent directly engaged with the learning content.
4. **Creating Learner Accountability.** Closely linked to the issue of interdependence is the challenge of creating learner accountability in learning groups. Accountability should be addressed at both the group and individual level and determining the appropriate balance between the two is the challenge. Over-emphasizing group accountability can lead to problems such as social loafing or free-riding (Latane, Williams, & Harkins, 1979; Wagner, 1995) where certain individuals pull back from fully contributing to the group efforts. On the other hand, over-emphasizing individual accountability can undermine the cohesiveness of the group. The structure of assessment in the learning environment will have a big impact on learner accountability.
5. **Developing Cooperative Group Skills.** Students who have developed cooperative group skills are more likely to gain from their collaborative learning experience than others (Johnson & Johnson, 1987; Johnson & Johnson, 1999). Some important skills talked about in the literature are: decision making, consensus building, dealing with conflict, and basic communication skills (Graham, 2002a). One might expect adult learners to have already developed many of these skills or at least that the skills might transfer directly from prior experiences with face-to-face groups. However, communicating in an online environment without the body language and visual cues available requires different styles of communication and increased awareness of potential misunderstandings.
6. **Establishing Group Norms.** Norms are shared expectations that drive and inhibit the actions of group members. There are many types of norms including value norms, leadership and decision-making norms, communication norms, and logistical norms that are important for computer-mediated learning groups (Graham, 2002b). Establishing communication norms is particularly important for computer-mediated groups because without effective communication, the group cannot function properly. Online communication can be a challenge because of the many differences between computer-mediated and face-to-face communication, including lower fidelity interactions and slower communication speeds. Three areas that should be addressed in establishing explicit group norms are: (1) choosing modes of communication, (2) communicating the unseen, and (3) acknowledging communication (Graham & Misanchuk, 2003).

FUTURE TRENDS

Over the past decade there has been increased emphasis placed on the social nature of learning. The proliferation of tools that support human interaction and collaboration are on the rise. Tools that foster collaboration such as asynchronous discussion boards, instant messaging, personal blogs, wikis, groupware, and so forth, are becoming commonplace in both industry and educational settings. Groupwork is an important dimension of collaborative learning. Future research will continue to explore how to make learning in groups more effective. Additionally, research will continue to support the development of tools that facilitate group collaboration and work.

CONCLUSION

Groupwork is an important instructional strategy used in face-to-face learning environments. Groupwork is also being used with increased frequency in computer-mediated environments in both corporate and educational sectors of society. This article discussed three important characteristics of groups (interdependence, computer-mediated versus face-to-face interaction, and learning groups versus work groups). Also examined were both benefits and challenges of computer-mediated learning groups. This article identifies six challenges associated with forming and working in computer-mediated groups. Appropriate group size and composition must be considered in order to provide a synergistic learning environment. Learner interdependence and accountability must be balanced in order to maximize participants' investment in the learning process and responsibility for their own contributions. Learners must have experience—and oftentimes, instruction—in appropriate cooperative learning techniques for a computer-mediated environment. The establishment of group norms can help all group processes run more smoothly, especially in the situation of limited visual and non-verbal cues of online interaction.

KEY TERMS

Blog: Short for Weblog. A form of Web-based communication that has increased in popularity in the last several years. Blogs facilitate easy publishing and sharing of ideas between individuals.

Computer-Mediated Communication (CMC): "The communication produced when human beings interact with one another by transmitting messages via networked computers" (Herring, 2001, p. 612).

Computer Supported Collaborative Learning (CSCL): "CSCL is a field of study centrally concerned with meaning and the practices of meaning-making in the context of joint activity, and the ways in which these practices are mediated through designed artifacts" (Stahl, 2002, p. 1).

Cooperation & Collaboration: Although the terms cooperation and collaboration are often used interchangeably, cooperative interaction implies more of a "divide and conquer" approach while collaborative interaction implies a more integrated process where shared meaning or understanding of an event or product is created.

Interdependence: The level of dependence that one group member has on other group members in order to complete the learning tasks.

Learning Group: A group of people, often with a fluid hierarchy and shifting roles, whose emphasis is learning before efficiency. The focus is on the process (the product being secondary), with the idea that the best learning outcomes will occur when participants take on challenges and unfamiliar tasks in order to gain competency in new areas.

Norms: Shared expectations that constrain and drive the action of group members.

Virtual Team: A team with members that are not co-located and so use technology to communicate and conduct their work. (This term is predominantly used in the corporate literature and means the same thing as computer-mediated team.)

Wiki: A Website to which many authors can contribute using a simple browser interface that allows them to modify existing pages.

Work Group: A group of people, often with a distinct hierarchy and role structure, whose emphasis is efficiency before learning. Focus is on the outcome and productivity, with the idea that the best product will be most efficiently created when everyone works using their present strengths.

Computing Curriculum Analysis and Development

Anthony Scime
State University of New York College at Brockport, USA

INTRODUCTION

Information technology (IT) is an umbrella term that encompasses disciplines dealing with the computer and its functions. These disciplines originated from interests in using the computer to solve problems, the theory of computation, and the development of the computer and its components.

Professionals from around the world with similar interests in IT came together and formed international professional organizations. The professional organizations span the disciplines of computer engineering (CE), computer science (CS), software engineering (SE), computer information systems (CIS), management information systems (MIS), and information technology (IT) (Freeman & Aspray, 1999). Note that information technology is both an umbrella term and a specific discipline under that umbrella.

These organizations exist to promote their profession and one method of promotion is through education. So, these professional organizations defined bodies of knowledge around the computer, which have been formalized and shaped as model curriculums. The organizations hope that colleges and universities will educate students in the IT disciplines to become knowledgeable professionals.

Because of the common interest in computing, there is a basic theory and a common technical core that exists among the model curricula (Denning, 1999; Tucker et al., 1991). Nevertheless each of the model curricula emphasizes a different perspective of IT. Each fills a different role in providing IT professionals. It falls upon the colleges and universities to select and modify the corresponding curriculum model to fit their needs.

BACKGROUND

Currently, there are a number of model curricula for computing (Table 1). A Joint Task Force on Computing Curricula created by the Association for Computing Machinery (ACM), and the IEEE Computer Society (IEEE-CS) developed Computing Curricula 2001 (CC 2001). This model focuses on programs in theoretical and applied computer science with various areas of emphasis in all areas of computing including computer engineering (CE), the engineering of computer hardware, and computer science (CS), the theory and design of hardware and software (Computing Curricula, 2001).

The field of information systems (IS) can be divided into the management of information systems (MIS), the engineering of computer information systems (CIS) and the use of existing commercial software applications to solve organizational problems or information technology (IT). The Information Resource Management Association (IRMA) and the Data Administration Managers Association (DAMA) have a curriculum model for MIS known as the Information Resource Management (IRM) model. It takes a management of data approach to information systems (Cohen, 2000). For a strong accounting and management MIS orientation, the Information Systems Auditing and Control Foundation has developed an interdisciplinary curriculum known as the Information Systems Auditing at the Undergraduate and Graduate Levels (ISA) model (ISACF, 1998).

IS 2002 (Information Systems, 2002) is a model curriculum developed through the joint efforts of the ACM, the Association for Information Systems (AIS), and the Association of Information Technology Professionals (AITP). This curriculum model focuses on information systems development as well as on management (Gorgone, Davis, Valacich, Topi, Feinstein, & Longenecker, 2002). The Information Systems Centric Curriculum (ISCC '99) model was developed by a task force that included members from academe and industry. It is oriented to large-scale system design and implementation. The focus is on the construction of the tools necessary for information management (Lidtke, Stokes, Haines, & Mulder, 1999).

The IT education special interest group of the ACM (SIGSITE) has developed a curriculum proposal. This curriculum is oriented toward the use of computing applications to solve organizational problems (IT Curriculum Proposal – Draft, 2002). An existing IT model is the Organizational and End User Information Systems (OEIS) model developed by the Office Systems Research Association. It is aimed at IT support of end-users. (Office Systems Research Association, 1996).

The Software Engineering Institute (SEI) has developed a model that follows the engineering approach of

Table 1. IT professional organizations and curriculum models

Professional Organization	Curriculum Models

An independent group of Academics and Professionals	Information Systems Centric Curriculum '99 (ISCC '99)

design first in the construction of software for embedded, large, and critical systems. The model strongly suggests specialization in a specific application domain (Bagert, Hilburn, Hislop, Lutz, McCracken, & Mangal, 1999).

Internationally, the International Federation for Information Processing (IFIP) in coordination with the United Nations Educational, Scientific and Cultural Organization (USESCO) has developed a framework within which schools can develop an IT curriculum (Mulder & van Weert, 2000). The Informatics Curriculum Framework 2000 (ICF-2000) considers the needs of developing countries for IT knowledgeable workers. These needs are balanced against the country's educational resources. The result is a tailored IT curriculum based on the established models.

CONSIDERATIONS IN DEVELOPING A CURRICULUM

To select or develop a curriculum, a school needs to assess their objectives and capabilities in providing graduates to the IT work force. A school with a strong liberal arts tradition has a different philosophy than a technically oriented school. A large university may have schools of computing and business; the focus of each may produce different information technology professionals. Some schools prepare students for further study while others are oriented to the job market. Schools with an international or national focus have different objectives than schools providing entry-level professionals locally.

The resources of a school may limit the curriculum as well. Time is a critical resource. Some model curricula require a student begin studying information technology courses in the first semester, others require only 4 or 5 semesters of IT and begin in the 3rd year of study. IT disciplines vary on the requirement for facilities. Courses requiring hands-on hardware to test theory or practice application require laboratories similar to those in an electrical engineering department. Some curricula stress practical application in commercial settings. This requires the school have close working relationships with local sponsors. The interests of the IT faculty also have an impact on curriculum development. Ideally, IT departments are well balanced in faculty expertise. However, it

Table 2. Technical core and role emphasis by discipline and curriculum model

Discipline	CIS	MIS			IT		SE	CE	CS
Technical Core — **Model**	ISCC '99	IS 2002	IRM	ISA	IT	OEIS	SEI	CC 2001	CC 2001
Role	CDM	CDS	C	DS	DS	CS	DM	CDM	CDM

Key: C – Conceptualizer D – Developer M – Modifier S – Supporter xR – Number of Required Courses xE – Number of Elective Courses

is possible for a balanced department to have a greater interest in the development of IT artifacts versus the management of those artifacts. IT is a very large discipline, for one small department to be able to provide expertise in all facets of IT is unlikely.

Having considered the previously mentioned considerations, a school should also consider the role for which they are preparing graduates. Students require different knowledge dependent upon the role they will perform within IT. The curriculum studied helps determine the graduate's role. All information technology education consists of various technical, computer-oriented topics ranging from a theoretical understanding of computing, through the design and support of practical applications for complex computer systems. The depth of knowledge in these topics varies with the specific IT discipline and model curriculum (Scime, 2002b).

The fundamental knowledge in all the information technology disciplines involves the development, modification, support, conceptualization, and management of software and hardware artifacts (Freeman & Aspray, 1999; Information Technology Association of America, 1997). Developers work with programming and modeling languages. Developers need multiple courses in at least one of these areas. Modifiers need strength in programming or application tools. Supporters need to understand the end-users as well as the technology. Although conceptualizers typically have graduate degrees, at the undergraduate level this thinking begins with a strong theory component and by relating IT to the real world. Finally, IT managers are also conceptualizers by bringing together the IT professionals to satisfy an organization's need for information.

Not emphasizing the same common technical core of IT knowledge is what makes the IT disciplines differ from one another. Some areas of the core are emphasized in different model curricula, and provide an orientation of knowledge toward one or more of the professional roles. By considering the number of required and elective courses for an element of the technical core in a model the strengths of the model can be estimated. The relationship of the emphasis of technical topics, and the IT disciplines and professional roles supported by the curriculum models is of value in selecting a model as a beginning to program development (Table 2) (Scime, 2002b).

FUTURE TRENDS

The ACM and IEEE-CS are currently working on extending their model (CC 2001) to include other computing disciplines. They expect to create four volumes of curriculum models. These will include a model for computer engineering, software engineering, and information systems, as well as the current model for computer science. The software engineering work is currently in first draft. The computer engineering model is currently a preliminary draft. The information systems model is expected to closely match AIS/AITP/ACM's current IS 2002 model.

As computing becomes more and more ubiquitous, the use of the computer and its theoretical basis will continue to expand and infiltrate other disciplines. Expansion will manifest itself as the creation and clear definition of sub-disciplines, such as CE, SE and IS are today. Infiltration is the inclusion of IT into the sciences, arts, and humanities, for example, the use of graphical information systems in earth science and criminal justice.

CONCLUSION

The constantly changing world of computing and the constantly changing world of business leads to the enviable weakness of computing education (Lidtke, Stokes, Haines, & Mulder, 1999). Each school needs to assess their educational philosophy and student needs to create the curriculum best for them. By closely following a model, a school's prospective students, student's potential employers, and graduate schools know the type of education received by the graduates. The school administration is assured that the IT department is providing a curriculum, which covers all of the central topics of IT and emphasizes the chosen information technology discipline (Scime, 2001, 2002a, 2002b).

Although the disciplines differ in emphasis, all businesses that use information (and they all do) will need information technologist from each of the disciplines. All are necessary, but not all need to be provided from the same source.

(1991). Computing Curricula 1991: Report of the ACM/IEEE-CS Joint Curriculum Task Force, Association of Computing Machinery.

KEY TERMS

Computer Engineering (CE): The engineering of computer hardware.

Computer Information Systems (CIS): Concerns information systems with an emphasis on information as an enterprise resource, and its design, development, implementation, and maintenance of information systems. Sometimes referred to as information systems.

Computer Science (CS): Hardware and software theory and design.

Computing Curricula 2001 (CC 2001): Developed by the Joint Task Force on Computing Curricula created by the ACM and the IEEE-CS. This model focuses on programs in theoretical and applied computer science (Computing Curricula, 2001).

Information Resource Management (IRM): Curriculum model 2000 of the IRMA and the DAMA focuses particularly on the disciples of information resource management and management information systems. It takes a management of data approach (Cohen, 2000).

Information Systems (IS): Use data to create information and knowledge to assist in operational, management, and strategic organizational decision-making. It is also an umbrella term for computer information systems, management information systems and information technology.

Information Systems 2002 (IS 2002): Model curriculum developed by the efforts of the ACM, AIS, and AITP. This curriculum model focuses on information systems development and management (Gorgone, Davis, Valacich, Topi, Feinstein, & Longenecker, 2002).

Information Systems Auditing (ISA) at the Undergraduate and Graduate Levels: Model developed by the ISACF Task Force for Development of Model Curricula. It is an interdisciplinary approach with a strong accounting and management orientation. (ISACF, 1998).

Information Systems Centric Curriculum (ISCC '99): Model developed by a task force that included members from academe and industry. It is oriented toward large-scale system design and implementation as opposed to automata theory and programming. The focus is on the construction of the tools necessary for information management (Lidtke, Stokes, Haines, & Mulder, 1999).

Information Technology (IT): Uses existing commercial software applications to solve organizational problems. Sometimes refer to as information systems. It is also the umbrella term for all the disciplines involved with the computer.

IT Curriculum Proposal: Being developed by SIGSITE, the curriculum is oriented toward the use of computing applications to solve organizational problems (IT Curriculum Proposal – Draft, 2002).

Management Information Systems (MIS): The management of information systems and data including management of the design, development, implementation, and maintenance of information systems. Sometimes referred to as information systems.

Organizational and End User Information Systems (OEIS): Model developed by the OSRA is aimed at IT support of end-users (Office Systems Research Association, 1996).

Software Engineering (SE): The engineering of software for embedded, large, and critical systems.

Software Engineering Institute (SEI) Model: Model developed at SEI that follows an engineering approach of design first. The model suggests specialization in a specific domain (Bagert, Hilburn, Hislop, Lutz, McCracken, & Mangal, 1999).

Concepts and Dynamics of the Application Service Provider Industry

Dohoon Kim
Kyung Hee University, Korea

INTRODUCTION: SOFTWARE AS A SERVICE

The enterprise intelligence through e-transformation is one of the cornerstones of the next-generation e-business era where the Internet constitutes the core business resource. Furthermore, the severe competitive landscape of e-business makes firms focus on their core capability and farm out staffing functions such as IT. Under this circumstance, enhancing intelligence and synergy through e-transformation will be accomplished by IT outsourcing via ASPs (application service providers). The ASP industry now provides an essential infrastructure for the Internet-based e-business transactions, thereby accelerating corporate e-transformation.

An ASP is generally defined as a third-party service firm that deploys, manages, and/or remotely hosts a software application through centrally located servers in a lease agreement. ASPs started their business by providing online application programs such as ERP (enterprise resource planning) and CRM (customer relationship management) solution packages to corporate customers. The first customers were small companies or local branches of multinational companies where IT outsourcing was the only option to deploy IT resources due to financial or regional constraints. As seen in these cases, the biggest merit of employing ASPs is that corporate customers do not have to own the applications and take responsibilities associated with initial and ongoing support and maintenance. Consequently, ASPs are differentiated from the existing IT services in that ASPs provide IT resources to multiple corporate clients on a one-to-many basis with a standardized service architecture and pricing scheme.

BACKGROUND: INDUSTRY VALUE CHAIN

The industry value chain does not allow a single service provider to control the entire service delivery process. Even if we confine our attention to the software delivery process in the value chain, the complexity does not reduce significantly. In order to deliver applications over the Internet, we need a mechanism to establish and maintain collaboration among independent functional divisions. Analysis of this nature of the value chain shows how the industry is likely to evolve and gives some insights into the strategic meaning of special types of convergence. In particular, we should point out two critical aspects of the value chain, which are required to survive in the market: a large customer base and stable relationship with other functional divisions. The structure of partnership among the players in the value chain is one of the major elements to classify emerging ASP business models. Table 1 summarizes key players in the ASP value chain.

There are a number of factors that are frequently cited as fueling or dashing the growth of the ASP market (Burris, 2001; Factor, 2002; Kim, 2002; Sparrow, 2003; Toigo, 2001). One of the striking characteristics observed so far is that immaturity of the industry is the most representative challenge in terms of the market factor: for example, the uncertainty as to whether existing and emerging ASPs are winning enough customers to validate an ASP business model for highly sophisticated enterprise applications. While some ASPs are gaining momentum with early adopters, there are many client companies that are unwilling to rent ERP applications due to the lack of trust in the industry itself in Korea (Kim & Choi, 2001).

Table 1. Key players in the ASP value chain model

- Software Vendors: including ISVs (independent software vendors), content providers (CPs), and so forth
- Network Infrastructure Providers: including telecommunication operators, ISPs (Internet service providers), and so forth
- Application Service Providers: as an intermediary or an organizer between software vendors and customers
- Individual and Corporate Customers: subscribers (end users) of the ASP services

Table 2. Drivers and challenges of the ASP industry

Category	Drivers	Challenges
Technology	◆ Reduce risk of technological obsolescence due to rapidly changing IT ◆ Provide a chance to utilize best-of-breed applications ◆ Avoid IT staffing shortage	◆ Unsolved security concerns ◆ Emerging, new technological requirements from the clients: e.g., SLA with client participation ◆ Unproved service reliability: e.g., network problems, system scalability and performance
Market	◆ Minimize up-front TCO (total cost ownership) ◆ Provide predictable cash flows	◆ Unproved client momentum ◆ Failure in giving clients sufficient trust due to unstable ASP industry

Moreover, it is security control and remote monitoring systems, SLA (service level agreement; Lee & Ben-Natan, 2002; Sturm, Morris, & Jander, 2000) management, and the global standardization process that should be further developed to support proliferation of ASPs. In the end will survive only a few successful ASPs that adapt themselves to the market requirements and take the most advantage of the competitive landscape.

ASP BUSINESS MODELS

The industry's short history raises the following questions. What changes will happen? Who will be the winners and losers? To answer these questions, Table 3 clarifies different types of the ASP business domains that are currently emerging. ASP's common value proposition to improve total benefits from IT outsourcing has been giving rise to various trials in designing the service

Table 3. ASP business models and capability profiles

Basic Types	Characteristics and Value-Added Components	Basic Capability
H-ASP (Horizontally Specialized ASP)	◆ Develop deep expertise within a given functional area (as opposed to one-stop shop): Substantial consulting services are possible ◆ ISV's need of partnership with systems integration and distribution companies ◆ Should be Web-based software provider ◆ Either own the software or develop proprietary integration in a specific field	◆ Well positioned to expand customer basis quickly ◆ Hard to copy the domain-specific knowledge
V-ASP (Vertically Specialized ASP)	◆ Industry-specific applications (in contrast to one-stop shop) ◆ Vertically oriented template methodology: easily deploy across multiple clients in the same industry	◆ Strong advantage in customized solutions ◆ Hard to copy the industry-specific knowledge
AIP (Application Infrastructure Provider)	◆ Originated from telecommunication company that owns networks and has operations experience ◆ Provide infrastructure management to ASPs ◆ Provide system management services including SLA ◆ Alleviate client concerns regarding network reliability, etc.	◆ High investment costs as an entry barrier: easy to protect their market share
XSP (Extended Service Provider)	◆ Provide total services from front end to back end with systems integration consulting ◆ Create new business process by rearranging suppliers and customers ◆ Help customers and even other service providers enter new markets, deploy services, and improve profitability easily while minimizing risk ◆ Build and integrate customized applications, thereby enabling clients to avoid the need to handle multiple ASP solutions	◆ Going back to one-stop-shop idea: Improved flexibility will be the core competitive edge for XSP

delivery processes, each of which corresponds to a business model suggested in the table. Therefore, this classification plays a key role in identifying and analyzing the collaborative networking structure in the ASP value chains.

FUTURE TRENDS: INDUSTRY DYNAMICS AND EVOLUTION

The guiding principles of the industry evolution, which have been leading the industry to face proliferation of ASP business models, are summarized into (a) economies of scale through positive feedback from the market and (b) integration across the value chain for attaining cost reduction and differentiation.

First, it is the economies of scale or increasing return that serves as the core economic guiding principle for ASPs. A survey on the Korean IT outsourcing market reveals that, in terms of the TCO (total cost ownership) of a typical ERP package, IT outsourcing through ASPs enables clients to save roughly 20% of their up-front license fee and 80% of the implementation and maintenance service costs (Kim & Choi, 2001). Accordingly, ASPs that host these applications basically seek to lower this 80% portion of the TCO upon the notion of a one-to-many relationship between an ASP and its clients. An ASP is usually able to leverage standardized solutions across multiple clients. Attaining client momentum and reducing the overall costs per client are the major economic motivations for ASPs to compete with each other, thereby creating a positive feedback mechanism through network externality on the demand side. In sum, the competition keeps going for the expansion of a customer base or market share, which provides a good surrogate measure of profit for this case.

Second, the competitive landscape is also defined by the unique nature of a service system market where independent hardware and software resources are combined and reorganized into a new package in alignment with partners along the value chain and even a customer's business process. These offerings aim at designing a seamless and proprietary service delivery process to sharpen the competitive edge while raising the entry barrier. This essential feature of integration in the service delivery process makes the various possible business models reduce into the different types of service product combinations along the value chain as presented in Table 1. The integration, however, should be verified by achieving savings in TCO, though it is not easy to measure the amount of cost reduction by a certain partnership structure. Accordingly, the cutthroat competition fueled by business domain integration not only drives down the price to an acceptable market price, but also creates diverse market segmentations based on the service product differentiation.

Furthermore, increasing switching costs and rising entry barriers, two basic phenomena regarding the guiding principles and competitive landscape, are common to all the business models. As a result, efforts to penetrate into different market segments and build new customer relationships at the niche will inevitably run into strong resistance from the incumbents. Some events like technological breakthroughs will be required in order for a specific ASP model to consolidate another. Therefore, various business models will thrive over a period of time before some giant players in each business model emerge. Despite a unique coexistence of diverse ASP business models, some hypotheses on the industry structure change and evolution can be derived from those observations together with the guiding principles.

First, the general trend will be that the total number of ASPs in the industry will reduce since the customer base is not large enough to keep all the incumbent ASPs alive. Cash flows generated from the market give winners resilience to possible occasional failures and allow them to better manage risk by diversifying a portfolio of value components to open a new market niche. It is this kind of positive feedback loop (Arthur, 1989; Nelson & Winter, 1978) from the economies of scale that accelerates the exit of losers from the market and shapes the industry structure (Shy, 2002).

Second, the industry has been concentrating more around horizontally and vertically specialized ASPs than around the pure ASPs (that is, a simple partnership with an ISV). The primary concern of the emerging ASPs is to build some value-added components to the service architecture, thereby making it hard for competitors to replicate their business model and for customers to replace the current provider. However, reliance on third-party ISVs could make it more difficult to resolve underlying performance issues that have been the subject of customer scrutiny. On the other hand, looking up the capability profiles of the ASP business models, we can conclude that both H-ASPs and V-ASPs hold a dominant position from this standpoint. If some technical constraints such as SLA and security requirements come to rise to the surface, AIP will gain technological competitiveness since delegating the control of core enterprise applications to an external provider requires ASPs to prove their capability of reliable and stable operations.

Last, we predict that the rate-of-demand increase will affect the industry structure: the pattern of market segmentation, the market share of each ASP type, and so forth. The speed of the market expansion will affect ASPs' selection of competitive priorities.

CONCLUSION

The ASP industry will shape the future e-business transactions, providing a great flexibility in redeploying a firm's resources. Although the industry is currently at its early stage of the industry life cycle, much attention is now paid to vertical or domain-specific expertise and flexible capabilities in addition to the basic offerings. In order to assess both the market and the supply side, classified are emerging ASP business models together with some driving forces shaping the evolutionary path. Some careful observations disclosed that (a) the capability of an ASP model hinges on the differentiation of service products to a large degree and (b) economies of scale play a key role in the dynamically evolving market mechanisms. ASPs that originally developed their proprietary solutions will be better positioned in terms of ultimate performance and scalability. Those ASPs will increase the chance to succeed in the market irrespective of how critical a given solution is to their client's day-to-day operations. Last, some technical factors that may affect the evolution path (for example, SLA regulation and security) should be considered in the near future.

KEY TERMS

AIP: An application infrastructure provider (AIP) is a type of ASP, which is usually originated from telecommunication operators that run their own networks and IDCs (Internet data centers). AIP focuses on server hosting and network infrastructure management for other ASPs and corporate clients, and provides value-added services based on its technology leadership, for example, online security and e-payment services.

ASP: An application service provider (ASP) is a third-party service firm that deploys, manages, and/or remotely hosts a software application through centrally located servers in a lease agreement.

Economies of Scale: Economies of scale are the achievement of lower average cost per unit through increased production, or the decrease in the marginal cost of production as a firm's extent of operations expands.

Horizontal ASP: Horizontal ASPs provide online applications for a specific business function such as human resource management, procurement, customer relations, and so forth.

IT Outsourcing: IT outsourcing is the outsourcing of enterprise information systems and management to computer manufacturers or software companies (the term outsourcing stems from using an outside resource). Companies can save purchasing cost, maintenance cost, and labor cost by outsourcing and paying for those services. Outsourcing has become a common practice in the US where companies are faced with uncertain returns of massive investment in IT resources.

SLA: A service level agreement (SLA) is a contract between a supplier and a customer that identifies (a) services supported at each of three layers—application, host (system), and network—(b) service parameters for each service, (c) levels of service quality, and (d) liabilities on the part of the supplier and the customer when service quality levels are not met.

Vertical ASP: Vertical ASPs provide online applications customized for a specific industry such as staff or operations scheduling for hospitals, material procurement for the steel industry, and so forth.

XSP: An extended service provider (XSP) provides total IT-related services from online applications through maintenance and reengineering of IT resources to business process consulting for its clients. Success of the XSP model should presume the rapid proliferation of the ASP services in an overly complex market. If the ASP service demand grows explosively in a short period of time, the XSP model will debut in the market earlier on, increasing the possibility of XSPs dominating the industry as they have scale advantage in terms of cost.

Value Chain: A value chain is a chain of activities in a group of collaborators who are designed to meet market demand. They are vendors involved in value chains across purchasing, procurement, manufacturing, warehousing, distribution, and sales of components, equipments, raw materials, and so forth to manage a series of resource and information flow.

Concepts of Emergence Index in Image Databases

Sagarmay Deb
University of Southern Queensland, Australia

INTRODUCTION

Images are generated everywhere from various sources. It could be satellite pictures, biomedical, scientific, entertainment, sports and many more, generated through video camera, ordinary camera, x-ray machine and so on. These images are stored in image databases. Content-based image retrieval (CBIR) technique is being applied to access these vast volumes of images from databases efficiently. Some of the areas where CBIR is applied are weather forecasting, scientific database management, art galleries, law enforcement and fashion design.

Initially image representation was based on various attributes of the image like height, length, angle and was accessed using those attributes extracted manually and managed within the framework of conventional database management systems. Queries are specified using these attributes. This entails a high level of image abstraction (Chang, 1988; Gudivada & Raghavan, 1995). Also there was feature-based object-recognition approach where the process was automated to extract images based on color, shape, texture and spatial relations among various objects of the image.

Recently, combinations of these two approaches, efficient image representation and query-processing algorithms, have been developed to access image databases. Recent CBIR research tries to combine both of these approaches and has given rise to efficient image representations and data models, query-processing algorithms, intelligent query interfaces and domain-independent system architecture.

As we mentioned, image retrieval can be based on low-level visual features such as color (Pass et al., 1996; Smith & Chang, 1996; Srisuk & Kurutach, 2002; Sural et al., 2002; Swain & Ballard, 1991; Traina et al., 2003), texture (Manjunath, 1996; Sheikholeslami, 1997; Smith & Chang, 1994; Zhou et al., 2001), shape (Safar, 2000; Shahabi & Safar, 1999; Tao & Grosky, 1999), high-level semantics (Forsyth et al., 1996; Torratha & Oliva, 1999) or both (Zhao & Grosky, 2001).

But most of the works done so far are based on the analysis of explicit meanings of images. But image has implicit meanings as well, which give more and different meanings than only explicit analysis provides. In this article we provide the concepts of emergence index and analysis of the implicit meanings of the image, which we believe should be taken into account in analysis of images of image or multimedia databases.

BACKGROUND

Concepts of Emergence

A feature of an image that is not explicit would be an emergent feature if it could be made explicit. There are three types of emergence: computational emergence, thermodynamic emergence and emergence relative to a model (Cariani, 1992). We use the latter one in our article.

Whenever we shift our focus on an existing shape, in other words an image, a new shape emerges. The representation of the new shape is based upon our view of the original shape. The new shape emerges as we change our view of the original shape. This is the most important idea of emergence.

Two classes of shape emergence have been identified: embedded shape emergence and illusory shape emergence (Gero, n.d.; Gero & Maher, 1994). These procedures could be based on geometrical, topological or dimensional studies of the original shape.

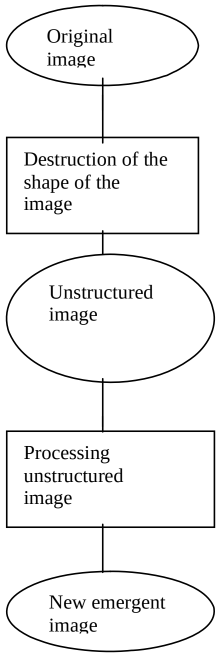
Model of Emergence

To extract emergent shape from an image, first we have to destroy the original shape of the image. This would give us an unstructured image. Now we take the unstructured image and find out the extra or implicit meaning out of it in addition to the original meaning, and this process gives rise to emergent image with implicit meaning, making explicit and emergent images generated. This can be defined in a model in Figure 1 (Gero & Yan, 1994):

Definition of Emergence Index

For image retrieval where the hidden or emergence meanings of the images are studied and based on those hidden meanings as well as explicit meanings, where there is no hidden meaning at all, an index of search is defined to retrieve images is called emergence index.

Figure 1. Model of emergence



When images are retrieved based on textual information, then various parameters and descriptions might define the input and the images of the database. Whenever there would be symmetry of parameters and descriptions, the image could be retrieved. As mentioned earlier, in CBIR, color, texture and shape are widely used as index to retrieve images. But in our studies, we can find the hidden meanings of the images and whenever those hidden meanings match with the input given, although the original image may not match at all with the input, we can retrieve that image.

When an input would come in the form of an image, the image could be studied based on features, constraints, variables and domains and converted into parametric form. Then the image database would be accessed and each image would be interpreted considering the items mentioned previously and also emergence and converted into parametric form like the input image. Whenever there would be a match between parameters of the input and the images of the database, these records would be selected. In other words, indexing would be decided by the outcome of emergence, which means more meaningful images could be found hidden in an image which would otherwise not be understood.

Many images of the database may not have any apparent similarities with the input, but emergence could bring out the hidden meaning of the image and could establish similarities with the input image. So emergence outcomes of the images would form the index structure of the search.

Analyses of Works Done

Attempts have been made to give rise to symbolic representation of shape where shape is defined as

$$S = \{N; \text{Constraints}\}$$

where N is the cardinality, that is, the number of infinite maximal lines constituting shape S, and the constraints limit the behaviors or properties resulting from the infinite maximal lines, based upon which particular shape is defined. Lines have been defined as Ik, Ij and so on with their intersection as Ikj. Then topological, geometric and dimensional properties are defined (Gero, 1992). Also symmetry has been found through the corresponding relevant positions of the lines and coordinates of one shape with that of the other, and in the process, emergence of the shapes are studied (Jun, 1994).

There is no direct approach to solve the problem of emergent index other than the ones mentioned previously. There is only an indirect approach where this conception has been applied. In a model named Copycat involving computer programs, the program makes all possible sets of consistent combinations of pairings once all plausible pairings have been made. In other words, it gives rise to something explicit that was implicit earlier, which is the essential feature of emergence phenomenon (Mitchell & Hofstadter, 1994).

MAIN THRUST OF THE ARTICLE

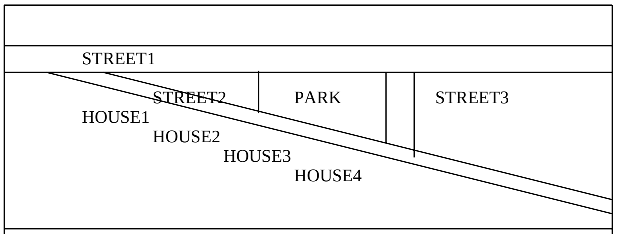
We attempt to study the problem of image query where a query made would be searched through the database to select those records where a similar shape has been found. But in addition to that we pick up records based on the emergence phenomena where the query input may not have an apparent match in a particular image of the database, but emergence phenomena could give rise to a similar structure in the same image and as such this image should be selected as a query result. For example, a square with single diagonal can be observed as two triangles. So whenever search intends to find a triangle, this image, which apparently is much different than triangle, would be selected because of emergence.

We calculate emergence index of images of image databases based on features, constraints, variables, domains and emergence.

Various mathematical tools that could be used in defining the image are:

- Geometric property
- Topological property

Figure 2. Geographic location



- Dimensional property
- Statistical properties

Structure of Emergence Index

Emergence indexes can be defined out of five factors

EI = f(D,F,V,C,E)

where EI stands for emergence index, D for domain where the image belongs, F for features, V for variables that can define the feature's constraints under which the features are defined, C for constraints and E for emergence characteristics of images.

We believe any image, static or in motion, could be expressed semantically in terms of the previously mentioned five parameters (Deb & Zhang, 2001).

Application of Emergence Index in Geographic Location

If we have a map of a geographic location like the one in Figure 2, then we find there are three streets, namely, STREET1, STREET2 and STREET3. There is a park between STREET1 and STREET2 and HOUSE1, HOUSE2, HOUSE3, HOUSE4 are four houses on STREET2.

We also notice that STREET1, STREET2 and STREET3 form a triangle surrounding PARK. In normal map interpretation this may not surface. But when hidden shape is searched we get a triangle. This is the emergence outcome of the search. This would help us to locate the places more accurately by referring to the triangle in the map. Also if there is an input in the form of a triangle, then this image, although a map, would be selected because of emergence.

CONCLUSION

Emergence is a phenomenon where we study the implicit or hidden meaning of an image. We introduced this concept in image database access and retrieval of images using this as an index for retrieval. This would give an entirely different search outcome than ordinary search where emergence is not considered, as consideration of hidden meanings could change the index of search. We discussed emergence, emergence index and approach as to how to apply this concept in image retrieval in this article.

KEY TERMS

Computational Emergence: Here it is assumed that computational interactions can generate different features or behaviors. This is one of the approaches in the field of artificial life.

Content-Based Image Retrieval: In this kind of retrieval, symmetry between input image and images of database are established based on contents of the images under consideration.

Embedded Shape Emergence: In embedded shape emergence, all the emergent shapes can be identified by set theory kind of procedures on the original shape under consideration. For example, in a set S={a,b,c,d,e}, we can find subsets like S1={a,b,c}, S2={c,d,e}, S3={a,c,e} and so on.

Emergence Index: Image retrieval where the hidden or emergence meanings of the images are studied and based on those hidden meanings as well as explicit meanings. Where there is no hidden meaning at all, an index of search is defined to retrieve images, called emergence index.

Emergence Relative to a Model: In this case, deviation of the behavior from the original model gives rise to emergence.

Illusory Shape Emergence: In illusory shape emergence, contours defining a shape are perceived even though no contours are physically present. Here set theory procedures are not enough and more effective procedures have to be applied to find these hidden shapes.

Thermodynamic Emergence: This is of the view that new stable features or behaviors can arise from equilibrium through the use of thermodynamic theory.

Conducting Ethical Research in Virtual Environments

Lynne D. Roberts
University of Western Australia, Australia

Leigh M. Smith
Curtin University of Technology, Australia

Clare M. Pollock
Curtin University of Technology, Australia

INTRODUCTION

The rapid growth of the Internet has been accompanied by a growth in the number and types of virtual environments supporting computer-mediated communication. This was soon followed by interest in using these virtual environments for research purposes: the recruitment of research participants, the conduct of research and the study of virtual environments. Early research using virtual environments raised a number of ethical issues and debates. As early as 1996, a forum in the *The Information Society* (vol. 12, no. 2) was devoted to ethical issues in conducting social science research online. The debate has continued with more recent collaborative attempts to develop guidelines for ethical research online (Ess & Association of Internet Researchers, 2002; Frankel & Siang, 1999).

BACKGROUND

The basic principles of ethical research with humans are integrity, respect, beneficence and justice (National Health & Medical Research Council, 1999). Based on these principles, many professional associations provide ethical guidelines, or codes, for the conduct of research. However, these codes have typically been developed for use in offline settings, prior to consideration of research being conducted online[1]. While these codes contain guiding principles for research generally, the translation of these principles into actions for conducting research in virtual environments is open to interpretation. The process of translating ethical guidelines into ethical practice online involves a deliberation of the options available to the researcher and the likely impact on research participants, their communities and the research process. Central concerns in this process are maintaining respect for individuals, their online identities and the ownership of words.

PUBLIC VS. PRIVATE SPACE

Research online can take place within a range of virtual environments that vary in terms of purpose, synchronicity, access, number of users and norms. A major issue in developing ethical research procedures for use within a particular virtual environment is determining whether the setting represents a private or public "space". Various attempts have been made to distinguish between the public and the private in virtual environments (see, for example, Lessig, 1995) but little agreement has been reached. There are currently no clear guidelines for researchers on what constitutes private versus public space in virtual environments, yet the distinction is important as it affects the rights of participants to be advised of the research and to give or withhold their informed consent.

The defining of public versus private space cannot be reduced to the single dimension of accessibility to the virtual environment. Interactions that occur within publicly accessible virtual environments may be perceived by participants to be private. Newsgroups can be accessed without restriction, yet newsgroup postings can be, and frequently are, high in self-disclosure and are perceived by many users to be private (Witmer, 1997). Similarly, support groups on sensitive issues may be conducted in publicly accessible sites with participants adhering to norms of confidentiality and privacy (Elgesem, 2002).

Some ethical codes exempt naturalistic observations and archival research from requiring informed consent where no harm or distress is likely to come to those researched and where their confidentiality is protected. King (1996) highlighted the potential for psychological harm to members of online groups where research is conducted and published without the prior knowledge and informed consent of participants. Where there has been the expectation of privacy within a group (however misinformed that expectation may be), the individual may feel violated upon hearing of, or reading, the results of that research.

Where the presumption is made that online communication occurs in public space simply because it is accessible without restriction, an anomaly may result in how research participants are treated in equivalent settings in on- and off-line research. For example, research on support groups off-line requires the informed consent of research participants, while similar research online may occur without the knowledge or informed consent of the participants, on the grounds that all postings are public documents (see, for example, Salem, Bogat & Reid's 1997 study of a depression support group).

Table 1 summarizes possible dimensions against which the public/private nature of a virtual environment can be assessed. Virtual environments where all dimensions fall on the left-hand side of the continuums may be deemed as public environments for research purposes and subject to guidelines for research in public settings. Virtual environments where all dimensions are on the right should be deemed as private environments, requiring informed consent from research participants. The difficulty arises with the majority of settings that do not fall clearly into public or private spaces. Researchers do not have the right to define virtual environments as public or private to meet their own research needs (Waskul & Douglass, 1996). Rather, account should be taken of the size and nature of the online forum and the intrusiveness of the study. Consideration should be made of the likely effect of the request to conduct research and the research itself on research participants and their communities. The process of requesting consent to research may in itself alter group dynamics (Sixsmith & Murray, 2001).

INFORMED CONSENT

Research conducted in virtual environments that have been conceptualized as private settings requires the informed consent of research participants. Obtaining informed consent in virtual environments is more problematic than in off-line research as participants are frequently geographically dispersed. In addition, research participants may be reluctant to divulge details of off-line identities required for the signing of consent forms. A range of options has been suggested for obtaining informed consent in online research (Bruckman, 1997; Flicker, Haans & Skinner, 2004; Jacobson, 1999; Roberts, Smith & Pollock, 2004; Smith & Leigh, 1997) and these have been summarized in Table 2. Selection of a method for obtaining informed consent will necessarily be dependent upon the type of virtual environment, the level of anonymity required by research participants, and their access to high-level computing facilities. Regardless of the method used, the information about the research should be presented in a format that the research participants can keep and refer back to at any time before, during, or after their research participation. Care needs to be taken to fully inform potential research participants of the possible consequences of their research involvement (Reid, 1996).

In addition to seeking consent from research participants in virtual environments, it may be advisable to also seek the consent of gatekeepers of the community and advise the community as a whole of the research being undertaken. Advising communities of a research project requires the public identification of the researcher. In some circumstances, the decision to research within a particular virtual environment may be made after the researcher has been either an active participant or "lurker" within that environment. We recommend that researchers make their researcher status overt as soon as the research process begins. This may include identifying as a researcher in pseudonyms (Roberts et al., 2004), descriptions (Allen, 1996) or objects (Reid, 1996); linking between research and social identities (Roberts et al., 2004); and posting information about the research.

Advising communities of a research project may take ongoing effort in public virtual environments without membership boundaries. Identifying oneself as a researcher once within an online group does not mean that absent or future members of the group are also informed of the researcher's role (Sixsmith & Murray, 2001). There may be a need to re-identify researcher status and restate and clarify the role of the researcher on an ongoing basis.

PROTECTING ANONYMITY AND CONFIDENTIALITY

Individuals typically adopt a pseudonym (or pseudonyms) for use in virtual environments, providing a level of anonymity. While it has been argued that research involv-

ing pseudonymous characters is exempt from regulations governing human subjects as "true" or offline identities are not known (Jacobson, 1999), there are often links between the individual and their pseudonyms that decrease the level of anonymity a pseudonym provides (Allen, 1996; Bruckman, 2002; Jacobson, 1996). These are presented in Table 3. The combination of these factors means that researchers cannot assume that pseudonyms provide adequate protection for offline identities. The degree of anonymity conferred in virtual environments does not reduce the ethical requirements for researchers to protect the anonymity of research participants and virtual interaction settings (Waskul & Douglass, 1996).

Protecting the anonymity of the individual extends to protecting the anonymity of their pseudonym(s), as representations of the individual online. Pseudonyms themselves gain reputations over time (Bruckman, 2002). Researchers can provide varying levels of protection to research participants' anonymity (see Table 4). The practice of replacing existing pseudonyms with other pseudonyms in research materials confers little additional protection to the existing pseudonym when text searches can be used to identify source documents (Allen, 1996). Further, other community members may seek to identify disguised identities and may share this information with others (Bruckman, 2002).

In addition to protecting the anonymity of research participants in research reports, the data collected needs to be kept secure in order to protect confidentiality. Maintaining the security of data collected in computer-mediated research poses unique difficulties. Confidentiality may be breached at the site of data collection, during transmission of data, or in the storage of data. Sites at which data is collected may not be secure and may be subject to surveillance by gate-keepers or "hackers" (Rhodes, Bowie & Hergenrather, 2003). Confidentiality of data may be breached during data transmission where another party intercepts data (Nosek, Banaji & Greenwald, 2002). This may include the Internet service provider of the research participant or researcher. Employers may also monitor employees' email (Sipior & Ward, 1995; Weisband & Reinig, 1995). Confidentiality of data may be

Table 3. Factors that decrease the anonymity afforded by pseudonyms

- Use of name, derivation of name or nickname
- Use of same pseudonym across virtual environments with differing requirements for identification
- Self-disclosure
- Active seeking of identifying information by others

breached during storage of data by hackers, employers or as a result of "open records" legislation (Pittenger, 2003). Online researchers need to provide the most secure forms of data collection, transmission and storage possible, aiming to minimize the risks of unauthorized persons gaining access to research data at any stage of the research process. The procedures used to ensure this will differ according to the type of virtual media used.

OWNERSHIP OF WORDS

The ownership of electronic messages has been contested. It is still unclear whether the individual who authored a message, the community to which it was sent, or anyone who has access to the message is the owner of the electronic message. Electronic postings may be considered original works protected by copyright, although this has not yet been legally tested (Sixsmith & Murray, 2001). If informed consent is not obtained to use electronic messages, copyright provisions suggest that they are subject to "fair dealing" for research purposes, and should be attributed to the author (Australian Copyright Council, 2001). Researchers who neither obtain informed consent, nor reference the material they are quoting, risk violating both ethical and copyright standards. With the consent of the research participant, quotes in research may be attributed to the individual, their online pseudonym, or used anonymously. Respect for research participants is demonstrated through asking, and abiding by, their preferences for anonymity, pseudonymity or identification. However, this is not without its problems. Individual preferences for identification may not be consistent with the norms or wishes of the community. There can be tensions between respecting copyright entitlements of individuals and protecting the privacy of other participants within a virtual environment. Roberts et al. (2004) highlighted the potential for negative impacts on the privacy of other virtual environment members when one research participant's work is fully attributed, including information on the virtual environment.

RETURNING RESEARCH FINDINGS TO THE COMMUNITY

A requirement in some ethical codes is to provide research participants with information about the outcome of the research. In addition to being a requirement, this can also demonstrate respect for the individuals who participated in the research. A summary of research findings can be provided to research participants in hardcopy or electronic format. Where research participants are reluctant to provide contact information that may link their on- and off-line identities the summary can be placed on a Web site or sent through the messaging system of the virtual community (Roberts et al., 2004).

FUTURE TRENDS

Rapidly changing technologies will result in the development of an increasing range of virtual environments that may be used for research purposes. The precise characteristics of these new virtual environments may vary greatly from the virtual environments available today. Before conducting research within each new type of environment researchers will need to address the intrusiveness of the proposed research, the perceived privacy of the research setting, the vulnerability of the community, the potential for harm to individuals and/or the community, and how confidentiality will be maintained and intellectual property rights respected in their research proposals (Eysenback & Till, 2001). This requires a consideration of the likely impacts of the research on both research participants and the communities in which the research is conducted. It should be guided by researcher's knowledge and adherence to the "netiquette" and social norms of the virtual environments concerned. Guided by the principles outlined in their ethical codes, researchers will need to develop ethically defensible strategies that balance the needs of research participants and their online communities and offers protection to both.

CONCLUSION

Our approach to the conduct of ethical research in virtual environments is based on a human research perspective, explicitly recognizing that communication online is conducted by individuals who interact via their online identities. Our focus is therefore on individuals rather than texts. We privilege the rights of individuals to make informed consent about whether or not traces of their interaction online (e.g., logs, postings) can be used for research purposes. We believe this approach is consistent with general ethical guidelines for human research in the social sciences. Alternative perspectives to the conduct of ethical research in virtual environments place a stronger emphasis on the cultural production of texts and performance (Bassett & O'Riordan, 2002; White, 2002) reflecting calls for an ethical pluralism in Internet research that recognizes a range of ethical perspectives as legitimate (Ess, 2002). Regardless of the perspective adopted, all research should comply with the principles of ethical research as outlined in professional associations' codes of ethics or by institutional review boards. In the absence of specific guidelines for online research and where review committees are unfamiliar with online research issues (Keller & Lee, 2003), we recommend researchers are guided by the principles outlined in their code, adapting the guidelines for use in virtual environments as necessary.

KEY TERMS

Computer-Mediated Communication: Communication between two or more individuals that occurs via computer networks. Computer-mediated communication may be text, audio, graphics or video based and occur synchronously (in "real time") or asynchronously (delayed).

Informed Consent: An individual's freely given consent to participate in research based on information provided by the researcher(s) about the research, possible risks associated with the research and the voluntary nature of participation. Informed consent must be obtained without coercion or undue influence.

Netiquette: The etiquette, or social rules, associated with communicating online. Netiquette may vary across virtual environments.

Private Space: Off-line, private space refers to geographical areas that are not for general or public use (e.g., your home). Online, the term private space is commonly used to refer to virtual environments, or parts of virtual environments that have restrictions on who may access them.

Pseudonym: The fictitious name adopted for use within a virtual environment. An individual may consistently use the same pseudonym or adopt several pseudonyms for use within and between virtual environments.

Public Space: Off-line, public space refers to geographical areas that are accessible to the general public (e.g., streets). Online, the term public space is commonly used to refer to virtual environments that do not have restrictions on access.

Virtual Identity: Representation of the individual in a virtual environment. The form of representation varies across virtual environments and may range from a pseudonym only (Internet Relay Chat), a pseudonym combined with a character description (Multi-User Dimensions) through to graphical representations, or avatars, in graphics based environments. An individual may have multiple virtual identities.

ENDNOTE

[1] Over time as codes are updated, consideration of research conducted online may be included. See, for example, the revised *Ethical Principles of Psychologists and Code of Conduct* (American Psychological Association, 2002).

C

Consistent Queries Over Databases with Integrity Constraints

Sergio Greco
DEIS Università della Calabria, Italy

Ester Zumpano
DEIS Università della Calabria, Italy

INTRODUCTION

The aim of data integration is to provide a uniform integrated access to multiple heterogeneous information sources, which were designed independently for autonomous applications and whose contents are strictly related.

Integrating data from different sources consists of two main steps: the first in which the various relations are merged together and the second in which some tuples are *removed* (or *inserted*) from the resulting database in order to satisfy integrity constraints.

There are several ways to integrate databases or possibly distributed information sources, but whatever, integration architecture we choose, the heterogeneity of the sources to be integrated, causes subtle problems. In particular, the database obtained from the integration process may be inconsistent with respect to integrity constraints, that is, one or more integrity constraints are not satisfied. Integrity constraints represent an important source of information about the real world. They are usually used to define constraints on data (functional dependencies, inclusion dependencies, etc.) and have, nowadays, a wide applicability in several contexts such as semantic query optimization, cooperative query answering, database integration and view update.

Since, the satisfaction of integrity constraints cannot generally be guaranteed, if the database is obtained from the integration of different information sources, in the evaluation of queries, we must compute answers which are consistent with the integrity constraints. The following example shows a case of inconsistency.

Example 1. Consider the following database schema consisting of the single binary relation *Teaches (Course, Professor)* where the attribute *Course* is a key for the relation. Assume there are two different instances for the relations *Teaches*, D1={(c1,p1),(c2,p2)} and D2={(c1,p1),(c2,p3)}.

The two instances satisfy the constraint that *Course* is a key but, from their union we derive a relation which does not satisfy the constraint since there are two distinct tuples with the same value for the attribute *Course*.

In the integration of two conflicting databases simple solutions could be based on the definition of preference criteria such as a partial order on the source information or a majority criteria (Lin and Mendelzon, 1996). However, these solutions are not generally satisfactory and more useful solutions are those based on 1) the computation of 'repairs' for the database, 2) the computation of consistent answers (Arenas et al., 1999).

The computation of repairs is based on the definition of minimal sets of insertion and deletion operations so that the resulting database satisfies all constraints. The computation of consistent answers is based on the identification of tuples satisfying integrity constraints and on the selection of tuples matching the goal.For instance, for the integrated database of *Example 1*, we have two alternative repairs consisting in the deletion of one of the tuples *(c2,p2)* and *(c2,p3)*. The consistent answer to a query over the relation *Teaches* contains the unique tuple *(c1,p1)* so that we don't know which professor teaches course *c2*.

Therefore, it is very important, in the presence of inconsistent data, to compute the set of consistent answers, but also to know which facts are unknown and if there are possible repairs for the database.

TECHNIQUES FOR QUERYING AND REPAIRING DATABASES

Recently, there have been several proposals considering the integration of databases as well as the computation of queries over inconsistent databases. Most of the techniques work for restricted from of constraints and only recently have there been proposals to consider more general constraints. In this the following we give an informal description of the main techniques proposed in the literature.

- In Agarwal et al. (1995) it is proposed an extension of relational algebra, called *flexible algebra*, to deal with data having tuples with the same value for the key attributes and conflicting values for the other attributes. The technique only considers constraints defining functional dependencies and it is sound only for the class of databases having dependencies determined by a primary key consisting of a single attribute.
- In Dung (1996) it is proposed the Integrated Relational Calculus, an extension of flexible algebra for other key functional dependencies based on the definition of *maximal consistent subsets* for a possibly inconsistent database. Dung proposed extending relations by also considering null values denoting the absence of information with the restriction that tuples cannot have null values for the key attributes. The Integrated Relational Calculus overcomes some drawbacks of the flexible relational algebra. Anyhow as both techniques consider restricted cases the computation of answers can be done efficiently.
- In Lin and Mendelzon (1996), it is proposed an approach taking into account the majority view of the knowledge bases in order to obtain a new relation which is consistent with the integrity constraints. The technique proposes a formal semantics to merge first-order theories under a set of constraints.

Example 2. Consider the following three relation instances which collect information regarding author, title and year of publication of papers:

- Bib1={(John,T1,1980),(Mary,T2,1990)},
- Bib2={(John,T1,1981),(Mary,T2,1990)},
- Bib3={(John,T1,1981), (Frank,T3,1990)}

From the integration of the three databases Bib1, Bib2 and Bib3 we obtain the database Bib={(John,T1,1980), (Mary,T2,1990), (Frank,T3,1990)}.

Thus, the technique, proposed by Lin and Mendelson, removes the conflict about the year of publication of the paper T1 written by the author John observing that two of the three source databases, that have to be integrated, store the value 1980; thus the information that is maintained is the one which is present in the majority of the knowledge bases.

However, the 'merging by majority' technique does not resolve conflicts in all cases since information is not always present in the majority of the databases and, therefore, it is not always possible to choose between alternative values. Thus, generally, the technique stores disjunctive information and this makes the computation of answers more complex (although the computation becomes efficient if the 'merging by majority' technique can be applied); moreover, the use of the majority criteria involves discarding inconsistent data, and hence the loss of potentially useful information.

- In Arenas et al. (1999) it is introduces a logical characterisation of the notion of consistent answer in a possibly inconsistent database. The technique is based on the computation of an equivalent query $T_\omega(Q)$ derived from the source query Q. The definition of $T_\omega(Q)$ is based on the notion of residue developed in the context of semantic query optimization.

More specifically, for each literal B, appearing in some integrity constraint, a residue *Res(B)* is computed. Intuitively, *Res(B)* is a universal quantified first order formula which must be true, because of the constraints, if B is true. Universal constraints can be rewritten as denials, i.e., logic rules with empty heads of the form $\leftarrow B_1 \wedge \ldots \wedge B_n$.

Let A be a literal, r a denial of the form $\leftarrow B_1 \wedge \ldots \wedge B_n$, B_i (for some $1 \le i \le n$) a literal unifying with A and θ the most general unifier for A and B_i such that variables in A are used to substitute variables in B_i but they are not substituted by other variables. Then, the residue of A with respect to r and B_i is:

$$\begin{aligned} Res(A,r,Bi) &= not((B_1 \wedge \ldots \wedge B_{i-1} \wedge B_{i+1} \wedge \ldots \wedge B_n)\ \theta) \\ &= not\ B_1\theta \vee \ldots \vee not\ B_{i-1}\theta \vee not\ B_{i+1}\theta \vee \ldots \vee not\ B_n\theta. \end{aligned}$$

The residue of A with respect to r is $Res(A,r) = \wedge_{B_i | A=B_i\theta}$ $Res(A,r,B_i)$ consisting of the conjunction of all the possible residues of A in r whereas the residue of A with respect to a set of integrity constraints IC is $Res(A) = \wedge_{r \in IC} Res(A,r)$.

Thus, the residue of a literal A is a first order formula which must be true if A is true. The operator $T_w(Q)$ is defined as follows:

$T_0(Q) = Q$;
$T_i(Q) = T_{i-1}(Q) \wedge R$ where R is a residue of some literal in $Ti\text{-}1$.

The operator T_w represents the fixpoint of T.

Example 3. Consider a database D consisting of the following two relations:

Supplier	Department	Item
c1	d1	i1
c2	d2	i2

Item	Type
i1	t
i2	t

with the integrity constraint, defined by the following first order formula:

$$\forall(X, Y, Z)\ [\ Supply(X,Y,Z) \wedge Class(Z,t) \supset X{=}c1\ ]$$

stating that only supplier *c1* can supply items of type *t*.

The database *D = { Supply(c1, d1, i1), Supply(c2, d2, i2), Class(i1, t), Class(i2, t) }* is inconsistent because the integrity constraint is not satisfied (an item of type *t* is also supplied by supplier *c2*).

This constraint can be rewritten as:

$$\leftarrow\ Supply(X,Y,Z) \wedge Class(Z,t) \wedge \mathrm{X} \neq \mathrm{c1},$$

where all variables are (implicitly) universally quantified. The residue of the literals appearing in the constraint are:

$$Res(Supply(X,Y,Z)\ =\ not\ Class(Z,t) \vee\ \ X = c1$$
$$Res(Class(Z,t))\ =\ not\ \ Supply(X,Y,Z) \vee\ X = c1$$

The iteration of the operator *T* to the query goal Class(Z,t) gives:

$$T0(Class(Z,t))\ =\ Class(Z,t),$$
$$T1(Class(Z,t)) = Class(Z,t) \wedge not\ Supply(X,Y,Z) \vee X = c1),$$
$$T2(Class(Z,t)) = Class(Z,t) \wedge (not\ Supply(X,Y,Z) \vee X = c1).$$

At Step 2 a fixpoint is reached since the literal *Class(Z,t)* has been "expanded" and the literal *not Supply(X,Y,Z)* does not have a residue associated to it. Thus, to answer the query *Q = Class(Z,t)* with the above integrity constraint, the query $T_\omega(Q){=}Class(Z,t) \wedge (\ not\ Supply(X,Y,Z) \vee X = c1)$ is evaluated. The computation of $T_\omega(Q)$ over the above database gives the result *Z=i1*.

The technique, more general than the previous ones, has been shown to be complete for universal binary integrity constraints and universal quantified queries. However, the rewriting of queries is complex since the termination conditions are not easy to detect and the computation of answers generally is not guaranteed to be polynomial.

- In Arenas et al. (2000) it is proposed an approach consisting in the use of a Logic Program with Exceptions (LPe) for obtaining consistent query answers. An LPe is a program with the syntax of an extended logic program (ELP), that is, in it we may find both logical (or strong) negation ($\neg$) and procedural negation (not). In this program, rules with a positive literal in the head represent a sort of general default, whereas rules with a logically negated head represent exceptions. The semantic of an LPe is obtained from the semantics for ELP's, by adding extra conditions that assign higher priority to exceptions. The method, given a set of integrity constraints ICs and an inconsistent database instance, consists in the direct specification of database repairs in a logic programming formalism. The resulting program will have both negative and positive exceptions, strong and procedural negations, and disjunctions of literals in the head of some of the clauses; that is it will be a disjunctive extended logic program with exceptions. As in (Arenas et al., 1999) the method considers a set of integrity constraints, IC, written in the standard format $\vee_{i=1}^{n} P_i(x_i) \vee \vee_{i=1}^{m}(\neg Q_i(y_i) \vee \varphi$ where φ is a formula containing only built-in predicates, and there is an implicit universal quantification in front. This method specifies the repairs of the database, D, that violate IC, by means of a logical program with exceptions, Π^D. In Π^D for each predicate *P* a new predicate P' is introduced and each occurrence of *P* is replaced by *P'*. More specifically, Π^D is obtained by introducing:

Persistence Defaults: For each base predicate *P*, the method introduces the persistence defaults:

$$P'(x)\ \leftarrow\ P(x),$$
$$\neg P'(x) \leftarrow\ not\ P(x).$$

The predicate *P'* is the repaired version of the predicate *P*, so it contains the tuples corresponding to *P* in a repair of the original database.

Stabilizing Exceptions: From each *IC* and for each negative literal *not* Q_{i0} in *IC*, the negative exception clause is introduced:

$$\neg Q'_{i0}(y_{i0}) \leftarrow \wedge_{i=1..n} \neg P'_i(x_i), \wedge_{i\neq 0} Q'_i(y_i), \varphi'$$

where φ' is a formula that is logically equivalent to the logical negation of φ. Similarly, for each positive literal P_{i1} in the constraint the positive exception clause:

$$P'_{i1}(x_{i1}) \leftarrow \wedge_{i\neq i1} \neg P'_i(x_i), \wedge_{i=1..m} Q'_i(y_i), \varphi$$

is generated. The meaning of the Stabilizing Exceptions is to make the ICs be satisfied by the new predicates. These exceptions are necessary but not sufficient to ensure that the changes the original subject should be subject to, in order to restore consistency, are propagated to the new predicates.

Triggering Exceptions: From the IC in standard form the disjunctive exception clause:

$$\vee_{i=1..n} P'_i(x_i) \vee \vee_{i=1..m} Q'_i(y_i) \leftarrow \wedge_{i=1..n} \; not\ P_i(x_i), \wedge_{i=1..m} Q_i(y_i), \varphi'$$

is produced.

The program Π^D constructed as shown above is a 'disjunctive extended repair logic program with exceptions for the database instance D'. In Π^D positive defaults are blocked by negative conclusions, and negative defaults, by positive conclusions.

Example 4. Consider the database $D = \{p(a), q(b)\}$ with the inclusion dependency *ID*: $p(X) \supset q(X)$

In order to specify the database repairs the new predicates *p'* and *q'* are introduced. The resulting repair program has four default rules expressing that *p'* and *q'* contain exactly what p and q contain, resp.:

$p'(x) \leftarrow p(x);$
$q'(x) \leftarrow q(x);$
$\neg p'(x) \leftarrow not\ p(x)$ *and*
$\neg q'(x) \leftarrow not\ q(x);$

two stabilizing exceptions :

$q'(x) \leftarrow p'(x);$
$\neg p'(x) \leftarrow \neg q'(x);$

and the triggering exception:

$\neg p'(x) \vee q'(x) \leftarrow p(x), not\ q(x).$

The answer sets are $\{ p(a), q(b), p'(a), q'(b), \neg p'(a) \}$ and $\{ p(a), q(b), p'(a), q'(b), q'(b) \}$ that correspond to the two expected database repairs.

The method can be applied to a set of domain independent binary integrity constraints *IC*, that is the constraint can be checked w.r.t. satisfaction by looking to the active domain, and in each *IC* appear at most two literals.

- In Greco and Zumpano (2000) a general framework for computing repairs and consistent answers over inconsistent databases with universally quantified variables was proposed. The technique is based on the rewriting of constraints into extended disjunctive rules with two different forms of negation (negation as failure and classical negation). The disjunctive program can be used for two different purposes: compute 'repairs' for the database, and produce consistent answers, i.e., a maximal set of atoms which do not violate the constraints. The technique is sound and complete (each stable model defines a repair and each repair is derived from a stable model) and more general than techniques previously proposed.

More specifically, the technique is based on the generation of an extended disjunctive program *LP* derived from the set of integrity constraints. The repairs for the database can be generated from the stable models of *LP*, whereas the computation of the consistent answers of a query *(g,P)* can be derived by considering the stable models of the program $P \cup LP$ over the database *D*.

Let *c* be a universally quantified constraint of the form:

$$\forall X \;\; [\, B_1 \wedge \ldots \wedge B_k \wedge not\ B_{k+1} \wedge \ldots \wedge not\ B_n \wedge \phi \supset B_0 \,]$$

then, *dj(c)* denotes the extended disjunctive rule

$$\neg B'_1 \vee \ldots \vee \neg B'_k \neg B'_{k+1} \wedge \ldots \vee B'_n \vee B'_0 \leftarrow (B_1 \vee B'_1), \ldots, (B_k \vee B'_k), (not\ B_{k+1} \vee \neg B'_{k+1}), \ldots, (not\ B_n \vee \neg B'_n), \phi, (not\ B_0 \vee \neg B'_0),$$

where B'_i denotes the atom derived from B_i, by replacing the predicate symbol *p* with the new symbol p_d if B_i is a base atom otherwise is equal to false. Let *IC* be a set of universally quantified integrity constraints, then $DP(IC) = \{ dj(c) \mid c \in IC \}$ whereas *LP(IC)* is the set of standard disjunctive rules derived from *DP(IC)* by rewriting the body disjunctions.

Clearly, given a database *D* and a set of constraints *IC*, $LP(IC)_D$ denotes the program derived from the union of the rules *LP(IC)* with the facts in *D* whereas $SM(LP(IC)_D)$ denotes the set of stable models of $LP(IC)_D$ and every stable model is consistent since it cannot contain two atoms of the form *A* and $\neg A$. The following example shows how constraints are rewritten.

Example 5. Consider the following integrity constraints:

$\forall X\ [\ p(X) \wedge not\ \ s(X) \supset q(X)\ ]$
$\forall X\ [\ q(X) \supset r(X)\ ]$

and the database D containing the facts p(a), p(b), s(a) and q(a).

The derived generalized extended disjunctive program is defined as follows:

$$\neg\, p_d(X) \vee s_d(X) \vee\; q_d(X) \leftarrow\; (p(X) \vee\; p_d(X)) \wedge$$
$$(\text{not}\;\; s(X) \vee \neg\, s_d(X)) \wedge (\text{not}\; q(X) \vee\; \neg\, q_d(X)).$$
$$\neg\, q_d(X) \neg\, r_d(X) \quad \leftarrow (q(X) \neg\, q_d(X)) \wedge (\text{not}\; r(X) \vee \neg r_d(X)).$$

The above rules can now be rewritten in standard form. Let P be the corresponding extended disjunctive Datalog program. The computation of the program P_D gives the following stable models:

$M_1 = D \cup \{\neg p_d(b), \neg q_d(a)\}$,
$M_2 = D \cup \{\neg p_d(b), r_d(a)\}$,
$M_3 = D \cup \{\neg q_d(a), s_d(b)\}$,
$M_4 = D \cup \{r_d(a), s_d(b)\}$,
$M_5 = D \cup \{q_d(b), \neg q_d(a), r_d(b)\}$ *and*
$M_6 = D \cup \{q_d(b), r_d(a), r_d(b)\}$.

A (generalized) extended disjunctive Datalog program can be simplified by eliminating from the body rules all literals whose predicate symbols are derived and do not appear in the head of any rule (these literals cannot be true). As mentioned before, the rewriting of constraints into disjunctive rules is useful for both (i) making the database consistent through the insertion and deletion of tuples, and (ii) computing consistent answers leaving the database inconsistent.

CONCLUSIONS AND FUTURE TRENDS

In the integration of knowledge from multiple sources two main steps are performed: the first in which the various relations are merged together and the second in which some tuples are removed (or inserted) from the resulting database in order to satisfy integrity constraints.

The database obtained from the merging of different sources could contain inconsistent data. In this chapter we investigated the problem of querying and repairing inconsistent databases. In particular we presented the different techniques for querying and repairing inconsistent databases (Agarwal et al., 1995; Lin and Mendelzon, 1996; Arenas et al., 1999; Greco and Zumpano, 2000).

As a future trend an interesting topic consists in specifying preference criteria so that selecting among a set of feasible repairs the preferable ones, i.e., those better conforming to the specified criteria. Preference criteria introduce desiderata on how to update the inconsistent database in order to make it consistent, thus they can be considered as a set of desiderata which are satisfied *if possible* by a generic repair. Therefore, informally a preferred repair is a repair that better satisfies preferences.

TERMS AND DEFINITIONS

Consistent Answer: A set of tuples, derived from the database, satisfying all integrity constraints.

Consistent Database: A database satisfying a set of integrity constraints.

Data Integration: A process providing a uniform integrated access to multiple heterogeneous information sources.

Database Repair: Minimal set of insert and delete operations which makes the database consistent.

Disjunctive Datalog Program: A set of rules of the form:

$$A_1 \vee \ldots \vee A_k \leftarrow B_1, ..., B_m, \text{not } B_{m+1}, \ldots, \text{not } B_n, \; k+m+n>0$$

where $A_1,\ldots,A_k, B_1,\ldots, B_n$ are atoms of the form $p(t_1,..., t_h)$, p is a predicate symbol of arity h and the terms $t_1,..., t_h$ are constants or variables.

Inconsistent Database: A database violating some integrity constraints.

Integrity Constraints: Set of constraints which must be satisfied by database instances.

C

Constructionist Perspective of Organizational Data Mining

Isabel Ramos
Universidade do Minho, Portugal

João Álvaro Carvalho
Universidade do Minho, Portugal

INTRODUCTION

Scientific or organizational knowledge creation has been addressed from different perspectives along the history of science and, in particular, of social sciences. The process is guided by the set of values, beliefs and norms shared by the members of the community to which the creator of this knowledge belongs, that is, it is guided by the adopted paradigm (Lincoln & Guba, 2000). The adopted paradigm determines how the nature of the studied reality is understood, the criteria that will be used to assess the validity of the created knowledge, and the construction and selection of methods, techniques and tools to structure and support the creation of knowledge. This set of ontological, epistemological, and methodological assumptions that characterize the paradigm one implicitly or explicitly uses to make sense of the surrounding reality is the cultural root of the intellectual enterprises. Those assumptions constrain the accomplishment of activities such as construction of theories, definition of inquiry strategies, interpretation of perceived phenomena, and dissemination of knowledge (Schwandt, 2000).

Traditionally, social realities such as organizations have been assumed to have an objective nature. Assuming this viewpoint, the knowledge we possess about things, processes, or events that occur regularly under definite circumstances, should be an adequate representation of them. Knowledge is the result of a meticulous, quantitative, and objective study of the phenomenon of interest. Its aim is to understand the phenomenon in order to be able to anticipate its occurrence and to control it.

Organizations can instead be understood as socially constructed realities. As such, they are subjective in nature since they do not exist apart from the organizational actors and other stakeholders. The stable patterns of action and interaction occurring internally and with the exterior of the organization are responsible for the impression of an objective existence.

BACKGROUND

The Rational and Emotional Nature of Personal Knowledge

Individual knowledge is actively constructed by the mind of the learner (Kafai & Resnick, 1996).

We make ideas instead of simply getting them from an external source. Idea making happens more effectively when the learner is engaged in designing and constructing an external artifact, which is meaningful for the learner, and he or she can reflect upon it and share it with others. From this constructionist description of the learning process, we can emphasize several elements associated with the creation of knowledge, namely, *cognition*, *introspection*, *action*, *interaction*, and *emotion*.

Through *cognitive* processes, humans construct mental representations of external and mental objects. *Introspection* is a specific type of cognition that permits the personal inquiry into subjective mental phenomena such as sensory experiences, feelings, emotions, and mental images (Damásio, 1999; Wallace, 2000). Through *action* and *interaction*, we create our experiences of the world we live in. The effective construction of personal knowledge requires the building of relationships between concepts and other mental constructs, in profoundly meaningful experiences (Shaw, 1996). All human experience is mediated by *emotions*, which drive our attention and concentration in order to help us to process external stimuli and to communicate with others.

The Historical and Socio-Cultural Context of Knowledge

A social reality is a construction in continuous reformulation that occurs whenever social actors develop social constructions that are external and sharable.

By the mere fact that people interact, influencing each other's mental constructs, social reality is in constant reconstruction. In this context, learning of new concepts and practices are happening continuously, either intentionally or unintentionally.

Learning happens inside specific mental and social spaces, meaning that what a group can learn is influenced by:

- The concepts, schemata, values, beliefs, and other mental constructs shared by the group.
- All knowledge we create about external things, events, and relationships, is based on and constrained by our mental constructs.
- The creation of knowledge is founded on the historical and socio-cultural context of its creators, providing a shared basis for the interaction inside a group. The continuous interaction of the group members, happening in a common environment, leads to similar mental constructs, a common interpretation of events, and the creation of shared meaning structures and external constructions.
- There is no viewpoint outside human subjectivity or historical and socio-cultural circumstances from which to study phenomena and to judge the inquiry process and the knowledge produced.

ODM AND KNOWLEDGE CREATION: PROBLEMS AND OPPORTUNITIES

ODM (also called Organizational Knowledge Discovery) has been defined as the process of analyzing organizational data from different perspectives and summarizing it into useful information for organizational actors who will use that information to increase revenues, reduce costs, or achieve other relevant organizational goals and objectives (Fayyad, Piatetsky-Shapiro, & Smyth, 1996; Matheus, Chan, & Piatetsky-Shapiro, 1993).

Data mining is a sub-process of the knowledge discovery. It leads to the finding of models of consumer behavior that can be used to guide the action of organizational actors. The models are built upon the patterns found out among data stored in large databases that are backed by statistical correlations among that data. Those patterns are extracted by specific mechanisms called data mining algorithms.

Attached to the discourse around the data mining tools, there is the idea that in the future, new and more powerful algorithms will be developed that will be able to find more valuable patterns and models, independently from human subjectivities and limitations. If it ever becomes possible to integrate the knowledge of the relevant business domain into the system, the algorithm would be able to decide the usefulness and validity of discovered patterns, correlations and models as well as to grow in sophistication by integrating these models in its knowledge of the business. The decision-making process would become extensively automated and guided by the objective reasoning of clear and rational rules implemented in a computer-based system.

However, this view has several drawbacks, namely:

1. Since all human knowledge has a tacit and non-expressible dimension, it will never be possible to integrate all relevant business knowledge in a repository to be analyzed by a data-mining algorithm.
2. The diversity of views about the business activities and their context is what allows for the emergence of organizational creativity and development, and the challenge of taken-for-granted concepts and practices (Bolman & Deal, 1991; Morgan, 1997; Palmer & Hardy, 2000). The stored knowledge representations are those around which there is some degree of consensus. This is important for the stability of work concepts and practices and to support organizational cohesion. However, they may also trap organizational actors in those concepts and practices, even when evidence shows they are threatening organizational success.
3. The relevance of knowledge representations stored in organizational repositories changes according to changes in the socio-cultural circumstances that offer the context for making sense of the representations. Only the organizational actors can understand those contexts and are able to give meaning to knowledge representations.
4. It is still believed that decision-making is or should be an essentially rational process, guided by cognitive processes such as planning, resolution of problems, and creativity (Sparrow, 1998). However, recent experiments in neurobiology show that emotion is an integral part of reasoning and decision-making (Damásio, 1999). Thus, only organizational actors can make decisions. The full automation of the process is not a realistic objective.

Instead of the present focus on the technological side of ODM, it would be interesting to adopt a constructionist approach and to focus on the social process of knowledge construction that makes ODM meaningful. With this new focus on people and the way they create and share knowledge, the main concern would be to mobilize the knowledge of organizational actors so the whole organization can benefit from it. This concern is justified by the awareness that the organization, seen as a community, is more intelligent than each one of its members, including any of its leaders.

LEVERAGING KNOWLEDGE CREATION IN ORGANIZATIONS: SOME CONSTRUCTIONIST GUIDELINES FOR ODM

With ODM, there is a special focus on knowledge about consumer behavior to support decision and action. ODM assists the organization in knowing the preferences of its customers and in anticipating their needs and reactions. The construction of this knowledge must be guided by the specific purposes of the several communities of practice that constitute the organization.

ODM and the knowledge it helps to create are social constructions. Repositories, data mining tools, and the resulting patterns, correlations and models are social artifacts that should be used to make ideas tangible, to negotiate meanings, and to facilitate communication between organizational actors. As such, they may become catalysts for the development of shared knowledge about consumer behavior, when they are used in the contexts of meaningful projects.

Data mining systems may become empowering tools in the sense that they make viable the analysis of large organizational repositories of knowledge representations. These knowledge representations are social constructions that connect organizational actors to a common view of the business concepts and practices that shape their intentions and interactions. Problems in the performance of organizational tasks or in organizational adaptation to environmental changes may reside in the inappropriateness of knowledge representations or in the tools used to extract rules and patterns from them. Knowledge representations were created and stored under specific historical and socio-cultural circumstances of which their readers must be aware in order to be able to understand their relevance or inadequacy.

Table 1 summarizes the constructionist guidelines for ODM, grouping them in two categories:

- guidelines that should be considered for the creation of rich learning environments in which data mining systems are used as social artifacts that leverage continuous learning, and
- guidelines that should be considered when using a specific data mining tool.

These guidelines are given from constructionist theories developed and applied in areas such as psychology, education, and organization theory.

FUTURE TRENDS

According to the assumptions of the constructionist perspective, ODM should be designed to involve organizational actors in the social construction of something

Table 1. A summary of constructionist guidelines for ODM

Creating rich learning environments	Using data mining tools
Work relationships must be strengthened in order to create the social cohesiveness needed for the ongoing production of shared constructions that engage the organization in developmental cycles.	Data mining results will support insight and creativity when organizational actors have enough time to reflect upon them and the opportunity to externalize and discuss their interpretations.
The construction of knowledge about customers' preferences and their future needs and reactions must be guided by the shared purposes of the specific communities of practice that constitute the organization.	Effective formal and informal communication must be fostered in order to become possible to discuss each other's interpretations of past experience in the light of the context in which it occurred.
Organizational repositories, data mining tools, and the results of data mining are social artifacts that should be used to make ideas tangible, to negotiate meanings, and to facilitate communication between organizational actors.	Theoretical tools, locally or externally developed, should be used to critically analyze the old meaning structures, facilitating the rearrangement of those structures.
Knowledge representations were created and stored under specific historical and socio-cultural circumstances of which their readers must be aware in order to be able to understand relevance or inadequacy of those representations.	The search and interpretation of patterns and models of consumer behavior should be guided by a multi-dimensional knowledge of the business domain, and work concepts and practices.

external and sharable. The designing of a marketing campaign, the making of a decision, the transformation of work concepts and practices are examples of social construction processes for which ODM could be viewed as relevant.

As a result of the process, the individual and shared knowledge will become more sophisticated, empowering the action of individuals and groups, and facilitating interaction. In this way, organizational actors consciously create cohesive and pluralist work environments, more prone to deal with problems and difficult decisions associated with consumer behavior. This perspective is more realistic than the traditional view of ODM as a process of making knowledge neutral and independent of the knower and social contexts in which it is created, in order to support decision-making processes idealized as inherently rational.

The tools used to support ODM fundamentally shape and define the process. Lack of appropriate tools impoverishes a social setting and makes social construction difficult. Future research is needed to study if current data mining systems facilitate organizational developmental activities. It will also be important to create practical experiences of designing and implementing the ODM process in specific organizational settings so that learning from a constructionist perspective can be supported.

CONCLUSION

This article describes ODM as a process for the social construction of knowledge. As such, the focus changes from the technology used to discover patterns in the stored data to the human and social issues surrounding knowledge creation in organizations.

Managers should provide the resources and the conditions for the emergence of rich learning environments in which data repositories and data mining tools sustain collective cognitive processes such as memory, reasoning, language and attention. In this way, ODM becomes a key organizational process in the construction of organizational representations of external realities. These representations will guide organizational decision and action. In accordance with this view, this article provides a summary of constructionist guidelines for ODM to help managers leveraging knowledge creation in organizations.

KEY TERMS

Constructionism: A set of theories that defines the human beings as active constructors of their own learning and development. This learning and development of knowledge happens more effectively when individuals are involved in the construction of something external, something that can be shared, or both.

Objective Social Reality: It has an independent existence from any account of it.

Objectivism: A set of theories that views true knowledge about external realities, and the process of its creation, as neutral and independent of the knowledge creator.

Rich Learning Environment: Learning environments in which the learner is empowered to create a strong connection with the reality of interest by directly experiencing with it in order to develop mental constructs that are deep, complex, pluralist, and emotionally rich.

Social Constructions: External and sharable concepts, associations, artifacts, and practices that people actively develop and maintain in their social settings. An organization is an example of a social construction that interconnects its members in a specific social setting, in which many other social constructions are continuously being developed and maintained.

Socially Constructed Reality: It is created through purposeful human action and interaction. This reality is shaped by the individual's subjective conceptual structures of meaning. It is reconstructed by the human interactions that support continuous reinterpretations and change of meanings. The social institutions are the means through which meanings are stabilized and the social reality assumes an objective appearance.

Contemporary IT-Assisted Retail Management

Herbert Kotzab
Copenhagen Business School, Denmark

INTRODUCTION

Retailing can be defined as a set of specific business processes that add value to products and services sold to end users (e.g., Levy & Weitz, 2003). Such retail business processes refer to *marketing processes* (like assortment in order to provide end users with a required mix of products and services in terms of quantity as well as quality; and advice, advertising, and credit processes, which ease the purchase for end users, for example, offering special payment modes or informing end users about the offers) and *logistics processes* (such as transportation, breaking bulk, and inventory handling). The orchestration of these functions leads to various types of retail formats such as store-based retailers (e.g., supermarkets, hypermarkets, or category killers), non-store-based retailers (e.g., mail-order retailing or electronic commerce), and hybrid retailers (e.g., home delivery services or party sales services; Coughlan, Anderson, Stern, & El-Ansary, 2001).

Although retailing plays a vital role in today's economy, retailing companies also face economic pressure as many players operate mainly in mature and stagnant markets (e.g., Seth & Randall, 2001). In order to face these specific challenges, retailing companies adapted strategies that allow them to gain economies of scale by offering highly customized solutions to their customers (see Table 1).

These strategies are called IT-assisted retail management strategies as they are built upon the latest developments in information technology (IT). The following chapter presents an overview of contemporary IT-based retail business models and frameworks that show how IT has created a new mandate for retail management. IT is defined here as the hard- and software that collects, transmits, processes, and circulates pictorial, vocal, textual, and numerical data and information (e.g., Hansen & Neumann, 2001; Chaffey, 2004). The following are technologies of special interest used in IT-assisted retail management.

- Mobile data-capturing terminals, light pens, bar-code readers, bar-code labels, disks, chip cards, RFID (radio frequence identification), sensors to collect information
- Database systems, tapes, CDs, DVDs, optical disks, document-retrieval systems to store information
- PCs, information retrieval, decision support systems, expert systems (MIS, EIS, MSS, ESS to process information)
- Services (e.g., fax, e-mail, EDI [electronic data interchange], Web-EDI, FTP, WAIS, World Wide Web, SMTP, TCP/IP), networks (videoconferencing, teleconferencing, voice mail, ISDN, LAN, WAN, fiber optic, and intra-, inter-, and extranet), devices (e.g., phones, TV, radio, fax machine, PC, PDA [personal digital assistant]) to transmit information

The increasing use of these technological possibilities leads to major changes in the strategic management of distribution channels as the layers are compressed and the distances between the first and last echelon of the channel are reduced (e.g., Coughlan et al., 2001; Porter, 2001). Leading retailers are aware of these possibilities and implement customized POS-data-based marketing strategies (IT-based retail marketing) and demand syn-

Table 1. Cornerstones of contemporary IT-based retail management (see Kotzab, Schnedlitz, & Neumayer, 2003)

IT-based retail marketing strategies	IT-based retail logistics systems
• Reengineered, IT-driven retail formats allowing a customized shopping experience • Development of new retail channels, e.g., Internet-based retail formats to address new customer segments • Category management in order to offer client-oriented sets of products, resulting from a joint-planning process with manufacturers based on real-time accessed client data	• The implementation of just-in-time-oriented replenishment systems by connecting the electronic point-of-sale (EPOS) systems with the manufacturers' ERP systems • The execution of IT-driven distribution-center operations with no-inventory-holding transit terminal structures • The realization of vendor-managed inventory programs on a continuous–replenishment basis to reduce inventory levels and to improve order cycles

chronized replenishment systems (IT-based retail logistics).

BACKGROUND

IT-Based Retail Marketing Processes

Business practice shows a huge variety of IT-based retailing marketing strategies that includes the use of smart cards, theft prevention, self-checkout systems, Web kiosks, and/or merchandise-planning systems. The common goal of all strategies is to obtain better information on consumer behavior in order to improve customer service. IT-based retail marketing affects in that sense all retail areas from the sales floor to the back offices (Kotzab, Schnedlitz, et al., 2003).

Referring to store-based retailing, IT influences the layout and the atmosphere of a store by optimizing the link between sales productivity and consumer excitement (Nymphenburg, 2001). Metro introduced recently its future store concept that promotes technologically driven innovations in IT-assisted retail marketing as offered by the combined use of RFID, electronic shelf labels, self-checkout systems, personal shopping agents, in-store media such as info terminals, loyalty cards, personal shopping assistants for shoppers, personal digital assistants for employees, and intelligent scales (e.g., Metro, 2003; NCR, 2003; Ody, 2002).

Another prototype of a modern supermarket can be found in Austria (see Kotzab, Schnedlitz, et al., 2003), where Rewe Austria operates in Purkersdorf (nearby Vienna) an outlet where shoppers self-register their purchases via self-scanning devices. Rewe also uses the "talking" or "communicating" shopping cart WATSON, whose technology is based on radio frequency. Whenever passing a labeled shelf, the cart announces a message to the shopper (Atlas New Media, 2001).

Other recent examples are presented by Carter and Lomas (2003), who refer to a Sainsbury store in Hazelgrove (UK) and a Darty store in France that represent the state of the art of technology-driven store layout.

IT also changed the organizational setup from hierarchical to hybrid or borderless arrangements such as category management (CM; Gruen, 2002). CM is a joint retailer and manufacturer effort that involves managing product categories as business units and customizing them on a store-by-store basis to satisfy end-user needs (Dussart, 1998). The purpose is to identify those combinations of products that make up consumers' expectations. CM replaces traditional product-focused strategies (e.g., brand management) and allows retailers and suppliers to faster react to shifts in the marketplace (Schröder, 2003). The increasing use of data-warehousing and data-mining approaches helps to use the scanner data more efficiently in order to establish customer-oriented assortments (Chen et al., 2000).

The RFID technology (e.g., AIMGLOBAL, 2004; Öztürk, 2003) especially seems to change retailing marketing but also logistics dramatically. The Exxon Speedpass program might be the new way of cashless payment as immediate authorization is possible and it reduces the waiting time enormously (Speedpass, 2003). Metro's future store concept also shows that self-scanning processes can also be replaced by RFID. Wal-Mart, however, intends to implement RFID with about 100 vendors in order to improve the replenishment processes (Ashcroft, 2003).

IT-Based Retail Logistics Processes

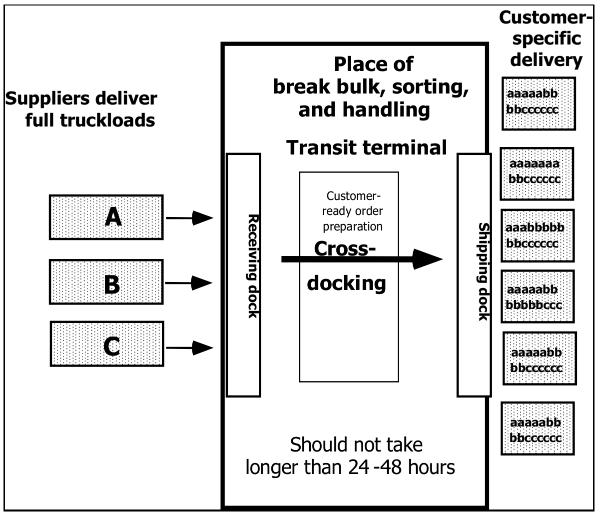
Logistics in a retailing context refers to multiechelon logistics systems with many nodes from the original supplier to the final store destination (Kotzab, 2002). The use of specific IT in retail logistics, such as EDI (e.g., EANCOM, EDIFACT, ANSI X.12), bar codes (e.g., EAN/UCC) and scanner technology, converted traditional retail logistics systems into just-in-time-oriented retail supply chain management systems. A channel-wide use of technology allows harmonization and synchronization of logistics operations between retailers and their suppliers, and give retailers additional profitability as such systems operate on a pull instead of a push base. Consequently, the total bullwhip effect in such channels is reduced (Lee & Whang, 2002).

The major IT-assisted retail logistics processes are cross-docking and continuous replenishment (Kotzab, Schnedlitz et al., 2003), and recently collaborative planning forecasting and replenishment (CPFR; Skjoett-Larsen, Thernoe, & Andresen, 2003).

Cross-docking is the metaterm for all IT-related flow-through activities within a distribution center that provide tailor-made deliveries on a just-in-time basis. Different vendors deliver full truckloads of their goods to a retailer's transit terminal (a reengineered distribution center; also called a transshipment point). The goods are there consolidated and/or broken to vendor-integrated, POS-required smaller delivery units (see Figure 1).

Cross-docking's basic idea is to avoid inventory at the distribution-center level, which leads to a lot of replacement of stock-holding activities through sorting, transportation, and handling activities, which are controlled by increased use of IT (e.g., EAN/UCC 128 in combination with EANCOM messages). The relevant literature offers various types of cross-docking operations depending whether vendors deliver prelabeled units

Figure 1. Basic cross-docking operation (Kotzab, 1997)



to the distribution center (complex cross-docking), full pallets or cases (full pallet cross-docking versus break-bulk cross-docking), or customized mixed or nonmixed pallets (e.g., Napolitano, 2000).

While cross-docking refers to IT-assisted logistics on a distribution-center level, vendor-managed inventory (VMI) or continuous replenishment (CRP) refer to all cooperative forms of an interfirm, automated replenishment program where the common goal is the automatic reinforcement of the supply of goods and the transfer of the burden of responsibility of storage from a retailer to a vendor.

Within any VMI/CRP setting, retailers retransfer the inventory competence back to their vendors by agreeing on certain average inventory levels on the distribution-center level, service levels, and/or other arrangements like the reduction or avoidance of out-of-stock situations (Raman, DeHoratius, & Zeynep, 2001). Within VMI/CRP, the former one-to-one relationship (where a seller and a buyer individually represented the goals of their companies) is replaced by interdepartmental, interorganizational teams, which are responsible for the ordering process (Waller, Johnson, & Davis, 1999).

A further development in IT-based retail logistics can be seen in the use of CPFR that is defined by the Voluntary Interindustry Commerce Standards (VICS) as "a collection of new business practices that leverage the Internet and electronic data interchange in order to radically reduce inventories and expenses while improving customer service" (VICS, 1998b). This definition suggests that the Internet and electronic data interchangeare substantial prerequisites of CPFR.

VICS also crafted a guideline in the form of a nine-step model detailing how to implement CPFR (VICS 1998a; see Table 2).

As Fliedner (2003, p. 15) points out, these steps can be seen as a "cyclic and iterative approach to derive consensus supply chain forecasts." The CPFR process builds to a large extent on the exchange of information among collaboration partners. This exchange of information can be carried out through the use of various technologies such as EDI, private networks, or the Internet (XML [extended markup language]). For the processing of information, a large number of software programs have

Figure 2. Basic continuous replenishment process (Glavanovits & Kotzab, 2002)

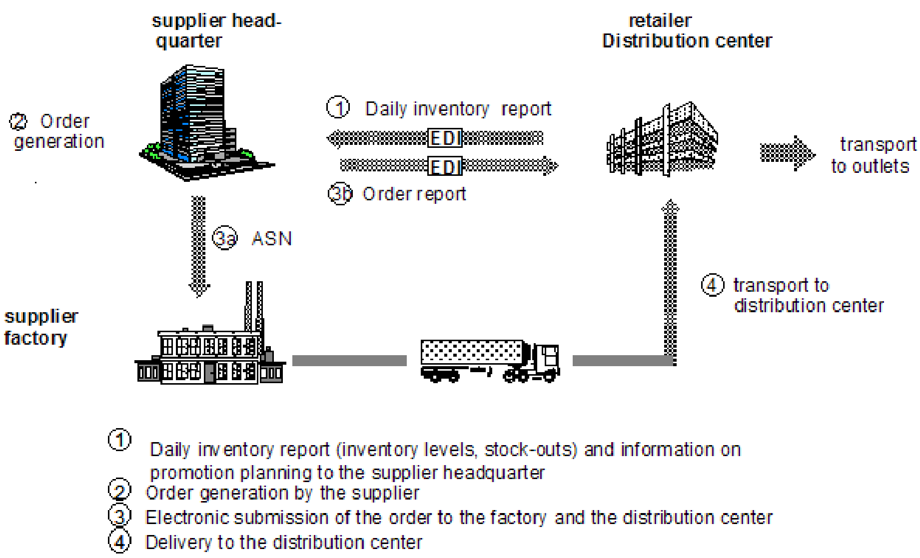


Table 2. CPFR implementation guideline (see Kotzab, Skjoett-Larsen, Andresen, & Thernoe, 2003)

Step	Activity	Description
1	Develop front-end agreement	A front-end agreement is developed. Criteria for success are established. Identification of the CPFR project owners in the companies. Financial reward and contribution system is agreed upon.
2	Create joint business plan	A joint business plan for the areas of collaboration is created. (plans regarding advertising campaigns, etc.)
3-5	Sales-forecast collaboration	The parties get together with each of their customer-demand prognoses to establish a common prognosis. In case of deviation from forecast, the partners meet to discuss deviations and to update the common forecast.
6-8	Order-forecast collaboration	The partners share replenishment plans and discuss deviations and constraints.
9	Order generation	The reordering process/goods flow is initiated. Result data is discussed (POS, orders, shipments). Forecast deviation and stock-level problems are identified and solved.

been developed to support the CPFR processes (e.g., Syncra, Logility, Manugistics; i2 Technologies, E-Millennium, E3, J.D. Edwards, Numetrix og Excentric, SAP, Oracle, Baan, or Peoplesoft; see Kotzab, Skjoett-Larsen, et al., 2003).

FUTURE TRENDS

A major revolution in retailing can be seen in Web-based retailing (e-tailing) as offered by pure virtual retailers (dot-coms, e.g., Amazon.com) or multichannel retailers ("bricks and clicks," e.g., Wal-Mart with Wal-mart.com). The business challenge of e-tailing can be seen rather in logistics than in order generating as the most prominent example of Webvan.com has shown. The concept of home delivery receives due to these developments a renaissance, for example, known as consumer direct services (Corbae & Balchandani, 2001). Experts estimate the total home delivery market in the grocery industry to be an over-100-billion-Euro business, including over 900 million deliveries per year to over 35 million households.

IT-assisted home delivery concepts try to optimize the so-called last mile to the consumer, which is the most expensive part of the total supply chain. There are plenty of home delivery systems, which either deliver the products directly to the homes or where customers collect their purchased goods at certain pickup points (e.g., Pflaum, Kille, Mirko, & Prockl, 2000, Punikavi, Yrjölä, & Holmström, 2001, Siebel, 2000). Prominent examples for pickup-point solutions are the Tower 24 concept or the pick-point concept (Burtscher & Köppel, 2002).

CONCLUSION

The chapter described the consequences of the use of IT in the field of retailing. It was shown how IT can be used in retail marketing to reengineer retail formats in order to allow a customized shopping experience. IT-assisted retail logistics refers to just-in-time-oriented demand-synchronized delivery systems. The increased use of such systems will lead in the future to more hybrid retail management strategies, where the organizational borders between retailers, suppliers, and even consumers will disappear.

KEY TERMS

Bar Codes: Simple form of optical character recognition, where information is encoded in printed bars of relative thickness and spacing. RFID combines this technology with radio frequency.

Electronic Data Interchange (EDI): Metaterm for a multitude of different electronic message standards that allow a computerized and highly structured, low-error communication between computers. A "merge" between EDI and Internet technology can be recently observed by the upcoming of Web-based EDI solutions, where on EDI partner does not have to install EDI, but uses common Web browsers to communicate via EDI.

Electronic Shelf Labels: Price tags that provide accurate pricing due to electronic linkage between the shelves and the checkout system. The technology is based on radio frequency, infra-red, and/or WLAN linking a master checkout with the shelves.

Intelligent Scale: A scale that is equipped with a special camera and identification software. Based on an object's structure, size, color, and thermal image, the scale automatically recognizes the item, weighs it, and prints out a price tag.

RFID (Radio Frequency Identification): Form of automated-radio-frequency-based identification of objects. RFID systems consist of an antenna, a transceiver for reading radio frequency and to transfer information, a processing device, and a transponder.

Scanner: Electronic devices that convert bar-code information into digitized electronic images.

Self-Checkout Systems: Self-checkout systems can occur at the end or during shopping processes whenever cash-desk operations are "outsourced" to consumers. In that case, consumers self-register their items with specific scanning devices.

Virtual Shopping Assistant: Small mobile computer with a touch screen and bar-code scanner that can be installed to a shopping trolley and can serve as a personal shopping advisor (e.g., offering a customized shopping list).

Content Description for Face Animation

Ali Arya
Simon Fraser University, Canada

INTRODUCTION

Face animation is a challenging area of computer graphics and multimedia systems research (Parke, 1996). Realistic personalized face animation is the basis for virtual software agents that can be used in many applications, including video conferencing, online training and customer service, visual effects in movies, and interactive games. A software agent can play the role of a trainer, a corporate representative, a specific person in an interactive virtual world, and even a virtual actor. Using this technology, movie producers can create new scenes including people who are not physically available. Furthermore, communication systems can represent a caller without any need to transmit high volume multimedia data over limited bandwidth lines. Adding intelligence to these agents makes them ideal for interactive applications such as online games and customer service. In general, the ability to generate new and realistic multimedia data for a specific character is of particular importance in cases where prerecorded footage is unavailable, difficult, or expensive to generate, or simply too limited due to the interactive nature of the application.

Personalized face animation includes all of the algorithms, data, modules, and activities required to create a multimedia presentation resembling a specific person. The input to such a system can be a combination of audio-visual data and textual commands and descriptions. A successful face animation system needs to have efficient yet powerful solutions for providing and displaying content, for example, a content description format, decoding algorithms, creating required content, and finally, an architecture to put different components together in a flexible way. Multimedia modeling and specification languages play a major role in content description for face animation systems both as general tools and in customized forms. Such descriptions can be used for authoring and also as run-time input to the animation system.

BACKGROUND

The diverse set of works in multimedia content description involves methods for describing the components of a multimedia presentation and their spatial and temporal relations. Historically, some of the first technical achievements in this area were related to video editing where temporal positioning of video elements is necessary. The SMPTE (Society of Motion Picture and Television Engineers) time coding that precisely specifies the location of audio/video events down to the frame level is the base for EDL (Edit Decision List) which relates pieces of recorded audio/video for editing (Ankeney, 1995; Little, 1994). Electronic program guide (EPG) is another example of content description for movies in the form of textual information added to the multimedia stream. More recent efforts by SMPTE are focused on a metadata dictionary that targets the definition of metadata description of content (see *http://www.smpte-ra.org/mdd*).

Motion Picture Expert Group (MPEG) is another major player in the field of standards for multimedia content description and delivery. MPEG-4 standard (Battista et al., 1999), introduced after MPEG-1 and MPEG-2, is one of the first comprehensive attempts to define the multimedia stream in terms of its forming components (objects such as audio, foreground figure, and background image). Users of MPEG-4 systems can use object content information (OCI) to send textual information about these objects. MPEG-7 standard, mainly motivated by the need for a better and more powerful search mechanism for multimedia content over the Internet, can also be used in a variety of other applications including multimedia authoring. The standard extends OCI and consists of a set of descriptors for multimedia features (similar to metadata in other works), schemes that show the structure of the descriptors, and a description/schema definition language based on eXtensible Markup Language (XML).

Most of these methods are not aimed at, and customized for, a certain type of multimedia stream or object. This may result in a wider range of applications but limits the capabilities for some frequently used subjects such as the human face. The study of facial movements and expressions started from a biological point of view by scientists such as John Bulwer and Charles Darwin (see Ekman & Friesen, 1978). More recently, one of the most important attempts to describe facial activities (movements) was the Facial Action Coding System (FACS). Introduced by Ekman and Friesen (1978), FACS defines 64 basic facial action units (AUs), such as raising brows, talking, and turning left and right. It should be noted though, that FACS does not provide any higher-level construct to describe the sequence of actions and spatial and temporal relations between facial activities. In other words, it is not designed to be a face animation description language.

MPEG-4 standard uses an approach similar to FACS to integrate face animation into multimedia communication, by introducing face definition parameters (FDPs) and face animation parameters (FAPs). FDPs define a face by giving coordinates and other information for its major feature points such as eyes' and lips' corners. They allow personalization of a generic face model to a particular face, and are more suitable for synthetic faces. FAPs, on the other hand, encode the movements of these facial features. There are more than 70 FAPs defined similar to FACS AUs.

Although MPEG-4 defines two sets of higher-level codes, that is, visemes and expressions, compared to low-level FACS AUs, but it still has only a set of animation commands and not an animation language. Synchronized Multimedia Integration Language (SMIL), an XML-based language, is designed to specify temporal relation of the components of a multimedia presentation, especially in Web applications (Bulterman, 2001).

There have also been different languages in the fields of virtual reality and computer graphics for modeling computer-generated scenes. Examples are Virtual Reality Modeling Language (VRML, *http://www.vrml.org*), its XML-based version known as X3D, and programming libraries like OpenGL (*http://www.opengl.org*). MPEG-4 standard includes Extensible MPEG-4 Textual format (XMT) framework to represent scene description in a textual format providing interoperability with languages such as SMIL and VRML.

None of these languages are customized for face animation, and they do not provide any explicit support for it, either. Recent advances in developing and using embodied conversational agents (ECAs), especially their Web-based applications, and growing acceptance of XML as a data representation language have drawn attention to markup languages for virtual characters. The basic idea is to define specific XML constructs related to agents' actions such as moving and talking. Virtual Human Markup Language (VHML, *http://www.vhml.org*) is an example in this regard (Marriott & Stallo, 2002). It comprises a number of special purpose languages, such as Emotion Markup Language (EML), Facial Animation Markup Language (FAML), and Body Animation Markup Language (BAML). A simple VHML document looks like this:

- <vhml>
  <person disposition=”angry”>
  <p>
  First I speak with an angry voice and look very angry,
  <surprised intensity=”50”>
  but suddenly I change to look more surprised.
  </surprised>
  </p>
  </person>
  </vhml>

Multimodal Presentation Markup Language (MPML, *http://www.miv.t.u-tokyo.ac.jp/MPML/en*) is another XML-based markup language developed to enable the description of multimodal presentation on the WWW, based on animated characters (Prendinger et al., 2002). MPML addresses the interactivity and decision-making not directly covered by VHML, but both suffer from a lack of explicit compatibility with MPEG-4 (XMT, FAPs, etc.).

Another important group of related works are behavioural modeling languages and tools for virtual agents. Behaviour Expression Animation Toolkit (BEAT) is an XML-based system, specifically designed for human animation purposes (Cassell et al., 2001). It is a toolkit for automatically suggesting expressions and gestures, based on a given text to be spoken. BEAT uses a knowledge base and a rule set, and provides synchronization data for facial activities, all in XML format. Although BEAT is not a general content description tool, it demonstrates some of the advantages of XML-based approaches together with the power of behavioural modeling.

Another group of researchers have proposed the concept of cognitive modeling for character animation (Funge et al., 1999). Their system is based on a set of geometric, behavioural, and cognitive models for the characters to be animated. In this approach not only the physical capabilities but also the behavioural and cognitive processes are defined and modeled. A special Cognitive Modeling Language (CML) is also developed to support this system. CML does not provide any explicit support for face animation and, unlike BEAT, is not XML-based. Neither is Parameterized Action Representation (PAR), another language proposed to describe and model actions of an agent, based on interaction with environment and the personality and emotions (Allbeck & Badler, 2002). In PAR, the agent personality is defined in terms of parameters such as openness, agreeableness, and extraversion. Similar parameters are defined for other aspects affecting the behaviour.

FACE MODELING LANGUAGE (FML)

Face Modeling Language (FML) is part of the ShowFace Personalized Face Animation Framework (Arya & Hamidzadeh, 2002). FML (*http://www.raminsoftworx.com/Research/fml_1.html*) is an XML-based language to provide structure content description, that is, a hierarchical description of animation events from low-level movements such as MPEG-4 FAPs to high-level stories. A sample FML document is shown here:

```
<fml>
 <model>    <!— Model Info —>
   <img src=”me.jpg” />
   <range dir=”0” val=”60” />
   <event id=”user” val=”-1” />
   <template name=”hello” >
       <seq begin=”0”>
           <talk begin=”0”>Hello</talk>
           <hdmv begin=”0” end=”5” dir=”0” val=”30” />
       </seq>
   </template>
 </model>
 <story>    <!— Story Timeline —>
   <action>
       <behavior template=”hello” />
       <excl ev_id=”user”>
           <talk ev_val=”0”>Hi</talk>
           <talk ev_val=”1”>Bye</talk>
       </excl>
       <par begin=”0”>
           <talk begin=”1”>Hello World</talk>
           <exp begin=”0” end=”3” type=”3” val=”50” />
       </par>
   </action>
 </story>
</fml>
```

Each FML module has two main parts: **model** and **story**. The former defines initialization, movement ranges, and behavioural templates. The latter describes the animation sequence in a hierarchical way. Each story consists of **actions** (independent meaningful sets of moves). At the lower level, there are time containers: **par**, **seq**, and **excl**. The first two construct parallel and sequential moves. **excl** is used for decision-making, that is, waiting for an event such as user input and taking different paths based on its value. The XML-based nature of this language allows the FML documents to be embedded in Web pages. Normal XML parsers can extract data and use them as input to an FML-enabled player through simple scripting. Such a script can also use an XML Document Object Model (DOM) to modify the FML document, for example, adding certain activities based on user input. This compatibility with Web browsing environments gives another level of interactivity and dynamic operation to FML-based systems.

Another aspect of FML is its compatibility with MPEG-4 face definition/animation parameters. This has been achieved by:

- Translation of FML documents to MPEG-4 codes by the media player;
- Embedded MPEG-4 elements (fap element is considered to allow direct embedding of FAPs in FML document); and
- Integrating FML into XMT framework by FML-to-MPEG converters.

FUTURE TRENDS

Rapid growth of “face-based” applications requires a more systematic and comprehensive approach to content description for facial animation. Some future trends in this regard can be:

- Behavioural modeling, that is, addition of language constructs that model and describe personality, mood, and behavioural rules;
- Better integration with MPEG-4 standard, for example, translation tools for dedicated face animation languages to/from MPEG-4 stream format; and
- Authoring tools, that is, user-friendly GUI environments to create scripts.

CONCLUSION

Content description, as a major issue in multimedia systems, is briefly discussed. Considering face animation systems as a challenging example, different approaches are reviewed. It can be seen that although general-purpose modeling, specification languages and coding systems are powerful means, a dedicated language for face animation is required to provide a higher level of abstraction, ease of programming, and compatibility with existing multimedia standards and technologies.

After reviewing some other languages, XML-based Face Modeling Language (FML) is introduced as a good example. FML allows event handling, and also sequential or simultaneous combination of supported face states, and can be converted to a set of MPEG-4 face animation parameters. Main contributions of FML are its hierarchical structure, animation configuration and modeling, flexibility for static and dynamic scenarios, and dedication to face animation. FML fully supports MPEG-4 FAPs using high-level constructs which can be translated to FAPS and also direct FAP embedding. Compatibility with MPEG-4 XMT and use of XML as a base are also among the important features in the language. Future extensions to FML can include more complicated behaviour modeling and better integration with MPEG-4 streams.

KEY TERMS

Agent: A virtual representation of real or imaginary human beings in software systems.

Bandwidth: Maximum data transfer capacity of a communication channel.

Cognitive Modeling: Algorithms for representing and simulating the cognitive process, for example, to add intelligence to software agents.

Document Object Model (DOM): An object-oriented model representing different components of a system and their interfaces. In XML, DOM allows working with language elements as interactive objects with data, methods, and events.

Extensible Markup Language (XML): A general-purpose data representation language similar to HyperText Markup Language (HTML) used in Web pages.

Face Model: General information required for recreating faces in a computer graphics system, for example, geometrical parameters.

Metadata: Information about the content as opposed to the data themselves.

Multimedia Stream: Progressively transmitted/received data corresponding to a multimedia presentation, as opposed to a file containing all the data.

Virtual Reality: Computer-generated environment that simulates three-dimensional reality.

Content Management in Organizations

Anne Honkaranta
University of Jyväskylä, Finland

Pasi Tyrväinen
University of Jyväskylä, Finland

INTRODUCTION

Content management may be characterized as "*a variety of tools and methods that are used together to collect, process, and deliver content of diverse types*" (McIntosh, 2000, p. 1). At least three differing approaches on content management may be identified: 1) Web content management, 2) Document management, and 3) Utilization of structured documents.

The Web has become a widely used, yet more complex platform for disseminating a portion of organizational content. Hence new means for creating, publishing and managing content on the Web have been sought (Grossniklaus & Norrie, 2002). A great deal of current research efforts (e.g., Boiko, 2002; Grossniklaus & Norrie, 2002; McIntosh, 2000; Weitzman et al., 2002) are targeted specifically for Web content management. The underlying approaches and conceptual base used can be traced to electronic publishing (e.g., Boiko, 2002), and to database-oriented approaches (e.g. McIntosh, 2000). Continuous adoption of new technologies and system versions (Balasuramanian & Bashan, 1998), and technology-driven development (Weitzman et al., 2002) are also characteristic to the Web content management approach.

Documents as identifiable units of content, flexibly structured for human comprehension (Murphy, 1998; Salminen, 2000), have traditionally been considered as containers for organizational content. Research on document management in organizations has included a multitude of focuses, from document standardization (Salminen, 2000), document metadata (Murphy, 1998), and requirements elicitation (Lyytikäinen, 2003), to document and information retrieval (Blair, 2002). Approaches and methods, such as the Stair Step method (Koulopoulos & Frappaolo, 1995) and the RASKE methodology (e.g., Salminen, 2000) have been developed. The wide selection of document management systems available (Doculabs, 1998) includes systems that are evolving towards content management (Medina, Meyers, Bragg, & Klima, 2002). The essential features of document management systems cover:

- library services and version management,
- management of user roles and access rights,
- support for document life-cycle and related workflows,
- management of *metadata*, as information about documents, and
- multichannel publishing for a multitude of devices and print.

In *structured documents*, such as documents defined by Extensible Markup Language (XML; Bray, Paoli, Sperberg-McQueen, Maler, & Yergeau, 2004), the content itself, the logical structure, and the visual layout for the content are separated from each other and made visible both for humans and computer software by using markup delimiters. The logical content is described as a hierarchy of named elements and associated attributes. A *Document Type Definition* (DTD) or an *XML schema* (Fallside, 2001) may be used to define the markup vocabulary and the structure for a class of XML documents. The research on structured documents has principally focused on document grammars and transformations (Lindén, 1997), assembly (Heikkinen, 2000), and schema design (Maler & El Andaloussi, 1996). XML standardization in organizations (Salminen, 2000), and Enterprise Application Integration (Linthicum, 2000) have also been studied. For content management, the structured documents provide means to access logical content units that are portions of contents within documents, and to separate the content from its layout properties.

BACKGROUND

Challenges on content management in organizations include finding the right focus, breadth and width for content management development with the limited resources available. A content management development project may cover the bulk of content used in an organization (e.g., Karjalainen, Päivärinta, Tyrväinen, & Rajala, 2000; Munkvold, Päivärinta, Hodne, & Stangeland, 2003), it may be focused only to a specific set of documents and related content (e.g., Honkaranta & Lyytikäinen, 2003; Honkaranta, Salminen & Peltola, 2005), or to a certain process, such as multichannel publishing (Boiko, 2002). In practice, a number of variations of content management focuses exist. An organization may need to combine research findings and technologies, and overcome the deficiencies of the diverse approaches developed for content management. The limitations of the approaches are discussed on the remainder of this section.

The Web content management approach focuses on the multichannel and Web content publishing. This approach suffers from immature systems and fast technical evolution, which make the approach laborious to adopt for organizations. The complexity on systems and technologies may consume a great deal of resources, causing that social aspects of content management may be overlooked. The conceptual base for the approach is inconsistent and immature (Grossniklaus & Norrie, 2002). Differing terms, such as object, component, content item, and content unit, may all be used to refer to the content. The phases of a content life-cycle may be overloaded with a myriad of concepts which are new to the people in an organization. For example, according to McIntosh (2000, p.1), a content life cycle consists of three main phases; 1) content assembly, 2) content production, and 3) content delivery, whereas Boiko (2002) utilizes concepts such as content acquisition, aggregation and metatorial processing. The lack of a concise conceptual base may hinder requirements elicitation and cause communicational breakdowns between system analysts and the people in an organization.

Applicability of document management approach and systems for content management have been limited by orientation towards managing content as document units only. For example, long documents are difficult to browse thorough, portions of document content may need to be reused in other documents, and long documents are inconvenient for Web delivery (e.g., Honkaranta, Salminen & Peltola, 2005). These factors have resulted in a trend towards use of smaller units of content than that of a document. Contemporary document management systems include limited capability to customize workflows for complex life-cycles of organizational content and for incorporating enhanced or multiple metadata standards. Document management software may have a limited functionality for design and management of a Web site of an organization. Despite the aforementioned deficiencies, document management approach and systems developed may provide a consistent base for content management development.

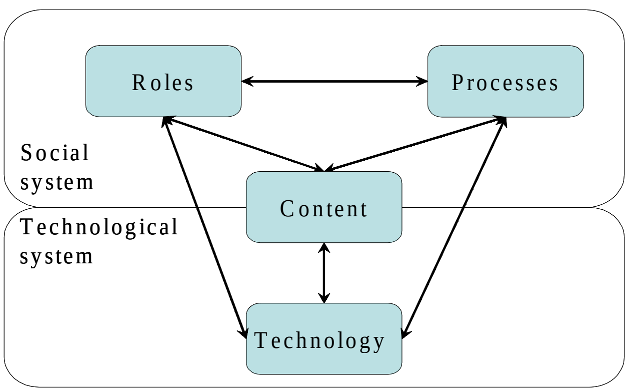
The benefits of the use of structured documents and related technologies have lately been recognized and adopted by both document management and Web content management approaches. Yet the use of XML poses multiple challenges. Even though there are systems and tools for managing XML documents as files or within databases (e.g., Bertino & Catia, 2001; Chaudhri, Rashid, & Zicari, 2003; Salminen & Tompa, 2001), the level of support for XML in document and content management systems is varying, and mostly missing from commonly used office software. In addition, developers lack knowledge about research findings and practical experience on adaptations and implementations of XML and related technologies in real-life organizations (e.g. Fahrenholz-Mann, 1999; Karjalainen & Tyrväinen, 2001; Salminen, 2000, Weitzman et al., 2002) since these are yet rarely reported.

ASPECTS AND CONCEPTS FOR DEVELOPING CONTENT MANAGEMENT IN ORGANIZATIONS

Content management in organizations is deeply intertwined with organizational work. Therefore development of content management should include the aspects of organizational work on which content is used and produced. We propose a framework for content management that includes both the technological and social system of an organization, allowing content management to be analyzed and evaluated from both aspects. The framework originates from the Leavitt's (1965) seminal framework for analyzing organizational change, and from contemporary research and empirical work. Figure 1 illustrates the framework while the rest of the chapter discusses the components of the framework and related concepts for content management development.

In the figure, the *social system* consists of processes and roles of people on the organization. Content is posi-

Figure 1. Framework for analyzing organizational content management



tioned between the social system and the *technological system*, the latter consisting of the technologies and the software used. The *content*, *i.e.* content units and metadata, must adhere to the operation of the social system with the technology available in the technical system of the organization. The components of the framework are interrelated. Whenever a change is implemented in one component, it will impact all other components of the framework. For example, adopting a Web content management system on the technology side will impact the publication processes, the roles of the people, and the content units used.

For content management, people's *roles* should be separated with regard to content management development vs. operational roles. Further, roles of content producers and users are needed both for content management *processes* and for operational processes, as they actually exist in the specific organization. For example, in new business models enhanced by digital rights management technology (Luoma & Tyrväinen, 2004; Rosenblatt, Trippe, & Mooney, 2002), content states related to content configurations, versions, revisions, and publicity of content should be taken into consideration both from the content management perspective and in the business process context.

Management of organizational *content* deals with complexity on identifying and designing logical, physical and processable units of content in organizations. The logical units of content are defined by social domain, and they have domain-oriented names; such as "Budget for Department of Computer Science and Information Systems". The *grain size* of logical content units may be varying, from content *aggregations* as collections of documents to documents, and to content units pertaining to a topical section of a document. For example, a budget document may consist of topical sections relating to different expense types. These topical sections may be used as independent units of content in one organizational process, and as an *assembly* which constitutes a document, or a Web page in another. Technical systems deal with physical units of content, such as folders and files, and with processable units of content, such as a field on a database or an XML element. Content management systems may use virtual folders for aggregating content units, and Web content management systems utilize *templates* for creating combinations of content and functionality for a Web site.

The amount of *metadata* related to the content increases while the size of the managed unit decreases. In overall, metadata is "*the sum total of what one can say about any information object at any level of aggregation*" (Gilliland-Swetland, 1998, p.1). Metadata may be used for defining properties of content unit instances and their mutual relationships, as well as for defining the organizational context, such as roles, processes, life-cycle states and audiences in which the content is used and produced. The metadata about organizational context is used for defining user roles and access rights for a system, as well as for workflow management. Documents may be independent content units providing a consistent whole for a human, while smaller content units need to be enriched with metadata for humans and especially for computer systems managing them. Specific purpose metadata may be used, e.g., for managing video and 3-dimensional content, and digital rights. Adoptation of a commonly used metadata standard, such as Dublin Core (1999), to an organization may include development of organization-specific metadata elements and attributes, defining optional and required values and pre-defined value lists, as well as tailoring the names of metadata elements.

The *technology* of organizational content management includes standards, architectures, technologies, tools, and applications. Contemporary content management systems may be roughly divided into three categories: platform systems, horizontal systems, and vertical systems. Relational and XML databases and other generic platforms provide a base-line onto which content management applications and functionalities may be built on. *Horizontal systems* are common-purpose document and content management systems, which already provide a base for managing content units as well as metadata and related processes and workflows. *Vertical systems* are systems that provide metadata and functionality related to management of specific content units or for a specific business processes. Examples of vertical systems are Customer Relationship Management (CRM), Supply Chain Management (SCM), and Product Data Management (PDM) systems, as well as patient information systems with specialized functionalities related their subject area.

FUTURE TRENDS

Content management combines approaches and findings from multiple historically separated approaches, such as document management, Web content management, and structured documents. These approaches have not yet been consolidated into a uniform research area. The conceptual base is inconsistent, and needs to be elaborated. Methods for content management need to be developed, and enhanced from existing ones.

Analysis and design of logical units of content in organizational settings is complex. The theory of genres as communicational, prototypical models for communication (Swales, 1999) provides a promising approach for identifying and analyzing logical content units on organizations. So forth, the genres have been operationalized for overcoming the shortcomings of the document concept while content units of an organization are identified (e.g., Karjalainen et al., 2000) and for analyzing the digitalization of organizational content (Tyrväinen & Päivärinta 2003), as an example.

CONCLUSION

Content management in organizations may consider the whole content of an organization, or just a specific portion of it. Content management combines approaches and findings from multiple historically separated approaches, such as document management, Web content management, and structured documents. These approaches have not yet been consolidated to a uniform research area. From socio-technical viewpoint the findings from, and systems developed for document management may provide a starting point for contemporary content management in organizations.

Characteristic for this emerging area of research and development is the move towards using units of content with varying grain sizes. A unit of content to be managed may be broader, similar, or smaller than traditional document. Due to increased popularity of content delivery on the Web, the use of content units smaller than a document has increased. Variance on content unit grain size is reflected to increasing number of kinds and amount of metadata needed for managing and processing the content. The content units defined by social systems are differing from those used and managed by technological systems. Social systems rely upon logical units of content with domain-oriented names, while technical systems use system-oriented terms, and deal with physical and processable units of content. Even though the use of XML (Bray et al., 2004) and related languages provide features for enhancing content management, there are still multiple challenges to be overcome.

KEY TERMS

Content Aggregation (noun/verb)**:** A set of existing content units collected together for a specific use purpose. An aggregation may contain several versions of the same unit of content, and its creation may require human involvement.

Content Assembly (noun/verb)**:** A collection of existing or new units of content which may be manipulated to produce content for a publication or for a specific target audience. May be produced (semi-)automatically or involve manual processing. A portion of training content for specialists only may be an assembly.

Content Management: Tools, methods, and processes to develop, implement and evaluate the management of content intended mainly for human comprehension. Content has a life-cycle, and its management involves associated metadata.

Content Seeding: Adding identifiers and metadata to content units or their parts to enable computerized assemblies and aggregations on the content.

Content Unit: The object with which the management metadata is associated. May be "a document", "a file", "a component", or "a section of a document" among others.

Document Management: Managing the content consisting of independent logical content units referred to, or manipulated as documents.

Metadata: Data describing the content from the viewpoint of humans or computers. Metadata may describe the domain in which content is used, as well as collections, classes, units or processable portions of the content and content instances. Metadata enables content search, classification, and processing. Whereas humans may use and interpret metadata about documents, the metadata about the small units of content is primarily meant for computerized manipulation of content.

Rendering: A process in which the layout and typography for content is created for a specific human viewer, program, or output device.

Template: A combination of static content, references to units of existing content, and program code for producing the content and navigation aids for a Web site.

Web Content Management: Management of content intended primarily for web delivery. Grain size of the content unit is typically smaller (e.g., a page or a paragraph) than that of documents.

Content–Based Image Retrieval Query Paradigms

Colin C. Venters
University of Manchester, UK

Richard J. Hartley
Manchester Metropolitan University, UK

William T. Hewitt
University of Manchester, UK

INTRODUCTION

The proliferation in volume of digital image data has exacerbated the general image retrieval problem, creating a need for efficient storage and flexible retrieval of vast amounts of image data (Chang, 1989). Whilst there have been significant technological advances with image data capture and storage, developments in effective image retrieval have not kept pace. Research in image retrieval has been divided into two areas: concept-based image retrieval and content-based image retrieval. The former focuses on the use of classification schemes or indexing terms to retrieve images while the latter focuses on the visual features of the image, such as colour, shape, texture, and spatial relationships.

The field of content-based image retrieval has been a thriving area of research and development for over a decade. Its origins lie in the subject areas of artificial intelligence, computer vision, image processing, information retrieval, pattern recognition, and signal processing. Advancement of the approach has been attributed to the early experiments conducted by Kato, Kurita, and Shimogaki (1991) into the automatic retrieval of images by colour and shape feature (Eakins & Graham, 1999). The approach focuses on the semiautomatic or automatic extraction, indexing, and retrieval of images by their visual attributes and characteristics. The process involves a direct matching operation between a query image and a database of stored images, where a feature vector or global signature has been computed for the unique visual properties of an image. Similarity is calculated by comparing the vector or signature of the query image against those of images stored in a database. The visual distance D between images can be measured by functions such as Euclidean distance, L_1 and L_2 distances, weighted Euclidean distance, city-block distance, and Minkowsky distance (Figures 1 to 6).

Figure 1. Euclidean distance

$$d(s_1, s_2) = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

Figure 2. Weighted Euclidean distance

$$D_H(I_Q, I_D) = \left(H(I_Q) - H(I_D)\right)^t A\left(H(I_Q) - H(I_D)\right)$$

Figure 3. L_1 distance

$$D_H(I_Q, I_D) = \sum_{j=1}^{n} \left| H(I_Q, j) - H(I_D, j) \right|$$

Figure 4. L_2 distance

$$D_H(I_Q, I_D) = \left(\sum_{j-1}^{n} \left(H(I_Q, j) - H(I_D, j) \right)^2 \right)$$

Figure 5. City-Block distance

$$d(s_1, s_2) = \|x_2 - x_1\| + \|y_2 - y_1\|$$

Figure 6. Minkowsky distance

$$d(s_1, s_2) = \sum_{k-1}^{n} |x_k - y_k|$$

The result of this process is a quantified similarity score that measures the visual distance between the two images, represented by the feature vectors, in a 2-D feature space (Del Bimbo, 1999). The most common image-matching feature characteristics are colour, shape, and texture.

Research in the field of content-based image retrieval has investigated only a small number of the problems inherent in the development of visual information management systems, with a considerable amount of attention being directed at the development and advancement of retrieval algorithms (Venters & Cooper, 2000). However, many research topics in this field, which are considered fundamental to the advancement of content-based image retrieval as a viable retrieval tool, have been largely ignored. One such area is the user interface.

BACKGROUND

The user interface provides the bridge between the end user and the system and is crucial to effective human-computer interaction. Retrieval is commonly obtained through an interactive session (Del Bimbo, 1999). To initiate a search, the user provides or creates the visual representation of their information need and then selects the features, range of model parameters, and similarity measure that are important. Smeulders, Worring, Santini, Gupta, and Jain (2000) defined an abstract query space to represent user interaction in a content-based image retrieval system (Figure 7).

Figure 7. Abstract query space (Smeulders et al., 2000)

$$Q = \{I_Q, F_Q, S_Q, Z_Q\}$$

To start a query session, an instantiation of $Q = \{I_Q, F_Q, S_Q, Z_Q\}$ is created. Where I_Q is the selection of images from the image archive I, F_Q is the selection of features derived from the images in I_Q, S_Q is the similarity function, and Z_Q is the goal-dependent semantics. The query space forms the basis of user interaction in a content-based image retrieval system, specifying queries and displaying results. Similarly, Rui and Huang (2001) state that an image object O can be modelled as a function of the image data D, features F, and representations R (Figure 8).

Figure 8. Image object model (Rui & Huang, 2001)

$$O = O(D, F, R)$$

Where D is the raw image data, $F = \{f_i\}$, $i = 1, \ldots, I$ is a set of visual features associated with the image object, such as colour, texture, or shape, and $R_i\{r_{ij}\}$, $j = 1, \ldots, J_i$ is a set of representations for a given feature, such as colour histogram or colour moments. Each representation of r_{ij} is a vector consisting of multiple components where K_{ij} is the length of the vector r_{ij}, i.e., $r_{ij} = \lfloor r_{ij_1}, \ldots, r_{ij_k}, \ldots, r_{ij} k_{ij} \rfloor$. In general, the majority of content-based image retrieval systems exemplify these interaction models although research activity has only explored specific elements. The models emphasise that user interaction is a complex interplay between the user and the system, suggesting that only highly skilled and specialised users would be able to utilise the system effectively to obtain relevant retrieval results.

VISUAL QUERY FORMULATION

Query formulation is a core activity in the process of information retrieval and a number of paradigms have been proposed for specifying a query Q_n in an image database I. Several database query languages have been proposed to support image query expression in both first- and second-generation image retrieval systems and are based on either the relational or tabular data models. The most widespread languages are extensions of the Structured Query Language (SQL) proposed by Codd (1970). With this approach the user formulates the query and the system retrieves a set of results. Examples include ISQL (Assmann, Venema, & Hohne, 1986), PROBE (Orenstein & Manola, 1988), Spatial SQL (Egenhofer, 1991), and $\sum QL$ (Chang & Jungert, 2001). A major criticism levelled at these languages is the potential complexity of the query statement required to express a simple query (Catarci, Costabile, Levialdi, & Batin, 1997).

As an alternative to the relational-based query language approach, Zloof (1977) proposed Query by Example (QBE). This is based on a tabular data model and employs a tabular query structure to express queries. The user specifies an example output of the query by directly constructing entries into relational skeletons instead of writing lengthy queries, and the system identifies the goal by generalizing an example. QBE is a revision of Codd's relational calculus language SQL. Several examples have been based on this approach, including Aggregate by Example (Klug, 1981), Time by Example (Tansel, Arkun, & Ozsoyoglu, 1989), Generalized Query by Example (Jacobs & Walczak, 1983), Office by Example (Whang et al., 1987), and Natural Forms Query Language (NFQL; Embley, 1989). The languages share a commonality in the method of query expression and differ only in their expansion or revision of the QBE paradigm to serve different application areas. Two languages specifically developed for image databases were Query by Pictorial Example (Chang & Fu, 1980) and PICQUERY (Joseph & Cardenas, 1988).

Content-based image retrieval requires the user to provide or create a visual example or representation of their query image Q_n as the basis of the search from the image archive *I*. Query by Visual Example (QVE) is the general term used to describe this approach. Several examples of this approach to query specification have been reported in the literature. Del Bimbo (1999) and Lew and Huang (2001) distinguish between different methods of QVE: query by browsing, query by icon, query by image, query by painting, and query by sketch.

QUERY BY BROWSING

Query by browsing permits users to browse the database by three methods: unstructured, semi-structured, and structured browsing. The simplest method of query by browsing is unstructured browsing, where the user is presented with a complete view of all the images contained in the database. Generally, the images are presented as thumbnails ordered by filename that the user can scroll through. Semi-structured browsing allows the user to search through the image collection by choosing example images. The system computes a similarity ranking on image features and disregards the least similar images after each iteration until the user is satisfied with the set of images left in the retrieval loop. Examples of this approach were proposed by Laaksonen, Koskela, Laakso, and Oja (2000) and Vendrig, Worring, and Smeulders (2001). With structured browsing, images are clustered into predefined, hierarchal classes based on a visual property such as colour. The images are presented as thumbnails and the user can move through the hierarchy until satisfied. Examples of this approach were proposed by Lai et al. (1999) and Brodley et al. (1999). The concept of browsing has been recognised in the field of information retrieval as a fundamental part of human information-seeking behaviour (Ellis, 1989; Wilson, 1981). Marchionini (1995) states that browsing is an approach to information seeking that is both informal and opportunistic. Nevertheless, the viability of browsing as an access strategy is heavily dependent on the size of the image collection and the effectiveness of any classification by which a physical order is imposed (Enser, 1995). No empirical studies have measured the ceiling or threshold of the maximum number of images a user is willing to search through in order to find a suitable image.

QUERY BY ICON

Query by icon allows the user to select an icon that represents a high-level concept of a category or idea. Icons are commonly found in graphical user interfaces (GUIs) and are a graphic representation of an entity, metaphor, or artefact. Similar to iconic-based visual query languages, the user physically places object icon(s) on a query canvas to specify relative locations, orientations, and sizes of objects within the desired image (Gupta & Jain, 1997). Several examples of this approach have been proposed over the years by Angelaccio, Catarci, and Santucci (1990), Del Bimbo, Campanai, and Nesi (1993), Papantonakis and King (1995), Aslandogan, Thier, and Yu, (1996), Chavda and Wood (1997), and Lee and Whang (2001). Lew and Huang (2001) suggest that the iconic query paradigm is the most intuitive query method, but that it is restricted to a vocabulary of visual concepts that can be reliably understood by the VIR system and semantics by the user.

QUERY BY IMAGE

Query by image allows the user to provide an example image as a representation of their query. The example can be either an image selected externally or internally from the system. Di Lecce and Guerriero (1999) characterize this as query by external pictorial example and query by internal pictorial example. Query by external pictorial example permits the user to submit their own image to the system and is generally perceived as the simplest approach to query formulation. However, it is based on the assumption that the user has a suitable representative image to use as the basis of their query. Query by internal pictorial example is query by browsing where the user selects an image from the system's database. All the images contained in the database are presented or a selection is generated randomly in an *n*-dimensional matrix. Similar to the problems associated with query by browsing, the main disadvantages of this method are providing suitable access mechanisms to retrieve the internal example and the size of the image collection the user is willing to search through in order to find a suitable image.

QUERY BY PAINTING

Query by painting allows the user to manually specify the percentage or the distribution of colour values. For example, the user is able to specify the percentages of colour within a composition, such as 50% green, 25% yellow, and 25% red (Figure 9). Similarly, the user is able to specify the *x y* positions of the of colour values on the query canvas (Figure 10). Examples of this approach were proposed by Flickner et al. (1995) and Del Bimbo, Mugnani, and Turco (1998).

Figure 9. Colour percentages (QBIC)

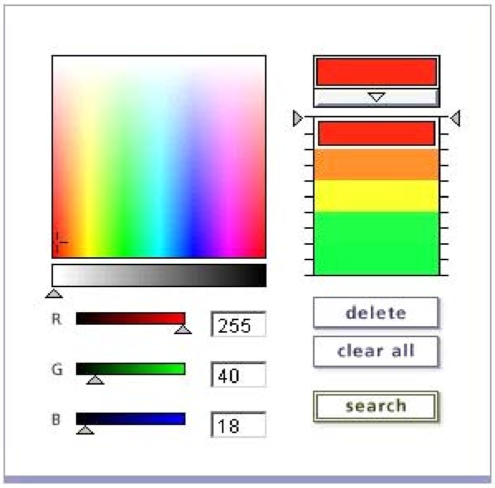

Figure 10. Colour distribution (QBIC)

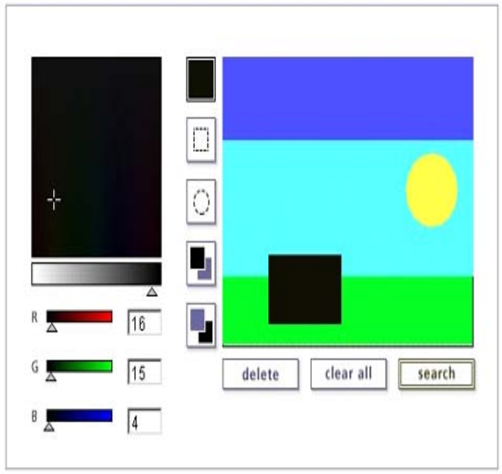

QUERY BY SKETCH

Query by sketch allows the user to draw a sketch of the desired image by combining several features commonly found in computer graphic applications. The sketch represents a template of either a completed object or scene. Kato, Kurita, Otsu, and Hirata (1992) were the first to provide a query by sketch, but other examples of this approach have since been proposed by Chuah, Roth, and Kerpedjiev (1997), Del Bimbo and Pala (1997), Muller, Eickeler, and Rigoll (1998), and Di Sciascio and Mongiello (1999). As Korfhage (1997) indicates, queries formulated by this method are simplistic, relatively crude sketches of the desired query image, and the tool has a limited functionality for expressing more complex image queries. Eakins (1992) stressed that drawing a shape query is inherently time-consuming and requires a certain modicum of artistic ability. Similarly, the effectiveness of shape-matching features is highly sensitive to noise and pixel arrangement in the query image. Bird, Elliott, Hayward (1999) demonstrated that the user blamed their own artistic drawing ability when query results where unsuccessful.

Query by image, painting, and sketch are the most widespread interaction methods of query formulation found in content-based image retrieval systems. As Zachary and Iyengar (1999) suggest, a good query method will be natural to use as well as capturing enough information from the user to extract meaningful results. However, supporting the expression of image queries by these modes of interaction is a nontrivial problem. Eakins (1992) stresses, the more complex the query in terms of shape and structure, the more difficult it will be for the user to express and produce a meaningful visual example. Similarly, Chang and Jungert (2001) state that most visual query systems (VQSs) restrict human-computer interaction to only one kind of interaction paradigm. They suggest that the presence of several paradigms, each one with its different characteristics and advantages, will help both naïve and experienced users in interacting with the system.

FUTURE TRENDS

Alternative methods have been proposed to extend the QVE paradigm. Gupta and Jain (1997) note that while most systems are limited in the query types they can handle, i.e., colour, shape, and texture, image query specification should not be performed exclusively within the query by visual example paradigm but should be extended through a range of different tools that serve as a visual information retrieval query language. They proposed a nine-component query language framework that included: image processing, feature-space manipulation, object specification, measurement specification, classification, spatial arrangement, temporal arrangement, annotation, and data definition. Several visualization tools for image browsing that have extended approaches used in text-based information visualizations systems have been proposed by Cinque, Levialdi, Malizia, and Olsen (1998), Santini and Jain (1997), and Nakazato and Huang (2001). Although there have been many prototypes of visualization in support of information retrieval, there has been little systematic evaluation to distinguish the benefits of the visualization per se from the various accompanying features (Korfhage, 1997). Assfalg, Del Bimbo, and Pala (2000) argue that virtual reality (VR) provides a realistic reproduction of a user's natural environment, particularly where images represent real-world scenes. They propose that the use of a non-immersive 3-D environment is a natural and effective interface to perform query by content. Three-dimensional virtual reality (3DVR) potentially represents the next generation of user interfaces for information retrieval. How they can be effectively applied in an operational setting is unclear and introduces a new avenue for further research.

CONCLUSION

Several commentators have highlighted the need to design and develop new user-interface metaphors and paradigms for specifying visual queries (Aigrain, Zhang, & Petkovic, 1996; Besser, 1996; Chang & Hsu, 1992; Del Bimbo, 1999; Eakins, 2001; Gudivada & Raghavan, 1995; Gupta & Jain, 1997; Jain, 1996; Rui, Huang, & Chang, 1999; Venters, Hartley, & Hewitt, 2003). However, despite being identified as one of the major research areas of the field, few studies have investigated the user interface. The requirement for end users to communicate their information needs accurately and effectively is crucial in any information retrieval system. How this may be achieved in practice with content-based image retrieval systems is not readily apparent (Eakins & Graham, 1999). A number of research questions from the macro- to the micro-level have been postulated regarding research into the user interface and content-based image retrieval. These include: What is the most efficient user interface for querying an image database ("CBIR Challenges," n.d.; Jain, 1993; Venters et al., 2003)? Is access to visual data best resolved by allowing the user to switch between browsing, navigation, and querying (Aigrain et al., 1996; Del Bimbo, 1999)? What is the most effective method for specifying an initial query to the system, and the best to refine search parameters if the retrieval results fail to meet user information needs (Eakins, 2001; Rui et al., 1999;)? The validity of the query by visual example paradigm and its effectiveness in supporting image query expression remain open and valid research issues that now require critical attention. The problem of what type of user interface is required to support human-computer interaction in a content-based image retrieval environment remains unsolved.

KEY TERMS

Concept-Based Image Retrieval: A term used to describe the classical approach to information management that focuses on the use of classification schemes and their indexing terms to retrieve images.

Content-Based Image Retrieval: A general term used to describe the semiautomatic or automatic extraction, indexing, and retrieval of images by their visual attributes and characteristics.

Digital Image: Image $f(x,y)$ that has been discretized both in spatial coordinates and brightness and consists of a set of elements, defined on an n-dimensional regular grid, that have the potential for display. It can be considered a matrix whose row and column indices identify a point in the image, and the corresponding matrix element values identify the grey level at that point. The elements of such a digital array are called image elements, picture elements, pixels, or pels.

Query: Formal expression of an information need.

Query by Browsing: Approach that permits users to browse the database by three methods: unstructured, semi-structured, and structured browsing.

Query by Icon: An approach that allows users to construct queries by selecting an icon that represents a high-level concept of a category or idea.

Query by Image: An approach that allows users to provide an example image as a representation of their query. The example can be either an image selected externally or internally from the system.

Query by Painting: An approach that allows users to manually specify the percentage or the distribution of colour values from a colour picker or wheel, such as RGB (red, green, blue) or HIS (hue, intensity, saturation).

Query by Sketch: An approach that allows users to draw a sketch of the desired image by combining several features commonly found in computer graphic applications. The sketch represents a template of either a completed object or scene.

Query by Visual Example: General term used to describe how users provide or create a visual example or representation of their query image Q_n as the basis of the search from the image archive I.

Query Language: Set of formally defined operators that allow queries to be expressed to a database. The execution of the query produces a set of results that are extracted from the data.

Content-Based Retrieval Concept

INTRODUCTION

Because of the demand for efficient management in images, much attention has been paid to image retrieval over the past few years. The text-based image retrieval system is commonly used in traditional search engines (Ratha et al., 1996), where a query is represented by keywords that are usually identified and classified by human beings. Since people have different understandings on a particular image, the consistency is difficult to maintain. When the database is larger, it is arduous to describe and classify the images because most images are complicated and have many different objects. There has been a trend towards developing the content-based retrieval system, which tries to retrieve images directly and automatically based on their visual contents.

A similar image retrieval system extracts the content of the query example ***q*** and compares it with that of each database image during querying. The answer to this query may be one or more images that are the most similar ones to ***q***. Similarity retrieval can work effectively when the user fails to express queries in a precise way. In this case, it is no longer necessary to retrieve an image extremely similar to the query example. Hence, similarity retrieval has more practical applications than an exact match does.

Content-Based Image Retrieval Systems

In a typical content-based image retrieval system, the query pattern is queried by an example in which a sample image or sketch is provided. The system then extracts appropriate visual features that can describe the image, and matches these features against the features of the images stored in the database. This type of query is easily expressed and formulated, since the user does not need to be familiar with the syntax of any special purpose image query language. The main advantage is that the retrieval process can be implemented automatically (Chen, 2001). The scope of this article is circumscribed to image abstraction and retrieval based on image content.

Human beings have a unique ability that can easily recognize the complex features in an image by utilizing the attributes of shape, texture, color, and spatial information. Many researchers analyze the color, texture, shape of an object, and spatial attributes of images, and use them as the features of the images. Therefore, one of the most important challenges in building an image retrieval system is the choice and representation of the visual attributes. A brief overview of the commonly used visual attributes shape, texture, color, and spatial relationship will be illustrated as follows.

Commonly Used Image Features in Content-Based Image Retrieval Systems

Shape characterizes the contour of an object that identifies the object in a meaningful form (Gevers & Smeulders, 2000; Zhang & Lu, 2002). Traditionally, shapes are described through a set of features such as area, axis-orientation, certain characteristic points, and so forth. These systems retrieve a subset of images that satisfy certain shape constraints. In the shape retrieval, the degree of similarity between two images is considered as the distance between the corresponding points.

Color attribute may simplify the object's identification and extraction in the image retrieval (Galdino & Borges, 2000; Gevers & Smeulders, 2000). Color may provide multiple measurements at a single pixel of the image, and often enable the classification to be done without complex spatial decision-making. Any resulting difference between colors is then evaluated as a distance between the corresponding color points. The color-based retrieval system measures the similarity of the two images with their distance in color space.

Texture attribute depicts the surface of an image object (Yao & Chen, 2002; Zhang & Tan, 2003). Intuitively, the term refers to properties such as smoothness, coarseness, and regularity of an image object. Generally, the structural homogeneity does not come from the presence of a single color or intensity, but it requires the interaction of various intensities within a region.

Retrieval by spatial constraints facilitates a class of queries based on the 2-D arrangement of objects in an image (Chang Erland & Li, 1989; Chang & Li, 1988; Chang, Shi & Yan, 1987; Lee & Hsu, 1992). The query is composed by placing sketches, symbols or icons on a plane where every symbol or icon is predefined for one type of objects in an image. The relationships between the objects can be broadly classified as either directional (also referred as projective) (Chang & Li, 1988; Chang, Shi & Yan, 1987) or topological (Lee & Hsu, 1992). Directional relationship is based on the relative location and the metric distance between two image objects. Topological relationships are based on set-theoretical concepts like union, intersection, disjunction and so forth. Spatial information is a higher-level attribute, which is increasingly more specific. For example, facial features are frequently presented in terms of spatial information (Sadeghi, Kittler & Messer, 2001).

Briefly, color attribute depicts the visual appearance of an image, characterized by the luminance and chrominance histograms of the image. Texture attribute refers to three components: bi-dimensional periodicity, mono-dimensional orientation, and complexity obtained through world decomposition. Shape attribute sketches the geometrical properties of objects in images. Spatial attribute represents the relative position relationships between objects of an image.

TYPICAL IMAGE RETRIEVAL SYSTEMS

This section briefly overviews the image retrieval systems based on the most commonly used image features: color, shape, texture, and spatial content.

The Color-Based Image Retrieval Systems

Generally, the color-based image retrieval system does not find the images whose colors are exactly matched, but images with similar pixel color information. This approach has been proven to be very successful in retrieving images since concepts of the color-based similarity measure is simple, and the convention algorithms are very easy to implement. Besides, this feature can resist noise and rotation variants in images.

However, this feature can only be used to take the global characteristics into account rather than the local one in an image, such as the color difference between neighboring objects in an image. For example, if a landscape image with blue sky on the top and green countryside at the bottom is employed as a query example, the system that retrieves the images with similar structures based on these global features often gives very unsatisfactory results. In addition, the color-based image retrieval system often fails to retrieve the images that are taken from the same scene in which the query example is also taken from under different time or conditions, for example, the images of a countryside taken at dusk or dawn under a clear or a cloudy sky. In another scenario, the same scene may be imaged by different devices. Using one image taken by one device as the query example may fail to find the same scene taken by other devices.

The Shape-Based Image Retrieval Systems

A shape-based image retrieval system is used to search for the images containing the objects, which are similar to the objects specified by a query. Since an object can be formed by a set of shapes in most cases (e.g., a car can be made of some little rectangles and circles), most similar objects have a high correlation in their set of shapes (Gevers & Smeulders, 2000; Zhang & Lu, 2002). The shape-based image retrieval system extracts the shapes of objects from images by segmentation, and classifies the shapes, where each shape has its own representation and variants to scaling, rotation, and transition.

Some criteria on shape representation and similarity measure for a well performing content-based image retrieval system should be achieved. Firstly, the representation of a shape should be invariant to scale, translation, and rotation. Secondly, the similarity measure between shape representations should conform to human perception; that is, perceptually similar shapes should have highly similar measures. Thirdly, the shape representation should be compact and easy to derive, and the calculation of similarity measure should be efficient.

However, how to locate and how to recognize objects from images is a real challenge. One of the obstacles is how to separate the objects from the background. Difficulties come from discrimination, occlusions, poor contrast, viewing conditions, noise, complicated objects, complicated backgrounds, and so forth. Moreover, the shape-based image retrieval system can only deal with the images that have simple object shapes. For complex object shapes, the region-based method has to build a binary sequence by using smaller grid cells, so that results that are more accurate can be obtained; nevertheless, the storage of indices and retrieval time may increase tremendously.

The Texture-Based Image Retrieval Systems

Literally, texture relates to the arrangement of the basic constituents of a material. In digital images, texture describes the spatial interrelationships of the image pixels.

Texture similarity can often be useful in distinguishing the areas of objects in images with similar color, such as sky and sea as well as leaves and grass. Texture queries can be formulated in the manner that is similar to the color queries by selecting an example of desired textures from a palette, or by supplying an example query image. The system then returns the images which are most similar to the query example in texture measures.

Making texture analysis is a real challenge. One way to perform content-based image retrieval using texture as the cue is by segmenting an image into a number of different texture regions and then performing a texture analysis algorithm on each texture segment. However, segmentation can sometimes be problematic for image retrieval. In addition, texture is quite difficult to describe and subject to the difference of human perception. No satisfactory quantitative definition of texture exists at this time.

The Spatial-Based Image Retrieval Systems

There are two kinds of spatial-based image retrieval systems: retrieval by spatial relationships (RSRs) and spatial access methods (SAMs). The RSR image retrieval system is to retrieve the images from a database that are similar to the query sample based on relative position relationships between the objects in the images. Hence, a physical image can be regarded as a symbolic image, each object of which is attached with a symbolic name. The centroid coordinates of the object with reference to the image frame are extracted as well. By searching for the logical images, the corresponding physical images can then be retrieved and displayed. Therefore, image retrieval can be simplified to the search of symbolic images.

Chang, Shi, and Yan (1987) used a 2D string representation to describe a symbolic image. Objects and their spatial relationships in a symbolic image can be characterized by a 2D string. An image query can be specified as a 2D string too. Consequently, the problem of image retrieval then turns out to be the matching of a 2D string. Subsequently, a great number of other image representations popped out that were derived from a 2D string, such as 2D G-string (Chang, Erland & Li, 1989), 2D B-string (Lee, Yang & Chen, 1992), 2D C-string (Lee & Hsu, 1992), and so forth. These representations adopt the description of orthogonal projection to delineate the spatial relationships between objects.

The SAM image retrieval systems are to manage large collections of points (or rectangles or other geometric objects) in the main memory or on the disk so that range queries can be efficiently answered. A range query specifies a region in the address space, requesting all the data objects that intersect it. They divide the whole space into several disjoint sub-regions, each with no more than P points (a point may represent a rectangle). P is usually the capacity of a disk page. Inserting a new point may result in further splitting a region. The split methods can be classified according to the attributes of the split (Gottschalk, Turney & Mudge, 1987).

Color attribute is most intuitive and straightforward for the user. Texture analysis systems are often developed to perform filtering in the transform domain in order to obtain feature images. The use of global color or texture features for the retrieval of images tends to be misleading, especially in homogeneous image collections. Though shape and texture are the essential visual attributes to derive potentially useful semantic information, there exists less understanding of the benefits to implement these attributes as compared to color, for efficient image retrieval. This approach apparently focuses on global frequency content of an image; however, many applications require the analysis to be localized in the spatial domain.

FUTURE TRENDS

Many visual attributes have been explored, such as color, shape, texture, and spatial features. For each feature, there exist multiple representations that model the human perception of the feature from different perspectives. There is a demand for developing an image content description to organize the features. The features should not only be just associated with the images, but also be invoked at the right place and the right time, whenever they are needed to assist retrieval.

Human beings tend to apply high-level concepts in their daily lives. However, most features, the current computer vision techniques automatically extracting from images, are low-level. To narrow down this semantic gap, it is necessary to link the low-level features to high-level concepts. On the high-level concept, it should allow the user to easily provide his or her evaluation of the current retrieval results to the computer. It is likely for different people to give an identical name; therefore, generating the representation by automatically extracting the objects from an original image is very difficult. Therefore, the spatial relationships between objects cannot be extracted automatically without human interaction with the current techniques of image understanding and recognition. More recent research emphasis is given to “interactive systems” and “human in the loop”.

Due to the perception subjectivity of image content, it is difficult to define a good criterion for measuring the similarity among images. That is, the subjectivity of image perception prevents us from defining objective evaluation criteria. Hence, it is urgent to find an appropriate way of evaluating the system performance guiding the research effort in the correct direction.

Establishing a well-balanced large-scale test bed is an important task too. A good test bed must be huge in scale for testing the scalability (for multidimensional indexing), and be balanced in image content for testing image feature effectiveness and overall system performance.

Human beings are the ultimate end users of the image retrieval system. This topic has attracted increasing attention in recent years, aiming at exploring how humans perceive image content and how one can integrate such a "human model" into the image retrieval systems. Recently, more studies of human perception focus on the psychophysical aspects of human perception.

CONCLUSION

A successful image retrieval system requires the seamless integration of the efforts of multiple research communities. To achieve a fast retrieval speed and make the retrieval system truly scalable to large-size image collections, an effective multidimensional indexing module is an indispensable part of the whole system. The interface collects the information from the users and displays back the retrieval results to the users in a meaningful way. To communicate with the user in a friendly manner, the query interface should be graphics-based.

In the iconic image representation, an icon is used to represent an object in an image. The iconic image representation has two advantages. First, once the images in the database are analyzed, it is not necessary to analyze the image again in a query processing. Secondly, since the size of the symbolic image is much smaller than that of the original image, this representation can be well suited to be distributed to database environments where a large number of image transmissions between distant nodes are required.

Typically, color, shape and texture attributes provide a global description of images, but they fail to consider the meaning of portrayed objects and the semantics of scenes. The descriptions of objects and the relative positions among objects provide a spatial configuration and a logical representation of images. Combining approaches for content-based image retrieval systems could be considered as complementary.

KEY TERMS

Color Feature: Analyzing the color distribution of pixels in an image.

Geometric Hashing: The technique identifying an object in the scene, together with its position and orientation.

Query by Example: The image retrieval system where a sample image or sketch can be provided as a query.

Shape Feature: Characterizing the contour of an object that identifies the object in a meaningful form.

Spatial Feature: Symbolizing the arrangement of objects within the image.

Symbolic Image: Consisting of a set of objects; each object stands for an entity in a real image.

Texture Feature: Depicting the surface of an image object.

C

Context-Aware Framework for ERP

Farhad Daneshgar
University of New South Wales, Australia

INTRODUCTION

Like many existing ERP models (e.g., Podolsky, 1998; Van Stijn & Wensley, 2001), the OOAB framework is also based on a widely accepted assumption that a corporate-wide information system consists of a set of potentially related subsystems; and as a result, information flows among these subsystems must be identified, and required resources planned, using an appropriate ERP methodology. However, up until now there existed no formalised framework that facilitates sharing of contextual knowledge in ERP processes. A unique attribute of the OOAB framework is that it treats ERP processes as a collaborative processes where various roles/actors collaboratively perform tasks in order to achieve a common overall goal. An object-oriented framework is presented in this article that facilitates sharing the contextual knowledge/resources that exist within ERP processes. Context is represented by a set of relevant collaborative semantic concepts or "objects". These are the objects that are localised/contextualised to specific sub-process within the ERP process.

BACKGROUND

From a purely object orientation perspective, a collaboration is defined as "the structure of instances playing roles in a behavior and their relationships" (OMG, 2001). The behaviour mentioned in this definition refers to an operation, or a use case, or any other behavioural classifier. This article provides an overview of a framework for analysing awareness requirements of the actors in ERP systems using an object-oriented awareness-based approach. A similar study was also conducted for developing a new version of this framework that takes into consideration the specific characteristics of virtual communities (Daneshgar, 2003). The proposed approach specialises the notion of collaboration and extends it to the ERP processes. This has roots in the activity network theory (Kaptilini et al., 1995) and is based on the fact that all ERP processes involve *multiple roles performing various tasks* using appropriate artefacts (e.g., departmental subsystems, databases, etc.) in order to achieve both their local as well as the overall organization-wide goals. Conceptually speaking, this will justify a frame-based object-oriented approach to analysis and design for ERP processes (Turban & Aaron, 2001). The conceptual model of the proposed framework is made of the following components:

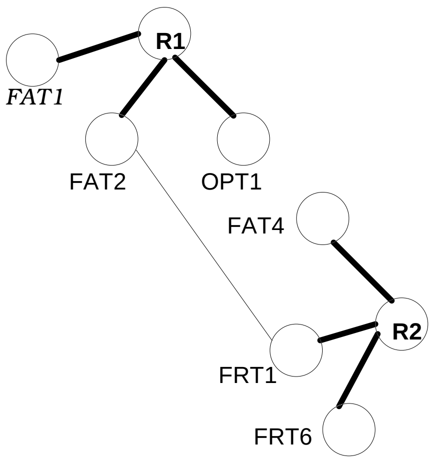
- a set of collaborative semantic concepts including roles, the tasks that these roles play within the process, and the artefacts that these roles use to perform various tasks within the process, and
- relationships among these semantic concepts.

This conceptual model can then be mapped directly to an object model and be used as an analytical tool for identifying awareness requirements of the actors within the ERP process. The fact that ERP is treated as a collaborative process calls for a mechanism for maintaining awareness requirements of the actors involved in this collaboration. Furthermore, due to its object orientation, the framework is capable of encapsulating all complications and dependencies in sub/local processes within individual tasks as well as resources required to perform those tasks, further relieving the ERP management and the associated software.

OOAB FRAMEWORK

A domain-specific conceptual model of a hypothetical ERP process that resembles an object diagram is shown in Figure 1. Use of a domain-specific conceptual model instead of a straight object diagram is justified by the fact that the ontological foundation of the framework prevents growth of the objects and relationships indefinitely, and as a result using an object model may hide such ontology. In Figure 1 there are two roles: R1 and R2; six tasks: FAT1, FAT2, OPT1, FAT4, FRT1 and FRT6 (all shown by circles). It also shows various resources by straight lines connecting tasks and roles. These lines represent rich ontological relationship between a pair of semantic concepts. Each task object requires certain resources for achieving its local/departmental goal or purpose (called *process resource*), as well as certain other resources for achieving the collaborative organization-wide goals of the ERP process (called *collaborative resource*). In Figure 1, a line

Figure 1. A representation of an ERP collaborative process model



connecting a role vertex to a task vertex is a process resource, whereas a line connecting two tasks together is a collaborative resource.

According to the framework, effective knowledge and/or resource exchange among actors is closely related to the level of awareness as defined in the awareness model that each actor possess about the ERP process. These awareness levels are defined in terms of the collaborative semantic concepts used within the ERP conceptual model as shown in Figure 1. Details of the proposed methodology for identifying awareness requirements of actors in ERP process follow:

STEP 1. Develop an ERP Process Model similar to that in Figure 1.
FA: Financial Accounting sub-process/task
OP: Order Processing sub-process/task
CS: Customer Service subprocess/task
FR: Financial Reporting subprocess/task
T1…T6: <appear as postfixes indicating various tasks>

STEP 2. Measure the actual levels of awareness for each role on the process model using the awareness model. In order to measure this level of awareness the actor must be exposed to all the objects on the ERP process model, and be asked to identify those objects that s/he is aware of. Selected pool of objects are then used by an awareness model in order to arrive at a number reflecting the actual level of awareness associated with that role.

STEP 3: The actor's actual level of awareness is then is compared against the required level of awareness; the latter is a parameter, provided by the task that the actor performs within the process. The difference between these two levels of awareness constitutes the collaborative requirement of the actor for that particular task. Factors that affect the required level of awareness of a task include organisational culture, and the nature of task itself. Without possessing such awareness level the actor will not be able to collaborate with others optimally. A comparison between the actual level of awareness of the actor and the required level of awareness of the task will result in one of the following two outcomes:

1. The task's required level of awareness is either equal to, or less than, the role's actual level of awareness. This indicates that the role is qualified, or has sufficient level of awareness for taking up the task, and the OOAB framework cannot enhance collaboration any further.
2. The task's required level of awareness exceeds the role's actual level of awareness. This indicates potential for enhancing collaboration. To do so it will be necessary to put the missing objects within the focus of the actor in a way that s/he can perceive these objects, receive required awareness, and perform that particular task successfully. This will require additional resources in order to enhance the actor's awareness level. These required resources may include one or more of process resources, collaborative resources, and other communication resources, for example resources that provide awareness about other roles and other tasks within the ERP process.

IMPLEMENTATION ISSUES

One method for integration of the OOAB framework with the existing ERP systems is by developing an organisational infrastructure that provides business intelligence to the users of the ERP system by maintaining contextual knowledge that these users/actors require for effective collaboration within the ERP process. The writer is in the process of developing an expert system that provides expert advice for answering the following two specific questions:

(i) In terms of awareness requirements, is an actor capable of performing certain tasks within the ERP process?
(ii) If not, what objects need to be put within his/her focus in order to enable the actor to perform the task properly?

The ERP collaborative process of Figure 1 consists of 15 objects, including two roles, six subprocesses/tasks, six role artefacts and one task artefact. Within each of these objects is encapsulated all relevant contextual knowledge as well as pointers to relevant objects as determined by the process map. Each task possesses a set of attributes and relevant methods; and each method consists of a set of steps that corresponds to codes describing a codified knowledge. These attributes will indicate to which subprocess the task belongs to. This will enable an actor to play various roles within different subprocesses without being permanently linked to a specific subprocess, a factor that can remove some complexities in existing ERP implementations.

FUTURE TRENDS AND CONCLUSION

It was shown that the OOAB methodology can enhance existing ERP systems by formally adhering to a framework that facilitates knowledge sharing among various actors in ERP processes in the following ways: This article introduces a novel concept for measuring collaboration in ERP processes; a concept that is non-existent in current ERP literature. This measure is based on a conceptual model of collaboration that can be directly transformed into an object model. This measure is used to determine required level of awareness of various actors within the ERP process. As far as the author is aware, this is a novel concept that results in treating the organisation-wide ERP process as a single collaborative process that consists of multiple sub-processes, called tasks, that are linked through formal artefacts. These artefacts utilise certain resources in order to carry/deliver contextual collaboration knowledge that is required for effective collaboration. Knowledge sharing occurs through various interaction acts such as exchanging the artefacts, creation of artefacts, and updating artefacts. As a result of its object-orientation and collaborativeness of the ERP process, and contrary to the existing process-based ERP frameworks that assume fixed roles within the ERP process, the OOAB framework enables an actor to assume multiple roles within different ERP subprocesses. This will provide another avenue for sharing contextual knowledge for sub-processes/tasks. The interdependency issue among various subprocesses is also simplified by encapsulating this knowledge within the task objects and relevant artefacts.

By reducing granularity of the collaborative process model, the same model representation can be applied for internal representation of the subprocesses, allowing smooth transition of modelling components from subprocesses to the ERP process, and vice-versa. This in turn will reduce much of the existing complexities in designing ERP systems where the system is permanently responsible to maintain such linkages, rather than delegating such responsibility to various objects within the system.

Work is in progress for incorporating communication and coordination dimensions to the existing collaboration dimesion in order to provide complete analysis of groupware systems that maintain awareness requirements of the actors within the ERP processes (Daneshgar et al., 2004; Sundarraj et al., 2002).

KEY TERMS

Action: A sequence of goal-directed steps.

Actual Level of Awareness: The awareness that a role actually possesses within the ERP process. Actual awareness is represented by an integer number ranging from zero to four, representing various levels of awareness. Actual awareness is a property of an actor who performs one or more roles within the ERP process.

Awareness: A specialised knowledge about the objects that leads an actor to an understanding of various aspects of the ERP collaborative process. It is defined and measured in terms of the semantic concepts (*task, role, process resource,* and *collaborative resource*) used in the map.

Awareness Model: A model that represents various levels of awareness. Level-0 awareness consists of the concepts that lead an actor to knowledge about all the tasks that an actor performs within the process.

Example: In Figure 1, level-0 awareness for the role "R1" is a sub-graph that consists of the tasks "FAT1," "FAT2," and "OPT1," as well as the process resources shown by thick lines connecting "R1" to these tasks. Level-1 awareness is a subgraph that consists of the R1's level-0 awareness subgraph, plus awareness about the concepts that leads an actor to knowledge about other related roles within the process. In Figure 1, level-1 awareness for the role "R1" is the sum of its level-0 awareness subgraph, plus one collaborative resource linking "FAT2" to "FRT1," plus "FRT1" itself, plus the process resources shown by thick lines connecting "FRT1" to "RT2," plus "RT2" itself. A role's level-2 awareness is its level-1 awareness, plus an awareness about all other (or, the rest of) roles within the process. Level-2 awareness is knowledge about the human boundary of the process. In Figure 1, there are no other roles that have not been known to the R1 already, and therefore the R1's level-2 and higher levels of awareness are irrelevant and identical to its level-1 awareness. However, for the sake of completeness, their definitions are presented.

A role's level-3 awareness is its level-2 awareness, plus awareness about all the interactions (represented by the process resources used/shared) that occur between any two roles within the process. And finally, level-4 awareness is the highest level of awareness that a role can have in any ERP process. It is defined as the knowledge about how everything fits together to form the ERP process. In other words, having this level of awareness will bring all the remaining concepts used in the ERP process model of Figure 1 within the focus of the role.

Collaborative Resources: An object representing a resource used/shared/exchanged by a pair of collaborating roles in order to perform certain simple tasks in collaboration with one another.

Process Resource: An object that represents a resource used by a role in order to perform a task in isolation from other tasks.

Required Level of Awareness: A property of a task. It represents the expected awareness from any actor who performs the task. Its value also ranges from 0 to 4.

Role: A set of norms expressed in terms of obligations, privileges, and rights assigned to an actor.

Task: An object with a set of attributes and actions to achieve a specific process goal using certain resource called *process resource.*

Contextual Metadata for Document Databases

Virpi Lyytikäinen
University of Jyväskylä, Finland

Pasi Tiitinen
University of Jyväskylä, Finland

Airi Salminen
University of Jyväskylä, Finland

INTRODUCTION

Metadata has always been an important means to support accessibility of information in document collections. Metadata can be, for example, bibliographic data manually created for each document at the time of document storage. The indexes created by Web search engines serve as metadata about the content of Web documents. In the semantic Web solutions, ontologies are used to store semantic metadata (Berners-Lee et al., 2001). Attaching a common ontology to a set of heterogeneous document databases may be used to support data integration. Creation of the common ontology requires profound understanding of the concepts used in the databases. It is a demanding task, especially in cases where the content of the documents is written in various natural languages. In this chapter, we propose the use of contextual metadata as another means to add meaning to document collections, and as a way to support data integration. By *contextual metadata*, we refer to data about the context where documents are created (e.g., data about business processes, organizations involved, and document types). We will restrict our discussion to contextual metadata on the level of collections, leaving metadata about particular document instances out of the discussion. Thus, the contextual metadata can be created, like ontologies, independently of the creation of instances in the databases.

BACKGROUND

European legal databases offer an example of a new means for data integration. Due to the development towards European integration, the legal information needed in a particular situation often concerns not only regulations of the home country, but also European Union regulations and those in foreign countries. The information may be scattered in various European legal databases with varying retrieval techniques. The databases are organized in different ways, and their content is written in different languages. Differences in legal systems aggravate the retrieval problems. Similar problems and needs may be identified in other types of environments, as well. For example, the information needed during manufacturing processes may be created in a number of cooperating organizations and scattered in heterogeneous intranet and extranet repositories.

Where the creation of ontologies requires analysis and a description of concepts used on a domain, creation of contextual metadata requires analysis of the environment where documents are created. We will first describe methods for collecting contextual metadata, and then we will show how the metadata can be visualized to users in a graphical interface. The graphical models providing contextual metadata aid the users in understanding the context of documents and in locating information from correct sources.

COLLECTING THE CONTEXTUAL METADATA

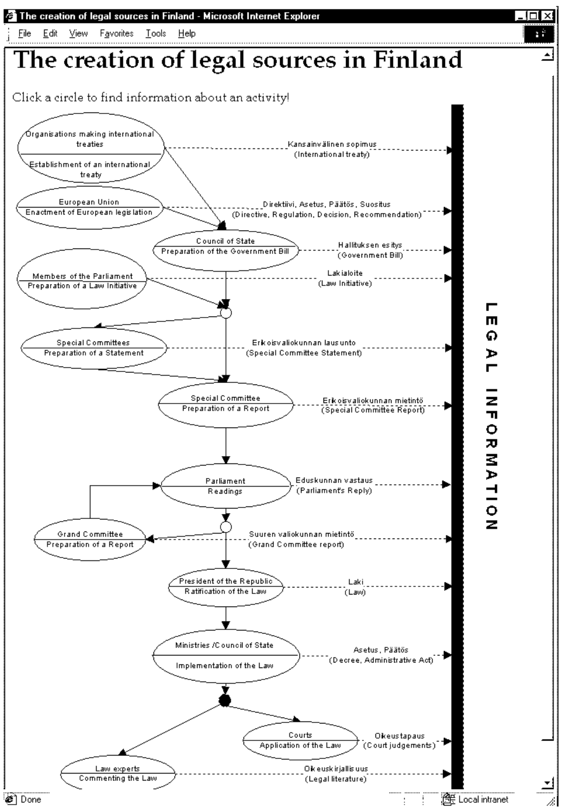
A special methodology called Rakenteisten Asiakirja Standardien KEhittäminen (RASKE) meaning “Development of standards for structured documents,” has been developed for analyzing and describing document management environments. The RASKE method was tailored from more general information systems analysis methods and tested in a project where document management practices in the Finnish Parliament and ministries were redesigned (Salminen, 2003; Salminen et al., 2000; Salminen et al., 2001). The major practical result of the project is that the Finnish Parliament currently creates all Parliamentary documents in SGML (Standard Generalized Markup Language) format (Goldfarb, 1990). The RASKE methodology offers tools for gathering and representing contextual and structural metadata about documents.

The modeling techniques of RASKE are intended for describing documents, processes where documents are created and manipulated, and actors and their roles in the activities of the processes. The most important origins of the techniques are in the object-based modeling methodology of Shlaer and Mellor (1992), in Information Control Nets (Ellis, 1979), and in the document structure specification methods of SGML standard and elm graphs (Goldfarb, 1990; Maler & El Andaloussi, 1996). From the various models created in a RASKE analysis, three kinds of models provide important contextual information. The *organizational framework model* describes the organizations involved and their roles on the analysis domain. The activities of the domain are described by process models. The *document output model* is a process model showing the activities and actors of a process together with the document types produced in the activities. The relationships of different document types are described by a *document-relationship diagram.* In addition to a set of models, the RASKE methodology produces textual descriptions (e.g., about document types and actor roles).

VISUALIZATION OF THE CONTEXTUAL METADATA

To support users in retrieving information created on a complex domain, we suggest using the models created

Figure 1. Process view describing the Finnish legal system



during the document analysis as metadata visualizations. The visualization of information itself is not a novel issue. Graphical models have been used, for example, in software engineering (e.g., UML) (Booch et al., 1999), business process redesign (Abeysinghe & Phalp, 1997), workflow management systems (Ellis, 1983), and computer supported cooperative work systems (Sarin et al., 1991). The visualizations we propose add, however, a new perspective for the uses of visual presentations. Our solution for visualizing contextual metadata by graphical models is intended to be used as a retrieval interface for distributed document repositories. The solution has been tested in the European User Views to Legislative Information in Structured Form (EULEGIS) project, whose main goal was to improve access to European legal information (Lyytikäinen et al., 2000). The EULEGIS prototype system demonstrated how a single-point access to various European legal databases could be implemented.

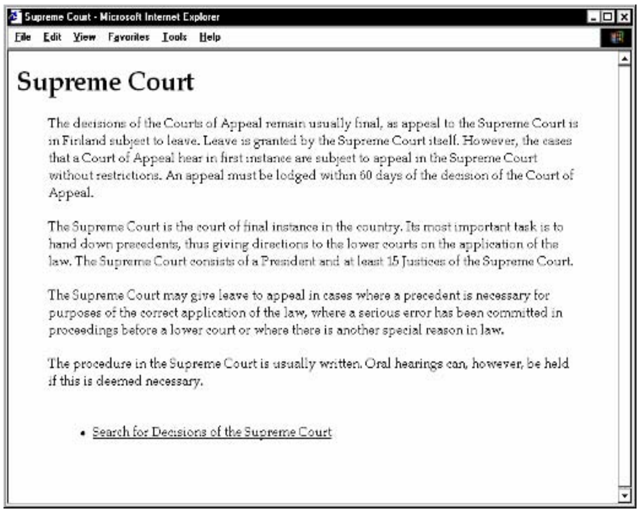
The three models discussed previously provide three different views to the information on the domain. The *actor view* describes the most significant actors on the domain; the *information source view* shows the different kinds of documents and their relationships; and the *process view* describes activities related to the information production process. In order to enable querying the document databases, links from each graphical element of the view to the query form of the relevant database can be defined.

The process view describing the Finnish legal system is shown in Figure 1. The graphical model originates from the document output model created during the RASKE analysis. The main activities of the process are depicted by circles. Each circle shows both the name of the activity and the actor(s) performing the activity. The order of activities is expressed by solid arrows between the activities. The information flow from an activity to the collective document repository is shown by a dashed arrow labelled with the type of the documents created in the activity. Additional textual information is linked to the graphical symbols. By clicking, for example, an activity symbol in the graph, the user can obtain more information about the activity. From this additional information, a link leads to a search form by which the user can search for the documents that originate from the selected activity. Similarily, the user can retrieve information about a particular actor and a search form for accessing documents created by the actor (see Figure 2).

The three views were implemented and tested in the EULEGIS prototype. The feedback from the users was encouraging. The views were seen as a good tool to become acquainted with a previously unfamiliar legal system and to limit the scope of a query statement.

For the dynamic generation of graphical views, the data pertaining to the models has to be formally defined.

Figure 2. Additional information about the Supreme Court in Finland



For this purpose, we have described the models in an XML (Extensible Markup Language) (Bray et al., 2000) document type definition (DTD). In the DTD, the data sources, documents, actors, and processes of a domain are defined, together with their relationships to each other (Lyytikäinen et al., 2000). The DTD is designed in a way that it enables the text in the models to be described in several languages.

FUTURE TRENDS

In the global and organizational networks, documents are increasingly created in complex interorganizational processes. At the same time, the improved authoring and communication technology increases document production. In Europe, the expansion of the European Union is creating a situation where organizations and citizens all over the Europe have a need for legal information, not only concerning their own country, but also in relation to foreign countries and the European Union. A similar trend also can be seen in the business world where corporations operate in global markets, and information related to a business process is produced in different countries.

To assure the accessibility of information created in complicated processes, different kinds of techniques are needed. The contextual metadata approach is a way to add meaning to document repositories. Another approach for the same purpose is to build ontologies describing concepts and their relationships on a domain. The techniques and methods for building and sharing ontologies are an active area of the current semantic Web research (Fensel et al., 2000).

CONCLUSION

On various domains, information needed by people is increasingly available in large and heterogeneous web repositories. The lack of the knowledge about the repositories, differences in the organization and user interfaces of the repositories, and the lack of knowledge about the context where information is created hinder the use of the repositories. In the article, we discussed how metadata about the context of the documents in the repositories can be used to improve information retrieval. Graphical information models were adopted to visualize the collected contextual metadata: information sources, their relationships to each other, actors, and activities in the documentation creation processes. The graphical interface has been tested in a prototype system. The test users regarded the interface as a valuable tool for retrieving information from heterogeneous databases. More systematic user testing is an important area of future research.

KEY TERMS

Contextual Metadata: Information describing the context where the object of the contextual metadata is created. The contextual metadata can cover, for example, information about the producers and production processes of documents.

Document Database: A collection of documents associated with a system to manage the documents and their content.

Document Type Definition (DTD): The capability of XML to specify constraints for a class of documents. A DTD defines element and attribute names and the hierarchic structure of the elements for the documents of a class.

Extensible Markup Language, XML: A markup language for representing information as structured documents. Developed from an earlier language called SGML (Standard Generalized Markup Language) for the purposes of information management on the Internet.

Legal System: The set of legal rules governing an entity. The entity in question can be, for example, a state, a group of states, an international organisation, a region, or a city.

Metadata: Data about data. In the context of document databases, metadata is data carrying information about documents, document collections, or parts of documents.

Semantic Web: An extension of the current Web where information resources are attached with metadata to support people and computers as they work in cooperation. The metadata is intended to give well-defined meaning to resources and to support automated reasoning about the meaning and trustworthiness of resources.

C

Contingency Theory, Agent-Based Systems, and a Virtual Advisor

University of Texas at Arlington, USA

INTRODUCTION

In this article, we investigate the potential of using a synthesis of organizational research, traditional systems analysis techniques, and agent-based computing in the creation and teaching of a Contingency Theoretic Systems Design (CTSD) model. To facilitate understanding of the new design model, we briefly provide the necessary background of these diverse fields, describe the conceptualization used in the integration process, and give a non-technical overview of an example implementation in a very complex design environment. The example utilized in this article is a Smart Agent Resource for Advising (SARA), an intelligent multi-agent advising system for college students. To test all of the potential of our CTSD model, we created SARA utilizing a distributed instructional model in a multi-university, multi-disciplinary cooperative design process.

Just as a dynamic task environment forces an organization to compress its management structure and to outsource non-core activities in order to become flexible, a dynamic software development environment forces designers to create modular software. Until now, cooperative development paradigms were too complex to facilitate inter-organizational cooperative development efforts. With the increasing popularity of standards-based Web services, the development of pervasive computing technologies, and the advent of more powerful rapid application development languages and IDEs, this limitation has been removed. Our purpose in this research is twofold: first, to test the viability of using Contingency Theory (CT), a sub-discipline of Management Organizational Theory (OT), in an agent-based system; and second, to use these new technologies in creating a distributed instructional model that will allow students to interact with others in diverse educational environments. As an example implementation, we create a virtual advisor that will facilitate student advising in distributed environments.

In the following sections, we outline the background theories involved in the conceptualization of our design model. We start with the shifts in systems design techniques and how CT can be applied to them and to various Multi-Agent Systems (MAS) to allow Contingency Theoretic Systems Design (CTSD). Once the necessary background is in place, we briefly discuss our new eLearning approach to cooperative distributed education. Finally, the structure of the SARA is discussed.

BACKGROUND

Multi-Agent Systems

Agents and communication protocols form the basic components of a multi-agent system. Agents exchange messages according to a protocol of expected messages delivered in a communication language in which the message content and format adhere to a shared standard. Individual agents make decisions, which may include contacting other agents for information, and perform processing to satisfy their goals

An agent is commonly defined as a program or collection of programs that lives for some purpose in a dynamic environment and can make decisions to perform actions to achieve its goals. In other words, agents are goal-based programs that must deal with changing access to resources, yet run continuously. Like the best administrative assistants, agents know and adapt to their master. Individual agents may be conceptualized as having beliefs, desires, and intentions that can communicate with other agents to satisfy their goals. Multi-agent systems are those in which multiple agents (usually) cooperate to perform some task. Agents may be independently developed and allow the decomposition of a complex task into a collection of interacting agents that together solve some problem. It is not necessary that an individual agent "understand" the overall system goals or structure.

Agent communication can be viewed at four distinct levels. The first level is the expected protocol for exchanging sequences of messages, like a script. For example, when negotiating, the parties expect bids to be offered, rejected, and counter-offered. The second level relates to the content or meaning of the messages. To enable inter-agent communication, an ontology is created. Examples of such concepts are things, events, and relationships. At the third level, a representation language defines the syntax for structuring the messages; The Knowledge Interchange Format (KIF) (Gensereth & Fikes, 1992) is one example. At the fourth level, an agent communication language (ACL) such as the Knowledge Query and Manipulation Language (KQML) or the Foundation for Intelligent Physical Agents (FIPA) ACL (Labrou, Finin, & Peng, 1999), defines message formats and message delivery. An example KQML message, in Sandia Lab's Java Expert System Shell (JESS) (Owen, 2004), that shows how an agent registers a service is shown below:

(register :sender student :receiver advisor :reply-with msg1 :language JESS :ontology SARA :content '(MajorCourses:Compliance Check Hours))

Just as human systems created to achieve complex goals are conceived of as organizations, multi-agent systems can be conceptualized as "organizations of agents". Individual components, whether human employees or software agents, need to be managed, guided toward a constructive goal, and coordinated toward the completion of the necessary individual tasks. In "empowered organizations", lower-level employees have the knowledge and authority to perform many tasks without the intervention of superiors. This conceptualization allows us to use well-established research from management organization theory (and Contingency Theory in particular) in creating guidelines for the design of agent-based systems.

ORGANIZATIONAL THEORY (OT)

While much of the background concerning OT is explained in the main chapter below, the following is a brief overview of the relevant research trends. OT examines an organization's structure, constituencies, processes, and operational results in an effort to understand the relationships involved in creating effective and efficient systems. A major division of OT, Contingency Theory (CT), postulates that no organization operates without constraints from environmental, personnel, technological, and informational influences (Andres & Zmud, 2001). This relationship is explained by the information processing theory (IPT) (Galbraith, 1973). IPT postulates that the more heterogeneous, unpredictable, and dependent upon other environmental resources a task is, the greater the information processing that the organization must be able to do in order to successfully accomplish it. As complexity and unpredictability increase, uncertainty increases due to incomplete information. As diversity of processes or outputs increases, inter-process coordination requirements and system complexity increase. As uncertainty increases, information-processing requirements increase. The basic premise of IPT is that the greater the complexity and uncertainty in the tasks in an organizational system, the greater the amount of information that the system must process (Galbraith, Downey, & Kates, 2001). A basic premise of our research is that this relationship is also true for information systems (Avgerou, 2001).

MAIN THRUST OF THE ARTICLE

Multi-Agent System Architectures Using CTSD

Contingency-theoretic system development (CTSD) adapts CT and IPT to the development and maintenance of software systems (Burnell, Durrett, Priest et al., 2002; Durrett, Burnell, & Priest, 2001, 2003). A business can organize employees in a number of different ways, for example by function or by project, and reorganize as the business environment changes. Software systems can benefit from this flexibility as well. The CTSD design approach is focused on design for maintainability, a crucial requirement for complex, dynamic systems.

Agent-based architectures are a means for structuring software systems that adhere to Contingency Theoretic principles. Each agent is viewed as an employee that has specific capabilities, responsibilities, and knowledge within an organization. Agents, like employees, are grouped into departments, as needed, to best satisfy the goals of the organization. Agents can communicate peer-to-peer within and across departments, and manager agents resolve conflicts and make resource allocation decisions.

Tightly interrelated tasks are grouped into one or more agents. Each of these groupings is referred to as a "software team", and parallels a department of employees that perform roughly equivalent jobs. For example, a set of agents that each handle one type of course requirement (e.g., lab, art appreciation) may be grouped into a team, where communication can occur quickly between these agents and with a "manager" agent that can resolve conflicts, exceptions, and course-independent tasks. An example agent in our system is encoded using JESS rules to check that student preferences (e.g., for afternoon courses) and constraints (e.g., no more than 12 hours per semester) are satisfied. Another agent offers heuristic advice as an actual advisor might. For example, a student may be able to enroll in 17 hours of math and science courses, but this may be strongly advised against, depending on the student's GPA and perhaps other factors.

Each agent in a multi-agent architecture has specific tasks to perform and communications requirements. Once an ontology and agent communication language has been specified, agents can be designed independently and integrated into the system to progressively add capabilities. Using CTSD principles, tasks that are dynamic and shared are grouped into support agents to enhance maintainability of the system. The primary architectural decision is to separate knowledge based on two criteria: the degree of dynamicism and the degree of complexity. Dynamicism is exemplified by how frequently knowledge is expected to change over time, while complexity determines how abstract that knowledge is. A simple example describing the latter is the fact that "a student must be a junior with a GPA greater than 3.0 in all math and science courses". Dynamicism within the SARA domain was determined by advisor interviews, and analysis of degree requirements changes over time at three universities, both large and small and private and public.

Using the above CTSD conceptualizations in previous research (Burnell, Priest, & Durrett, 2002, 2003; Durrett, Burnell, & Priest, 2000), we have developed and tested the following CTSD guidelines for creating MAS:

1. *Describe business activity and identify tasks*: Allow management and developers to refine the overall purpose of the software being designed.
2. *Determine task predictability*: Since a basic premise of CT is that the control structure of a business process must match the environment in which it operates, we must identify the predictability of each task.
3. *Assign tasks to employees*: Once the level of predictability has been estimated for each task, the granularity of the employees being created can be determined and component designs finalized.
4. *Group employees into teams*: As with human organizations, our employees can be grouped along any of several dimensions, including task, workflow, product, manager, or communication requirements, as required by the operating environment.
5. *Identify communications needs:* Once teams are determined, the communication requirements of individual employees, and of teams, can be determined.
6. *Construct management groups*: In software systems operating in a dynamic environment, management is required only when employees are unable to handle events

.

We show the application of these guidelines in a distributed instructional environment in a multi-university, multi-disciplinary cooperative design process.

Multi-Agent System Architectures Using CTSD

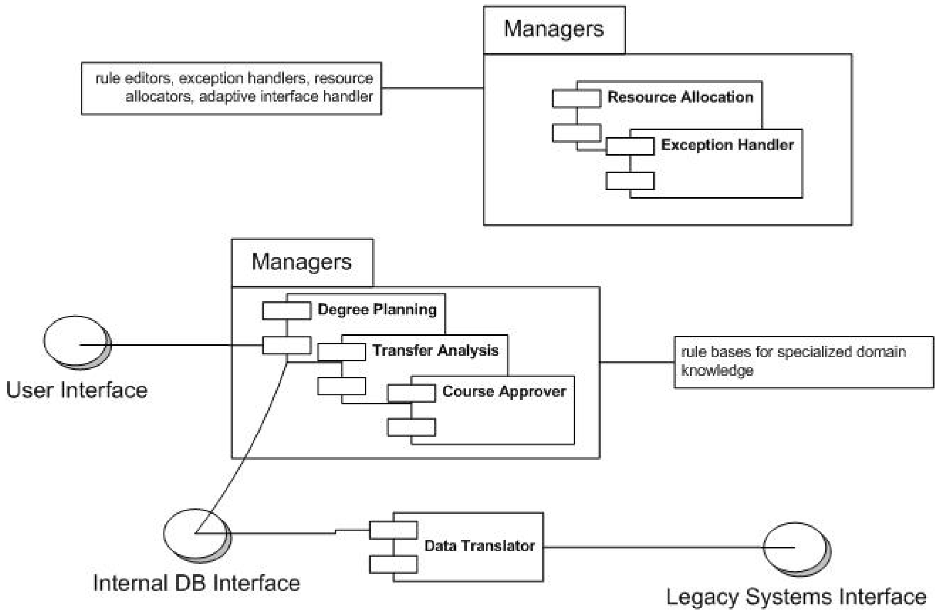
Our example implementation of the above CTSD guidelines is SARA, an interactive tool intended to aid in the planning, scheduling, and advising process to complete a college student's degree. SARA, along with the instructional environment in which it was created, is described very briefly next; for more detailed information on SARA or our distributed instructional model please see any of the Burnell, Durrett, or Priest references in the reference section.

As described previously, CTSD is most effective in complex dynamic environments. To create this environment, SARA was designed in a collaborative education project among three major universities, the University of Texas at Arlington (UTA), Texas Christian University in Fort Worth (TCU), and Texas Tech University in Lubbock (TTU). Teams of students at UTA are in industrial engineering and software design courses. The TCU students are in computer science and have had coursework in artificial intelligence, and the TTU teams are in courses that study application servers and server-based JAVA databases. In creating SARA, responsibilities have been purposefully segregated to create the necessity of interdisciplinary cooperation. Current trends in industry are toward outsourcing in many major Fortune 500 companies (Fox, 2004). In order to do this effectively, the designer and the coders must communicate in an online forum and adapt to rapidly changing conditions. Therefore, we have attempted to emulate this CTSD type environment through our interdependent classes. Also, previous research has shown that a major hurdle to software development is the communication among the programmers, the users, the executives, and the domain experts. A major component of successful software development is overcoming this communication hurdle. We have attempted to emulate these trends in the design of SARA.

Design of SARA

SARA gives students the resources and knowledge to troubleshoot issues with their current degree plan. A profile of student preferences and a transcript of completed courses allow the system to generate customized degree plans. Students can also manually customize degree plans and create schedules course-by-course that are checked for requirements compliance. Errors in

Figure 1. Prototype architecture (from Priest et al., 2002)



plans and schedules are explained so that the student can make corrections. Advisors can review degree plans on the system and send comments back to the students, without their having to physically meet. Thus, some of the most time consuming tasks in advising are eliminated (Priest, Burnell, & Durrett, 2002).

The current prototype of SARA that is depicted in the following diagrams and text is the work of several semesters work at all 3 universities. As a result of these cooperative efforts, a basic system prototype (shown in Figure 1) has been developed, initial system databases have been designed and implemented (shown in Figure 2), and smart user interfaces that utilize MAS (shown in Figure 3) were created. The user interfaces were designed primarily by the TCU teams, the basic CTSD-based analysis and thus overall system requirements were created by the UTA students, and the backend database design and application server support were provided by the TTU students.

The architecture depicted previously (in Figure 1) follows the CTSD guidelines discussed. Given the dynamic, complex environment in which the system will operate, we have segregated tasks into individual software teams and empowered the constituent agents with as much decision making ability as possible. Exceptional situations are handled by "manager agents" and by other exception handlers.

The prototype SARA database module depicted next (in Figure 2) was created to provide the flexibility required by the MAS system architecture. Initial implementations are on MySQL, and migration to IBM DB2 to provide for more system automation is planned.

The MAS-based user interfaces (one example of which is depicted in Figure 3) were created using data from TCU's course schedule. They allow students to do most of the routine work in degree planning, freeing up advising time for more meaningful discussions. Once proposed plans are created, they can be evaluated and approved off-line.

FUTURE TRENDS

Our future plans include broadening the scope of the project just described using an open source software development model. Our intent is to research the potential in open source design models for relieving some of the coordination issues inherent in a resource limited project such as ours. We hope that this new model will relieve some of the faculty coordination required and still allow (or force) students to cooperate with each other even though in different disciplines and locations.

CONCLUSION

In the project just described, we have developed a multi-agent system for college advising using the contingency-theoretic system development (CTSD) process. Multi-

Figure 2. SARA database entity diagram

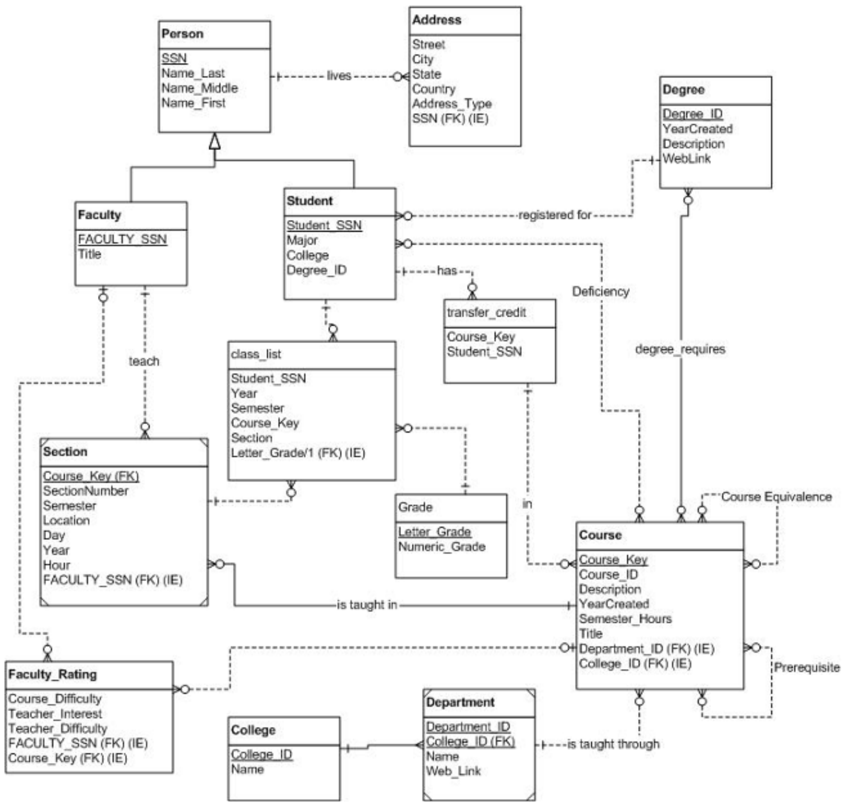


Figure 3. Custom degree planner interface

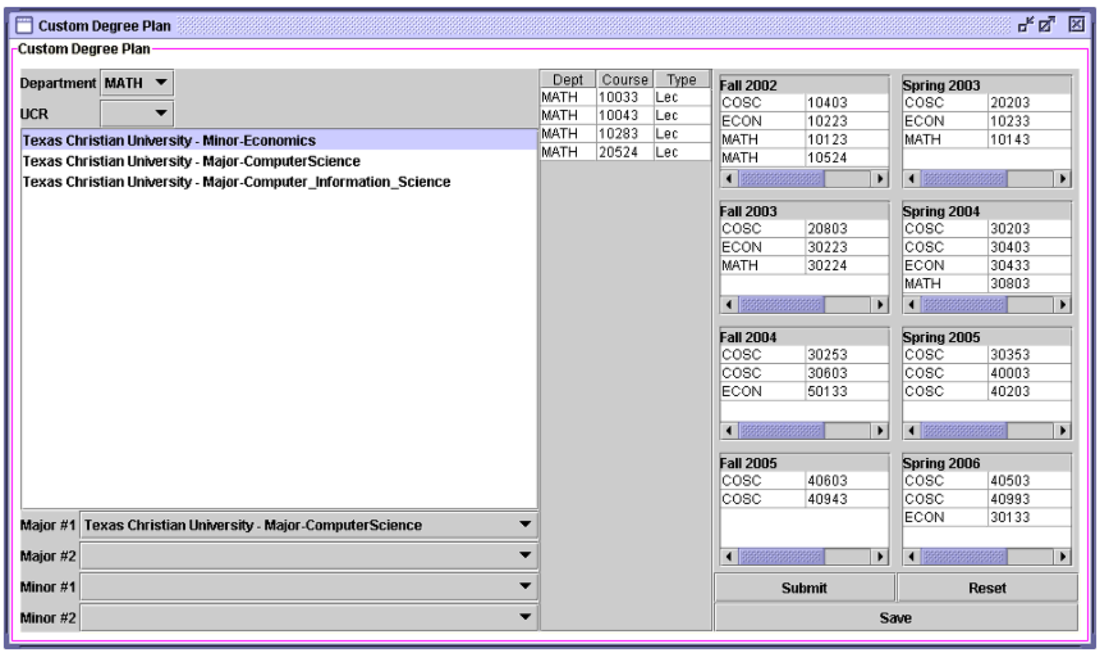

disciplinary teams of students at three universities were employed to create the system. Once the ontology and agent communication language are defined, individual agents are constructed incrementally. The resulting system is a hierarchy of intelligent agents that together provide support for course scheduling and degree planning and that are adaptable to changing environments. The CTSD process applied to the creation of intelligent multi-agent systems results in maintainable systems operating in complex, dynamic domains. As such domains become increasingly automated, training and support tools for distributed CTSD will be needed. We have created an approach for such training that has been successfully applied to SARA and other projects over the last three years. Support tools will need to be created that capture not only the system design, but provide knowledge-based analysis of designs based on the principles we have defined.

KEY TERMS

Contingency Theoretic Software Development (CTSD): A new model for MAS design using tenets from CT and IPT. The CTSD design approach is focused on design for maintainability, a crucial requirement for complex, dynamic systems.

Contingency Theory (CT): A research branch of organizational theory that suggests that an organization's structure reflects its adaptation to the environment in which it operates. Hierarchical organizations operate best in stable, simple environments while flat, team-based organizations are better adapted to dynamic, complex task environments.

E-Learning: Any form of education or training that utilizes online media and remote connectivity for all or part of its curricula. This model includes both purely online courses and those in brick-and-mortar universities facilitated by email, the Internet, newsgroups, or chat.

Information Processing Theory (IPT): An explanation for the organization structure-environment relationship suggested by CT. IPT suggests that the information processing requirements dictated through interactions with the environment force certain structures in order to be efficient and effective.

Multi-Agent Systems (MAS): Multi-agent systems are those in which multiple agents (usually) cooperate to perform some task.

Ontology: An ontology is a well-defined set of concepts that are ordered in some manner to create an agreed-upon vocabulary for exchanging information.

Smart Agent: A program or collection of programs that lives for some purpose in a dynamic environment and can make decisions to perform actions to achieve its goals. Individual agents may be conceptualized as having beliefs, desires, and intentions that can communicate with other agents to satisfy their goals.

Software Team: Groups of agents which have tasks that are tightly interrelated; these teams roughly parallel a department of employees.

Contract-Based Workflow Design Patterns in M-Commerce

V.K. Murthy
University of New South Wales, Australia

E.V. Krishnamurthy
Australian National University, Australia

INTRODUCTION

This overview describes an object-based workflow paradigm to support long and short duration transactions in a mobile e-commerce (or m-commerce) environment. In this environment, the traditional transaction model needs to be replaced by a more realistic model, called a "workflow model" between clients and servers (peers) that interact, compete and cooperate, realizing an intergalactic client-server program. The various types of task patterns that arise in m-commerce, for example, reservation, purchasing, require a "what if" programming approach consisting of intention and actions for trial-error design before an actual commitment is made. Such an approach enables us to take care of the unpredictable nature of connectivity of the mobile devices and the networks and also provide for the trial and error program design required in m-commerce.

BACKGROUND

A mobile computing environment consists of fixed host computers and mobile client computers that are linked together by a network (wired or wireless) so that these computers can communicate among themselves using messages. The mobile clients (MC) are capable of connecting to the fixed network via a wireless link. Fixed host (FH) provides mobile application services and information to mobile clients. MC supports query invoking and information filtering from FH to provide personal information service. We model a mobile computing environment as a collection of different types of objects by identifying each computer (mobile and stationary) as an object. This model is called Mobile Object Programming System (MOPS).

A mobile object programming system (MOPS) (Vitek & Tschudin, 1997) is interpreted as a collection of objects interacting through messages. Each object maintains its own share of data and has its own program piece to manipulate it. That is each object combines datastructure and functionality. The objects are active and behave like actors in a movie, each following its own script and interacting with other objects.

A task submitted from a mobile client is called a mobile transaction. It is a distributed task that can be executed partly within that mobile client (MC) as an internal transaction (Intran) and partly in other fixed hosts (FH) as external transactions (Extran). Each FH has a coordinator FHC that receives external transaction operations from mobile hosts and monitors their execution in the database servers within the fixed host. Similarly each MC has a coordinator MCC.

Conventionally, transactions are assumed (Bacon, 1993; Krishnamurthy & Murthy, 1992) to satisfy the ACID properties, namely:

- **Atomicity:** All or none of transaction happens;
- **Consistency:** A transaction preserves the consistency in database before and after its execution;
- **Isolation:** Intermediate results are not externally made visible until commitment;
- **Durability:** The effects are made permanent when a transaction succeeds and recovers under failure.

The ACID properties turn out to be restrictive for mobile transactions and need to be relaxed as illustrated by the following example on flight reservation.

Here, one needs to have the following tasks: select a suitable airline that offers cheaper fares, ensure there is vacancy, and make an advanced booking (that is to be confirmed later). These individual steps are really not traditional transactions, but well-defined program pieces that can be carried out concurrently and may need to follow a predefined partial order to satisfy certain predicates (e.g., seat availability) invariant criteria (number of seats is determined by the size of aircraft) and synchronization (one step requires the completion of other step). Therefore, the steps need not be atomic, need not be immediately consistent, and need not satisfy isolation property since intermediate non-commit states are to be made visible (called externalization). Furthermore, such steps are liable to be cancelled eventually and require a suitable rollback preserving some local states. Also, in a cooperative mobile environment it may be necessary to allow data exchange between some transactions during their execution thereby necessitating the relaxation of the isolation property.

Thus in a mobile environment, we need a new model where:

(i) The isolation property is removed making the intermediate results visible.
(ii) The precedence order in execution and other dependencies are taken care by modifying the atomicity requirement.

This model is called "a workflow" between the MC and FH. The workflow model, its contract based formulation and the e-commerce patterns described here result from the basic work on contract model of Wachter and Reuter (1995), the design by contract by Meyer (1992a, 1992b) and the design patterns and contracts by Jezequel, Train, and Mingins (2000).

MAIN THRUST OF THIS ARTICLE

The main thrust of this article is to describe the workflow paradigm for applications in m-commerce. Unlike the transactional paradigm, which is severely restricted by the ACID properties, the workflow permits more general properties that are suitable for m-commerce applications. We illustrate some of the important applications and the design of suitable protocols. We also classify some workflow patterns arisng in e-commerce and the language support needed.

WORKFLOWS: EXTERNAL AND INTERNAL

A global workflow (we call it an external workflow or *Extran*) T(ij) is defined as a workflow between two objects O(i) and O(j); this consists of a message sent from O(i) to execute a desired workflow in O(j). This message is received by O(j). O(j) has a behavior specified by: Pre(T(ij)), G(j), C(j), Post (T(ij))S(j), where Pre() and Post() are respectively the pre and post states that are active before and after the workflow T(ij). G(j) is a guard of O(j) to signal when the required precondition is met, and C(j) is the command function; S(j) signals when the post condition is achieved. Here, the script specifies what message O(j) can accept and what actions it performs when it receives the message while in state Pre(T(ij)) to satisfy the post condition post(T(ij)). The Extran T(ij) can trigger in O(j) numeric, symbolic or database computations.

Each Extran T(ij) from object i to object j triggers a set of serializable computations in O(j) either in a total order or in a partial order depending upon whether parallelism, concurrency and interleaving are possible locally within O(j). If the object O(j) is "made up" of subobjects, we may have to execute a workflow consisting of several local workflows (called internal workflow or Intran). After executing Intran, each object reaches a new state from an old state using its internal command set C(j); before executing the commands, the required precondition is met, and after completion of the command set, the post condition is ensured in the new state. This is the design by contract approach (Meyer, 1992a, 1992b) and widely used in the language Eiffel. The precondition is specified by "require" and post condition by "ensure", see Meyer (1992a, 1992b).

We shall see in the next section that the Extran and Intran have more general properties than the ACID properties mentioned earlier.

CHEMICAL REACTIVITY-LIKE PROPERTIES

The Extran and Intran have more general properties called "chemical reactivity properties", since they resemble chemical reactions: molecularity, contractual obligation, opacity during a molecular action, and retry or rescue through a recovery protocol bringing the system back into the invariant state. These are defined as below:

(i) **Molecularity:** If there is a crash during a composite operation, all of the effects of the sub-operation are lost. If there is no crash, the composite or molecular operation is complete. That is, a molecule is synthesised fully or not at all.
(ii) **Contractual obligation:** Invocation of a single composite operation takes the program from one consistent state to another. This means precondition and post condition of a contract holds. Thus, conventional consistency is replaced by contractual obligation.
(iii) **Opacity:** The results of the sub-operations of composite operation should not be revealed until the composite operation is complete.
(iv) **Durability:** If a crash occurs and contract fails and a component cannot meet its obligation and fails in its contract, an exception is raised. Then we have three possibilities:
    a. Exception is not justified: It is a false alarm we may ignore.

b. If we have anticipated the exception when we wrote the routine and provided an alternative way to fulfill the contract, then the system will try that alternative. This is called resumption.

c. If, however, we are still unable to fulfill the contract, we go into graceful degradation or surrender with honour. Then bring all the objects to an acceptable state (pre- committed-state) and signal failure. This is called organized panic. This should restore the invariant. At this point, we initiate retry. The effect of retry is to execute the body of the routine again.
Remark: In Eiffel (Jezequel et al., 2000; Meyer, 1992a, 1992b; Wiener, 1996) the rescue clause does all of the above (this is essentially RESTART after recovery in transaction processing)
Also in MOPS, the chemical reactivity properties are generalized further: Since a number of remote objects are invoked, the coordinators FHC and MCC should ensure all the remote actions and the local actions are complete. If anyone fails the whole program has to be abandoned, and we need to retry, rescue and bring the system to its invariant state. Contractual obligation is extended to all objects under concurrent invocation and partial failures.
No results are revealed from any objects until all the actions are complete and the coordinator commits.

(v) **Retry/Rescue and Reset:** If false alarm then retry; else rescue and restart so that all the invariants in all objects are rest to their pre-action state.

Recall that we have two types of transactions " Extran (external transaction) between a MC and an FH, and Intran (internal transaction) that take place locally within each MC or in FH. We split the Extrans into intention and action transactions, where the intention transactions have the ACID properties, and the action transactions are long duration transactions supported by a recovery protocol. The intention transactions are again local to each MC or FH and based on the decision in this phase, the action transaction takes place through a protocol (called intention-action protocol (IAP)) provided with a time-out strategy and recovery to cope up with failures of disconnection. We now illustrate the applications of the intention-action protocol.

HOTEL RESERVATION PROBLEM

Consider the hotel reservation problem. The hotel database has a set of rooms and each room has a status available or unavailable on specified dates. The object Alloc stores the confirmed allocation of rooms to named guests and Int-alloc holds the intentional reservations intention-committed. We assume that each guest has a unique ID and is not permitted to hold multiple reservations in the same hotel.

The hotel database has two integrity constraints:

(i) The number of confirmed + intentional reservations do not exceed the number of rooms on any date.
(ii) The set of rooms that are unavailable on any date are those already allocated to the guests in Alloc plus those in Int-Alloc on those dates.

The following transactions act on the hotel database.

(i) Reservation request from guest within a deadline (Extran);
(ii) Reservation availability from hotel and intention commit (Intran);
(iii) Send negative intent or (positive intent + deadline) to guest to confirm (Extran);
(iv) Reservation acceptance or cancellation by the guest (Extran);
(v) After cancellation by the guest or FH-deadline, the intent reservations are cancelled and rooms are made available and the Int-Alloc is suitably modified and committed (Intran); and
(vi) After the confirmation by guest within FH-deadline the Int-Alloc rooms are transferred to Alloc and committed (Intran).

Note that transaction 2, 5, 6 are Intrans with ACID properties while 1,3,4 are Extrans using IA-protocol.

E-CHECKING

The electronic check (e-check) was introduced by Financial Services Technology Consortium (FSTC) [www.fstc.org]. This system has functions, such as: deposit and clear, cash and transfer. It has entities: payee, payer, payer bank, payee bank and clearing house. E-check can be an effective system over integrated networks. E-check can be used for high value transactions, business-to-business (B2B) payments, and so forth. At every stage of this system, the intention-action protocol and time-tolerant and time-critical transactions arise (Dani & Radha Krishna, 2000; Wang & Das, 2001). Using intention-action, log and time stamps, we can incorporate fairness, non-repudiation and timeliness of financial transactions.

When a check is presented, the bank verifies the details, signature and validates the check and security codes and accepts or rejects a check within a time limit. Hence, the time stamp also plays an important role in clearing and depositing checks in time order of issue whenever there is not adequate balance in the account, in order to resolve the conflicts and appropriately inform the payee and payer. Also using logs non-repudiation can be achieved so that the participants cannot deny a particular intention, event or action.

FUTURE TRENDS

Two important aspects require further research and development: The analysis of workflow patterns that arise in e-commerce and the development of appropriate software tools for the design of contract-based workflow patterns. These aspects are described in the following section.

WORKFLOW PATTERNS IN E-COMMERCE

Certain special behavioral patterns (Gamma et al., 1995; Jezequel et al., 2000; Shalloway & Trott, 2002) of workflows occur in e-commerce applications. A pattern enforces a problem solving discipline for a design architecture. It consists of three parts: a context, a problem and a solution. The context is a description of the environment before the pattern is applied. It outlines the preconditions under which the problem and its solution appear. The context shows where and when the pattern will work. It is usually introduced with the help of a scenario. Problem describes the goals and objectives of a situation. Solution describes the means to achieve the goals and objectives through a suitable protocol.

In e-commerce, we encounter the following patterns; there can be other workflow patterns which are combinations of these patterns.

(i) **Conventional transactions with ACID properties:** These occur at the *lowest level of a workflow*.

(ii) **Supply-chain pattern:** Here the context is *a sequence of conventional transactions between a customer and a seller through a set of intermediary agents*. Here, the workflow is successful, if and only if each individual transaction in a chain is successful. An abort in any transaction will be considered unsuccessful, restoring the consistency of the initial state.

(iii) **Mutually exclusive- collectively exhaustive pattern:** Here, the context is *a single buyer trying to acquire goods from several suppliers to complete a given task through several mutually exclusive transactions* and collectively exhaustive transactions. Here, the workflow is considered successful only if all the mutually exclusive transactions are all committed. If any one is aborted this workflow is unsuccessful and the initial states are restored.

(iv) **Negotiated choice pattern:** Here, the context is that *a customer bargains and negotiates with several suppliers* simultaneously to obtain a particular product at a bargain price. This workflow is successful, if and only if one of the transactions is committed and soon after that time the rest of the transactions are aborted respecting the contract. In the latter case, the states are properly restored.

(v) **Auction Pattern:** Auction process is *a controlled competition among a set of clients and auctioneer* coordinated by the auctioneer. In the auction pattern, the transactions happen between an auctioneer and several clients through communication and these are successively revised. The rules of the English auction pattern are as follows:

a. The auctioneer-agent begins the process and opens the auction.
b. At every step, decided by a time stamp, only one of the client-agent is permitted to bid; the auctioneer relays this information. The bidding client agent is called active, and it does not bid more than once and this client becomes inactive until a new round begins.
c. After the auctioneer relays the information, a new client becomes active and bids a value strictly greater than a finite fixed amount of the earlier bid. (This is English auction; it can be modified for other auctions).
d. If within a time-out period no client-agent responds, the last bid is chosen for the sale of the goods and the auction is closed.

Table 1 summarizes the patterns.

LANGUAGE SUPPORT

Eiffel, Java, and UML are powerful languages to implement mobile object programming systems. They provide for software contracts that capture mutual obligations through program constructs such as: “require [else]” for precondition and “ensure [then]”for post condition, assertions, invariants. Eiffel provides for a good semantics

Table 1. Workflow patterns in e-commerce

Name of Pattern	Properties
Conventional Transaction	Has ACID properties: ***one customer, and one supplier*** ; commitment. or abort.
Supply Chain	Workflow between ***a customer and several sellers consisting of a set of transactions through intermediary agents***. The workflow is successful if and only if each individual transaction in the chain is successful.
Mutually Exclusive-Collectively Exhaustive	Workflow consisting of several ***mutually exclusive and collectively exhaustive transactions between a customer and several suppliers*** to acquire different items. The workflow is successful if and only if all the transactions are committed.
Negotiated Choice	Workflow takes place between a ***customer and several suppliers; the customer bargains and negotiates with several suppliers*** simultaneously to obtain a particular product at a bargain price. This workflow is successful, if and only if one of the transactions is committed .
English Auction	A ***controlled competition among a set of clients and an auctioneer*** coordinated by the auctioneer. Here the last bid with the highest value is chosen for the sale of the goods and the auction is closed with one successful bidder.

for exception handling through a "rescue" clause and "retry" clause for dealing with the recovery and resumption. The tool called "iContract" (Kramer, 1998) provides developers with supports for design by contract using Java. UML (Unified Modeling Language) and OCL (Object constraint Language) (Warmer & Kleppe, 1999) has also been gaining importance.

CONCLUSION

We described the mobile-object based workflow paradigm for mobile e-business by splitting the transactions into external and internal transactions. Also, we described the intention-action protocol and how to implement them by contractual design using Eiffel, i-contract tool of Java and UML. We also described several kinds of behavioral patterns that arise in e-commerce and how the contract-based workflow scheme becomes a useful vehicle for implementing these patterns through software.

KEY TERMS

Acid Properties:

- **Atomicity:** All or none of transaction happens;
- **Consistency:** A transaction preserves the consistency in database before and after its execution;
- **Isolation:** Intermediate results are not externally made visible until commitment;
- **Durability:** The effects are made permanent when a transaction succeeds and recovers under failure.

Contract: A consistent and fault tolerant execution of a program from one consistent state to another consistent state achieving the required precondition and ensuring that the post condition is met .

Intergalactic Client-Server Program: In the mobile computing environment, the traditional transaction model is replaced by a more realistic model called a "workflow model" between several clients and servers that interact, compete and cooperate. This is called "an intergalactic client-server program (ICSP)".

Intran: A transaction that is executed within a mobile host (MH) as an internal transactions (for brevity, Intran) using its own internal operations and data.

Extran: An external transaction that is requested by a mobile host to be performed in another external computing environment, using message communication.

Pattern: Enforces a problem solving discipline for design architecture. It consists of three parts: a *context*, a *problem* and a *solution*. The terms context, problem and solution are defined below:

- **Context:** Describes the environment before the pattern is applied. It outlines the preconditions under which the problem and its solution appears. Thus the context shows where and when the pattern will work. It is usually introduced with the help of a scenario.
- **Problem:** Describes the goals and objectives of a situation.
- **Solution:** Describes the means to achieve the goals and objectives.

Script: A condition-event structure that describes a stereotyped sequence of events in a particular context. Scripts are useful because, in the real world, there are patterns in the occurrence of events. Events described in a script form a causal chain.

Workflow: A collection of simpler tasks organized to accomplish some well-defined total task. Here each simple task defines some unit of work to be carried out as in a transaction. A workflow ties together a group of tasks by specifying execution dependencies and the dataflow between tasks. Also, there may be a constraint that a particular task cannot begin until some other task ends.

Contracting Mechanisms in the IS/IT Outsourcing Phenomenon

Khamis Al-Gharbi
Sultan Qaboos University, Oman

INTRODUCTION

As organisations need diverse and high quality IS/IT services to survive and excel in the rapidly changing business environment (Lacity & Willcocks, 2001), regular attempts have been made by organisations to sustain competitiveness through increasing their investments in IS/IT operations and resources. However, this has pushed for pursuing different options and alternatives as organisations strive to maximise their flexibility and control (Lacity, Willcocks, & Feeny, 1996). To accomplish this objective, more and more organisations are constantly looking to IS/IT outsourcing by external vendors as a viable option rather than pursuing in-house IT developments (Lacity & Willcocks).

As the central key issue in the successful IS/IT outsourcing operation is the right contract (Lacity & Hirschheim, 1995), the purpose of this chapter is to gain a deeper understanding of the contracting mechanisms that surround IS/IT outsourcing operations.

IS/IT OUTSOURCING DEFINITION AND BACKGROUND

Precise definitions of IS/IT outsourcing differ in the literature, but there is a general agreement that it is the carrying out of IS/IT functions by a third party (Ketler & Walstrom, 1993). In the context of this chapter, however, IS/IT outsourcing refers to information systems/ information technology functions only.

Cheon, Grover, and Teng (1995, p. 209) define IS/IT outsourcing as "the organisational decision to turn over part or all of an organisation's IS functions to external services provider(s) in order for an organisation to be able to achieve its goals. This definition includes the following external services: applications development and maintenance, systems operations, network/communications management, end-user computing support, systems planning and management, and purchase of application software, but excludes business consulting services, after-sale vendors services, and the lease of telephones lines. An organisation can obtain these services through complete outsourcing, facilities management, systems integration, time-sharing, and other contracts (including rental, installation and procurement, and maintenance and programming)."

GLOBAL BUSINESS SCOPE OF THE IS/IT OUTSOURCING MARKET

International Data Corporation (IDC, July 24, 2001) indicated that global spending on IT services would reach US$700.3 billion by 2005, up from US$439.9 billion in 2001. IDC found that the United States would remain the biggest spender on IT services at US$335 billion in 2005, up from US$206.9 billion this year. The Outsourcing Institute (2000) expects a growth in small business outsourcing contracts exceeding 25%. IDC (July 24, 2001) found that spending in Western Europe will grow from US$127.5 billion to US$192.4 billion in the same period, and spending in Japan will increase from US$53.2 billion to US$75.2 billion. Spending on IT services in the rest of the world will amount to US$52.5 billion to US$97.7 billion.

Even though the above-mentioned forecasts implicitly point to increasing size and scope of contracts, Currie (2000, p. 177) observes, "most companies tend to prefer to enter outsourcing contracts which are smaller (in money), shorter (in duration) and more narrow in scope (range of IT services)." However, the megadeals which involve total outsourcing continue to gain media attention due to the dollar value of such deals (Lacity & Willcocks, 2001).

IDC (July 12, 2001) indicated that spending on IT services in Asia-Pacific (excluding Japan) is predicted to rise from US$18 billion by the end of 2001 to US$42 billion by 2005. China will have the biggest growth in IT services spending, up to US$9 billion in 2005 from US$900 million in 2000.

IDC (2003) reveals the fastest growth for IT outsourcing services will be in government, financial markets, services, and discrete manufacturing. At the same time, the market opportunity for IT outsourcing services can differ significantly depending on the vertical industry. The report (IDC, 2003), which presents the 5-year forecast for the U.S. IT outsourcing market within 16 vertical markets, indicates a range in the compound annual growth rate (CAGR) from 3.5% in communications/media and education to 7.4% in government.

IS/IT OUTSOURCING IN PRACTICE

There are different types of IS/IT outsourcing. For example, Grover, Cheon, and Teng (1994) have proposed the following taxonomy: (1) complete outsourcing, (2) facilities management outsourcing, (3) systems integration outsourcing, (4) time-sharing outsourcing, and (5) other types of outsourcing. Additionally, Lacity and Hirschheim (1995) provide a taxonomy of IT outsourcing options. They are divided into three categories of IS/IT outsourcing: body shop, project management, and total outsourcing.

INSOURCING

According to Lacity and Willcocks (1998), total insourcing is "the decision to retain the management and provision of more than 80% of the IT budget internally after evaluating the IT services market" (p. 371).

SELECTIVE IS/IT OUTSOURCING

According to Lacity and Willcocks (1998), selective outsourcing is "the decision to source selected IT functions from external provider(s) while still providing between 20% and 80% of the IT budget internally. This strategy may include single or multiple vendors" (p. 371). Currie and Irani (1999) believe that "selective sourcing" is a variant of multiple-supplier sourcing.

TOTAL IS/IT OUTSOURCING

According to Lacity and Willcocks (1998), total outsourcing is "the decision to transfer the equivalent of more than 80% of the IT budget for IT assets, leases, staff, and management responsibility to an external IT provider" (p. 371).

CONTRACT DEFINITION, APPROACH AND THEORY

A contract is defined as: "An agreement between two or more people or organisations, 'parties' to the contract, which creates rights and obligations for those parties. These obligations can be legally enforced by a party who is entitled to their benefits" (Klinger & Burnett, 1994, p. 58). It is normally "a bargain made between at least two parties with an offer by one party which has been accepted by the other party with some benefits gained" (Klinger & Burnett, p. 59). A contract enables the different parties to achieve their strategic and commercial aims. It regulates the relationship of the different parties, pointing out risk and costs. It also can provide a framework for continuing to work together in the computing environment with consideration given to "certain wrongs" such as negligence, "deceit or defamation are legally known as torts" (Klinger & Burnett, p.59). A good contract is often the central key to a successful IT outsourcing relationship (Lee, 1995). As Lacity and Hirschheim (1995, p. 243) explain, "the contract is the only mechanism that establishes a balance of power in the outsourcing relationship." The contract usually defines the rights, liability, and expectations of both the outsourcing parties (i.e., the vendor and the organisation) and is often the only solid mechanism for regulating the relationship between them. However, research on IT outsourcing negotiations and contract building tend to be mostly theoretical and very limited in scope (Lee). Currie (1995) points out that one of the most significant problems of any IT outsourcing deal is "defining the legal contract that underpins the client-supplier relationship" (p. 194).

Contracts are an important and critical part of outsourcing decisions and can be very complicated due to the fact that there is often a transfer of assets, including people, equipment, software, and buildings from the client to the vendor. For the terms of the contract to be enforceable, they must be "verifiable." Based on their empirical research, Diromualdo and Gurbaxani (1998) identified elements "critical" to the success of contractual agreements, including: (1) the contract type, (2) performance measurement and evaluation scheme, (3) the compensation systems, and (4) assignment of decision-making rights to the vendor.

IS/IT CONTRACT TYPES

For each given transaction, IT managers can choose between two governance mechanisms to govern the transaction:

- **Hierarchical governance:** produce the transaction internally
- **Market governance:** purchase the transaction from an IT service provider

Also, Fitzgerald and Willcocks (1994) distinguish six types of contracts, each with a different price mechanism (see Figure 1).

Moreover, outsourcing contracts range from fixed fee to incentive types with penalties in case of unsatisfactory performance. Further, many contracts also contain early termination provisions and incentives schemes for technology change. Penalties and incentives are important features of any type of IS/IT outsourcing contract, as they serve as "inducements to the vendor and as mechanisms by which the outsourcer can manage shirking in the relationship" (Ngwenyama & Bryson, 1999, p. 353).

IS/IT outsourcing contracts had evolved from the buyer/supplier perspectives of service bureau and facilities management contracts to the partnership perspective of system integration outsourcing. At the same time, Lacity and Willcocks (1998) name the IT contracts as "fee-for-service contracts," where detailed information about requirements, service levels, performance metrics, penalties for nonperformance, and price are discussed and documented.

In addition, Diromualdo and Gurbaxani (1998) note that different types of contracts apply in different circumstances. For example, the strategic alliance or joint venture type would be chosen if the organisation required a specialized expertise and knowledge of the business process as well as tight control over the resources involved in the work. In general, the literature distinguishes between two types of contracts: (1) comprehensive contracts and (2) incomplete contracts.

1. Comprehensive (Complete) Contracts

A comprehensive (complete) contract specifies every possible contingency. Indeed, such a contract never needs to be revised or complemented (Richmond, Seidman, & Whinston, 1992). A contract for the purchase of computer supplies can be an example of a comprehensive contract.

2. Incomplete Contracts (Flexibility)

Most business contracts are incomplete because when a contingency arises the different parties must bargain to resolve the conflict. In this sense, the contract must provide for "arbitration and renegotiation" (Richmond et al., 1992). Additionally, Harris, Guiunipero, and Hult (1998) suggest that the term so-called "incomplete contract" is synonymous with a flexible contract. Most outsourcing contracts are incomplete since rapidly changing technology, uncertainty (i.e., complexity), and organisational environments make it so difficult to specify every contingency in the contract. Moreover, using incentive contracts is another mechanism to provide the agreement of IT outsourcing with flexibility. This means that the contract can include some method by which the vendor shares in any cost savings or increased profits made under the agreement.

CRITICAL CRITERIA FOR CONTRACT NEGOTIATION

The key clauses and schedules that constitute the main contractual issues are:

Before a thorough discussion of the criteria of contract negotiation starts, there is a need to discuss:

Figure 1. Types of outsourcing contracts (Adapted from Fitzgerald & Willcocks, 1994)

Contract	Basis of Payment
Time and material fixed fee	Actual use of personnel and material lump sum for a defined workload or service
Fixed fee	A lump sum for a defined workload or service
Fixed fee plus variable element	Predicted changes in, for example, workloads on business circumstances
Cost plus management fee	Real costs incurred by vendor plus a percentage
Fee plus incentive scheme	Some benefits that accrue to client company, or performance over and above an agreed baseline
Share of risk and reward	How well client company or joint venture performs

Need for Negotiation

Negotiations may be defined as: "the bargaining process between two or more parties seeking to secure predetermined objectives, usually with a clear sense of purpose" (Klinger & Burnett, 1994, p. 13). In fact, compromise is an essential feature of most successful negotiations. Additionally, negotiations can be costly and can range from a telephone discussion on some key issues through to meetings. In the same time, negotiations require much skill in how to negotiate and compromise. To build a strong contract, much negotiation is needed between the different parties to discuss all possible contingencies and also the service level agreement (SLA) of the contract.

Service Level Agreement (SLA)

The SLA is usually a major part of any outsourcing contract and has been considered as the most important component of any outsourcing deal (Richmond et al., 1992). In short, the SLA refers to the "details and/or quantifies in schedules the minimum level of service which the customer (i.e., client organisation) will obtain" (Parry, 1997). In addition, the SLA contains the technical details of the proposed systems, performance levels and standards, methods of monitoring, the output (i.e., deliverables), procession priorities, response time, termination notice, and so on. It is to be noted that there is mounting evidence that poor IS/IT outsourcing decisions are the direct result of an inadequate definition of customer requirements or the SLA (Richmond et al.).

Furthermore, Kern and Willcocks (2000) identify typical clauses and exhibits for service enforcement and monitoring:

- Application development measure performance (i.e., allows organisation to monitor development).
- Benchmarking (i.e., the organisation can compare at any time IT services with other services).
- Customer satisfaction survey.
- Performance reporting requirements (i.e., reports on service to be provided by the vendor in time intervals).
- Performance implies that the supplier provides products or services and the customer (i.e., client) pays for them. And also the work must be completed before the payment has to be made.

Price Mechanism and Flexibility

Pricing scheme is the central key to any outsourcing agreement. In fact, Diromualdo and Gurbaxani (1998) call it "vendor compensation" (p. 71). The pricing schedule is either specified in advance for the duration of the contract or negotiated each year. A major task in determining the future cost (i.e., price schedule) is quite difficult given the uncertainty in future technologies and business conditions. At the same time, any additional services outside the previously agreed service scope (e.g., overtime) will be charged according to the agreed price rates. Also, the timing of the payments has to be agreed on in advance.

Contract Duration

The performance of an obligation should be done in a "reasonable time" that the two parties have agreed on.

It is widely believed that in order to achieve a flexible contract, the contract duration should be short (Fitzgerald & Willcocks, 1994). However, it is difficult to define a short contract precisely, but it could be argued that a contract that is tied to the "technological life cycle" would be a short contract (Harris et al., 1998).

Termination Clause

The contract itself often contains termination conditions. There are two different types of terminations, early and exit. In addition, the contract may permit either party to terminate on notice to the other party.

Early Termination

If the parties involved in the agreement decide during the course of the contract that they wish to terminate the agreement, they can agree to discharge it (Klinger & Burnett, 1994). Sometimes, one party wants to release the second party from completing the contract. There have been some high-profile outsourcing disasters, where some organisations terminated the contract with the IT vendors for a number of reasons (Currie & Irani, 1999). However, it should be borne in mind that switching costs are expensive, whether the organisations choose to move to another vendor or rebuild an in-house department.

Exit Termination (Provisions)

According to Shepherd (1999, p. 79), exit provisions define the "responsibilities of each of the parties when the contract is terminated." It may also include arrangements of services while handing over to another vendor or the internal IS department. The importance of the "exit provision" stems from the fact that the organisation is potentially exposed to risk from the IT services in case of contract termination.

Key Vendor Personnel

It has been argued that it is of fundamental importance to the organisation to know who will be responsible for the IT services or technology from the vendor side. In other words, the key vendor's employees should be explicitly listed within the scope of the contract, with their expertise and experience, as remaining with the account for specified time periods.

Dispute Resolution

Kern and Willcocks (2000) assume that the contract should point out clearly what is the "resolution mechanism" to deal with any dispute among the different parties. Further, if the dispute cannot be resolved in the first instance, the contract should be able to direct to a further "escalation procedure," where the appropriate people or group should be contacted (e.g., arbitration). As a final resolution, a neutral third-party advisor will be appointed to solve the problem.

Post-Contract Management

The post-contract management agenda is mainly concerned with enforcing the contract and achieving the stipulated terms after it has been signed by the different parties.

FUTURE TRENDS

The growth in IS/IT outsourcing is being fueled by IT technological advances and new business opportunities. The technological trends behind the next generation of IS/IT outsourcing include the growth of universal IP networking, development of server-based computing, and better distributed systems management (Wreden, 1999, p. 128). The market has fragmented into a confusing mix of application service providers (ASPs), Webhosting, and e-commerce providers and network-integration experts.

CONCLUSION

IS/IT outsourcing contracts are expected to increase dramatically in number in coming years, forcing IT managers to face an array of complicated choices in picking IS/IT vendors and monitoring contracts.

One main aspect of this chapter, an aspect often overlooked by organisations, has been to illustrate the importance of the contracting mechanisms throughout the IS/IT outsourcing process and operation.

The success of an IT outsourcing relationship depends primarily on both parties' ability to negotiate and sign up a successful contract, which ultimately eliminates the risk factors mainly in three areas: complexity, governance, and flexibility.

Bearing in mind these considerations, the most critical contracting lines and issues have been identified, and the theoretical guidelines for successful IT contracts have been shown throughout this chapter.

KEY TERMS

Comprehensive (Complete) Contracts: A comprehensive (complete) contract specifies every possible contingency and pays attention to all different and tiny issues.

Contract: "An agreement between two or more people or organisations, 'parties' to the contract, which creates rights and obligations for those parties."

Incomplete Contracts (Flexibility): Most outsourcing contracts are incomplete since rapidly changing technology, uncertainty (i.e., complexity), and organisational environments make it so difficult to specify every contingency in the contract.

Insourcing: "The decision to retain the management and provision of more than 80% of the IT budget internally after evaluating the IT services market."

IS/IT Outsourcing: "The organisational decision to turn over part or all of an organisation's IS functions to external services provider(s)."

Selective IS/IT Outsourcing: "The decision to source selected IT functions from external provider(s) while still providing between 20% and 80% of the IT budget internally."

Service Level Agreement (SLA): "Details and/or quantifies in schedules the minimum level of service which the customer (i.e., client organisation) will obtain."

Total IS/IT Outsourcing: "The decision to transfer the equivalent of more than 80% of the IT budget for IT assets, leases, staff, and management responsibility to an external IT provider."

Cooperation of Geographic and Multidimensional Databases

Elaheh Pourabbas
National Research Council, Rome, Italy

INTRODUCTION

In recent years, the enormous increase of independent databases widely accessible through computer networks has strongly motivated the interoperability among database systems. Interoperability allows the sharing and exchange of information and processes in heterogeneous, independent, and distributed database systems. This task is particularly important in the field of decision support systems. These systems through the analysis of data in very large databases identify the unusual trends in particular applications for creating opportunities for new business or for forecasting production needs.

Currently, in the research community, geographic information systems (GISs) and multidimensional databases (MDDBs) are seen as the most promising and efficient information technologies for supporting decision making. Geographic information systems, which are geographic-database- (GDB) dependent, through graphic display functionalities and complex spatial data structures, facilitate the storage and manipulation of geographic data.

Multidimensional databases refer either to statistical databases (Chan & Shoshani, 1981; Rafanelli & Shoshani, 1990), which mostly represent applications in the socio-economic area, or OLAP (online analytical processing) databases (Agrawal, Gupta & Sarawagi, 1997; OLAP Council, 1997), which emphasize business applications. Similar to statistical databases, OLAP databases have a data model that represents one or more "summary measures" over a multidimensional space of "dimensions," where each dimension can be defined over a hierarchy of "levels" (Shoshani, 1997). In this area, mostly the aspects of handling the multidimensional data and summarizations over the dimensions have been largely investigated. However, unlike OLAP databases, statistical databases may have only the summarized data available for reasons of privacy. These databases are often referred to by the term "summary databases."

The common key elements between geographic and multidimensional data that allow effective support in data cooperating are basically *time* and *space*. In literature, space has been considered as a bridge element for cooperating GDB and MDDB, on which our attention will be focused.

A feature notably lacking in most GDBs is the capability of accessing and manipulating business data, which are stored in MDDBs. We tackle this task by a novel approach that shares a number of characteristics and goals with the approaches proposed in literature. They aimed at defining a set of operators applicable to either spatial or summary data without dealing with the "logical organization" of databases at all. Similar to these models, our approach is addressed for cooperative query answering but it provides a data model for the summary data manipulation in the context of GDB. In addition, the above-mentioned models are based on multidimensional data formed by solely one location dimension, whereas in our approach we also consider data defined by more than one location dimension and we analyze their effect on data modeling and query answering.

BACKGROUND

In the database community, the cooperation between GDB and MDDB is indicated by taking into account the notion of map generalization. Map generalization is intended to consider the impact of scale and resolution on spatial data querying (see Muller, Lagrange, & Weibel, 1995). In this context, some attempts have been made to look for a standard set of multidimensional (or statistical) operators based on aggregation and disaggregation.

Gargano, Nardelli, & Talamo (1991), for instance, have extended the relational algebra essentially by defining two algebraic operators that are able to manipulate either the spatial extension of geographic data or summary data. They are named *G-Compose* and *G-Decompose*. The first operator is denoted by $G-Compose_X(F_y;Y)$, where X and Y are two nonintersecting subsets of attributes of a relation R. In the case of spatial data, it "merges" all tuples of R which are already projected on Y in a single one whose Y value is generated by the application of the spatial fusion function. This function, which is represented by F_y, takes a subset of geometric attributes of a given type and returns a single geometric attribute of the same type. In the case of summary data, F_y aggregates the numeric value of Y attributes. The effect of G-Decompose is that all tuples of R projected on Y are "decomposed." In this proposal, the fundamental issues of hierarchies and data aggregation for either spatial or summary data have been omitted.

These issues are discussed later in an approach proposed by Rigaux and Scholl (1995). In this work, the authors make the bridge between the geographic and statistical disciplines by defining an aggregation technique over a hierarchy of space partitions. Their model is based on the concept of "partition" that is used for partitioning either geometric space or other sets (e.g., a set of people). They introduced a relation called *cover*, which is represented by the schema $O = \{A_1, \ldots, A_n, A_g\}$, such that $\pi_{A_g}(O)$ is a partition and there is a bi-univocal functional dependency between the attributes $A_1, \ldots, A_n$ and A_g. They defined the *geometric projection* operator on a subset of attributes $S = \{A_1, \ldots, A_q\}$ as follows:

$$apply_{\Sigma_{Geo}}\ (nest_S(\pi_{S,A_g}(O)),$$

where $\pi_{A_g}(O)$ is the N1NF grouping operation (see Abiteboul & Bidoit, 1986) on S, $nest_S(\pi_{S,A_g}O)$ gives the result with the schema $\{A_1, \ldots, A_q, B\}$ where $B = set(A_g)$, and Σ_{Geo} performs the spatial aggregation function UNION on attribute $B = set(A_g)$. They used the relation cover for representing summary data, in which each descriptive attribute A can be defined on a hierarchical domain. The same operator is redefined as below:

$$apply_{\Sigma_{Geo}}\ (nest_S(gen_{A:A'}(O))),$$

where before applying the nest operator, the abstraction level of hierarchy to which the attribute A belongs is changed. It is indicated by $gen_{A:A'}(O)$. Note, in this case Σ_{Geo} performs the numeric aggregation function SUM.

The model proposed by Rigaux and Scholl (1995) is addressed to generate maps in multiple representations of data using the hierarchy of space partitions and the hierarchy induced by a partial order relationship in the domain of an attribute. In this proposal only one location dimension hierarchy for summary data is considered.

While the above models give a formal definition for the cooperation between spatial and multidimensional environments, some other works consider the architectural aspects of an integration system. For instance, Kouba, Matousek, and Miksovsky (2000) tried to identify some requirements for the correct and consistent functionality of system interconnection. They proposed an integration module that has two different roles: One is the transformation of data from external data sources, and the other refers to the integration of GIS and data warehouse through their common components, that is, location. The GIS under consideration is based on an object-oriented model that identifies the basic GIS elements that are classes and objects. In the GIS system, the structure of the geographical class hierarchy is stored in a metadata object for accessing directly from the integration module. Furthermore, the implementation aspects of the integration of the Microsoft SQL Server 7 Data Warehouse and ArcView GIS System are discussed.

Sindoni G., De Francisci S., Paolucci M., and Tininini L. (2001) have considered the integration of several spatiotemporal data collections of the Italian National Statistics Institute. The integration system is defined mainly by a historical database containing the temporal variation of territorial administrative partitions, a statistical data warehouse providing statistical data from a number of different surveys, and a GIS providing the cartography of the Italian territory up to census tract level. The implemented cooperative system manages the maps of the temporal evolution of a certain number of administrative regions and links to these maps the content of the above-mentioned statistical database of a given year.

A LOGICAL APPROACH

For describing the logical data model, we consider an object-oriented GDB and a cube-based MDDB, the main components of which are indicated in Table 1.

Cooperation by Binding Elements

In order to clarify the need for such cooperation, let us consider the case of a GDB user wishing to display a query result on a map with different combinations of geographic and nongeographic data. Let the query be as follows: "Find all the Italian regions which are adjacent to the Tuscany region, in which the number of cars sold in 1990, in the case of <Corolla>, was greater than 10,000."

For answering this query, it is necessary not only to retrieve the adjacent regions, but also to perform some OLAP operations on the time and product dimensions of the Car_Sales cube shown in Figure 1a. The former analyzes the topological spatial relationship (i.e., adjacency) and can be performed only in GDB. The solution of such queries depends essentially on a data model that enables the component databases to cooperate but remain independent. The main idea of our approach is to explore the additional input that can come to GDB from MDDB.

As we have shown in Table 1 and in Figure 1b, an object-oriented geographic database is characterized by

Table 1. A summary of data models and components of databases

Geographic Database		*Multidimensional Database*	
Geographic Class	$gc = < n, sc, P, M >$, where - n is the name of gc - sc is the class - parent of gc - $P = A_g \cup A_{\bar{g}}$ is set of attributes, where $A_g = \{point, polyline, region\}$ is geometric type $A_{\bar{g}}$ is set of alphanumeric type attributes - M is set of methods go represents an instance of gc	Cube Schema	$C = < C_{name}, L, f_c >$, where - C_{name} denotes the name of the cube - L is a set of levels - $f_c : L_T \to M$ is a function by which a measure (M) is associated with the tuples defined over the combinations of levels (denoted by L_T)
Geographic Object	$go = < id, gc, V, T >$, where - id is the identifier of a go; it is unique - gc the class to which it belongs; it is also unique - V represents the ordered set of the alphanumeric attribute values - T is the ordered set of pairs (latitude, longitude)	Dimension	$D = < L, \preceq >$, where - L is a set of levels - $\preceq$ is a partial order over L's elements such that for each pair of levels l_i and l_j, $l_i \preceq l_j$ if $dom(l_i) \preceq dom(l_j)$ - for any two levels l' and l'', which belong to different dimensions, $l' \cap l'' = 0$
Relationships	- $Full-contains$ represents spatial inclusion relationship among geographic classes and geographic objects, and it is a total and surjective function. It introduces hierarchy over geographic classes/objects. - ISA represents inheritance relationship among class and its subclasses.	Relationship	- *Complete containment* relationship is a total and surjective function between any two levels of a given dimension. This relationship introduces hierarchy over different levels/instance levels of a dimension.
Function λ	l_g and I_g represent, respectively, a geographic level of a cube and its instance - Intensional level : $\lambda : gc \to l_g$ - Extensional level: $\lambda : go \to I_g$	Function λ^{-1}	l_g and I_g represent, respectively, a geographic level of a cube and its instance - Intensional level : $\lambda^{-1} : l_g \to gc$ - Extensional level: $\lambda^{-1} : I_g \to go$
Operators	Topological operators derived from the topological relationships and they are *disjoint, touch, equal, inside, contains, covers, covered by, and overlap* (for a detailed description see Egenhofer & Herring, 1990).	Operators	- $roll-up^{f_{agg}(f_c)}_{l_1 \to l_2}(C)$ allows level changing $l_1 \to l_2$ and yields more aggregate data - $slice^{f_{agg}(f_c)}_{L_2, L_3}(C)$ omits L_1 from the set of levels L_1, L_2, L_3; it is composed by projection and grouped by operators - $dice_\theta(C)$ performs selection according to predicate θ

classes that are organized through hierarchies whose common semantics are space inclusion. The model of MDDB is mainly characterized by the structure of its dimensions, hierarchies over dimensions, and measures. The actual cooperation is provided by linking dynamically the common spatial components of both databases. This link is based on two kinds of correspondences (see Function λ, and Function λ^{-1} in Table 1).

- *Level correspondence* maps a given geographic class of a geographic taxonomy to the corresponding level belonging to the location dimension and vice versa.
- *Level instance correspondence* results from the previous step and maps a generic instance of a geographic class to its corresponding instance of location dimension level and vice versa. In this step, for a correct correspondence any instance changes should be propagated in both environments.

The link extends the geographic class schema through some special attributes, called *binding attributes*, which are added to the set of alphanumeric attributes (see Pourabbas, 2003). A binding attribute of a geographic class is a cube derived from a given cube in a multidimensional database whose geographic level is mapped to the corresponding class name. In Figure 1a, for instance, one of the binding attributes of the geographic class MUNICIPALITY is:

$$< Car\_Sales, \{ model, month\}, f_{Car\_Sales} >,$$

where

$$f_{Car\_Sales} : \{model : Model, month : Month\}_{\mathcal{T}} \rightarrow numeric .$$

The schema of this binding attribute is identical to the schema of the cube *Car_Sales* in MDDB. However, the set of its levels is defined by the levels of the cube except one, Municipality, which is mapped to the class name MUNICIPALITY by λ^{-1}.

Note that the λ, λ^{-1}, full-contains, and complete containment functions indicated in Table 1 play a central role either in linking the heterogeneous environments or in providing data that lack in one environment by knowing data and their relationships in another. For instance, let us suppose only the geographic variable Municipality be defined in MDDB, and let us consider two geographic classes MUNICIPALITY and PROVINCE in GDB (see Figure 1b) between which the full-contains relationship holds. The geographic level Province can be generated by λ, and the complete containment relationship that is equivalent to the full-contains relationship is defined from Municipality to Province.

Generally speaking, a cube can be defined with more geographic levels. The different geographic levels of a cube reflect the cases where each of them is a specialization of a given level of possibly the same location hierarchy. For instance, let us consider the Shoe-Sales cube defined by Province of Distribution, Region of Production, and Month shown in Figure 2.

The geographic levels of such a cube are two specializations of Province and Region in the location dimension hierarchy: Municipality→Province→Region. Consequently, their correspondences obtained by the function λ^{-1} would also have been specializations of the geographic classes PROVINCE and REGION, named PROVINCE OF DISTRIBUTION and REGION OF PRODUCTION. The process of binding attribute generation will yield the subcubes illustrated in Figure 2 in the schema of the above-mentioned geographic classes. The instances of these geographic classes will assume different semantics. A given instance of the first geographic class represents the province of the distribution of shoes which are made in several regions and months, while in the second case an instance represents a region of shoe production in which the items are distributed over several provinces and months.

Query Resolution

Let us recall the query mentioned in the previous subsection. The procedure for solving this query is defined by the following steps.

1) Identify the geographic class and object(s) involved by the geographic operators in the query, and give the results of these operations.
   In our query, they are Region and Tuscany, and the geographic operator is Touch. The result of this

Figure 1. Binding attributes and hierarchies

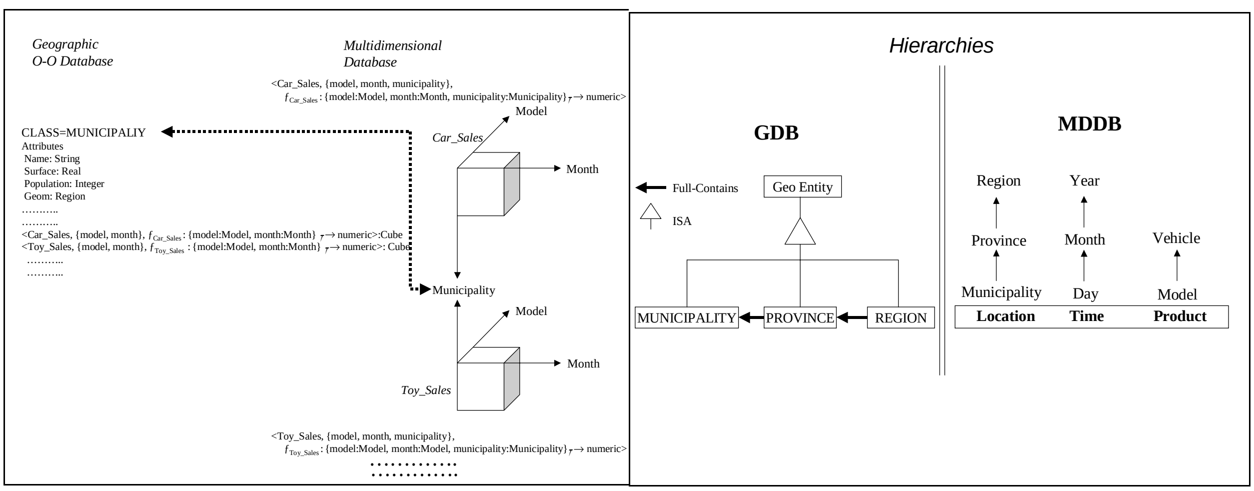

Figure 2. Binding attributes in the case of cube with more geographic levels

Cube

$< Shoe\_Sales, \{Province\ of\ distribution, Region\ of\ production, Month\}, f_{Shoe\_Sales} >$

Specializations of Geographic Classes

CLASS = PROVINCE OF DISTRIBUTION
Attributes
Name : String
....
$< \text{Shoe\_Sales}, \{\text{Region of production, month}\}, f_{Shoe\_Sales} >$: Cube

CLASS = REGION OF PRODUCTION
attributes
name : string
....
$< \text{Shoe\_Sales}, \{\text{Province of distribution, month}\}, f_{Shoe\_Sales} >$: Cube

operator is formed by the instances Liguria, Emilia-Romagna, Umbria, and Lazio.

2) Identify the target of the query that forms the binding attribute in the geographic class.
In our case, it is Car_Sales in regions.
3) Select the cube identified by the binding attribute in MDDB.
In our query, select the cube Car_Sales.
4) Perform aggregations over dimensions of the cube. In our case, it means to obtain Car-Sales by Region, Model, Year from Car-Sales by Municipality, Model, Month. It requires performing two roll-up operations over the latter cube along the Location dimension, which are Municipality → Province and Province → Region. These operations yield Car-Sales by Region, Model, Month. Then, it should be followed by another aggregation over the Time dimension (Month → Year) for obtaining Car-Sales by Region, Model, Year.
5) Select the values of the measure that satisfy the constraints.

In our query, the constraints are Year = 1990, Model = Corolla, and Car_Sales > 10,000. The final measure is obtained by a dice (or selection) operation.

6) Pass the list of the geographic level instances that satisfy the query to GDB.

In our query, it means to compare the list of regions provided by Step 6 with the list of Step 1 in order to identify and visualize the maps of the regions that satisfy the query constraints.

Inferring Binding Attributes

An important aspect related to the concept of binding attribute is *inferring*, with which we mean the maximum number of cubes inferred from a given binding attribute. The inferred cubes can be classified into two categories named covering and deduced.

The covering attributes are based on a process that is able to generate new binding attributes for the parent class based on those of its subclasses, which are related to each other by the full-contains relationship. One important issue related to full-contains, which is based on the well-known "part-whole" relationship, is "value propagation" (Halper, Geller & Perl, 1993; Liu & Halper, 1999). It reflects the interlevel flow of values in the classes of objects organized by hierarchies and allows the "driving" of attributes. Therefore, in order to assimilate the power of value propagation in the context of the full-contains relationship, we introduce the *is-derived* relationship between any two geographic classes or objects. For instance, let us consider the geographic classes PROVINCE and MUNICIPALITY in Figure 1b, which are related by the full-contains relationship. As a consequence of the is-derived relationship, the binding attribute of the PROVINCE (e.g., Milan) can be inferred from the binding attribute $< Car\_Sales, \{model, month\}, f_{Car\_Sales} >$ of the MUNICIPALITY, as follows:

$$slice_{model,month}(dice_{province=Milan}($$

$$(roll-up^{sum(Car\_Sales)}_{Municipality \rightarrow \text{Province}}(Car\_Sales)))$$

The deduced attributes may result from the aggregation over the levels of a given binding attribute in a geographic class through roll-up and slice (or projection) operators. In the case of Car-Sales by Model, Month of the class MUNICIPALITY shown in Figure 1a, they are Car-Sales by Model, Car-Sales by Month, Car-Sales by Vehicle, Month, Car-Sales by Model, Year, Car-Sales by Vehicle, Year, Car-Sales by Vehicle, Car-Sales by Year, and Car-Sales that is the grand total.

Overall, the number of base, covering, and deduced binding attributes of a cube is given by the following formula:

$$A_{Tot} = \left(\prod_{k=1}^{N} (f_k + 1) \right) \left(\sum_{h=1}^{G} \frac{l_h}{l_h + 1} \right),$$

where N represents the total number of levels (geographic and nongeographic), G represents the number of geographic levels, l_h represents the number of base and covering binding attributes generated by a geographic level, and f_k is the number of deduced binding attributes.

The covering and deduced attributes indicate essentially the set of possible answers to a class of queries that can be formulated on the base binding attributes. This fact highlights the usability of binding attributes.

FUTURE TRENDS

We have shown that our approach provides the interoperability of geographic and multidimensional databases through their binding elements, and guarantees the autonomy of data sources. In other words, unlike the models proposed in literature, our approach avoids a different application of a unique set of operators to heterogeneous data sources. This fact enables us to interact with each component database in order to benefit from its own functionalities, and at the same time keep them cooperative through a set of functions.

The discussion up to this point has focused upon the space feature for realizing the interoperability. However, the role of the time feature in such cooperation forms an interesting issue to be considered in future work.

An important assumption made in this work concerns the summarizability of a data cube, which means no cell contains a “not available” value and there is no missing value. In many cases the partial availability of data is realistic and, consequently, the comprehensive aggregation of summary data is compromised. The answering of joint aggregate queries formulated on cubes with missing and/or nonavailable data values can create another open problem.

We discussed the problem of answering spatiosummary queries in the context of GDB. Research that considers this question in the special light of MDDB could raise another interesting issue to be examined.

CONCLUSION

We have presented a logical data model, based on the extension of the geographical data model, which provides the capability of answering queries by the cooperation with MDDB. The cooperation of spatiosummary data is obtained by introducing new attributes into the geographic data structure, called binding attributes. The main idea behind them is to retrieve and manipulate data stored in MDDB and invoked from queries formulated in GDB.

KEY TERMS

Cube: It is a group of data cells arranged by the dimensions of the data. Assigning a value to each dimension of a cube, the measure is obtained by a mapping from this assignment.

Data Warehouse: A system for storing, retrieving, and managing large amounts of data using some sophisticated techniques of cleaning, filtering, hashing, and compression.

Map Generalization: This process is used to convert spatial data from one scale-dependent representation into another by calculating the geometry of a more abstract object through the union of the geometries of lower level objects.

Hierarchy: The structures created by an abstraction process by which a selection of a set of attributes, objects, or actions from a much larger set of attributes, objects, or actions according to certain criteria is defined.

OLAP: Online analytical processing is a category of software technology that allows users to transform raw data according to predefined or user-defined functions, and quickly and interactively performs slice, dice, and roll-up operations in various dimensions.

Spatial Partition: The subdivision of the 2D plane into pairs of disjoint regions where each region is associated with an attribute that can have a simple or complex geometric structure.

Topological Eelationships: The intersections of boundary and interior of two regions embedded in R^2.

MINING CREDIT RISK ANALYSIS DATA

The widespread use of databases and the fast increase in the volume of data they store are creating problems and new opportunities for credit companies. These companies are realizing the necessity of making efficient use of the information stored in their databases, extracting useful knowledge to support their decision-making processes.

Nowadays, knowledge is the most valuable asset a company or nation may have. Several companies are investing large sums of money in the development of new computational tools able to extract meaningful knowledge from large volumes of data collected over many years. Among such companies, companies working with credit risk analysis have invested heavily in sophisticated computational tools to perform efficient data mining in their databases.

Credit risk analysis is concerned with the evaluation of the profit and guaranty of a credit application. A typical credit risk analysis database is composed of several thousands of credit applications. These credit applications can be related to either companies or people. Examples of personal credit applications include for student loans, personal loans, credit card concessions, and home mortgages. Examples of company credits are loans, stocks, and bonds (Ross, Westerfield, & Jaffe, 1993).

Usually, the higher the value of the credit asked, the more rigorous is the credit risk analysis. Some large companies have whole departments dedicated to credit risk analysis.

The traditional approach employed by bank managers largely depends on their previous experience and does not follow the procedures defined by their institutions. Besides, several deficiencies in the data set available for credit risk assessment, together with the high volume of data currently available, make the manual analysis almost impossible. The treatment of these large databases overcomes the human capability of understanding and efficiently dealing with them, creating the need for a new generation of computational tools and techniques to perform automatic and intelligent analysis of large databases.

Credit analysis is essentially a classification task that involves the evaluation of the reliability and profitability of a credit application. The application of data mining techniques for credit risk analysis may provide important information that can improve the understanding of the current credit market and support the work of credit analysts (Carvalho, Braga, Rezende, Ludermir, & Martineli, 2002; Eberlein, Breckling, & Kokic, 2000; He, Hawkins, Graco, & Yao, 2000; Horst, Padilha, Rocha, Rezende, & Carvalho, 1998).

The extraction of useful knowledge from large databases is called knowledge discovery in databases (KDD). KDD is a demanding task and requires the use of sophisticated computing techniques (Brachman & Anand, 1996; Fayyad, Piatetsky-Shapiro, Amith, & Smyth, 1996). The recent advances in hardware and software make possible the development of new computing tools to support such tasks. According to Fayyad, Piatetsky-Shapiro, Amith, and Smyth (1996), KDD comprises a sequence of stages:

1. Selection
2. Preprocessing
3. Transformation
4. Data mining
5. Interpretation/evaluation

It is then important to stress the difference between KDD and data mining (DM). While KDD denotes the whole process of knowledge discovery, DM is a component of this process. The DM stage is used as the extraction of patterns or models from observed data. KDD can be understood as a process that contains, at least, the steps of application domain understanding, data selection and preprocessing, DM, knowledge evaluation and consolidation, and use of the knowledge. At the core of the knowledge discovery process, the DM step usually takes only a small part (estimated at 15–25%) of the overall effort (Brachman & Anand, 1996).

The KDD process begins with the understanding of the application domain, considering aspects such as the objectives of the application and the data sources. Next, a representative sample, selected according to statistical techniques, is removed from the database, preprocessed, and submitted to the methods and tools of the DM stage, with the objective of finding patterns/models (knowledge) in the data. This knowledge is then evaluated regarding its quality and usefulness, so that it can be used to support a decision-making process.

Credit analysis databases usually cover a huge number of transactions performed over several years. The analysis of these data may lead to a better understanding of the customer's profile, thus supporting the offer of new products or services. These data usually hold valuable information, e.g., trends and patterns, that can be employed to improve credit assessment. The large amount makes its manual analysis an impossible task. In many cases, several related features need to be simultaneously considered in order to accurately model credit user behavior. This need for automatic extraction of useful knowledge from a large amount of data is widely recognized.

DM techniques are employed to discover strategic information hidden in large databases. Before they are explored, these databases are cleaned. Next, a representative set of samples is selected. Machine-learning techniques are then applied to these selected samples. The use of data mining techniques on a credit risk analysis database allows the extraction of several relevant information regarding credit card transactions.

The data present in a database must be adequately prepared before data mining techniques can be applied to it. The main steps employed for data preparation are as follows:

1. Preprocess the data to the format specified by the algorithm to be used
2. Reduce the number of samples/instances
3. Reduce the number of features/attributes
4. Features construction, which is the combination of one or more attributes in order to transform irrelevant attributes to more significant attributes
5. Elimination of noise and treatment of missing values

Once the data have been prepared, machine-learning (ML) techniques can be employed to discover useful knowledge. The quality of a knowledge extraction technique can be evaluated by different measures, such as accuracy, comprehensibility, and new, useful knowledge.

CRITICAL ISSUES OF CREDIT RISK ANALYSIS DATA MINING

There are, of course, a few problems that can arise from the use of data mining techniques for credit risk analysis. The main advantages and problems associated with this technology are briefly presented in Table 1. Current Internet technology may allow the invasion of company databases, which may lead to the access of confidential data. Besides, the stored data may be made available to other companies or used without the knowledge or authoriza-

Table 1. A summary of critical issues of credit risk analysis data mining

Training of employees Credit analysts should be trained with the new tools available and shown the benefits of the new technology
User ignorance and perceptions Lack of adequate understanding of the data mining and its usefulness
Inadequate information Applicants may have supplied incorrect information,intentionally or not
Maintain integrity of data Maintain up-to-date and accurate information on the databases
Security Maintain secure and safe systems and denying unauthorized users access
Privacy and confidentiality agreements Address individual's right to privacy and the sharing of confidential information

tion of the customer. On the other hand, the extraction of useful information from credit risk analysis databases should result in benefits not only to the companies, but also to the customers, with the offering of better and more convenient credit products.

CONCLUSION

Several companies perform data mining on personal data stored in their databases. This is particularly true for credit risk analysis databases, where customers' personal data can be employed to improve the quality of credit assessment and support the offer of new credit products. Data mining systems usually employ artificial intelligence and statistical techniques to acquire relevant, interesting, and new knowledge for most applications, including credit risk analysis. Although one cannot avoid the use of these sophisticated techniques to support credit assessment, great care should be taken to guarantee privacy and that personal rights are not violated when working with private information.

KEY TERMS

Consumer Credit: A loan to an individual to purchase goods and services for personal, family, or household use.

Credit: Delivery of a value in exchange of a promise that this value will be paid back in the future.

Credit Scoring: A numerical method of determining an applicant's loan suitability based on various credit factors, such as types of established credit, credit ratings, residential and occupational stability, and ability to pay back loan.

Data: The set of samples, facts, or cases in a data repository. As an example of a sample, consider the field values of a particular credit application in a bank database.

Data Mining: The process of extracting meaningful information from very large databases. It is one of the main steps of the KDD process.

KDD: This is the process of knowledge discovery in large databases.

Knowledge: Knowledge is defined according to the domain, considering usefulness, originality, and understanding.

Machine Learning: Subarea of artificial intelligence that includes techniques able to learn new concepts from a set of samples.

Critical Realism as an Underlying Philosophy for IS Research

Philip J. Dobson
Edith Cowan University, Australia

INTRODUCTION

Many recent articles from within the information systems (IS) arena present an old-fashioned view of realism. For example, Iivari, Hirschheim, and Klein (1998) saw classical realism as seeing "data as describing objective facts, information systems as consisting of technological structures ('hardware'), human beings as subject to causal laws (determinism), and organizations as relatively stable structures" (p. 172). Wilson (1999) saw the realist perspective as relying on "the availability of a set of formal constraints which have the characteristics of abstractness, generality, invariance across contexts."

Fitzgerald and Howcroft (1998) presented a realist ontology as one of the foundational elements of positivism in discussing the polarity between hard and soft approaches in IS. Realism is placed alongside positivist, objectivist, etic epistemologies and quantitative, confirmatory, deductive, laboratory-focussed and nomothetic methodologies. Such a traditional view of realism is perhaps justified within the IS arena, as it reflects the historical focus of its use, however, there now needs to be a greater recognition of the newer forms of realism—forms of realism that specifically address all of the positivist leanings emphasised by Fitzgerald and Howcroft (1998). A particular example of this newer form of realism is critical realism. This modern realist approach is primarily founded on the writings of the social sciences philosopher Bhaskar (1978, 1979, 1986, 1989, 1991). The usefulness of such an approach has recently been recognized in the IS arena by Dobson (2001) and Mingers (2002).

BACKGROUND

Bhaskar's brand of realism (referred to by Searle, 1995, as a form of external realism) argues that there exists a reality totally independent of our representations of it; the reality and the "representation of reality" operating in different domains—roughly a transitive epistemological dimension and an intransitive ontological dimension. For the realist, the most important driver for decisions on methodological approach will always be the intransitive dimension—the target being to unearth the real mechanisms and structures underlying perceived events. Critical realism acknowledges that observation is value laden, as Bhaskar pointed out in a recent interview:

...there is no conflict between seeing our scientific views as being about objectively given real worlds, and understanding our beliefs about them as subject to all kinds of historical and other determinations. (Norris, 1999)

The critical realist agrees that our knowledge of reality is a result of social conditioning and thus cannot be understood independently of the social actors involved in the knowledge derivation process. However, it takes issue with the belief that the reality is a product of this knowledge derivation process. The critical realist asserts that "real objects are subject to value laden observation"; the *reality* and the value-laden *observation of reality* operate in two different dimensions, one intransitive and relatively enduring and the other transitive and changing.

An important aspect of a critical realist approach is that it not only provides direction on the characteristics and behaviour of the underlying objects of enquiry, but it also provides direction as to how to examine these objects. The philosophy is presented as an underlabourer to social enquiry in that it can help with "clearing the ground a little...removing some of the rubbish that lies in the way of knowledge" (Locke, 1894, p. 14). This integral and important role for philosophy in the enquiry process can help to avoid many potentially false pathways and avenues.

For example, Bhaskar (1979) presented fundamental difficulties with the way that prediction and falsification have been used in the open systems evident within the social arena. For the critical realist, a major issue with social investigation is the inability to create closure—the aim of "experiment" in the natural sciences. Bhaskar (1979) argued that this inability implies that theory cannot be used in a predictive manner and can only play an explanatory role in social investigations, because:

...in the absence of spontaneously occurring, and given the impossibility of artificially creating, closed systems , the human sciences must confront the problem of the direct scientific study of phenomena that only manifest

themselves in open systems—for which orthodox philosophy of science, with its tacit presupposition of closure, is literally useless. In particular it follows from this condition that criteria for the rational appraisal and development of theories in the social sciences, which are denied (in principle) decisive test situations, cannot be predictive and so must be exclusively explanatory. (p. 27)

As Mingers (2002) suggested, such an argument has specific ramifications with respect to the use of statistical reasoning to predict future results. Bhaskar (1979) argued that the primary measure of the "goodness" of a theory is in its explanatory power. From Bhaskar's perspective, predictive use of theories is not possible in open social systems, and therefore, predictive power cannot be a measure of goodness. From this point of view, theory acts as primarily an explanatory tool for explaining events in hindsight.

Critical realism uses abductive or retroductive reasoning as its main focus. Positivist approaches are associated more with deductive or inductive reasoning. Deductive reasoning is the fundamental reasoning of mathematics, whereby some statement "*p*" leads to implications "*q*"—a movement from the general to the particular. For example, the general claim that "all crows are black" moves to the particular inference that the next one seen will be black. For the crows example, retroductive or abductive reasoning follows from an observation of numerous black crows to a theory as to a mechanism to explain why crows are disposed to be black. As Mingers (2002) described:

We take some unexplained phenomenon and propose hypothetical mechanisms that, if they existed, would generate or cause that which is to be explained. So, we move from experiences in the empirical domain to possible structures in the real domain. This does not of itself prove that the mechanism exists, and we may have competing explanations, so the next step is to work toward eliminating some explanations and supporting others. (p. 300)

Outhwaite (1987) similarly suggested that the critical realist method involves "the postulation of a possible [structure or] mechanism, the attempt to collect evidence for or against its existence and the elimination of possible alternatives" (p. 58). The realist agrees that we have a good explanation when (a) the postulated mechanism is capable of explaining the phenomenon, (b) we have good reason to believe in its existence, and (c) we cannot think of any equally good alternatives. Such an explanatory target suggests that philosophical considerations must play an important role in the critical realist method, because such an approach often requires transcending, or speculating, perhaps nonobservable mechanisms and structures to explain perceived happenings. Such initial proposition is transcendental or metaphysical in its focus, and as such, any explanation or discovery made is seen to be fallible and extendable as knowledge grows. As Wad (2001) argued:

If we take explanation to be the core purpose of science, critical realism seems to emphasise thinking instead of experiencing, and especially the process of abstraction from the domains of the actual and the empirical world to the transfactual mechanisms of the real world. (p. 2).

This type of thinking is called transcendental by Bhaskar, in that it gives an important role to the crossing of the divide between the empirical and speculative activities of scientific work. As Wad pointed out, this is necessary because often the experienced world of events is not explainable in terms of the empirical facts but only by way of incorporating nonexperienced mechanisms incorporated in objects that may be within or outside our domain of investigation.

RESEARCH IMPLICATIONS

Sayer (2000) contended: "Compared to positivism and interpretivism, critical realism endorses or is compatible with a relatively wide range of research methods, but it implies that the particular choices should depend on the nature of the object of study and what one wants to learn about it" (p. 19). As Mingers (2002) suggested, critical realism supports methodological pluralism in that it suggests that an external reality is open to multiple interpretations and understandings.

Yet, critical realism also has important things to say about the objects of enquiry in that it is an ontologically bold philosophy (Outhwaite, 1987, p. 34). It not only encompasses an external realism in its distinction between the world and our experience of it, but it also suggests a stratified ontology and a so-called depth realism in defining the objects that make up such a world. This concept suggests that reality is made up of three ontologically distinct realms: first, the empirical, that is experience; second, the actual, that is events (i.e., the actual objects of experience); and third, the transcendental, nonactual or deep, that is structures, mechanisms, and associated powers. This so-called depth realism proposes that "the world is composed not only of events and our experience or impression of them, but also of (irreducible) structures and mechanisms, powers and tendencies, etc. that, although not directly observable, nevertheless underlie actual events that we experience and govern or produce them" (Lawson, 1997, p. 8). Critical realism, in its use of retroduction, involves a movement from a surface phenomenon to a deeper causal thing; it involves the steady unearthing of deeper levels of structures and mechanisms.

The ontological complexity assumed by critical realism is, however, matched with a conservative epistemology heavily dependent on scientific argument. As Wad (2001) said, critical realism has little to say concerning practical advice:

One may get the feeling that critical realism develops a huge superstructure of ontological and epistemological insights, but when it comes to practical research we are left with the usual methodological suspects, delivered by inductivists, positivist and empirical-analytical scientists. (p. 12)

As Stones (1996) argued, realist methodologies need to be able to account for the underlying ontological richness they implicitly assume. They also need to reflect the belief that any knowledge gains are typically provisional, fallible, incomplete, and extendable. Realist methodologies and writings, thus, must reflect a continual commitment to caution, scepticism, and reflexivity.

FUTURE TRENDS

Critical realism is becoming influential in a range of disciplines, including geography (Pratt, 1995; Yeung, 1997), economics (Lawson, 1997; Fleetwood, 1999), organization theory (Tsang & Kwan, 1999), accounting (Manicas, 1993), human geography (Sayer, 1985), nursing (Ryan & Porter,1996; Wainwright, 1997), logistics and network theory (Aastrup, 2002), and library science (Spasser, 2002). The application of critical realism within the IS field has been limited to date. Mutch (1995, 1999, 2002) has applied critical realist thinking in the examination of organizational use of information. In so doing, he commented on how difficult it is to apply such a wide-ranging and sweeping philosophical position to day-to-day research issues. Mingers (2001, 2002) examined the implications of a critical realist approach, particularly in its support for pluralist research. Dobson (2001, 2002) argued for a closer integration of philosophical matters within IS research and proposed a critical realist approach. Information systems are social systems, and it makes sense to apply a modern social philosophy such as critical realism to their examination.

CONCLUSION

In researching the social context within which information technology (IT) and IS operate, a modern social philosophy such as critical realism has considerable potential. It can provide useful insight into the type of (retroductive) questions that may be asked and also the means by which an examination can progress. The integrated nature of the philosophy encourages a consistency in research in that it recognizes the tripartite connections between ontology, methodology, and practical theory. As Archer (1995) argued:

The social ontology endorsed does play a powerful regulatory role vis-à-vis the explanatory methodology for the basic reason that it conceptualises social reality in certain terms. Thus identifying what there is to be explained and also ruling out explanations in terms of entities or properties which are deemed non-existent. Conversely, regulation is mutual, for what is held to exist cannot remain immune from what is really, actually or factually found to be the case. Such consistency is a general requirement and it usually requires two-way adjustment. (p. 17)

The required consistency between ontological and epistemological matters has led to the critical realist observation that many of the things that traditionally have been done in researching the social arena are actually inconsistent with the underlying nature of the social objects proposed (see, for example, Lawson, 1997, who presented some of the inconsistencies evident in traditional use of economic theory in the social arena). There are, however, few practical examples of the use of critical realism in the IS field and the obvious potential it has is not yet realized. While, as Wilson (1999) observed, the realist argument has shown a remarkable resilience and resourcefulness in the face of the "rise of relativism," and more practical examples of its application need to be developed. Carlsson (2003) examines IS evaluation from a critical realist perspective.

KEY TERMS

Author's Note: In philosophy, definitions become a basis for debate—they often reflect the area from which the author derives. Perhaps the following reflect realist origins.

Closed and Open Systems: A *closed system* is one restricted in such a way that laws have uniform effects. An *open system* is one that is not closed. Closed systems do not usually occur spontaneously in nature and generally require human intervention, such as in laboratory experiments (from www.raggedclaws.com/criticalrealism).

Critical Realism: The careful or critical application of the scientific approach to the social sciences.

Epistemology: The study of knowledge or how we come to know.

Ontology: The study of what exists.

Philosophy: "The critical examination of the grounds for fundamental beliefs and an analysis of the basic concepts employed in the expression of such beliefs" (*Encyclopaedia Britannica*, p. 388, *Micropedia*, Vol. 9, 1985) or the "rational, methodical, and systematic consideration of those topics that are of greatest concern to man" (*Macropedia*, Vol. 25, p. 742, 1985 edition).

Realism: The belief that there is a reality independent of our perceptions of it.

Transitive and Intransitive Dimensions: The *intransitive dimension* in the philosophy of science corresponds roughly to ontology, and the *transitive dimension* corresponds roughly to epistemology. Intransitive objects exist and act independently of our knowledge of them (except when we use our knowledge to intervene (see www.raggedclaws.com/criticalrealism).

Critical Realism in IS Research

Sven A. Carlsson
Lund University, Sweden

INTRODUCTION AND BACKGROUND

The Information Systems (IS) field is dominated by research approaches and theories based in positivism (Arnott, Pervan, O'Donnell, & Dodson, 2004; Chen & Hirschheim, 2004; Schultze & Leidner, 2003). IS scholars have pointed out weaknesses in these approaches and theories and in response different strands of post-modern theories and constructivism have gained popularity—see Lee, Liebenau, and DeGross, (1997), Trauth (2001), Whitman and Woszczynski (2004), and Michael Myers' "Qualitative Research in Information Systems" (http://www.qual.auckland.ac.nz). The approaches and theories argued for include interpretivism, ethnography, grounded theory, and theories like Giddens' (1984) structuration theory and Latour's (1987) actor-network theory. (For simplicity, we refer to these different approaches and theories as "post-approaches" and "post-theories" when distinction is not required).

Although these approaches and theories overcome some of the problems noted with "traditional" approaches and theories, they have at least three major weaknesses and limitations. First, their fascination with the voices of those studied leads to IS research as mere reportages and local narratives. Second, their focus on agency leads to them ignoring the structural (systemic) dimension—the agency/structure dimension is collapsed, leading to a flat treatment of the dimension. Third, their rejection of objectivist elements leads to problems when researching artifacts like IT-based IS. For elaborate critiques of post-approaches and post-theories, see Lòpez and Potter (2001) and Archer, Bhaskar, Collier, Lawson, and Norrie (1998).

An alternative to traditional positivistic models of social science as well as an alternative to post-approaches and post-theories is critical realism (Bhaskar, 1978, 1989, 1998; Harré & Secord, 1972). Critical realism (CR) argues that social reality is not simply composed of agents' meanings, but that there exist structural factors influencing agents' lived experiences. CR starts from an ontology that identifies structures and mechanisms through which events and discourses are generated as being fundamental to the constitution of our natural and social reality. This article briefly presents critical realism and exemplifies how it can be used in IS research.

CRITICAL REALISM

Critical realism has primarily been developed by Roy Bhaskar and can be seen as a specific form of realism. Unfortunately, Bhaskar is an opaque writer, but clear summaries of CR are available in Sayer (2000) and Archer et al. (1998). CR's manifesto is to recognize the reality of the natural order and the events and discourses of the social world. It holds that:

… we will only be able to understand—and so change—the social world if we identify the structures at work that generate those events or discourses… These structures are not spontaneously apparent in the observable pattern of events; they can only be identified through the practical and theoretical work of the social sciences. (Bhaskar, 1989, p. 2)

Bhaskar (1978) outlines what he calls three domains: the *real*, the *actual*, and the *empirical*. The real domain consists of underlying structures and mechanisms, and relations; events and behavior; and experiences. The generative mechanisms, residing in the real domain, exist independently of but capable of producing patterns of events. Relations generate behaviors in the social world. The domain of the actual consists of these events and behaviors. Hence, the actual domain is the domain in which observed events or observed patterns of events occur. The domain of the empirical consists of what we experience, hence, it is the domain of experienced events. Bhaskar (1978, p. 13) argues that:

…real structures exist independently of and are often out of phase with the actual patterns of events. Indeed it is only because of the latter we need to perform experiments and only because of the former that we can make sense of our performances of them. Similarly it can be shown to be a condition of the intelligibility of perception that events occur independently of experiences. And experiences are often (epistemically speaking) 'out of phase' with events—e.g., when they are misidentified. It is partly because of this possibility that the scientist needs a scientific education or training. Thus I [Bhaskar] will argue that what I call the domains of the real, the actual and the empirical are distinct.

CR also argues that the real world is ontologically stratified and differentiated. The real world consists of a plurality of structures and mechanisms that generate the events that occur.

USING CRITICAL REALISM IN IS RESEARCH

CR has primarily been occupied with philosophical issues and fairly abstract discussions. In recent years, attention has been paid to how to actually carry out research with CR as a philosophical underpinning—see Layder (1998), Robson (2002), and Kazi (2003). This section briefly presents how CR can be used in IS research by discussing how CR can be used in theory development and how CR can be used in IS evaluation research.

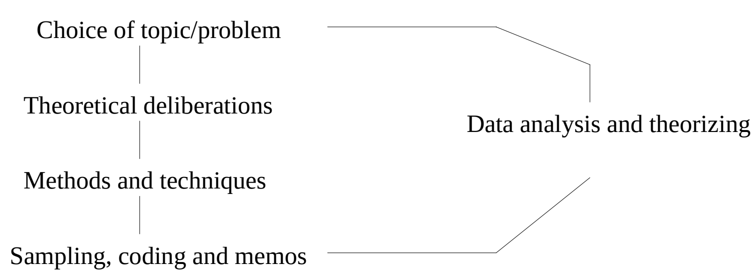
Bhaskar (1998) says that explanations (theories) are accomplished by the RRRE model of explanation comprising a four-phase process: (1) *Resolution* of a complex event into its components (causal analysis); (2) *Redescription* of component causes; (3) *Retrodiction* to possible (antecedent) causes of components via independently validated normic statements; and (4) *Elimination* of alternative possible causes of components. This is a rather abstract description of explanation development, and here we will instead use Layder's (1998) less abstract "adaptive theory." It is an approach for generating theory in conjunction with empirical research. It attempts to combine the use of pre-existing theory and theory generated from empirical data. Figure 1 depicts the different elements of the research process. There is not some necessary or fixed temporal sequence. Layder stresses that theorizing should be a continuous process accompanying the research at all stages. Concerning research methods and research design, CR is supportive of: (1) the use of both quantitative and qualitative methods, (2) the use of extensive and intensive research design, and (3) the use of fixed and flexible research design.

To exemplify how CR and Layder's adaptive theory can be used in IS research, we will use a project on the use of Executive Information Systems (EIS). The project was done together with Dorothy Leidner.1 Here a new discussion of the research is carried out. The overall purpose of the study was to increase our understanding of the development and use of EIS, i.e., develop EIS theory.

Layder's adaptive theory approach has eight overall parameters. One parameter says that adaptive theory "uses both inductive and deductive procedures for developing and elaborating theory" (Layder, 1998). The adaptive theory suggests the use of both forms of theory generation within the same frame of reference and particularly within the same research project. We generated a number of hypotheses (a deductive procedure), based on previous EIS studies and theories as well as Huber's (1990) propositions on the effects of advanced IT on organizational design, intelligence, and decision making. These were empirically tested. From a CR perspective, the purpose of this was to find patterns in the data that would be addressed in the intensive part of the study. [For a discussion of the use of statistics in CR studies, see Mingers (2003).] We also used an inductive procedure. Although, previous theories as well as the results from the extensive part of the project were fed into the intensive part, we primarily used an inductive approach to generate tentative explanations of EIS development and use from the data. The central mode of inference (explanation) in CR research is retroduction. It enables a researcher, using induction and deduction, to investigate the potential causal mechanisms and the conditions under which certain outcomes will or will not be realized. The inductive and deductive procedures led us to formulate explanations in terms of what mechanisms and contexts would lead (or not lead) to certain outcomes—outcomes being types of EIS use with their specific effects.

Another parameter says that adaptive theory "embraces both objectivism and subjectivism in terms of its ontological presuppositions" (Layder, 1998). The adaptive theory conceives the social world as including both subjective and objective aspects and mixtures of the two. In our study, one objective aspect was the IT used in the different EIS and one subjective aspect was perceived effects of EIS use.

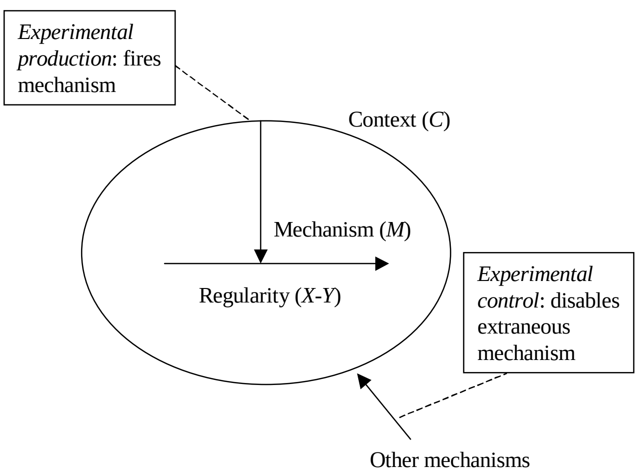
Figure 1. Elements of the research process (Layder, 1998)



Two other parameters say that adaptive theory "assumes that the social world is complex, multi-faceted (layered) and densely compacted" and "focuses on the multifarious interconnections between human agency, social activities, and social organization (structures and systems)" (Layder, 1998). In our study, we focused the "interconnections" between agency and structure. We addressed *self* (e.g., perceptions of EIS), *situated activity* (e.g., use of EIS in day-to-day work), *setting* (e.g., organizational structure and culture), and *context*, (e.g., national culture and economic situation). Based on our data, we can hypothesize that national culture can in certain contexts affect (generate) how EIS are developed and used and how they are perceived. We can also hypothesize that organizational "strategy" and "structure" as well as "economic situation" can in certain contexts affect (generate) how EIS are developed and used and how they are perceived.

Our study and the results (theory) were influenced by, e.g., Huber's propositions, the "theory" saying that EIS are systems for providing top managers with critical information, and Quinn's competing values approach (Quinn, Faerman, Thompson, & McGrath, 1996). The latter theory was brought in to theorize around the data from the intensive (inductive) part of the study. Adaptive theorizing was ever present in the research process. In line with CR, we tried to go beneath the empirical to explain *why* we found what we found through hypothesizing the mechanisms that shape the actual and the events. Our study led us to argue that it is a misconception to think of EIS as systems that just provide top managers with information. EIS are systems that support managerial cognition and behavior—providing information is only one of several means, and it can be one important means in organizational change. Based on our study, we "hypothesize" that "tentative" mechanisms are, for example, national culture, economic development, and organizational strategy and culture. We also hypothesized how the mechanisms together with different actors lead to the development and use of different types of EIS, for example, EIS for personal productivity enhancement respectively EIS for organizational change.

Figure 2. Realistic experiment (Pawson & Tilley, 1997)



IS evaluation (research) is of critical concern to practitioners and academics. Pawson and Tilley (1997) and Kazi (2003) advocate evaluation approaches that draw on the principle of CR and which, according to Bryman (2001, p. 40) see:

> *...the outcome of an intervention [like the implementation of an EIS] as the result of generative mechanisms and the contexts of those mechanisms. A focus of the former element entails examining the causal factors that inhibit or promote change when an intervention occurs.*

Driving realistic IS evaluation research is the goal to produce ever more detailed answers to the question of *why* an IS initiative—e.g., an EIS implementation—works, for *whom*, and in *what* circumstances. This means that evaluation researchers attend to how and why an IS initiative has the potential to cause (desired) changes. Realistic IS evaluation research is applied research, but theory is essential in every aspects of IS evaluation research. The goal is not to develop theory per se, but to develop theories for practitioners, stakeholders, and participants.

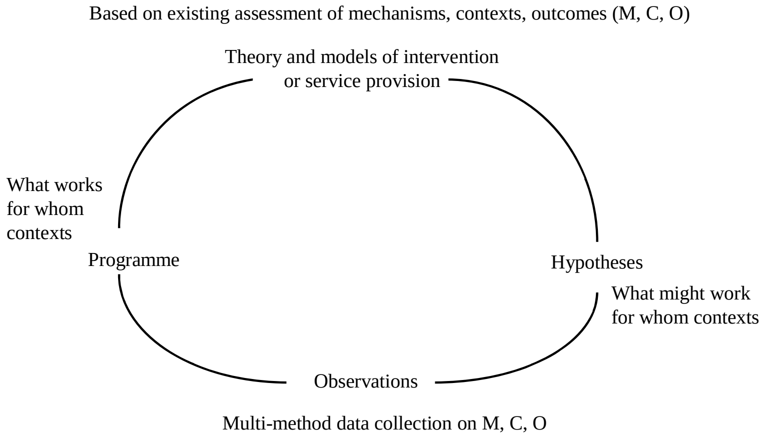
A realistic evaluation researcher works as an experimental scientist, but not according to the logics of the traditional experimental research. Said Bhaskar (1998, p. 53):

> *The experimental scientist must perform two essential functions in an experiment. First, he must trigger the mechanism under study to ensure that it is active; and secondly, he must prevent any interference with the operation of the mechanism. These activities could be designated as 'experimental production' and 'experimental control.'*

Figure 2 depicts the realistic experiment.

Realistic evaluation researchers do not conceive that IS initiatives "work." It is the action of stakeholders that makes them work, and the causal potential of an IS initiative takes the form of providing reasons and resources to enable different stakeholders and participants to "make" changes. This means that a realistic evaluation researcher seeks to understand *why* an IS initiative works through an understanding of the action mechanisms. It also means that a realistic evaluation researcher seeks to understand *for whom* and *in what circumstances (contexts)* an IS initiative works through

Figure 3. Realistic effectiveness cycle (Kazi, 2003; Pawson & Tilley, 1997)



the study of contextual conditioning. Realistic evaluation researchers orient their thinking to context-mechanism-outcome (CMO) configurations. A CMO configuration is a proposition stating what it is about an IS initiative (IS implementation) that works, for whom, and in what circumstances. A refined CMO configuration is the finding of IS evaluation research—the output of a realistic evaluation study.

Realistic IS evaluation based on the above may be implemented through a realistic effectiveness cycle (Kazi, 2003; Pawson & Tilley, 1997) (see Figure 3). The starting point is theory. Theory includes proposition on how the mechanisms introduced by an IS invention into pre-existing contexts can generate desired outcomes. This entails theoretical analysis of mechanisms, contexts, and expected outcomes. This can be done using a logic of analogy and metaphor. The second step consists of generating "hypotheses." Typically, the following questions would be addressed in the hypotheses: (1) what changes or outcomes will be brought about by an IS intervention?; (2) what contexts impinge on this?; and (3) what mechanisms (social, cultural and others) would enable these changes, and which one may disable the intervention? The third step is the selection of appropriate data collection methods—realists are committed to methodological pluralism. In this step it might be possible to provide evidence of the IS intervention's ability to change reality. Based on the result from the third step, we may return to the programme (the IS intervention) to make it more specific as an intervention of practice. Next, but not finally, we return to theory. The theory may be developed, the hypotheses refined, the data collection methods enhanced, etc. This leads to the development of transferable and cumulative lessons from IS evaluation research.

CONCLUSION AND FURTHER RESEARCH

This article argued that CR can be used in IS research. CR overcomes problems associated with positivism, constructivism, and postmodernism.

Although CR has influenced a number of social science fields [2] e.g., organization and management studies (Ackroyd & Fleetwood, 2000; Reed, 2003; Tsang & Kwan, 1999; Tsoukas, 1989) and social research approaches and methods (Byrne, 1998; Robson, 2002), it is almost invisible in the IS field. CR's potential for IS research has been argued by, for example, Carlsson (2003a, 2003b, 2004), Dobson (2001a, 2001b), Mingers (2003, 2004a, b), and Mutch (2002). They argue for the use of CR in IS research and discuss how CR can be used in IS research.

Bhaskar has further elaborated on CR, and in the future, his more recent works, e.g., Bhaskar (2002), could be explored in IS research.

KEY TERMS

Constructivism (or Social Constructivism): Asserts that (social) actors socially construct reality.

Context-Mechanism-Outcome Pattern: Realist evaluation researchers orient their thinking to context-mechanism-outcome (CMO) pattern configurations. A CMO configuration is a proposition stating what it is about an IS initiative that works, for whom, and in what circumstances. A refined CMO configuration is the finding of IS evaluation research.

Critical Realism: Asserts that the study of the social world should be concerned with the identification of the structures and mechanisms through which events and discourses are generated.

Empiricism: Asserts that only knowledge gained through experience and senses is acceptable in studies of reality.

Positivism: Asserts that reality is the sum of sense impression—in large, equating social sciences with natural sciences. Primarily uses deductive logic and quantitative research methods.

Postmodernism: A position critical of realism that rejects the view of social sciences as a search for overarching explanations of the social world. Has a preference for qualitative methods.

Realism: A position acknowledging a reality independent of actors' (including researchers') thoughts and beliefs.

Realist IS Evaluation: Evaluation (research) based on critical realism aiming at producing ever more detailed answers to the question of *why* an IS initiative works (better), for *whom,* and in *what* circumstances (contexts).

Retroduction: The central mode of inference (explanation) in critical realism research. Enables a researcher to investigate the potential causal mechanisms and the conditions under which certain outcomes will or will not be realized.

Critical Strategies for IS Projects

Dane Peterson

Chung S. Kim
Southwest Missouri State University, USA

INTRODUCTION

Despite enormous progress in the methodologies and technologies used in the development and implementation of information systems (IS), the failure to achieve IS success on a consistent basis continues to plague the efforts of many companies (Clegg et al., 1997). The success or failure of an IS has been defined in a variety of ways depending on a number of factors, such as the nature of the system and the perspective of the various stakeholders (i.e., IS developers, users, and management). In general, IS success is often subjectively assessed on the basis of how well the system achieves strategic, informational, and transactional benefits for the organization (Mirani & Lederer, 1998).

In order to increase the likelihood of IS success, a variety of approaches and recommendations have been offered. One of the earliest and most popular proposals for increasing IS success was based on the concept of critical success factors (CSF). This proposal assumes that IS failure can be significantly reduced by identifying a small set of factors that are essential for the achievement of IS success (Rockart, 1979). Use of the CSFs approach may make the IS planning process more efficient by providing managers with a decision aid for determining the key areas that are likely to need the most attention and how scarce resources should be allocated. Identification of CSF may also enhance communication about potential problems that may arise due to differences in the perspectives among various stakeholders. Another potential advantage of the CSF approach is that it facilitates the learning process. That is, the CSF approach increases stakeholders' understanding of the IS development process and the ultimate objectives of the system and how the overall development process can be evaluated (Pollalis & Frieze, 1993).

BACKGROUND

Some researchers have attempted to identify the critical factors based on an examination of which factors are statistically related to IS success. In this approach, user satisfaction is often used as measure of IS success. One of the first examples of a study based on this approach used a discriminant analysis procedure to examine which factors best distinguished between successful and unsuccessful projects (Ginzberg, 1981). The results indicated that organizational commitment, commitment to change, and extent of project definition and planning were the best predictors of user satisfaction.

Perhaps because some researchers are not convinced that user satisfaction provides a sufficient surrogate measure of the overall success and benefits of an IS (see Mirani & Lederer, 1998), many investigators have attempted to identify the CSFs based on the views of IS experts. In these studies, IS experts directly assessed the relative importance of potential success factors (e.g., Burn & Szeto, 2000; Jiang, Klein & Balloun, 1996). In general, the results of studies examining the views of IS experts have demonstrated some agreement with respect to the CSFs, although some differences have been observed among the various studies.

Much of the early research on the CSF approach assumed that once the key factors were identified, the same critical factors might apply to the development of all IS. However, as the nature and types of IS have become increasing diverse over the past two decades, much of the recent research has adapted the CSF approach to identifying the key elements that apply to various types of IS and to new areas of IS applications. For example, studies have attempted to identify the CSFs in areas involving executive information systems (Chen & Lee, 2003; Poon & Wagner, 2001), object-oriented analysis and design (Pei & Cutone, 1995), computer-assisted software engineering (Summer & Ryan, 1994), geographical information systems (Nasirin & Birks, 2003), data warehousing (Mukherjee & D'Souza, 2003), emerging information systems in the public sector (Bajjaly, 1999), implementation of integrated services digital networks (Lai & Clark, 1998), enterprise resource planning systems (Akkermans & van Helden, 2002; Al-Mashari, Al-Mudimigh & Zairi, 2003; Umble, Haft & Umble, 2003), information systems requirements gathering (Havelka & Sooun, 2002), the IT alignment planning process (Peak & Guynes, 2003), strategic planning in Eastern cultures (Ang & Teo, 1997), managing decentralized information technology (Birge, 1997), performance of information centers (Guimaraes, Gupta & Rather, 1999), outsourcing implementation (Kim & Young-Soo, 2003; Soliman, Chen & Frolick, 2003), extranet adoption in e-supply chain (Chow, 2004), and facilitating participation of many people in the IS planning process (Peffers, Gengler & Tunnanen, 2003).

Another perspective for remedying the problem of low IS success rates is to identify the causes of IS failure (Williams & Ramaprasad, 1996). According to this viewpoint, there may be inhibiting factors that play a key role in causing IS failure, and therefore it is important to identify both CSFs and critical failure factors (CFFs). Otherwise, a disproportionate amount of attention may be devoted to enhancing factors only to discover that there are inhibiting factors that prevent IS success.

Several studies have surveyed IS experts in attempts to identify the key factors contributing to unsuccessful or abandoned IS projects (e.g., Jiang, Klein & Balloun, 1998; Lyytinen, 1988). For example, Ewusi-Mensah (1997) examined abandoned IS projects and found that poorly defined project goals, lack of project team experience and expertise, inappropriate technology, lack of top management involvement, and escalating project costs were among the reasons for IS failure.

Many of the factors identified as CFFs are the same factors identified as CSFs. Thus, a CFF may simply be the absence of the CSF. However, there appears to be enough differences in the results of studies on CSFs and CFFs to warrant an investigation on the possibility of both enhancing and inhibiting factors (e.g., Lyytinen, 1987).

PURPOSE OF STUDY

Although numerous studies have investigated potential CSFs or CFFs, apparently there has not been any attempt to examine both types of factors in a single study. One objective of this study was to examine if there are any differences in the relative importance of the factors believed to contribute to the success and failure of IS projects.

Consistent with the notion that CSFs may vary depending on the nature and type of IS, a second goal of this study was to examine potential cultural differences in IS developers' views on CSF. A limitation of prior research attempting to identify the CSFs and CFFs is that almost all of the research has focused on the views of IS developers in Western cultures. With an increasing number of corporations developing and implementing IS applications that cross national boundaries and span diverse cultures, there is a need to determine if the factors viewed as most important by IS developers in the Western culture are the same factors viewed as most important by IS developers in other cultures. It may be particularly important to investigate the views of IS developers in Eastern Asia. Several countries in Eastern Asia play a significant role in the area of global information technology (McIntosh, 1999). In addition, the vast differences between Western and Eastern cultures have created a number of obstacles to the successful development of global IS when Asian offices are involved (Burnson, 1989). Thus, this study focused on an investigation of the views of IS developers from Korea.

The present study addressed the following two goals.

1. Which factors do IS developers in Korea view as most important for contributing to IS success and to IS failure?
2. How similar are the views of IS developers in Korea regarding CSFs and CFFs to the results reported in previous studies involving IS developers from Western cultures?

RESEARCH METHODOLOGY

Critical Factors: Based on prior studies examining CSFs and CFFs, this study identified 18 potential factors. These factors are controllable and applicable to IS developers in international environments. The 18 factors are listed in Table 1. The failure factors are expressed as the absence or insufficient condition of the success factors.

Respondents: A systematic random sampling procedure was used to distribute the surveys to IS developer in 10 Korean organizations. The number of IS developers surveyed in each organization ranged from 4 to 29, resulting in a total of 127 useable surveys. Most of the respondents had a least a college degree (83.5%). The average age of the respondents was 32.24 with a standard deviation of 4.42 years. The average number of years of experience in the field was 6.25.

RESULTS AND CONCLUSIONS

The sample means and rank order of importance for the CSFs and CFFs are presented in Table 1. As illustrated in Table 1, user participation, clearly stated objectives, and top management support were viewed as highly critical with regard to both IS success and IS failure. In general, the factors viewed as least important by IS developers from Korea were technical factors and/or tactic-related operational factors (e.g., methodology, prototyping, etc.). Apparently IS developers view organizational factors as more crucial for IS success, possibly because they have

Table 1. Means, ranks, and t-test statistics for CSF's and CFF's

Critical Factors	CSF Mean	CSF Rank	CFF Mean	CFF Rank	t-statistic
(Insufficient) User participation	6.07	1	5.89	1	-2.59**
(Lack of) Clearly stated objectives	6.06	2	5.38	4	1.10
(Lack of) Team member commitment	5.95	3	5.02	11	3.08**
(Lack of) Top management support	5.91	4	5.57	3	-0.08
(Lack of) Project Leader's monitoring/control	5.84	5	5.17	9	0.78
Project leader's (in)experience	5.80	6	5.63	2	1.58
(Ill)Alignment of project and corporate goals	5.71	7	5.05	10	1.12
Use of (in)appropriate technology	5.69	8	4.98	12	0.56
(Lack of) Detailed project plan	5.65	9	5.19	6	-1.44
(No attempt to) Reengineer business process	5.65	9	5.18	7	-0.88
(Im)Proper project scope	5.54	11	5.20	5	-3.17**
(In)Adequate training for team	5.47	12	5.18	7	0.55
(Lack of) Project leader's feedback	5.45	13	4.85	13	1.97*
(Lack of) Team members' self-control	5.41	14	4.67	14	-0.37
Utilizing an (in)effective methodology	5.41	14	4.59	16	0.27
Team member (in)experience	5.36	16	4.65	15	0.62
(Little use of)Utilizing a prototype	5.11	17	4.44	18	-0.07
(Insufficient) Peer review on project progress	5.11	17	4.56	17	-0.05

less control over these factors compared to technical/operational factors.

Generally, the importance ratings for the CSFs were very similar to those for the CFFs. This conclusion is confirmed by the high positive correlation between the means for the CSFs and CFFs ($r = .841$). Since the success factors were rated higher in importance for success than the failure factors were for contributing to the lack of success (e.g., user participation was 6.07 for success and 5.89 for contributing to failure), the responses from each IS developer were standardized in order to compare the relative importance of the 18 success and failure factors. The last column of Table 1 shows the results of related samples t-tests based on the standardized scores. Only 3 of the 18 factors were significant. The two factors viewed as more likely to contribute to IS failure, user participation and project scope, are factors that are generally outside the control of IS developers. The factor viewed as more likely to contribute to IS success, team member commitment, is generally within the domain of the IS developers.

Briefly, the perceptions of critical factors by IS developers from Korea are generally similar to those observed in studies involving IS developers in Western cultures (Ewusi-Mensah, 1997; Ginzberg, 1981; Jiang et al., 1996; Lyytinen, 1988; Pinto & Prescott, 1990). However, Korean IS developers viewed characteristics of the project leaders (monitoring and experience) as more important than what is generally observed in studies involving IS developers in Western cultures. This may be explained in terms of the high power distance culture of Korea. In a high power distance culture, managers are expected to make most of the decisions and take responsibility for project success. Thus, it might seem reasonable to expect that IS developers in Korea would consider project leaders as more important to IS success.

In summary, factors within the domain of the IS developers appear to be more likely to be viewed as CSFs, while factors outside the domain of IS developers are more likely to be viewed as CFFs. However for the most part, the results of this study demonstrate a strong relationship between perceptions of CSFs and CFFs. The views of developers from Korea were generally consistent with results based on surveys of developers from Western cultures, except that Korean IS developers view project leaders as more crucial.

FUTURE TRENDS

Since the introduction of the concept of CSFs, ISs have become increasing diverse. It seems likely that the most crucial factors could vary depending on a number of characteristics of the IS (operational vs. strategic IS (Burn & Szeto, 2000), cultural differences among the IS developers (Kim & Peterson, 2002), and IS lifecycle stage (Pinto & Prescott, 1990)). Thus the list of potential CSFs identified in past research may best serve as a list of potential risk areas that may be encountered in the development of a specific IS (Schmidt et al., 2001). Future research may examine the best methods that IS developers can use to assess the potential risks of each critical factor and procedures to overcome the risks in the development of a specific type of IS or IS application.

KEY TERMS

Business Process Reengineering: Redesign of business processes with the purpose of a dramatic improvement in business performances and productivity.

Critical Failure Factors: CFFs are the limited number of areas which, without careful monitoring of these areas, may lead to a failure of a system.

Critical Success Factors: CSFs are the limited number of areas in which results, if they are satisfactory, will ensure successful competitive performance for the organization.

Detailed Project Plan: A plan(s) that specifies detailed schedules, milestones, humanpower, and equipment requirements necessary for complementing a project.

Peer Review on Project Progress: A structured walk-through is a widely used technique to provide a test of a proposed system design and is often implemented as a peer feedback and review process.

Proper Project Scope: The scope of the project defines the boundary of the project or which aspects of the system will be included in the project.

Prototype: A simplified and smaller model system that still demonstrates the essence of the system.

Critical Success Factors for Distance Education Programs

Ben Martz
University of Colorado at Colorado Springs, USA

Venkat Reddy
University of Colorado at Colorado Springs, USA

INTRODUCTION

Distance education is playing an ever-growing role in the education industry. As such, it is prudent to explore and understand driving conditions that underlie this growth. Understanding these drivers and their corresponding concerns (Table 1) can help educators in the distance education field better prepare for the industry.

BACKGROUND

Distance education's primary driver is that it is the major growth segment in the education industry. In 1999, nearly 80% of the public, four-year institutions and over 60% of the public, two-year institutions offered distance education courses. Over 1.6 million students are enrolled in distance courses today. Over 90% of all colleges are expected to offer some online courses by 2004 (Institute of Higher Education Policy, 2000). Corporations envision online training warehouses saving large amounts of training dollars. Combined, the virtual education market and its sister market, corporate learning, are predicted to grow to over $21 billion by the end of 2003 (Svetcov, 2000).

A second major driver is employer expectations. Fundamental job market expectations are changing. Today, employees are not expected to stay in the same job for long periods of time; 20-plus year careers are not expected. The current modes of careers include multiple careers, combinations of part-time work in multiple jobs, telecommuting, leaving and re-entering into the full-time work force, switching jobs, and so forth, and today's employee easily accepts the need to maintain a level of knowledge current with the career demands (Boyatzis & Kram, 1999). To complement these changes in employer expectations, employees have begun to accept the need for life-long learning.

A third driver is the profit potential. Cost savings may be obtained and if significant enough may drive up demand and costs may be lowered. For example, elective classes that do not have enough students enrolled in them on-campus may pick up enough distance students to make teaching the course more feasible (Creahan & Hoge, 1998). A final driver is the institution's mission. Most educational institutions serve a geographical region, either by charter or mission, and a distance-learning program may be a practical method to help satisfy this strategic mission (Creahan & Hoge, 1998).

However, the "commercialization" of education raises its own concerns about the basic process of learning (Noble, 1999). For example, are there any problems fundamental to the distance environment because of limited social interaction?

Retention may be one such problem. Carr (2000) reports a 50% drop-out rate for online courses. Tinto (1975) compared the learning retention of distance groups with traditional groups and found that the social integration was a key factor in successful retention of traditional

Table 1. Influences on the distance education industry

Table 1. Influences on the distance education industry	
Drivers	Concerns
Growth segment in education industry	Retention
Job market expectations	Fading Back
Life-long learning as an education paradigm	Less social learning
Profit center for educational institutions	Trust & isolation
Possible strategic competence	Impact of technology

groups. Haythornthwaite et al. (2000) think they found another one. They looked at how social cues such as text without voice, voice without body language, class attendance without seating arrangements, and students signing in without attending Internet class impacted students "fading back." They found that the likelihood of students "fading back" is greater in distance-learning classes than in face-to-face classes. From the United Kingdom, Hogan and Kwiatkowski (1998) argue that the emotional aspects of this teaching method have been ignored. Similar concerns are raised from Australia, where technology has been supporting distance- teaching for many years, as Hearn and Scott (1998) suggest that before adopting technology for distance teaching, education must acknowledge the social context of learning. Finally, two other factors, trust and isolation, have been researched by Kirkman et al. (2002), whereby communication helped improve the measures of trust in students using the virtual environment.

By definition, the paradigm of distance education changes the traditional education environment by expanding it to cover geographically dispersed learning. In turn, this means that students will probably respond differently to this environment than they do to the traditional classroom. In addition, academic researchers have always been interested in explaining how people react to the introduction of technology. This body of work can be useful to the distance education environment.

Poole and DeSanctis (1990) suggested a model called adaptive structuration theory (AST). The fundamental premise of the model is that the technology under study is the limiting factor or the constraint for communication. It further proposes that the users of the technology, the senders and the receivers, figure out alternative ways to send information over the channel (technology). A good example here is how a sender of e-mail may use combinations of keyboard characters or emoticons (i.e., :) – sarcastic smile, ;) – wink, :o – exclamation of surprise) to communicate more about their emotion on a subject to the receiver.

Ultimately, the key to realizing the potential of distance education is trading off the benefits and the concerns to produce a quality product. In the new Malcolm Baldridge evaluation criteria, companies are asked to better show a program's effectiveness through customer satisfaction. In turn, Gustafsson et al. (2000) show customer satisfaction linked significantly to quality at Volvo Car Corporation. Finally, in their more broad analysis of well-run companies, Peters and Waterman (1982) deemed customer satisfaction as a key factor contributing to the companies' performance.

Table 2. Questions that correlate significantly to satisfaction

ID	Question Statement	Correlation	
		Coef.	Sign.
16	I was satisfied with the content of the course	.605	.000
17	The tests were fair assessments of my knowledge	.473	.000
18	I would take another distance course with this professor	.755	.000
19	I would take another distance course	.398	.000
20	The course workload was fair	.467	.000
21	The amount of interaction with the professor and other students was what I expected.	.710	.000
22	The course used groups to help with learning	.495	.000
23	I would like to have had more interaction with the professor.	-.508	.000
26	The course content was valuable to me personally	.439	.000
28	Grading was fair	.735	.000
30	Often I felt "lost" in the distance class	-.394	.000
31	The class instructions were explicit	.452	.000
33	Feedback from the instructor was timely	.592	.000
34	I received personalized feedback from the instructor	.499	.000
36	I would have learned more if I had taken this class on-campus (as opposed to online)	-.400	.000
37	This course made me think critically about the issues covered.	.423	.000
38	I think technology (email, web, discussion forums) was utilized effectively in this class	.559	.000
39	I felt that I could customize my learning more in the distance format	.254	.001
42	The course content was valuable to me professionally	.442	.000
43	I missed the interaction of a "live," traditional classroom	-.341	.002
46	Overall, the program is a good value (quality/cost)	.258(1)	.017
LOHITECH	Aggregate of Yes votes in Q6 through Q15	.270(1)	.012
(1) While significant, the low correlation coefficient below .300 should be noted			

With these perspectives in mind, we suggest that these areas interact to identify satisfaction as one important measure of quality for distance education programs. Therefore, one of the key factors to a program's success will be the satisfaction of one of its key stakeholders – its students. If one can identify what helps satisfies students in a distance education environment, one has a better chance to develop a successful program.

THE RESEARCH STUDY

The distance program used in this study is one of the largest, online, AACSB-accredited MBA programs in the world (US News and World Report, 2001). The methodology used a questionnaire with a battery of 49 questions to gather the data. The questions were developed using the concepts and ideas from literature discussed earlier as a guide.

Once the subject identified his or her reference course, that subject's grade was obtained from administrative records and recorded. In addition, four other demographic questions gathered information on gender, number of courses taken, student status, amount of time expected to spend in the reference course, and the amount of time actually spent in the reference course (Martz et al., 2004).

Two sets of questions were used. The first set asked about the student's use of different technologies (i.e., chat, e-mail, streaming video, etc.) in the class and if used, how effective (five-point Likert: 1 = LO …. 5 = HIGH) did they believe the technology to be in helping them with the class. We created a new variable, LOHITECH, for analysis purposes. Using LOHITECH, respondents can be placed in one of two groups: one group that reported using three or less technologies, while the second group reported using four or more technologies in their reference class. The second set of questions asked students to rate (five-point Likert: 1 = Strongly Agree …. 5 = Strongly Disagree) their experience with the reference distance course against statements concerning potential influences for satisfaction. These questions associated a five-point rating scale to statements about the issues identified earlier. The order of the questions was randomly determined and the questionnaire was reviewed for biased or misleading questions by non-authors.

The questionnaire was sent to 341 students enrolled in the distance MBA program. In Fall 2002, the program served 206 students from 39 states and 12 countries. The majority of these students are employed full-time. The program used in this study has been running since Fall 1996 and has over 179 graduates. It offers an AACSB accredited MBA and its curriculum parallels the on-campus curriculum. Close to 33% of the enrolled students are female. The oldest student enrolled is 60 years old and the youngest is 22. The average age of all students enrolled is 35. Over 25 PhD qualified instructors participate in developing and delivering the distance program annually. Recently, the news magazine *US News and World Report* (2001) classified the program as one of the top 26 distance education programs.

There were 131 useable questionnaires returned. The students' final grade for their reference course was obtained and added to the questionnaire record as a variable. These were separated into two groups: 30 that had not yet taken a course and 101 that had completed at least one course. This second group, those students who had completed at least one course, provided the focus for this study.

RESEARCH RESULTS

Question 24, "Overall, I was satisfied with the course," was used as the subject's level of general satisfaction. The data set was loaded into SPSS for analysis. Table 2 shows that 23 variables, including LOHITECH, proved significantly correlated to satisfaction (Q24).

The large number of significant variables leads to the need for a more detailed analysis on how to group them (StatSoft, 2002). Kerlinger (1986, p. 590) suggests the use of factor analysis in this case "to explore variable areas in order to identify the factors presumably underlying the variables". An SPSS factor analysis was performed with a Varimax Extraction on those questions that had proven

Table 3. Correlation of final constructs to satisfaction

Construct (Component: Loading)	Correlation	Significance
Professor Interaction (Q18: .576, Q21: .643, Q33: .794, Q34: .849)	.771	.000
Fairness (Q17: .722, Q20: .738, Q28: .626, Q31: .512)	.695	.000
Course Content (Q16: .596, Q26: .850, Q39: .689, Q42: .825)	.588	.000
Classroom Interaction (Q23: -.354, Q30: -.514, Q36: -.809, Q43: -.770)	-.515	.000
Technology Use & Value (LOHITECH: .508, Q19: .596, Q22: .542, Q37: .494, Q38: .478, Q46: .700)	.624	.000

significantly correlated to satisfaction. All reliability coefficients (Cronbach Alpha) are above .7000 and all Eigenvalues are above 1.00, indicating an acceptable level for a viable factor (Kline, 1993; Nunnally, 1978). Finally, the five components explain 66.932% of the variance.

In summary, 22 variables from the questionnaire proved significantly correlated to satisfaction. A factor analysis of those 22 variables extracted five possible constructs. These constructs were labeled: Interaction with the Professor; Fairness; Content of the Course; Classroom Interaction; and Value, Technology & Learning, based upon the key characteristics of the underlying questions. Table 3 shows the results of combining the ratings for the questions in each construct and correlating each of them to satisfaction. As can be seen from the table, the constructs hold up well as five indicators of satisfaction.

FUTURE TRENDS

As mentioned earlier, the organization, the school in this case, is a key stakeholder in the success of a distance education program. The future success of distance programs depends largely on satisfying these critical success factors. Distance education courses and programs are not only used for providing an alternative delivery method for students but also to generate revenues for the offering unit/college/university. As the number of distance courses and programs increase at an exponential rate, the necessity to enhance quality and revenues also takes prominence. We conclude with a set of operational recommendations that can impact online program success (Table 4).

The data in this study indicate that a timely and personalized feedback by professors results in a higher level of satisfaction by students. The administrators therefore have to work closely with their faculty and offer them ways to enrich the teacher-student relationships. Paradoxically, a faculty member needs to use technologies to add a personal touch to the virtual classroom. For example, faculty should be encouraged to increase the usage of discussion forums, respond to e-mail within 24 to 48 hours, and keep students up-to-date with the latest happenings related to the course.

The data also indicate that good course content and explicit instructions increase student satisfaction in the virtual classroom. It may well be that this basically sets and manages the expectations for the distance student. This result suggests that faculty should have complete Web sites with syllabi and detailed instructions. In turn, this suggests that distance education administrators should focus their attention on providing faculty with support such as good Web site design, instructional designer support, test design, user interaction techniques, and so forth, appropriate for distance learning.

Since distance students' notion of value intertwines learning and technology, it is imperative that distance administrators offer, and faculty use, the available technology in the distance program. Technology in this case not only refers to the actual software and hardware features of the platform but also how well technology is adapted to the best practices of teaching. The results imply that if technology is available but not used, it lowers satisfaction. So, technology options that are not being used in a course should not appear available. For the program administrator, this would suggest adoption of distance platforms that are customizable at the course level with respect to displaying technological options.

CONCLUSION

This study attempts to identify potential indicators for satisfaction with distance education. A body of possible

Table 4. Recommendations to increase online program success

1	Have instructors use a 24-48-hour turnaround for e-mail.
2	Have instructors use a 1-week turnaround for graded assignments.
3	Provide weekly “keeping in touch” communications.
4	Provide clear expectation of workload.
5	Provide explicit grading policies.
6	Explicitly separate technical and pedagogical issues.
7	Have policies in place that deal effectively with technical problems.
8	Provide detailed unambiguous instructions for coursework submission.
9	Provide faculty with instructional design support.
10	Do not force student interaction without good pedagogical rationale.
11	Do not force technological interaction without good pedagogical purpose.
12	Collect regular student and faculty feedback for continuous improvement.

indicators was derived from the literature surrounding the traditional versus virtual classroom debate. A 49-question questionnaire was developed from the indicators and was administered to MBA students in an established distance education program. One hundred and one questionnaires from students with one or more distance classes were analyzed with the result that 22 variables correlated significantly to satisfaction. A factor analysis of the questionnaire data extracted five basic constructs: Professor Interaction, Fairness, Course Content, Classroom Interaction and Technology Use & Value. Several recommendations for implementing and managing a distance program were extracted from these constructs and discussed.

KEY TERMS

Classroom Interaction: The interaction that can only be achieved face-to- face in a classroom. For example, the real-time feedback of facial expressions is not (yet) available in a distance course and so would be considered "classroom interaction".

Concerns of "Commercialization": The negative factors that the implantation and use of distance education may create.

Course Content: The main themes covered in a course.

Critical Success Factors: The few key areas in which activities must "go right" so that a project of program succeeds (Rockart, 1979).

Exploratory Factor Analysis: A process used to identify statistically significant constructs underlying a set of data.

Fairness: A subjective term defining the level to which a student feels he or she was treated fairly by the professor with respect to the class, including but not limited to test questions, grading, schedule flexibility, and so forth.

Market Drivers for Distance Education: The key elements that seem to be driving the diffusion and usage of distance education in the marketplace.

Professor Interaction: The amount of communication (e-mail, phone calls, video, chat rooms, etc.) that occurs between a student and the professor.

Satisfaction Constructs for Distance Education: Five constructs identified that seem to help identify satisfaction in distance education programs.

Technology Use: The usage of a technology whether it be e-mail, chat rooms, automated tests, software, and so forth.

Technology Value: The user's benefits (perceived and actual) over the costs (perceived and actual) created by the use of technology.

Critical Success Factors of ERP Implementation

Leopoldo E. Colmenares
University Simon Bolivar, Venezuela

Jim O. Otieno
Middlesex University, UK

INTRODUCTION

An enterprise resource planning (ERP) system is an integrated set of programs that provides support for core organizational activities, such as manufacturing and logistics, finance and accounting, sales and marketing, and human resources. An ERP system helps the different parts of an organization share data and knowledge, reduce costs, and improve management of business processes. In spite of their benefits, many ERP systems fail (Stratman & Roth, 1999). Implementing an ERP system is a major undertaking. About 90% of ERP implementations are late or over budget (Martin, 1998), and the success rate of ERP systems implementation is only about 33% (Zhang et al., 2003).

Over the past few years, limited research has been conducted about ERP implementation issues: mainly, case studies in individual organizations have been reported. A major problem with such ERP case studies is that very few implementation failures have been recorded in the literature, and thus, the reasons why implementations fail are not known to practitioners and researchers. That is a motivation toward conducting empirical studies to explore critical factors that affect ERP systems implementation. A recent summary of ERP literature stated that research of critical success factors (CSFs) in ERP implementation is rare and fragmented (Nah, Lau, & Kuang, 2001). The idea of identifying CSFs as a basis for determining the information needs of managers was popularized by Rockart (1979). CSFs are those factors that are critical to the success of any organization, in the sense that, if objectives associated with the factors are not achieved, the organization will fail—perhaps catastrophically (Rockart, 1979). In the context of ERP project implementation, CSFs represent the essential ingredients, without which a project stands little chance of success. This study examines the CSFs for implementing ERP systems in Venezuela. Managers from seven corporations, who were identified as having key roles in ERP systems implementation, were surveyed in order to assess empirically which CSFs are critical in leading a successful implementation of ERP systems in Venezuela. This article is organized into four sections. First, ERP-related literature is reviewed. The next section introduces the research methodology, followed by presentation of the results. The article ends with the conclusions and implications for future research and practice.

BACKGROUND

Implementing an ERP system is not an easy task. It can cause dramatic changes that need to be carefully administered if the potential advantages of an ERP solution (Al-Mudimigh, Zairi, & Al-Mashari, 2001) are to be gained. In some well-documented cases, spectacular results have been achieved (Johnston, 2002). There is, on the other hand, a relatively high failure rate: it was reported that three-quarters of ERP projects were judged to be unsuccessful by the ERP implementing firms (Kyung & Young, 2002). Also, failures are much less extensively documented. As a result, pitfalls to be avoided tend to be less well known. Venezuelan companies are just starting to use ERP systems. They started applying ERP concepts late in the 1990s. Because of the complex and integrated nature of ERP, and the large investment involved, it is imperative for organizations to study the experiences of others and to learn from their practices and success factors (Zairi et al., 2000). Identifying CSFs relevant to local companies is one way to increase the chances of a successful local implementation (Sum, Ang, & Yeo, 1997).

A literature review was conducted to understand the CSFs in successful ERP implementations. The review covered numerous articles (Bingi, Sharma, & Godla, 1999; Esteves & Pastor, 2001; Falkowski et al., 1998; Holland & Light, 1999; Nah, Lau, & Kuang, 2001; Rosario, 2000; Stefanou, 1999; Sumner, 1999; Wee, 2000). The literature varies according to the variables required for implementation success, so there is no general consensus as to the factors that are key to success in ERP implementation. It is probably a combination of factors that is important in explaining ERP implementation success (Zhang et al., 2003). From the review, 20 factors emerged as critical to the successful implementation of ERP systems. They were obtained after careful analysis and grouping of related subfactors:

1. Top management support
2. User training
3. Use of consultants
4. User participation
5. Vendor package selection
6. Use of steering committee
7. Discipline and standardization
8. Minimal customization
9. Use of vendor's development tools
10. Best people full time

17. Presence of a champion
18. Interdepartmental cooperation and communication
19. Management of expectations
20. Vendor/customer partnership

RESEARCH METHODOLOGY

The choice of an appropriate research methodology is critical in guiding researchers on how best to meet research objectives. In this study, the purpose was to discover the perceptions and experiences of companies using ERP systems in Venezuela, and to use that information as the basis of data collection. The analysis has enabled the identification CSFs of ERP systems implementation in Venezuelan companies.

The targets of the study were the organizations that implemented ERP systems successfully. The key informant method was used for collecting information in a social setting by surveying (or interviewing) a selected number of participants. Seven firms were identified from the list provided by ERP vendors. We contacted the ERP project managers in charge of ERP implementation of each company. About 100 questionnaires were sent to the ERP project managers of each firm, who forwarded the questionnaires to the project team members in charge of individual processes. A total of 72 questionnaires were returned, of which 69 were valid.

The questionnaire consisted of two main parts: the company background and the CSFs. The first part was designed to determine characteristics such as size of the company, type of industry, location of company, etc. The second part consisted of 20 statements about the success factors of ERP systems implementation derived from the literature review. The language used in the survey was Spanish. Translation was easy, because Venezuelans used original English terms for many technical and management concepts and especially for information systems and computing concepts.

Participants were requested to rate the importance of each CSF using a five-point Likert scale, where a score of 5 indicated "extremely critical," and a score of 1 indicated "not critical." This method was employed on the grounds that a rating method avoids the problem of having to consider 20 CSFs simultaneously in order to rank them. The data collected were then analyzed by using SPSS. Based on the responses, descriptive statistics, factor analysis (FA), and reliability tests were carried out to identify the CSFs for the successful implementation of ERP systems and data validity, respectively.

RESULTS

Ranking

The importance rating of the 20 CSFs is listed in Table I. The individual mean value of the Likert rating scale is the popular usage indicator for measuring an item's importance, without regard to the other items; therefore, the higher the value, the more important the factor. Most items are rated above the 3.0 scale (midpoint). The three most important factors, in order of declining importance, are top management support, presence of a champion, and project management, with a mean value ranging from 4.80–4.64. Just as the literature argues, these are key items for ERP implementation management (Johnston, 2002). Conversely, use of steering committee, business process reengineering, and use of vendor's development tools, are the three items lowest in the list, with a mean value ranging from 2.95–2.06.

Factor Analysis

In an attempt to reduce the number of items (CSFs), and to understand their underlying structure, a factor analysis (FA) was performed. FA is a data reduction technique that uses correlations between data variables. The underlying assumption of FA is that a number of factors exist to explain the correlations or interrelationships among observed variables (Chatfield & Collins, 1992). For the present study, FA was performed on all 20 variables using principal components extraction (Tabachnick & Fidell, 1989). The goal of this method is to extract maximum variance from the data set within each factor. It is basically used to reduce a large number of variables to a smaller number of components. The measure of sampling adequacy for the 20 items was 0.87, indicating that the items were suitable for factoring (Kaiser, 1974).

Table 1.Ranking of CSFs

Rank	CSF	Mean	Standard Deviation
1	Top management support	4.80	0.62
2	Presence of a champion	4.75	0.85
3	Project management	4.64	0.92
4	Best people full time	4.58	0.60
5	Effective communications	4.51	0.85
6	Interdepartmental cooperation and communication	4.40	0.91
7	Management of expectations	4.36	1.02
8	Technical and business knowledge	4.33	1.21
9	User participation	4.22	0.82
10	Discipline and standardization	4.09	0.85
11	Vendor package selection	4.02	0.61
12	User training	4.01	1.12
13	Implementation approach	4.00	1.20
14	Clear goals, focus, and scope	3.89	1.14
15	Use of consultants	3.75	0.85
16	Minimal customization	3.68	1.52
17	Vendor/customer partnership	3.15	0.52
18	Use of steering committee	2.95	0.63
19	Business process reengineering	2.84	0.55
20	Use of vendor's development tools	2.06	0.42

Notes: N: 69; Scale: 1–5 (5: "extremely critical," 1: "not critical")

A three-stage factor analysis was conducted with an orthogonal (varimax) rotation to obtain a stable factor structure (Rai et al., 1996), resulting in easily interpretable factors. Under this three-round factor analysis, items were omitted according to the following two criteria: (1) no loading greater than 0.35, or (2) loading greater than 0.35 on two or more factors (Kim & Mueller, 1978).

Table 2 shows the results of this analysis. A first-factor analysis was conducted and produced five factors. According to the two criteria, three items were dropped. A second factor analysis on the remaining 17 items resulted in four factors and the dropping of three items. Finally, a three-factor structure was derived that kept a total of 14 items after three iterations. The minimum eigenvalue from a varimax rotation for which a factor was to be retained was set at 1.0 in order to satisfy the minimum eigenvalue criterion (Nunnally, 1978). The three factors are as follows:

1. *Factor 1*, named "ERP implementation management," comprises six items relating to implementation management: top management support, presence of a champion, project management, management of expectations, implementation approach, and clear goals, focus, and scope.
2. *Factor 2*, named "user aptitudes and communication," comprises four items relating to user participation: effective communication, interdepartmental cooperation and communication, user participation, and user training.
3. *Factor 3*, named "technical knowledge," comprises four items relating to knowledge of business and ERP: best people full time, technical and business knowledge, use of consultants, and discipline and standardization.

Cronbach alpha coefficients were calculated to test the reliability of these CSFs, as shown in the last row of Table 2. The reliability of coefficients obtained ranges from 0.56 (Factor 3) to 0.88 (Factor 1). Srinivasan (1985) proposed that a coefficient of 0.7 or higher is acceptable, while a coefficient of 0.5 or higher is considered sufficient when dealing with exploratory research combined with unvalidated data. Thus, the reliability coefficients in this study are deemed acceptable. The strength of factor analysis is that it provides a basis for data reduction. Rather than look at all 20 items, only three factors need be examined. That simplifies the rankings and clarifies the most important items. Rather than focus on individual items, practitioners and researchers can focus on the broad set of items represented by the essential factors.

FUTURE TRENDS

Many companies around the world are following the trend toward making large investments in implementing ERP systems. Several approaches and methodologies of ERP project implementation recognise a series of critical factors that must be carefully considered to ensure successful implementation of an ERP system project. In essence, there are dominant critical factors hypothesised to play an overriding role in the implementation of an ERP project, and they should be ongoing throughout all implementation levels. Clearly, the dominant factors are those that will shape the overall project culture and, subsequently, the organisational cultura, as ERP is far reaching in nature.

Post-ERP activity seems to follow a clear path. A Deloitte Consulting study of 62 companies segments post-ERP activity into three stages. The first stage entails a three- to nine-month productivity decline that is overcome by redefining jobs, establishing new procedures, fine-tuning ERP software, and taking charge of the new streams of information created by the platform. The second stage, which lasts from six to 18 months, involves skills development, structural changes, process integration, and add-on technologies that expand ERP functionality. The third stage, of one to two years in duration, is one of transformation, where the synergies of people, processes, and technology reach a peak. Perhaps most important, ERP forces discipline and organization around processes, making the alignment of IT and business goals more likely in the post-ERP era.

CONCLUSION

Despite the benefits that can be achieved, there is already evidence of failure in projects related to ERP systems implementation (Davenport, 1998). It is, therefore, important to find out what the CSFs are that drive ERP project success.

Table 2. Results of factor analysis

		Factor Loading (Final Factor Structure 3rd FA)		
CSF	**Mean**	**F1**	**F2**	**F3**
Top management support	4.80	0.608		
Presence of a champion	4.75	0.541		
Project management	4.64	0.586		
Best people full time	4.58			0.741
Effective communications	4.51		0.565	
Management of expectations	4.40	0.420		
Interdepartmental cooperation and communication	4.36		0.452	
Technical and business knowledge	4.33			0.584
User participation	4.22		0.562	
Discipline and standardization	4.09			0.387
Vendor package selection	4.02			
User training	4.01		0.510	
Implementation approach	4.00	0.478		
Clear goals, focus, and scope	3.89	0.411		
Use of consultants	3.75			0.573
Minimal customization	3.68			
Vendor/customer partnership	3.15			
Use of steering committee	2.95			
Business process reengineering	2.84			
Use of vendor’s development tools	2.06			
Eigenvalue		7.56	2.54	1.20
Percentage of variance		58.50	14.36	8.65
Cumulative percentage of variance		58.50	72.86	81.51
Cronbach alpha coefficient		0.88	0.74	0.56

According to the respondents in this study, the six top CSFs for ERP systems implementation in Venezuelans firms are top management support, presence of a champion, project management, best people full time, effective communications, and management of expectations.

This research has derived three composite CSFs in ERP systems implementation in Venezuela:

1. ERP implementation management
2. User's aptitudes and communication
3. Technical knowledge

Four of the six top individual items contribute to the composite factor of ERP implementation management, which is, by far, the most important. It is made up of items that are concerned with the management of ERP systems implementation projects.

The results of ranking ERP CSFs in this study are largely consistent with the literature review, though the relative ranking of some factors varied. In the literature, top management support, change management, presence of a champion, and management of expectations are the four most often cited critical factors.

A majority of factors, 12, were rated as critical (rating >4). Only one factor, business process reengineering, which is rated as critical in most articles reviewed, was not rated as critical in this study (rating <3). Hence, the perceptions on CSFs of Venezuelan managers involved in ERP systems implementation projects are largely consistent with the findings reported in the literature.

There are a number of questions still to be determined. For example, although this article establishes the relative importance of CSFs in seven firms, it has not established the reasons. Future studies could look at differences by size of firms, by industry type, by number of locations, by number of customers, etc.

Finally, it should be noted that all CSFs are based on previous research; the success items can be modified when further research is conducted. For instance, discovery-oriented research through comprehensive interviews with several top-level managers in an attempt to identify new CSFs is an option.

KEY TERMS

Business Process Reengineering (BPR): Any radical change in the way in which an organisation performs its business activities; BPR involves a fundamental rethink of the business processes followed by a redesign of business activities to enhance all or most of its critical measures—costs, quality of service, staff dynamics, etc.

Critical Success Factors (CSFs): CSFs indicate the few key areas of activity in which favorable results are absolutely necessary for the manager to succeed.

Enterprise Resource Planning (ERP) System: Business software package for running every aspect of a company, including managing orders, inventory, accounting, and logistics. Well-known ERP software providers include BAAN, Oracle, PeopleSoft, and SAP, collectively known to industry insiders as the "BOPS."

Factor Analysis: Any of several methods for reducing correlational data to a smaller number of dimensions or factors; beginning with a correlation matrix, a small number of components or factors are extracted that are regarded as the basic variables that account for the interrelations observed in the data.

Project Management: This is the ensemble of activities concerned with successfully achieving a set of goals. This includes planning, scheduling, and maintaining progress of the activities that comprise the project.

Software Package: Written programs or procedures or rules and associated documentation that pertain to the operation of a computer system and that are stored in read/write memory.

Systems Implementation: Customisation or parameterization and adaptation of the software application according to the needs of the organisation.

Critical Trends in Telecommunications

John H. Nugent
University of Dallas, USA

INTRODUCTION

As in all industries, in order to win in a market, it is important to know as much as possible about that market and have at one's disposal tools that will provide insight and competitive advantage when properly, collectively, consistently, and timely applied. This article presents a series of powerful but easy-to-use and understand analytical and operational tools that deliver insight and competitive advantage to the wireless telecommunications professional. It should be stated, moreover, that as with all good tools, the tools and models as presented herein transition across industry lines and are not limited to the wireless telecommunications industry alone.

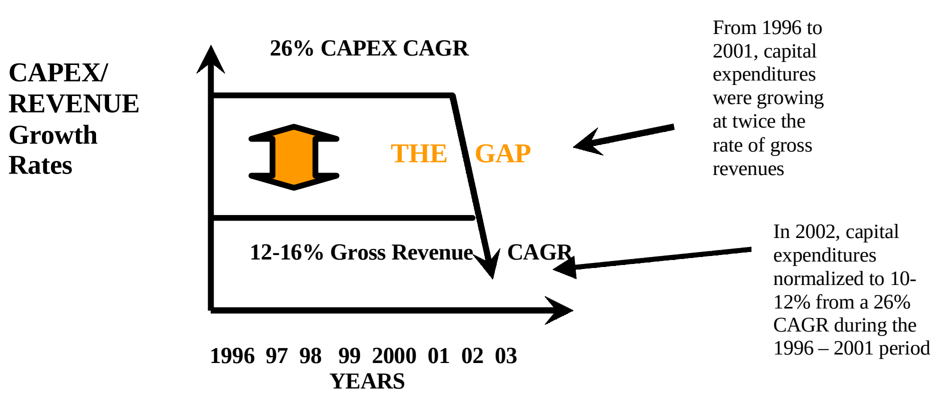
BACKGROUND: ANALYTICAL TOOLS AND MODELS

Because of the turmoil experienced in the telecommunications industry over the past several years, it is useful to view tools that can assist the telecommunications professional with understanding the market(s) and the trends at play. Looking at the telecommunications market from 1996 to 2003, it can be seen that the market exploded in the first half of this period with a 26% cumulative annual capital expenditure growth rate (CAPEX CAGR), and collapsed in the later part of this period (Lehman Brothers, 2000; Hilliard Consulting Group, Inc., 2003).

When capital expenditures so far outstrip gross revenue growth, one knows this situation cannot continue unabated. That is, a return to a more normal state must return. In order to discern approximately when a return to a more normal state will come about, one may examine the underlying market drivers (Nugent, 2001, 2003). Market drivers will often signal the size, breadth and depth of a market.

During the period noted (1996-2003), several large drivers were evident. The first was identified as the Y2K driver. Here, many firms determined it to be better, easier, and less costly and risky to replace versus remediate infrastructure equipment. But. here it was known this driver would be satiated by 2000. A second major driver was The Telecommunications Act of 1996 (www.fcc.gov). This act brought about the creation of many new telecom competitors that raised billions of dollars in the equity and debt markets that went on a spending spree. However, most of these firms had flawed business plans, and through competitive thrusts by the incumbents in the form of administrative delay, regulatory appeal, and litigation, these new entrants were literally bled dry via the consumption of cash in non-revenue producing activities such as regulatory appeals and litigation, and doomed to failure (Nugent, 2001, 2003). Understanding how significant incumbents fight and how they use the most strategic weapons of all – cash position and cash flow – the demise of these new incumbents could be foreseen. Another significant driver was the explosion in the number of

Figure 1. Revenue capital expenditure growth rate comparisons



Source: Hilliard Consulting Group, Inc., 2003 wireless customers brought about by the "Digital One Rate" plan initiated by AT&T. Here, wireless growth exploded from approximately 50 million subscribers to over 120 million in just several years. However, there are models that indicate this type of market satiates at approximately 50% of the overall population or 70% of the adult population (Nugent, 2003). In the U.S., this satiation point is approximately 145 million narrowband voice subscribers – approximately where we are today. So this spending spurt on narrowband voice wireless customer premise equipment (CPE), and infrastructure equipment could have also been estimated to end as the market approached satiation.

Hence, the telecommunications market downturn should not have been a surprise to anyone, as an understanding of the principal market drivers would have permitted an estimate of the market's size, breadth and depth.

FUTURE TRENDS

At a high level, it is also important to understand where a market is today, and where it is going to be tomorrow. To help understand these conditions, a State, Gap, and Trend (SG&T) Analysis tool provides helpful insight (Hilliard Consulting Group, Inc., 2003; Wolford-Ulrich, 2004):

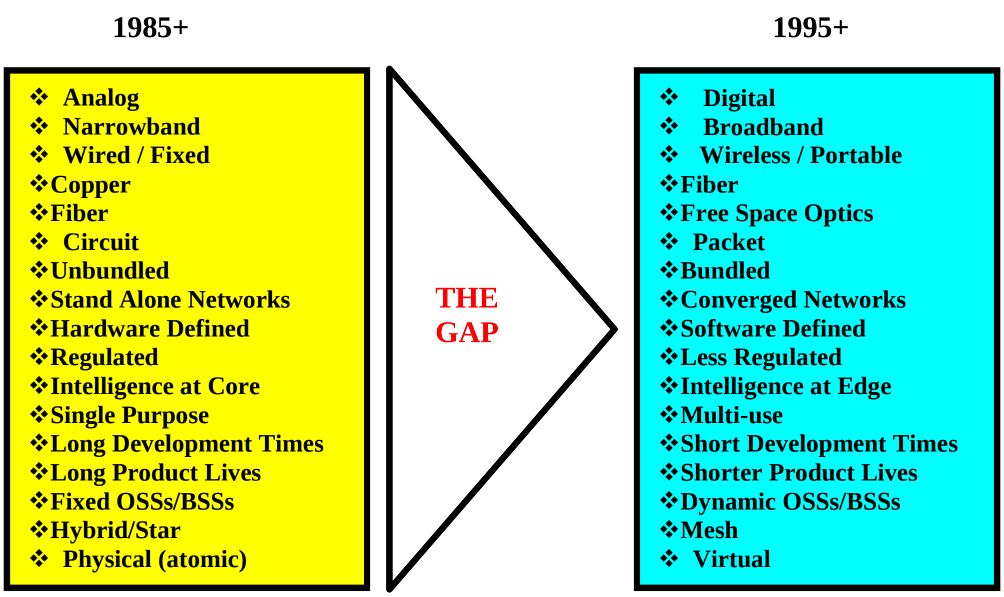
The development of a SG&T tool calls for a "one for one" transition (a "this to that" scenario over a period of time – there can be no ambiguities). Hence, a current and future state can be determined with some clarity.

An examination of this SG&T tool presented below indicates that the telecommunications world is moving from a fixed, tethered, narrowband, analog, circuit-based world, to one principally comprised of mobile, wireless, broadband, digital, packet-based communications. This transition portends significant issues for land-based carriers whose assets principally are in big physical plant (central offices, switching facilities, tethered trunks and circuits, etc.). This model further indicates that land-based carriers' assets are probably depreciating significantly faster than their balance sheets indicate. Supporting this premise is the decline in the number of residential landlines from approximately 168 million lines in 2001 to approximately 152 million landlines in 2003 (FCC/Solomon Smith Barney, 2002).

Moving from a macro model of market trends (SG&T) analysis previously, it can also be seen on a micro level (Product Curve) what attributes successive telecommunications products must follow to win in future markets (Hilliard Consulting Group, Inc., 2003). Here, a Product Curve model is most helpful.

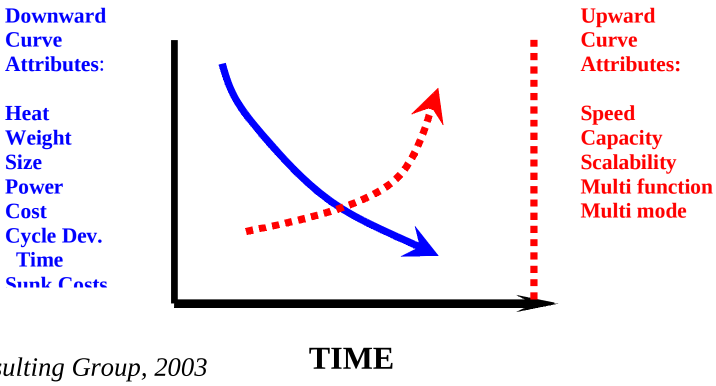
The product curve demonstrates that devices (network and CPE) need to become smaller, consume less power, weigh less, give off less heat, cost less, be developed in faster and faster cycle times, and have less in sunk development costs, while at the same time do more: operate at faster speeds and higher capacities while performing more functions to win in future markets. The product curve also portends troubles for land-line carriers as it can be seen in not too many years, the central office

Figure 2. State gap and trend analysis: Technology transition



Source: Hillard Consulting Group (2003)

Figure 3. Product curve



Source: Hilliard Consulting Group, 2003

of today will be displaced by a laptop wireless broadband tool of tomorrow. The SG&T Analysis and the Product Curve shown above only highlight some important attributes, there are numerous others that may, and should be added for a fuller comprehension of the industry.

To see the product curve in action, a comparison of the original Motorola "Brick" cell phone may be made with the sleek small wireless communication devices we use today. Here, we can see that the devices have become smaller, weigh less, consume less power, cost less, give off less heat, but do more.

Mix Shift Analyses are another way to discern important market changes (Hilliard Consulting Group, Inc., 2003). Here, many consulting firms forecast where we are today, and likely will be tomorrow.

MIX SHIFTS

These mix shift analyses indicate that the telecommunications industry will move from a tethered to a wireless world in the relatively near future, while at the same time the mix of telecommunications traffic will shift from principally voice to principally data. This mix shift does not mean that voice traffic will decline; rather it indicates that data traffic will grow dramatically compared to voice over the period indicated. Moreover, voice will largely become data as Voice over the Internet Protocol becomes more the norm. This trend is highlighted in the SG&A analysis above where we see a shift from circuit to packet communications.

Table 1. Transport shift

Transport \ Year	2003	2008	2015
Landline	80%	50%	10%
Wireless	20%	50%	90%

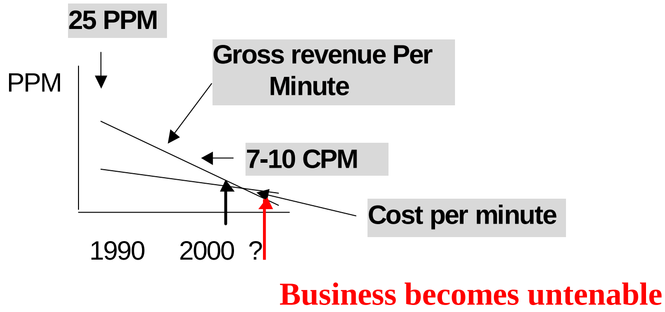
Figure 4. The minute margin squeeze model for the interexchange carrier (IXC) market



PPM = Price Per Minute, CPM = Cost Per Minute
Source: Hilliard Consulting Group, Inc. (2003)

Operational Tools and Models

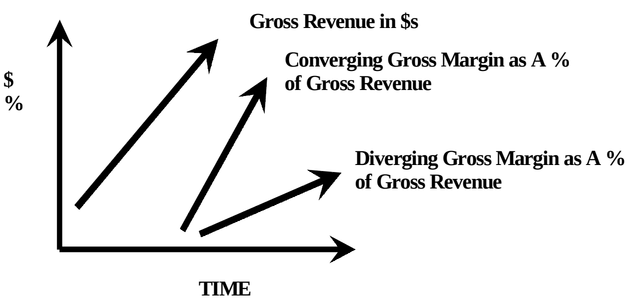
In undertaking a business analysis, there are several tools that work extremely well in examining the performance (present and future) of a telecommunications enterprise.

One set of such tools is referred to as slope analysis tools (Nugent, 2003). Here, a unit price/unit cost model may be used to take current operating parameters and project trends discerned here to future periods in order to foresee likely outcomes (and change strategies today if needed before others discern such trends).

The form of a unit price/unit cost model examined is the Minute Margin Squeeze Model.

This unit price/unit cost model indicates that unit prices are declining significantly faster than unit costs. By plotting actual data for a few years (1990-1993) and then extending these slopes to future periods, one is able to discern likely outcomes. In this case, it would appear the long distance market (IXC) would become quite unattractive after 2002. Viewing the trending in the narrowband voice market, we see a similar trend (58 cents/minute in 1993 to 10 cents or less a minute today).

Figure 5. Converging/diverging gross margin analysis



Source: Hilliard Consulting Group, Inc. (2003)

Another form of slope analysis is the Converging/ Diverging Gross Margin Analysis. Here, actual data from the income statement is plotted for several periods. Converging gross margins indicate increasing operational efficiency while diverging gross margins signify decreasing operational efficiency.

Examining AT&T's Initial Public Offering (IPO) for its wireless unit demonstrates the importance of this tool. The IPO for AT&T's wireless unit was well received and the stock price climbed immediately. However, a reading of the offering document would have shown that the gross margin decreased (DIVERGED) by over 50% in the preceding annual period. This indicated significant operational troubles. By discerning this diverging gross margin and drilling down to determine the reasons, one would have discerned that AT&T's successful "Digital One Rate Offering" caught the company short, far short, of network capacity to support demand. Hence, AT&T had to go off-net and pay other carriers high fees to originate or terminate its traffic. This understanding would have highlighted additional issues facing AT&T Wireless: either take on more debt or dilute current shareholders further by issuing more stock in order to build more infrastructure.

One final operational tool is the Discriminant Function Algorithm (DFA) used to discern changes in corporate health on a prospective basis – inflection points (Amdocs Corp, 2003; Slywotzky, Morrison, Moser, Mundt, & Quella, 1999). This model uses Altman's Z Score algorithm for determining bankruptcy on a prospective basis (Altman, 1983). However, unlike Altman where he uses absolute scores, the DFA model only cares about changes in score - either positive or negative (Nugent, 2003). As an example of what this tools yields on a prospective basis, AT&T is again viewed.

As can be seen, AT&T's Z Score declined from over 5 in 1997 to under 1 by 2001. This is a dramatic negative decline. Yet, during much of this period, Wall Street was in love with this stock. Had one begun plotting this Z score in 1997, one could have discerned by 1999 that things were heading south long before others foresaw this decline.

CONCLUSION

High level analytical and operational tools and models can assist the wireless telecommunications professional in understanding the telecommunications market's characteristics, life cycles, trends, directions, limits, drivers, and likely prospective performance. These tools demonstrate that wireless communications will follow the same life cycle characteristics as wireline communications. Proper utilization of such tools can lead to important and timely insights hopefully leading to competitive advantage based upon an early detection of changes in marketplace dynamics.

KEY TERMS

Capital Equipment Expenditures (CAPEX): Usually measured as a percent of gross revenue.

Converging/Diverging Gross Margin Analysis: A slope analysis tool used to plot actual sales and gross margin data for several periods in order to discern trends and likely outcomes. Measure operational efficiency or inefficiency.

Cumulative Annual Growth Rate (CAGR): The percent of growth from one annual period to the next.

Customer Premise Equipment (CPE): End-user equipment.

Discriminant Function Algorithm: A term developed for Edward Altman in describing his Z Score analytical tool in determining the likelihood of an enterprise going into bankruptcy on a prospective basis. Used as a method for determining inflection points – changes in corporate health versus for bankruptcy prediction.

Inflection Points: Significant changes in corporate performance.

Interexchange Carriers (IXC): Long distance companies that transport inter local access transport area (LATA) traffic.

Local Access Transport Area (LATA): A geographic area defined by the FCC.

Minute Margin Squeeze: Also known as unit price/unit cost model.

Mix Shifts: Shifts in the market between major components usually requiring different technology or solutions.

Product Curve: This tool takes a micro view of transitioning requirements or attributes successive solutions must adhere to in order to win in the future market place.

Slope Analysis: The plotting and visualization of certain operating functions in order to discern trends, often before others see them thereby permitting alteration of strategies in order to gain competitive advantage.

State Gap & Trend Analysis: A tool used to present in a structured format current market or technology states as well as future states. This analysis requires a "one for one" transition – a "this to that" view. This model calls for no ambiguities. The perilous part of this tool is determining how to transition the gap – where one has to be by when with what.

Unit Price/Unit Cost Model: A slope analysis tool used to plot actual unit prices and unit costs for several periods in order to discern future trends and likely outcomes.

Cross-Cultural Research in MIS

INTRODUCTION AND BACKGROUND

"Globalization of business highlights the need to understand the management of organizations that span different nations and cultures" (Srite et al., 2003, p. 31). In these multinational and transcultural organizations, there is a growing call for utilizing information technology (IT) to achieve efficiencies, coordination, and communication. However, cultural differences between countries may have an impact on the effectiveness and efficiency of IT deployment. Despite its importance, the effect of cultural factors has received limited attention from information systems' (IS) researchers. In a review of cross-cultural research specifically focused on the MIS area (Evaristo, Karahanna, & Srite, 2000), a very limited number of studies were found that could be classified as cross-cultural. Additionally, even though many of the studies found provided useful insights, raised interesting questions, and generally contributed toward the advancement of the state of the art in its field, with few exceptions, no study specifically addressed equivalency issues central to measurement in cross-cultural research. It is this methodological issue of equivalency that is the focus of this article.

METHODOLOGICAL ISSUES

Methodological considerations are of the utmost importance to cross-cultural studies, because valid comparisons require cross-culturally equivalent research instruments, data collection procedures, research sites, and respondents. Ensuring equivalency is an essential element of cross-cultural studies and is necessary to avoid confounds and contaminating effects of various extraneous elements.

Cross-cultural research has some unique methodological idiosyncrasies that are not pertinent to intracultural research. One characteristic that typifies cross-cultural studies is their comparative nature, i.e., they involve a comparison across two or more separate cultures on a focal phenomenon. Any observed differences across cultures give rise to many alternative explanations. Particularly when results are different than expected (e.g., no statistical significance, factor analysis items do not load as expected, or reliability assessment is low), researchers may question whether results are true differences due to culture or merely measurement artifacts (Mullen, 1995).

Methodological considerations in carrying out cross-cultural research attempt to rule out alternative explanations for these differences and enhance the interpretability of results (van de Vijver & Leung, 1997). Clearly, the choice and appropriateness of the methodology can make a difference in any research endeavor. In cross-cultural research, however, one could go to the extreme of classifying this as one of the most critical decisions. In this section, we briefly review such cross-cultural methodological considerations. Specifically, this section will address equivalence (Hui & Triandis, 1985; Poortinga, 1989; Mullen, 1995) and bias (Poortinga & van de Vijver, 1987; van de Vijver & Leung, 1997; van de Vijver & Poortinga, 1997) as key methodological concerns inherent in cross-cultural research. Then, sampling, wording, and translation are discussed as important means of overcoming some identified biases.

Equivalence

Achieving cross-cultural equivalence is an essential prerequisite in ensuring valid cross-cultural comparisons. Equivalence cannot be assumed a priori. Each cross-cultural study needs to establish cross-cultural equivalence. As such, equivalence has been extensively discussed in cross-cultural research, albeit using different terms to describe the phenomenon (Mullen, 1995; Poortinga, 1989).

To alleviate confusion created by the multiplicity of concepts and terms used to describe different but somewhat overlapping aspects of equivalence, Hui and Triandis (1985) integrated prior research into a summary framework that consists of four levels of equivalence: conceptual/ functional equivalence, equivalence in construct operationalization, item equivalence, and scalar equivalence. Even though each level of equivalence is a prerequisite for the subsequent levels, in practice, the distinction between adjacent levels of equivalence often becomes blurry. Nonetheless, the objective in cross-cultural research is to achieve all four types of equivalence. Hui and Triandis' (1985) four levels of equivalence are discussed as follows:

1. *Conceptual/functional equivalence* is the first requirement for cross-cultural comparisons and refers to whether a given construct has similar meaning across cultures. Furthermore, to be functionally equivalent, the construct should be embedded in the same nomological network of antecedents, consequents, and correlates across cultures. For instance, workers from different cultures may rate "supervisor is considerate" as a very important characteristic; however, the meaning of "considerate" may vary considerably across cultures (Hoecklin, 1994).
2. *Equivalence in construct operationalization* refers to whether a construct is manifested and operationalized the same way across cultures. Not only should the construct be operationalized using the same procedure across cultures, but the operationalization should also be equally meaningful.
3. *Item equivalence* refers to whether identical instruments are used to measure the constructs across cultures. This is necessary if the cultures are to be numerically compared.
4. *Scalar equivalence* (or full score comparability; see van de Vijver and Leung, 1997) occurs if the instrument has achieved all prior levels of equivalence, and the construct is measured on the same metric. This implies that "a numerical value on the scale refers to same degree, intensity, or magnitude of the construct regardless of the population of which the respondent is a member" (Hui & Triandis, 1985, p. 135).

Bias: Sources, Detection, and Prevention

To achieve equivalence, one has to first identify and understand factors that may introduce biases in cross-cultural comparisons. Van de Vijner and Poortinga (1997) described three different types of biases: construct bias, method bias, and item bias:

1. *Construct bias* occurs when a construct measured is not equivalent across cultures both at a conceptual level and at an operational level. This can result from different definitions of the construct across cultures, lack of overlap in the behaviors associated with a construct [e.g., behaviors associated with being a good son or daughter (filial piety) vary across cultures], poor sampling of relevant behaviors to be represented by items on instruments, and incomplete coverage of the construct (van de Vijver & Leung, 1997). Construct bias can lead to lack of conceptual/functional equivalence and lack of equivalence in construct operationalization.
2. *Method bias* refers to bias in the scores on an instrument that can arise from characteristics of an instrument or its administration (van de Vijver & Leung, 1997), which results in subjects across cultures not responding to measurement scales in the same manner (Mullen, 1995). Method bias gives rise to concerns about the internal validity of the study. One source of method bias is sample inequivalency in terms of demographics, educational experience, organizational position, etc. Other method bias concerns relate to differential social desirability of responses (Ross & Mirowsky, 1984) and inconsistent scoring across populations (termed "selection-instrumentation effects" by Cook and Campbell, 1979, p. 53). For instance, on Likert scales, Koreans tend to avoid extremes and prefer to respond using the midpoints on the scales (Lee & Green, 1991), while Hispanics tend to choose extremes (Hui & Triandis, 1985). Differential scoring methods may also arise if respondents from a particular culture or country are not familiar with the type of instrument being used.
3. *Item bias* refers to measurement artifacts. These can arise from poor item translation, complex wording of items, or items inappropriate for a cultural context. Consequently, item bias is best prevented through careful attention to these issues. Like method bias, item bias can influence conceptual/functional equivalence, equivalence of operationalization, and item equivalence.

Table 1 presents a summary of how the three types of bias can be prevented or detected. The next section discusses three important methods of bias prevention: sampling, wording, and translation. This article concludes by presenting a set of cross-cultural methodological guidelines derived by a committee of international scholars.

Table 1. Types of bias, prevention, and detection

	Detection	Prevention
Construct bias (focus: constructs)	• Informants describe construct and associated behaviors • Factor analysis • Multidimensional scaling • Simultaneous confirmatory factor analysis in several populations • Comparison of correlation matrices • Nomological network	• Informants describe construct and associated behaviors in each culture
Method bias (focus: administration procedures)	• Repeated administration of instrument • Method triangulation • Monomethod-multitrait matrix	• Sampling (matching, statistical controls) • Identical physical conditions of administering the instrument • Unambiguous communication between interviewer and interviewee • Ensured familiarity with the stimuli used in the study
Item bias (focus: operationalization)	• Analysis of variance • Item response theory • Delta plots • Standardized *p*-difference • Mantel–Haenszel procedure • Alternating least squares optimal scaling • Multiple group LISREL	• Wording • Translation

Sampling

Sampling decisions in cross-cultural studies involve two distinct levels: sampling of cultures and sampling of subjects (van de Vijver & Leung, 1997). Sampling of cultures involves decisions associated with selecting the cultures to be compared in the study. Many studies involve a convenience sample of cultures, typically ones where the researcher has preestablished contacts. Even though this strategy reduces the considerable costs of conducting cross-cultural research, it may hinder interpretability of results, particularly when no differences are observed across cultures (van de Vijver & Leung, 1997). Systematic sampling of cultures, on the other hand, identifies cultures based on theoretical considerations. Typically, this involves selecting cultures that are at different points along a theoretical continuum, such as a cultural dimension. Random sampling of cultures involves selection of a large number of cultures randomly and allows for wider generalizability of results.

Most cross-cultural studies discussing sampling considerations, however, refer to sampling of subjects. Ensuring sample equivalency is an important methodological consideration in cross-cultural research, and it refers to the inclusion of subjects that are similar on demographic, educational, and socioeconomic characteristics. Sample equivalency can be achieved by either matching subjects across groups based on these background variables or statistically controlling for the differences by including such demographic variables as covariates in the cross-cultural comparisons (van de Vijver & Leung, 1997).

Wording and Translation

This is one of the key problems in cross-cultural methods, because in most cases, different cultures also have different languages. Even in cases when subjects from different countries are conversant with English, they may miss the nuances of the intended meanings in questionnaire items (e.g., British, Canadian, and American English all have unique terms). Researchers should ensure that measurement instruments keep the same meanings after translation. Moreover, a given latent construct should be measured by the same questionnaire items in different populations. In fact, researchers such as Irvine and Carrol (1980) made a convincing case for using factor-matching procedures to test for invariance of factor structures across groups before any quantitative analysis is performed.

To translate correctly, there is a need to translate to the target language. This needs to be performed by a native speaker of the target language. Then, the text must be back-translated to the original language, this time by a different native speaker of the original language. Brislin (1986) provided fairly complete guidelines for this process.

IMPLICATIONS

Judging by the issues described above, achieving cross-cultural equivalence is straightforward. However, it is also clear that many precautions can be taken to prevent construct, method, and item bias and thus increase the level of equivalence. These range from sampling, wording, and translation, to careful attention to administration procedures across cultures. A number of guidelines for cross-cultural research have been put forth by an international committee of scholars (Hambleton, 1994; van de Vijver & Hambleton, 1996). Even though the primary focus of these is on research on psychological and educational issues, these guidelines easily generalize to MIS research.

In addition to prevention, various statistical tools can assist in the detection of the various types of biases. In summary, similar patterns of functional relationships among variables need to be shown (Triandis, 1976). Moreover, multimethod measurement can help us to avoid the confound between the interaction of the method and groups studied and is unlikely to share the same statistical underlying assumptions, or even require strong conceptualization ability (Hui & Triandis, 1985). This idea is similar to the notions of multiple operationism and conceptual replication (Campbell & Fiske 1959). Hui and Triandis (1985) claimed that this may not be as difficult as one may think, as long as there is prior planning of research. As an example, Hui and Triandis (1985) mentioned that an instrument may be improved by proper translation techniques, and:

…then establish conceptual/functional equivalence as well as instrument equivalence by the nomological network method and by examination of internal structure congruence. After that, the response pattern method and regressional methods can be used to test item equivalence and scalar equivalence. (p. 149)

The major implication of methodological problems is complications in making valid inferences from cross-cultural data. Clearly, there are many problems with correctly inferring from data in a cross-cultural research project and attributing results to true cross-cultural differences. To do so, alternative explanations need to be ruled out. Establishing (and not merely assuming) the four levels of cross-cultural equivalence previously discussed in this article is a major step in this direction.

FUTURE DIRECTIONS AND CONCLUSION

Initial attempts at reviews of cross-cultural research in MIS (Evaristo, Karahanna, & Srite, 2000) show that, for the most part, MIS studies have refrained from testing theories across cultures, and when comparisons are made, they are often post hoc comparisons utilizing data from prior published studies in other countries. Clearly, this provides some insights into differences across cultures but suffers from a number of methodological shortcomings. In fact, the conclusions of Evaristo, Karahanna, and Srite (2000) were as follows:

In summary, we suggest that there are mainly three points where the MIS cross-cultural research is lacking: lack of theory base (testing or building); inclusion of culture as antecedents of constructs, and general improvement in methodologies used.

All three points are related, although to different extents, to methodological issues. The conclusion is that one critical issue that cross-cultural research in MIS needs to address before reaching the same level of sophistication and quality already attained by mainstream MIS research is to attend to methodological concerns. The current article is a step ahead in this direction and sets the stage for future research.

KEY TERMS

Conceptual/Functional Equivalence: Refers to whether a given construct has similar meaning across cultures.

Construct Bias: Occurs when a construct measured is not equivalent across cultures both at a conceptual level and at an operational level.

Equivalence in Construct Operationalization: Refers to whether a construct is manifested and operationalized the same way across cultures.

Item Bias: Refers to measurement artifacts.

Item Equivalence: Refers to whether identical instruments are used to measure the constructs across cultures.

Method Bias: Refers to when subjects across cultures do not respond to measurement scales in the same manner. Bias in the scores on an instrument can arise due to characteristics of the instrument or its administration.

Multinational Corporation: A firm that has operations in multiple countries.

Scalar Equivalence: Refers to whether the construct is measured on the same metric across cultures. This occurs if the instrument has achieved all prior levels of equivalence, and the construct is measured on the same metric.

Transcultural Organization: A firm that operates across multiple cultures.

Cross–Culture Communication

Andrew Targowski
Western Michigan University, USA

Ali Metwalli
Western Michigan University, USA

INTRODUCTION

In this millennium, global organizations will increasingly focus on the critical value of the cross-cultural communication process, efficiency, competence and its cost of doing business. In order to successfully communicate cross-culturally, knowledge and understanding of cultural factors such as values, attitudes, beliefs and behaviors should be acquired. Because culture is a powerful force that strongly influences communication behavior, culture and communication are inseparably linked.

Worldwide, in 1983-2003, countries have experienced a phenomenal growth in international trade and foreign direct investment. Similarly, they have discovered the importance of cross-cultural communication. As a result, practitioners and scholars are paying attention to the fact that cultural dimensions influence management practices (Adler, 1983; Child, 1981; Hofstede, 1980; Laurent, 1983; Maruyama, 1984; Triandis, 1982-1983). In recent years, the empirical work in the cross-cultural arena has focused on the role of culture on employee behavior in communicating within business organizations (Tayeh, 1988). But current work on cross-cultural business communication has paid little attention to either (a) how to adapt these seminal works on general communication to the needs of intercultural business or (b) how to create new models more relevant to cross-cultural business exchanges (Limaye, 1991, p. 283). So far there is no adequate model that can explain the cross-cultural communication process and efficiency, let alone estimate the cost of doing business with other cultures worldwide.

The purpose of this article is to define the framework for a cross-cultural asymmetric communication process, efficiency and cost of doing business in the global economy. The research method is based on the architectural design of a cross-cultural communication process and system and their quantitative analysis. Their attributes are estimated in a normative way on a scale from 1 to 5, when 5 is the best value. The attributes for two selected cultures (Western-West and Egyptian) are estimated by expert opinions.

BACKGROUND

A Concept of Culture

A culture is a value-guided, continuous process of developing patterned human behavior within and across cultures and civilizations. Cultures do not satisfy needs; rather, they demand values. In turn, values in their broadest sense define the member of any culture's need for rationality, meaningfulness in emotional experience, richness of imagination and depth of faith (Laszlo, 1972). Human communication, therefore, is a vehicle for cultural dissemination on the one hand, while on the other hand is itself culture-driven.

Cultures are components of a civilization that guide their behavioral patterns. For example, Western civilization currently is composed of the following cultures:

- The Western-West, containing Western Europe and Northern America
- The Western Central, embracing Poland, the Czech Republic, Slovakia, Hungary, Estonia, Latvia, Lithuania, Croatia, and Slovene
- The Western-East, containing Greece and Israel
- The Western-Latin, composed of Latin America's states

There is some opinion that after the end of the Cold War in 1989/1991, that world politics is entering a new phase, and intellectuals have not hesitated to proliferate a vision of what it will be - the end of history (Fukuyama, 1989) or the clash of civilizations (Huntington, 1993). Huntington (1993) predicts that the fundamental source of conflict in this new world will not be primarily ideological or primarily economic. He perceives that the great divisions among humankind and their dominating source of conflict will be cultural.

THE CROSS-CULTURE COMMUNICATIONS PROCESS

We assume that doing business in the global economy depends mostly on the partners' ability to successfully communicate in a cross-cultural environment. People pursue and communicate many common aims, including the values of pure biological survival, social collaboration, creative expression, organizational adaptability or business undertakings. From such common values one can form a hierarchy of human cultural layers:

1. Biological culture layer
2. Personal culture layer
3. Group culture layer
4. Organization culture layer (ex. business enterprise)
5. Regional culture layer
6. National culture layer
7. Global culture layer (including supra-national, regional ones)

Those layers of cultures and the communication climate associated with them filter messages and intentions of business partners and determine the success of business undertakings. A model of the cross-cultural communication process is shown in Figure 1 (Targowski & Bowman, 1988).

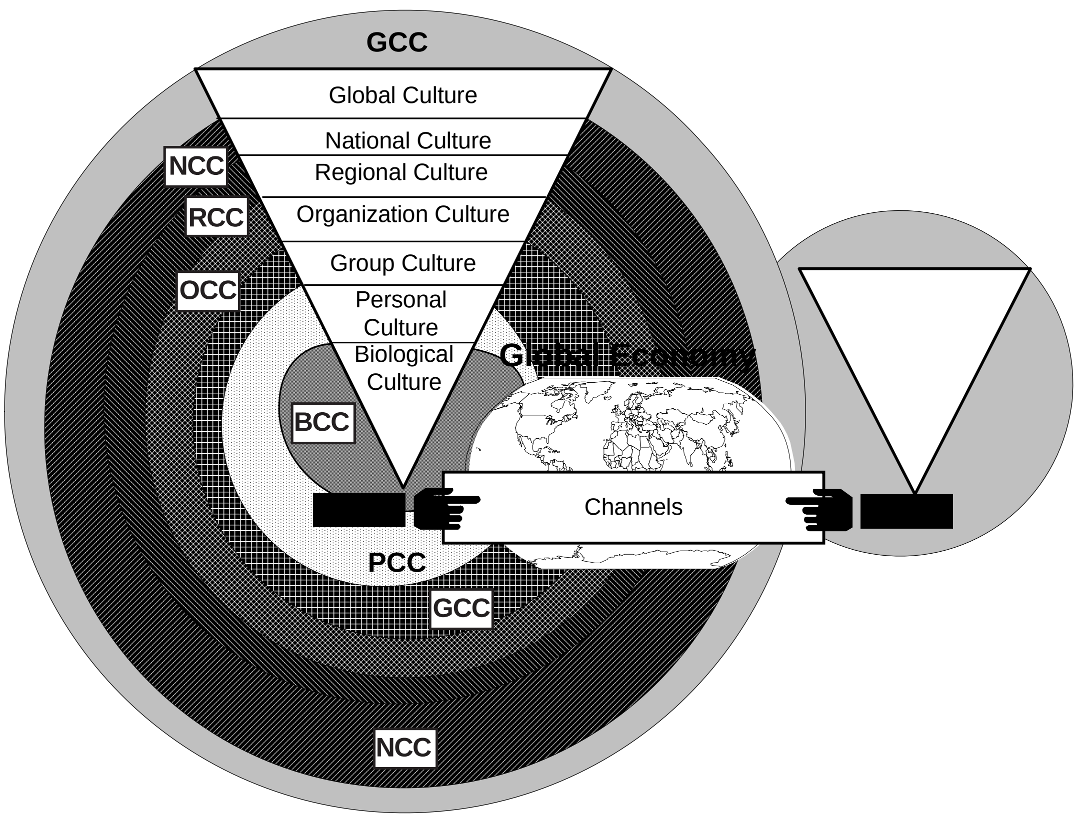
The model of the cross-culture communication process takes place at least between two partners who, in order to communicate, must send both a message and their intentions through several layers of cultures. For example, to communicate in the global economy between two different cultures each partner filters a message and intentions through seven layers of culture (biological, personal, group, organization, regional, national, and global). Of course, to be successful, such cross-culture communication must be based upon a good understanding of rules and practices that govern each layer of culture.

Let's define components of the cross-culture communication process in the global economy.

A). Global Economy

The global economy is largely understood in terms of worldwide economic and political convergence around liberal market principles and the increasing real-time integration of business, technological and financial systems (World Bank, 1997). The globalization process is supported by electronic communication that makes geography, borders, and time zones irrelevant to the way we

Figure 1. The culture layers and communication climates in the cross-culture communication process



conduct our business and personal lives. The "death of distance" will be the single most important economic force shaping all of society over the next half century (Cairncross, 1997). Friends, colleagues, and customers could easily be anywhere – around the corner or around the world – and new ways of communicating will effectively wipe out distance as a cost factor, indeed as a perceptible concept from our lives.

The growth of the global economy triggers the growth of a global information infrastructure (GII), which improves connections among organizations and individuals. Most people on earth will eventually have access to computer networks that are all switched, interactive, and broadband with capacity to receive TV-quality motion pictures. While the Internet will continue to exist in its form, it will also be integrated into other services, such as telephone and television (Targowski, 1996).

Although the Communication Revolution has increased connections among partners through technology, it simultaneously requires a better understanding of rules and practices of cross-cultural communication, regardless of applied media.

B). Culture Layers

The biological culture layer is the basic layer that provides common reactions based on the same physical needs which result from a common biological makeup. This layer is common for humankind in all civilizations and cultures.

The personal culture layer is the means with which the individual survives, operates and develops within the group, organization, region, nation, and globe. The essence of an individual's personal culture is the acceptance of underlying assumptions or "theories-in-use" (Argyris, 1976; Argyris & Schon, 1974). These assumptions are, for the individual, an undebatable understanding of reality, time and space (Schein, 1985). Each individual is additionally a member of various groups, organizations, regional, national, and global cultures.

The group culture layer is a managerial or an employee's tool used to accomplish an organizational task or to protect the interests of group members (formal or informal). A ggroup here may be defined as any collection of individuals united by a common relationship (i.e., work, profession or family).

The organization culture layer is a management tool that uses professional communication to influence organizational performance (Sypher et al., 1985) and that is created (or destroyed) by its leaders (Schein, 1985). A derivative of organization culture is a corporate culture that is a set of broad, tacitly understood rules (policies) informing employees how to behave under a variety of circumstances.

The regional culture layer contains commonalities based on the values of variables that individuals bear within a given region of a nation. Regional variables derive from two sources: 1) environmental influences (Borisoff & Victor, 1989; Farmerer & Richman, 1966; Terpstra & David, 1985) that have particular historical, political, economic, and social characteristics; and 2) traditions whose participants have similar ways of viewing space, time, things, and people (Schein, 1985; Weiss, 1988).

Regional culture may extend beyond national boundaries. In such cases, regional culture is *supranational*. For example, European culture encompasses dozens of nations with some shared values. Supranational culture can also be global (Featherstone, 1990). Regional culture may act as a subset of a particular national culture. In such cases, regional culture is *subnational*. For example, Brittany has a distinct regional culture within France but remains as a part of French national culture. Finally, regional culture may overlap with national culture. For example, Australian culture is at the same time both the culture of a nation state and that of a region (when compared to European or Latin American regions) that happens to be conterminous with a nation state.

The national culture layer is a set of common understandings, traditions, ways of thinking, feeling, behaving, and communication based on the same values of variables that influence communication through the nation. National culture is a learned behavior of its members'

historical experience. For example one can recognize an American culture, Chinese culture, Egyptian culture or Polish culture, and so forth.

The global culture layer is the new emerging layer, triggered by the developments of the global economy. At this layer, partners from different cultures and civilizations deliberately apply the same patterns of behavior in order to achieve successful communication in business (political, social, and so forth) endeavors.

Figure 2 provides a structure of a culture layer.

C). Communication Climates

Communication climate (or "atmosphere") can be defined as a set of conditions that transform cultural behavior and information into desired (or undesired) states of a given entity (person, group, organization, region, nation, globe) through the communication process. Communication climate refers to the atmosphere or prevailing condition that exists within a specific entity. For example, within China there are at least three communication climates; the most open communication climate exists in Hong Kong, a less open communication climate is allowed in special economic zones such as in Shenzhen, and a closed communication climate is controlled in the remaining parts of China.

Communication climate consists of seven components: space (territory), style, time, desire for interaction (or relationship), frequency (participation), tone (receptivity or friendliness), and quality. Table 1 provides weighted attributes of communication climates for all layers of culture except the biological communication climate, which more or less is similar for all cultures.

D) Communication Channel

A communication channel is the vehicle or medium in which a message travels. Thus channels range from light waves for nonverbal cues to radio or computers as modes for transmitting sound and visual messages. For example, the effective operation of a highly complex weapon system might hinge on adherence to formal channels of communication, while effective performance in investment banking might rely on informal as well as formal communication channels. The formal channels of communication help create and maintain authority, as well as give authenticity to messages, but they also inhibit communication; indeed, they alienate members. In the global economy, informal channels such as the Internet prevail. They create a horizontal society that exchanges messages which otherwise would not have been created.

THE EFFICIENCY OF CROSS-CULTURAL COMMUNICATION

To apply these attributes in cross-cultural communication, let's take an example of communication in the global economy between Western-West and Egyptian cultures. To assess the influence of each attribute in the communication process, apply weights on the scale from 1 to 5, where 5 is the highest value of the attribute. Table 2 compares those attributes of two cultures, based on the authors' expertise within both cultures.

The cultural difference (D_c) in attribute weights of Western-West culture richness (R_{WW}) and Egyptian culture (R_E) is:

$$D_c = R_{WW} - R_E = 91\text{-}75 = 16 \text{ points} \qquad [1]$$

in favor of Western-West culture. It means that both cultures are not at the same developmental level, yet to succeed in communication between both partners in the global economy both partners must invest in their own abilities to cross-communicate successfully. We will see farther how to evaluate the cost of such investments.

The efficiency of Western-West culture in the global economy is h = 91%, which means that only nine times out of 100 a Western-West businessperson may miscommunicate because of a lack of cultural understanding of a business partner. On the other hand, the Egyptian culture's efficiency in the global economy is h = 75%, which means that an Egyptian businessperson may miscommunicate 25 times out of 100. Almost every fourth transaction will be miscommunicated because of a failure to account for cultural differences.

The role of the communication climate in cross-cultural communication is to facilitate that communication. For example, let us examine a case of communication between the Western-West and Egyptian cultures. Table 3 illustrates that comparison.

The communication climate difference (D_{CC}) between both cultures is:

$$D_{CC} = A_{WW} - A_E = 29\text{-}27 = 2 \text{ points} \qquad [2]$$

in favor of Western-West culture. This means that a Western-West businessperson entering into a transaction with an Egyptian partner should decrease the cultural difference (D_C) = 14 points by D_{CC} = 2, calculated previously. The modified culture difference of Western-West culture ($D_{MC/WW}$) after the adjustment by the communication climate difference is:

$$D_{MC/WW} = D_C - D_{CC} = 16 - 2 = 14 \text{ points} \qquad [3]$$

On the other hand, the Egyptian partner has to increase the Egyptian culture difference ($D_{MC/E}$) by the same coefficient:

$$D_{MC/E} = D_C - D_{CC} = 16 + 2 = 18 \text{ points} \qquad [4]$$

After the adjustments, the modified culture difference (D_{MC}) between Western-West culture and Egyptian culture has increased for Egyptian culture ($D_{MC/E}$) from 14 points to 16 points, and for Western-West culture ($D_{MC/WW}$) it has decreased from 14 to 12 points. The communication climate favors Western-West culture, while it disfavors the Egyptian culture. In other words, a businessperson from a Western-West culture has a communication advantage in the global economy, while a businessperson from the Egyptian culture has to work harder at the communication effort in order to succeed in the global economy.

Table 3. The comparison of communication climate attributes (A) of Western-West (A_{WW}) and Egyptian cultures (A_E) in the global economy settings

Global Comm. Climate	Western-West Culture	Egyptian Culture
Territory (Space)	3-Formal	5-Personal
Style	5-Open	4-Semi-open
Time	5-Fixed	2-Semi-flexible
Relationship	4-Friendly	5-V. Friendly
Frequency (Participation)	5-High	3-High
Tone (Friendliness)	4-Guiding	2-Commanding
Quality	3-Paracommunication	4-Paracommunication
TOTAL POINTS	A_{WW} = 29	A_E = 27

Source: Two experts'/authors' opinion

The ability of a Western-West culture's businessperson (B_{WW}) to deal with a business partner from Egyptian culture is:

$$B_{WW} = R_{WW} : D_{MC/WW} = 91 : 14 = 6.5 \qquad [5]$$

The ability of the Egyptian culture's business partner (B_E) to deal with a business partner from Western-West culture is:

$$B_E = R_E : D_{MC/E} = 75 : 18 = 4.2 \qquad [6]$$

The culture's ability reflects how a given culture's strength can overcome cultural differences. The comparison of both cultures' abilities reflects a partner's cultural strength at the business table.

It also reflects his/her competitive advantage (V). Competitive advantage of a Western-West partner over an Egyptian partner can be computed in the following manner:

$$V_{WW} = B_{WW} : B_E = 6.5 : 4.2 = 1.6 \text{ or } 160\% \qquad [7]$$

In our example, B_{WW} is 1.6 (160%) times stronger than B_E. In common language, this comparison means that in a global economy of bilateral relationships, an American businessperson has almost twice the strength in overcoming cultural differences than does the Egyptian partner. If such knowledge is known to either partner, it can bring competitive advantage to him/her.

THE CULTURE COST FACTOR IN THE GLOBAL ECONOMY

A business entering the global economy is aware that it has to improve the understanding of foreign markets' dynamics and practices. Usually the new entry to the foreign market is associated with two types of cost:

- The explicit cost (C_E) can be anticipated, planned and quantifiable (transportation, building purchase or rental, interpreter's salary and all other overhead costs) in terms of its financial impact on doing business in a specific culture.
- The implicit cost (C_I) of cultural differences is intuitively understandable, but it is usually very difficult to predict or evaluate its structure and range. So, to guarantee success, it is very critical for a global firm to identify, examine and project the implicit costs associated with entering a foreign market.

The following conceptual framework of the implicit cost of the culture factor (C_I) will provide a definition and range of that type of cost:

$$C_I = f(GNP_C, R_C, D_{MC}, N_D, N_W) \qquad [8]$$

Where:

GNP – Gross National Product per capita of a given culture in terms of purchasing power parity (*ppp*);
R_C - Richness of a given culture;
D_{MC} - Adjusted modified culture difference between involved cultures;
N_D - Number of working days in another culture;
N_W - Number of workers in another culture.

Based on the variables' relationships in formula [8] one can define a formula for the culture factor cost of the culture that has a positive culture difference ($+D_{MC}$):

$$C_{I(+D)} = [(\$GNP_{C(+D)} - \$GNP_{C(-D)}) : (R_{C(+D)} + D_{MC})] \times (N_D \times N_W) \qquad [9]$$

In the case of the richer culture (formula [9]), the culture difference (D_{MC}) is in favor of that culture ($R_{C(+D)}$); therefore, both variables are added to decrease the cost of overcoming the culture difference.

This formula provides a balance between economic means, expressed in a GNP level and culture richness (R). In other words, low-rich cultures (measured by a low R) with high GNPs will not communicate in the global economy at the low cost. By analogy, they may remind their associates of the behavior of a *nouveau riche*, whose manners are sometimes questionable. New millionaires from countries that are being transformed from a central planning to a market economy sometimes invade the French Riviera and behave there like an elephant in a china shop. Due to a limited practice in the market economy and old attitudes, very often those *nouveau riche* prefer quick deals rather than long-term business collaboration. They are aware that their low-rich culture does not generate enough confidence in partners from a rich culture to establish long-term business relations. An additional factor plays a role too. A fresh business culture in some of those countries, very often driven by mafias, does not motivate those businesspersons to long-term commitments. As a result of it, they prefer to invest abroad rather than in their own countries. In effect, their business cultures do not develop. They misdevelop.

In the case of the less rich culture (formula [10], the culture difference (D_{MC}) is not in favor of that culture ($R_{C(-D)}$); therefore D_{MC} is subtracted from $R_{C(+D)}$ to increase the cost of overcoming the culture difference.

$$C_{I(-D)} = [(\$GNP_{C(-D)} - \$GNP_{C(-D)}) : (R_{C(-D)} - D_{MC})] \times (N_D \times N_W) \quad [10]$$

The application of these formulas to the example of cross-cultural communication between a Western-West culture [9] and an Egyptian culture [10] for the business duration = 30 days and the involvement of one worker provides the following results [GNP according to World Bank (1998/99)]:

$$C_{WW} = [(\$28{,}740 - \$2{,}940) : (91 + 14)] \times [30 \times 1] = \$7{,}400 \quad [11]$$

$$C_E = [(\$28{,}740 - \$2{,}940) : (75 - 18)] \times [30 \times 1] = \$13{,}600 \quad [12]$$

The richer culture (Western-West), in order to successfully communicate a business plan with the Egyptian culture, must invest only $7,400 to overcome culture differences. However, the less rich culture should spend 1.8 times more than the rich culture to overcome culture differences in 20 culture components (Table 2) and seven culture communication climate attributes (Table 3).

This example only confirms the old truth, that the comprehensive development of a rich culture takes a long time and requires many means. The paradox of this example is that the culture of Egypt is about 6,000 years old, while the Western-West culture is 1,200 years old, but has developed more comprehensively with much, much bigger means and this is reflected in the GNP per capita of both cultures. Apparently 1+ millennium is enough time to enrich the culture of Western civilization.

The cost of overcoming culture differences should focus on learning through education, training, and practice with all culture categories that are disadvantageous. To see the scope of that effort one must analyze the comparison of those two cultures, provided in Table 2 and Table 3.

FUTURE TRENDS

In the global economy cross-cultural communication becomes the basic skills of business communication. The more open the world will be, the more cross-cultural communication will be required not only in business but also in politics, where "dialog among civilizations" is the only solution in transforming from conflicts into peace.

CONCLUSION

This article has outlined and defined a framework for an asymmetric cross-cultural communication process, its efficiency and the cost of doing business in the global economy. A universal system design was developed not only to compare and quantify cultural efficiency and the attributes of communication climates through seven cultural layers (biological, personal, group, organization, regional, national and global), but also to explain the cross-cultural communication process and quantify the cultural cost in the global economy. This culture-specific design will help reduce miscommunication between partners across cultures and raise the awareness of the differences in the level of efficiency and cost in the communication process, behavior and practices between Western and non-Western cultural patterns.

Based on the presented framework, one can state that in order to be successful in cross-cultural communication in the global economy, engaged parties should be aware of the following five efficiency and cost rules:

- Culture Richness Rule I: A party from a less-rich culture (lower R) will more frequently miscommunicate with a party from a richer culture (higher R). (Formula 1).
- Communication Climate Rule II: A party from a "warmer" communication climate (higher A) will be in the advantageous position with a party from a "cooler" communication climate (lower A). (Formulas 3 and 4).
- Communication Ability Rule III: When large differences exist between cultures, the party from the richer culture has the best chance to communicate its own message (higher R). (Formulas 5 and 6).
- Communication Competitive Advantage Rule IV: The difference in communication ability gives a measurable competitive advantage to the more skillful communicator. (Formula 7).
- Communication Cost Rule V: A party with a higher GNP and a richer culture communicates in the cross-culture setting at lower costs than a party with the opposite attributes. (Formulas 8, 9, and 10).

The presented framework of asymmetric cross-cultural communication in the global economy provides pragmatic tools about how to define a communication strategy, train representatives and conduct business talks in order to achieve success.

KEY TERMS

Asymmetric Communication: A process in which both communicating parties are at different levels of economic and social development.

Communication Climate: Or "atmosphere," can be defined as a set of conditions that transform cultural behavior and information into desired (or undesired) states of a given entity (person, group, organization, region, nation, globe) through the communication process.

Cross-Culture Communication: A process of communicating among different cultures.

Culture: A value-guided, continuous process of developing patterned human behavior within and across cultures and civilizations.

Global Culture: The new emerging layer of cultures, triggered by the developments of the global economy. At this layer, partners from different cultures and civilizations deliberately apply the same patterns of behavior in order to achieve successful communication in business (political, social, and so forth) endeavors.

Global Economy: Largely understood in terms of worldwide economic and political convergence around liberal market principles and the increasing real-time integration of business, technological and financial systems.

Culture and Anonymity in GSS Meetings

Moez Limayem
City University of Hong Kong, Hong Kong

INTRODUCTION

Group support systems (GSSs) are an increasingly popular means of aiding decision making in a variety of organizational settings, by combining the computer, communication, and decision technologies to improve the decision-making process (Briggs, Nunamaker, & Sprague, 1998). Such technologies make use of anonymity as a key tool to improve the quality of decisions (Nunamaker et al., 1991; Pinsonneault & Heppel, 1997; Postmes & Lea, 2000).

Managers spend a considerable part of their work in meetings and participating in group decisions. Anonymity is generally believed to create an environment that improves group participation, communication, and the objective evaluation of ideas, enhancing the productivity of groups and their decision-making processes. Anonymity, as a distinct aspect of GSS, was expected to increase productivity by reducing the level of social or production blocking, increasing the number of interpersonal exchanges, and reducing the probability of any one member dominating the meeting (Newby, Soutar, & Watson, 2003). Barreto and Ellemers (2002) manipulated two aspects of anonymity separately: visibility of respondents (i.e., participants could or could not see who the other group members were) and visibility of responses (participants could or could not see the responses given by other group members). Results show that when group identification is low, anonymity manipulations affect group members' efforts.

A number of empirical findings have suggested that the use of anonymity and process structure in electronic brainstorming (EBS) generally promote a positive effect on the number of ideas generated (Jessup, Connolly, & Galegher, 1990; Gallupe, Bastianutti, & Cooper, 1991), and quality of ideas achieved in decision making (Zigurs & Buckland, 1998). However, the anonymity function inherent in multiworkstation GSSs has been found to heighten conflict, as members tend to communicate more aggressively because they tend to be more critical (Connolly, Jessup, & Valacich, 1990; Jessup, Connolly, & Tansik, 1990; Valacich et al., 1992); to have no effects on inhibition (Valacich, Dennis, & Connoly, 1994; Valacich et al., 1992); to increase group polarization (Sia, Tan, & Wei, 2002); and to have no effects on group performance (Valacich, Dennis, & Connoly, 1994). Other empirical findings show that, in terms of effectiveness, nominal brainstorming may be equal to (Gallupe, Cooper, & Bastianutti, 1991; Cooper et al., 1998; Barki & Pinsonneault, 2001) or sometimes less than (Valacich, Dennis, & Connoly, 1994; Dennis & Valacich, 1993) electronic brainstorming, indicating that at least as far as laboratory studies are concerned, empirical investigations have proved inconclusive.

BACKGROUND

Ferraro (1998) provided a succinct definition of culture as follows: "Culture is everything that people have, think, and do as members of their society."

Culture has been defined as the collective programming of the mind that distinguishes the members of one group or category of people from another (Hofstede, 1991; Tan, Watson, & Wei, 1995). Culture involves the beliefs, value systems, and norms of a given organization or society, and can exist at national, regional, and corporate levels. In fact, even information systems theories and research are heavily influenced by the culture in which they developed, and a theory grounded in one culture may not be applicable in other countries (Tan, Watson, & Wei, 1995; Triandis, 1987). The theories explaining the effects of GSS have come mainly from a North American perspective and may need to be adjusted for appropriate explanation of the same phenomena in different contexts. Therefore, in order to incorporate a global dimension, theories and models that attempt to explain the effectiveness of technology will need to take into account the cultural background of the group being examined.

Hofstede (1991) identified five dimensions of culture based on his IBM study in 72 different countries:

- *Uncertainty avoidance* is the degree to which a society feels threatened by uncertain and ambiguous situations, which leads members of the society to support beliefs promising certainty and to maintain institutions protecting conformity.
- *Masculinity* refers to a preference for achievement, heroism, assertiveness, and material success; as opposed to *femininity*, which implies a preference for relationships, modesty, caring for the weak, and quality of life.
- *Long-term orientation* stands for the fostering of virtues oriented toward future rewards, in particu-

lar, perseverance and thrift. Its opposite pole, short-term orientation, stands for the fostering of virtues related to the past and present, in particular, respect for tradition, preservation of "face," and fulfillment of social obligation.

- *Power distance* is the extent to which society accepts the fact that power in institutions and organizations is unevenly distributed, and how this fact of inequality is dealt with. It is found that individuals in societies with low power-distance cultures (e.g., United States) may be more inclined to adopt technologies that reduce power distance (Reinig & Mejias, 2003).
- *Individualism* refers to a preference for a loose-knit social framework in society in which individuals are only supposed to take care of themselves and their immediate families. This is opposed to *collectivism*, which implies a preference for a tightly knit social framework in which individuals can expect their relatives and clan to protect them in exchange for loyalty. The people of collectivistic-culture societies (e.g., Hong Kong) may use technologies to sustain group harmony and agreement.

It is interesting that power distance and individualism are found to be inversely related (Hofstede, 1991; Kim et al., 1994; Triandis, 1995). Many Western countries, such as the United States, Great Britain, and Australia, have been described as individualistic, low power-distance cultures, while many Asian countries, such as Hong Kong, Singapore, and China, have been described as collectivistic, high power-distance cultures (Hofstede, 1991).

CULTURE IN GSS STUDIES

Culture was not specifically considered as an important dimension in the early studies of GSS. However, with globalization, it is becoming increasingly important to adapt this tool to the cultural background of the organization or group that intends to use it effectively. These dimensions have been investigated in cross-culture GSS studies (such as those of Robichaux & Cooper, 1998; Tan et al., 1998; Tung & Quaddus, 2002; Watson, Ho, & Raman, 1994). Among the five dimensions, power-distance and individualism have been shown to have impacts on group behavior and group outcomes (Tan et al., 1998; Watson, Ho, & Raman, 1994). This occurs because the anonymity and simultaneous input features of GSS support low power-distance and individualistic cultural norms of desirable group behavior (Watson, Ho, & Raman, 1994).

Watson, Ho, and Raman (1994) later provided empirical support for the inclusion of culture as a dimension of GSS to add to DeSanctis' and Gallupe's (1987) dimensions of group size, member proximity, and task type. Their study examined U.S. and Singaporean cultures using GSS, and the findings suggested that Singaporean groups tended to have a higher pre-meeting consensus and less change in consensus than the U.S. group. This may be explained with reference to the collectivist nature of Singaporean culture, as collectivists have a tendency toward group consensus (Mejias et al., 1997).

Tan, Watson, and Wei (1995) suggested ways that different cultures can be studied with other important variables, such as task type and group size. The study focused on finding a way to examine the robustness of previous and current GSS research across different cultures and to add a cultural perspective to existing GSS knowledge. Hofstede's dimension of power distance was examined in relation to GSS, and the possible impacts of GSS intervention in both high and low power-distance countries were explored.

In studies examining only Singaporean groups (Tan, Watson, & Wei, 1995), the use of GSS resulted in a decreased impact of status and normative influences on decision making. These findings showed that change in consensus was greater in U.S. groups than in Singaporean groups, and influence was more equal in Singaporean groups than in U.S. groups. The higher power-distance of Singaporean groups may explain the differences between these two meeting outcomes, and the study supports the proposition that GSS can overcome the effect of high power-distance on group meetings.

A study comparing North American and Mexican groups participating in GSS sessions showed differences in terms of perception of consensus and satisfaction levels of group members (Mejias et al., 1997). U.S. and Mexican groups were also studied for GSS' effects on participation equity, with Mexican groups reporting higher participation equity levels than U.S. GSS groups (Mejias et al., 1997). It was suggested that high power-distance cultures benefit from GSS, and that these findings indicate that culture has a significant bearing on crucial aspects of GSS meeting outcomes.

Limayem, Khalifa, and Coombes (2003) conducted a study to explain the different effects of anonymity on the behavior of Hong Kong and Canadian groups during GSS sessions. In the Hong Kong Chinese culture, group interactions tend to emphasize harmony, conformance, and reciprocal respect rather than openness and spontaneity. However, the Canadian group's culture, which frequently exhibits openness and spontaneity, will usually allow individuals to deviate from the norm. Anonymity was found to have more significant positive effects for Hong

Kong groups. With anonymity, the performance of the Hong Kong group improved significantly in terms of number of contributions, quality of contributions, and perceived level of participation. No significant differences in the performance measures were found for the Canadian groups, except for the quality of contributions, which deteriorated with anonymity. A qualitative analysis of this negative effect revealed social loafing and lack of accountability as possible causes.

In sum, studies into the use of GSS by different cultures have indicated that there are differences between different cultures using GSS, and that cultural dimensions, such as those proposed by Hofstede (1991), have some relevance in explaining these differences. However, there is still uncertainty as to the specific impacts of culture on the performance of groups in anonymous GSS sessions, and, therefore, more must be done to clearly understand how different cultures respond to anonymity.

FUTURE TRENDS

As we move into the world of virtual organizations and electronic commerce, the use of GSS by groups of different cultures becomes an irreversible trend. For practitioners or users of GSS, groupware applications, or other electronic communication systems, the implications are important. We cannot simply think of anonymity as a concept that is good or bad. The use of anonymity should depend on the culture in which it is applied. For example, it is probably not a good idea to use anonymity in some cases where the culture of the group does not emphasize status hierarchies, conformance, mutual obligation, and reciprocity. In these situations, anonymity could even lead to negative outcomes, such as social loafing due to the reduction in motivation and effort that occurs when individuals work in anonymous groups. Conversely, it may be beneficial to use anonymity for GSS-supported groups with cultures that normally exhibit higher levels of conformance pressure and evaluation apprehension.

In a broader sense, GSS and groupware designers and developers should pay special attention to the implementation of anonymity features. For example, they could make it easier for users to turn these features on and off to accommodate the cultures of the groups using the systems. Finally, facilitators should remember that studies suggest that culture influences participation in the GSS environment (Tung & Quaddus, 2002). Therefore, facilitators should study the culture of the group using the technology before blindly using anonymity to generate or evaluate ideas.

CONCLUSION

Culture is clearly an important factor affecting a group's response to anonymity in the GSS context. Therefore, culture's influence on group structure and evaluation apprehension is important for designers, facilitators, and users of GSS to consider. Considering the lack of research on the effects of culture on GSS, further research in this field would appear to be worthwhile. This may be conducted on other interactions associated with cultures using the anonymous function of GSS. This research also has fascinating implications for technology's effect on other cultures. An interesting line of research for the future will be to isolate the relative impact of anonymity with different cultures engaged in different tasks and situations. The knowledge gained from this and other continuing studies will assist in the effective application of GSS in increasingly diverse and global contexts.

KEY TERMS

Anonymity in GSS: The situation when participants' names are not made public in a GSS environment.

Culture: The collective programming of the mind, which distinguishes the members of one group or category of people from another.

Group Support Systems (GSS): Any combination of hardware and software that enhances groupwork.

Individualism: Refers to a preference for a loose-knit social framework in society in which individuals are only supposed to take care of themselves and their immediate families. This is opposed to collectivism, which implies a preference for a tightly knit social framework in which individuals can expect their relatives and clan to protect them in exchange for loyalty.

Long-Term Orientation: This stands for the fostering of virtues oriented toward future rewards, in particular, perseverance and thrift. Its opposite pole, short-term orientation, stands for the fostering of virtues related to the past and present, in particular, respect for tradition, preservation of "face" and fulfilling social obligations.

Masculinity: Refers to a preference for achievement, heroism, assertiveness, and material success; as opposed to femininity, which implies a preference for relationships, modesty, caring for the weak, and quality of life.

Power Distance: The extent to which society accepts the fact that power in institutions and organizations is unevenly distributed.

Uncertainty Avoidance: The degree to which a society feels threatened by uncertain and ambiguous situations, which leads them to support beliefs promising certainty and to maintain institutions protecting conformity.

Current Multicast Technology

Gabor Hosszu
Budapest University of Technology and Economics, Hungary

INTRODUCTION

Multicast technology is one-to-many communication, oppositely from the usual one-to-one (unicast) communication, which provides an efficient solution to create multiparty collaborative software by delivering the data flows on an appropriate distribution tree. The root of the distribution tree is the sender and its leaves are the receivers. Many Internet applications, such as distributed simulation, remote education, and videoconference require the underlayer network to support multicast communication.

The main problem of the multicasting is, however, how to construct and maintain the path, called delivery or distribution tree. There are solutions in different levels of the protocol stack, including datalink-layer, network-layer, and application-layer. Only the second and the third level multicast have practical importance; therefore we focus on these in the following.

The network-layer multicast is based on the Internet protocol (IP), which is why this kind of multicasting is called IP multicast. This technology is bandwidth conserving and reduces traffic by simultaneously disseminating a single stream of information to potentially thousands of corporate recipients. Multicast packets are replicated in the network at the point where paths are multiplied by multicast routing protocols, resulting in the most efficient delivery of data to multiple receivers. The main advantage of the multicasting is the smaller bandwidth usage than a normal unicast-based transmission.

The application-layer multicast (ALM) uses a different approach. In this technology, the multiplying nodes are host and the transmission is based on unicast. However, even the application-layer multicast has serious advantages over the pure unicast transmission, since in case of the traditional unicast, the sender has to create as many parallel data streams as receivers joined to the session. However, in case of ALM the sender has to serve a limited number of data streams, since the other group members as nodes also act as multiplication points. In such a way, they create a distribution tree.

BACKGROUND

The traditional unicast require the source to send more than one copy of the data, since there are point-to-point connections between the sender and each of the receivers. Even low-bandwidth applications can benefit from using multicast when there are thousands of receivers. High-bandwidth applications, such as video streaming, may require a large portion of the available network bandwidth for a single stream. In these applications, multicast is the only way to send to more than one receiver simultaneously.

The current Internet applications manage a large and widely distributed set of users, have multiple data streams that vary in content and media type, and make use of multiple unicast and multicast streams in a single session. Examples of these distributed, interactive applications include corporate communications, distance learning, video conferencing, stock quotes, software distribution, network news, collaborative visualization, distributed interactive simulations, and multiplayer games.

Table 1. The IP address ranges

Name	Purpose	Address Range
Class A	Unicast addresses for large networks	1.0.0.0 - 127.255.255.255
Class B	Unicast addresses for medium networks	128.0.0.0 - 191.255.255.255
Class C	Unicast addresses for small networks	192.0.0.0 - 223.255.255.255
Class D	Multicast addresses	224.0.0.0 - 239.255.255.255
Class E	Reserved	240.0.0.0 - 255.255.255.254

THE IP MULTICAST APPROACH

Special IP-addresses are used in the IP-multicast, which do not belong to certain hosts, but define multicast channels. Table 1 presents the address ranges of the IP address space. The Class A, B and C are used for the traditional unicast communication; the Class D addresses are applicable for multicasting.

The first model of the IP-multicasting was proposed by Steve Deering in 1988 in his PhD dissertation, and its first standard was published in the RFC 1112 (Deering, 1989). The most important idea in Deering's model for the multicasting is the so-called multicast group concept. Table 2 summarizes the main factors of this concept.

THE IP MULTICAST ROUTING

The first issue of multicast delivery is the communication between the host and the local router. The host does not have routing functionality; it uses a special signaling protocol, the Internet Group Management Protocol (IGMP), to let the local router know that the host became interested in the traffic of a certain multicast group.

The multicast delivery in the inter-router area is based on the multicast-enable routers, which have multicast routing protocols in their protocol stack. The multicast routing protocols differ from each other according to the underlying unicast routing protocols used. Table 3 presents the most popular multicast routing protocols and their most important properties (Hosszú, 2001).

An important step in creating the delivery tree is to discover all the routers interested in the given multicast session. In case of the DVMRP (Waitzman, 1988), MOSPF (Moy, 1994) and dense mode version of the PIM multicast routing protocols, the routers periodically flood the whole network with a multicast data packet, forwarding it to every router (Adams et al., 2003). Routers not interested in that session send a prune message back to the source of the packet and so the following packets will not be forwarded to these. The flooding step generates a huge amount of unnecessary packets, which is acceptable in dense mode situation, where the majority of the routers are interested in a multicast delivery. This routing method is called flood-and-prune model, and its operation is demonstrated in Figure 1.

In the sparse mode case, where only a small fraction of the routers are interested in a multicast session, the periodically executed flooding means an unacceptable load in the inter-routing area. In such a situation that multicast routing protocols can efficiently operate, rendezvous points (RP) are used to join to a multicast session and in such a way that the periodical flooding phase is avoided. In case of the PIM-SM routing protocol (Fenner et al., 2004), if a host wants to send multicast traffic, it will send the data packets to its local router, and then it forwards the data to the RP, which is now a designated remote router. The other host interested in that multicast traffic will send an IGMP join message to its local router, in order to become a receiver. Then the local router will send a PIM-SM joint message to the RP. Figure 2 shows this mechanism, where two receivers join to the multicast session.

After completing the join phase, the RP continuously forwards the multicast traffic toward the local router of the receiver. The data from the source to the RP is an encapsulated unicast PIM-SM control message. Figure 3 demonstrates this phase.

The root of such a delivery tree is the RP. A more optimized tree can be obtained, if the routers realize that a shorter path can be created between the source and the receiver. In this case the PIM-SM routers can switch over from the RP-rooted tree to the source-rooted tree. Figure 4 shows the created source-rooted tree.

Besides constructing the tree, its stability is also an important problem, since the routing protocol must upgrade at least a part of the tree whenever a member joins or leaves the multicast session (Van Mieghem & Janic, 2002).

Another serious routing problem of the IP-multicast is the inter-AS (autonomous system) multicast routing, since transmitting multicast traffic is not easy among the peering ASs. To overcome this limitation, different wide-area protocols are developed. The current practice is the usage of the protocol set MBGP/PIM-SM/MSDP; however, it has scalability problems, since it uses flooding to inform

Table 2. Components of the multicast group concept

- **IP-style semantics:** Similarly to the traditional (unicast) IP communication, a source can send data at any time; for this it does not have to join to the group of hosts.
- **Open groups:** The source does not have to know the members of the groups for sending data and the receivers (members of the group) do not have to know the source.
- **Variable groups:** The hosts can create, join to or leave any group at any time. The communication does not need any control center to coordinate the activity of the hosts.

Table 3. The widely used multicast routing protocols

Name	Main properties
Distance Vector Multicast Routing Protocol (DVMRP)	Its main problem is that it is not scalable for wide-area usage due to its flooding property.
Multicast Open Shortest Path First (MOSPF)	It uses the underlying OSPF unicast routing tables. Due to the huge control information packets among the routers, it is not scalable for wide-area usage.
Protocol Independent Multicast (PIM)	It can interoperate with any underlying unicast routing protocol. Its sparse mode version called PIM-SM is used for wide-area routing.

the receivers in the remote ASs about a local multicast source (Fenner & Meyer, 2003). The long-term solution may be MASC/MBGP/BGMP stack, which constructs a multicast tree from the ASs and avoids the flooding among them (Rajvaidya & Almeroth, 2003).

From the viewpoint of the market-oriented applications, the Deering's multicast model had to modify in order to be less vulnerable. For instance, a malicious sender can send noisy data to a multicast channel, which is used by other users. In order to avoid such an unwilling situation, the multicast concepts called source-specific multicast (SSM) were developed, where the host specifies not only the multicast group (class D) address sending an IGMP join message to the local router, but also the set of sources, from which it accepts multicast data (Almeroth et al., 2001). In this network the routers can also distinguish data streams having the same multicast address but originating from different sources, if they use SSM routing protocol such as the source-specific version of the PIM-SM, called PIM-SSM (Meyer et al., 2004).

THE CONNECTIONLESS AND CONNECTION ORIENTED TRANSMISSIONS

There are two basic types of communication; one is called connectionless, where the sender starts to send the data packets without any previous negotiation phase with the receiver. Such a method is used in the Internet, where the sender host or router forwards the IP packets without any delivery guarantees. The IP-multicast is similar to the conventional IP unicast communication from the point of view that quality of data transmission is non-reliable, the so-called best-effort. It means that there is not any guarantee for any parameter of the transmission, such as the delay, the error-free delivery, and so forth. Its reason is the connectionless property of the Internet protocol, where there is not any logical connection among the communicating entities in the network level. When a router sends data, it has no any knowledge if the other router receives that data properly or not.

Figure 1. Operation of a flood-and-prune multicast routing algorithm

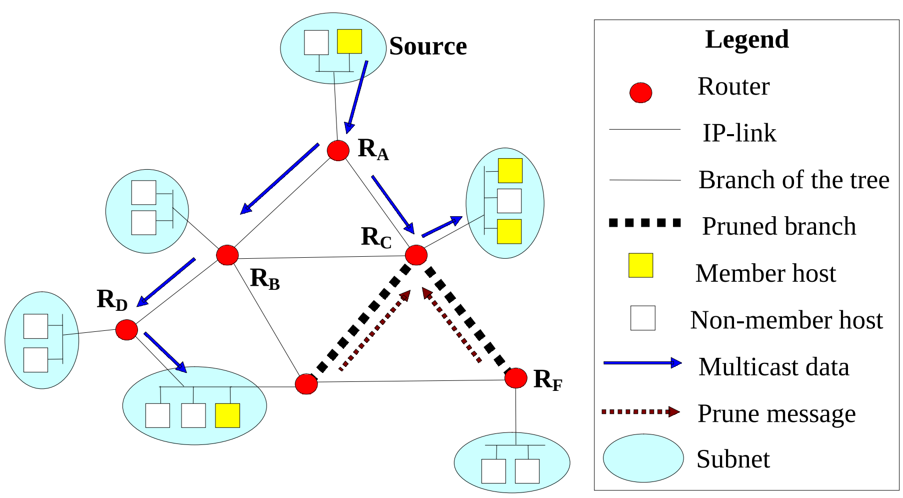

Figure 2. The joining phase in the PIM-SM operation

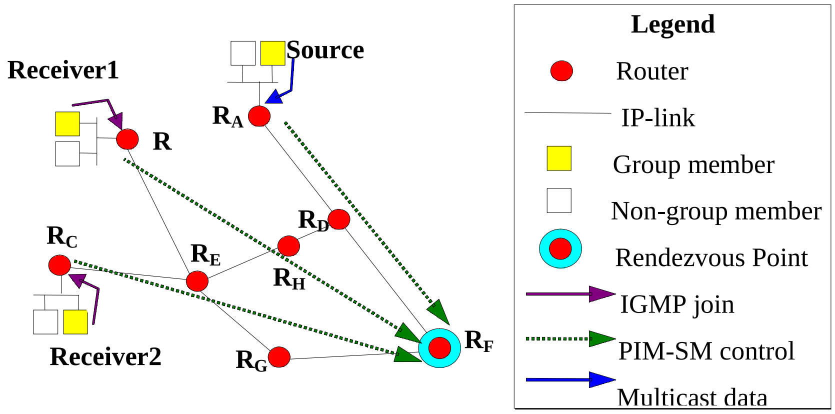

The other communication form is connection oriented, where the sender and the receiver negotiate with some communication parameters such as the sending rate. An example of the connection oriented data transfer is the Transmission Control Protocol (TCP) that is used in the unicast to get reliable delivery. However, the TCP is not usable for multicasting, since the TCP receiver client acknowledges every packet, and in the case of a large number of receivers, this could cause serious congestion at the network link of the multicast source. That is why the multicast applications use the User Datagram Protocol (UDP) for transmission, which has no reliable mechanism.

METHODS TO INCREASE THE RELIABILITY OF THE MULTICAST

Since most of the multicast applications are media-related software, for example, media conference, voice distribution, shared whiteboard, or various collaborative media tools, they need more reliability than the best-effort delivery. In order to increase the reliability of multicast applications, additional multicast transport protocols are used to achieve the required level (Whetten & Taskale, 2000). Such a protocol is the NORM: NACK-Oriented Reliable Multicast Protocol (Adamson et al., 2004).

The multicast transport protocols have many different property attributes of the data delivery. These attributes can be represented by the protocol parameters. Each protocol parameter describes different reliability mechanisms for the same delivery attribute. Such a protocol parameter is, for instance, the repair method, which can get the values such as "retransmission," "forward-error correction," "interleaving," or different ways of the "local receiver-based repairs". Another parameter is the acknowledgement type, the possible values of which may be "tree-based," "ring-based" or a "simple direct form".

Figure 3. The data transmission among the hosts and the PIM-SM routers

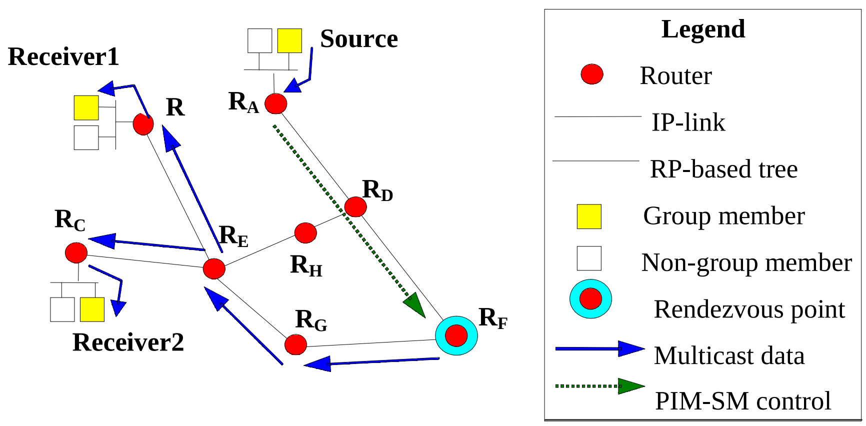

Figure 4. The data transmission through the source-rooted tree

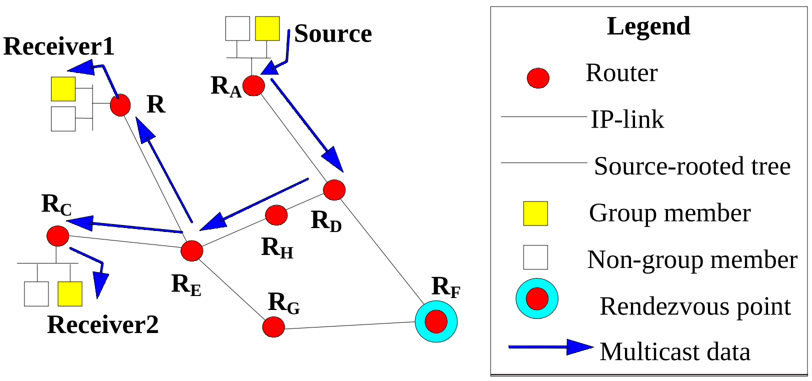


The various applications have different reliability requirements, and therefore these protocol parameters should be optimized in order to create the multicast transport protocol best suited for a given application. However, applying any appropriate mathematical optimization method, at the selection of the protocol parameters mentioned previously, a linearly independent (in other words, orthogonal) set of parameters must be applied. To do this a hyperspace of the parameters is created where all transport protocol corresponds to one point of this space. The optimization procedure means to find the most suitable point in this space to provide the best performances of multicast. The possible values of protocol parameters (which are the types of various mechanisms as the components of these) are the realizations of the protocol functionalities. A quasi-orthogonal subset of the protocol parameters and their possible values are presented in Table 4. These parameters represent the well-known reliable mechanisms of the transport protocols.

To carry out a correct optimization procedure on the appropriately selected protocol parameters, a well usable simulation program should be applied in order to obtain statistically confident results for multicast data transfer. Using an appropriate simulator, the optimized transport protocol can be synthesized for a given media application, satisfying the requirements. That means that by a mathematical method an optimal point in the hyperspace of the protocol parameters can be found.

THE APPLICATION-LAYER MULTICAST TECHNOLOGY

The application-layer multicast (ALM) is also called host-multicast, since the nodes are responsible for the multicast delivery, not the routers. The main difference between the host-multicast and the IP-multicast is that in the case of the ALM, the hosts use unicast between them and the

Table 4. The selected set of the protocol parameters

Protocol parameter	Values
Flow control	Window-based, Rate-based, Multigroup multicast, Receiver give-up, None
Data accuracy	Reliable, Atomic, Non-reliable
Feedback addressee	Original source, Intermediate host, Every member, None
State control	Sender-based, Receiver-based, Shared, None
Feedback control	Structure-based, Timer-based, Representatives-based, Rate-based, None
Way of sending repair	Unicast, Multicast, None
Scope of repair	Global, Global to secondary group, Global to individual members, Local, None
Session membership control	Explicit, Implicit, None

multiplication points of the tree are the hosts themselves, not the routers, as in the IP-multicast (Banerjee et al., 2002; Castro, 2002; Zhang et al., 2002). Table 5 compares the properties of the host-multicast and the IP-multicast.

ALM is a new approach to providing multicast services to group applications. In this peer-to-peer (P2P) architecture, members organize themselves into an overlay topology for data delivery that adapts to the changing network conditions and group dynamics. P2P systems are distributed virtual networks that operate without centralized control. To find a particular piece of data within the network, P2P systems explicitly or implicitly provide a lookup mechanism that matches a given string (called a key) to one or more network nodes responsible for the value associated with that key.

Some of the ALM schemes can take advantage of IP-multicast support where available. However, such additional IP-layer capabilities are not essential for these protocols, and therefore they can be easily deployed in the Internet today. Current Internet P2P applications typically provide lookup functions using time-to-live (TTL) scope controlled flooding procedures. With this approach, the querying node wraps the query in a single message and sends it to all known neighbors. The neighbors check these to see if they are able to reply to the query by matching it to keys in their internal database. If they find a match, they send a response; otherwise, they forward the query to their own neighbors and increase the message's hop count. If the hop count becomes higher than the TTL limit, the forwarding will be cancelled. The TTL value thus determines a boundary for the query that controls its propagation.

THE THEMATIC MULTICAST CONCEPT (TMC)

As an example of the current searching works in the field of ALM, a novel concept of modeling relative density of members is the bunched mode. The bunched mode means a typical multicast scenario where many interested hosts are in certain institutes relatively far from each other. The members of a multicast group are locally in dense mode; however, these spots are far from each other, with their situation globally being similar to the sparse mode. This situation is typical when the collaborative media application has a special topic. That is why this model of communication is called thematic multicast concept (TMC). A typical TMC scenario is shown in Figure 5.

The group-member hosts in a bunch locally elect the designated members (DM). The DM calculates the shortest unicast IP tunnels among them. They exchange their IP addresses and shortest unicast paths among them. In such a way, all of them know all possible shortest unicast paths and calculate the same topology of the inter-bunch IP tunnels. This application-level routing mechanism, called shortest tunnel first (STF), is similar to the MOSPF routing in the network level. The MOSPF routers exchange the link-state information, but in the case of STF, the DMs exchange the path information to every other one, since there are UDP/IP paths to every other DM.

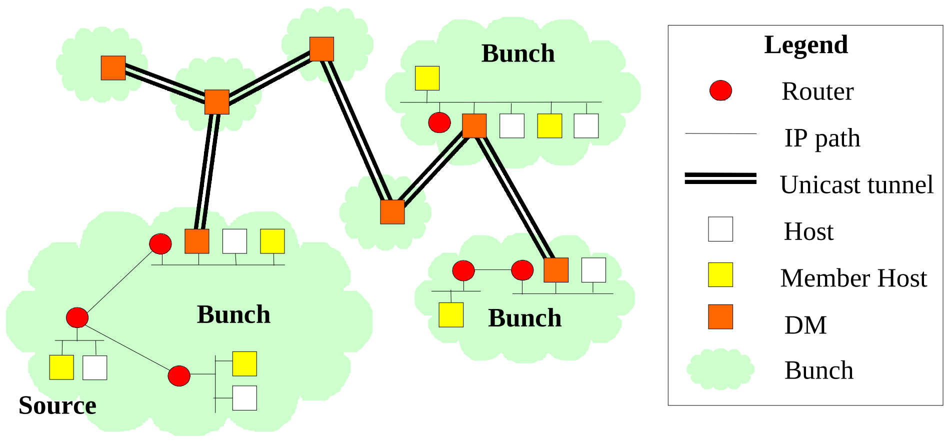
FUTURE TRENDS

Due to the increasing bandwidth, the users send more and more media content through the Internet. The collaborative applications also have strong demands. Therefore the multicast as a communication model will be used in the future. The choice between the IP multicast and the application-layer multicast, however, remains an open question. The most important advantage of the IP multicast is the reliable operation of the intermediate nodes, oppositely to the easy deployment of the ALM. The networking applications, which have a limited number of users, will prefer the ALM as multicasting technology; however, the stable, long-term applications with a number of users (e.g., media streaming) will prefer the IP multicast due to

Table 5. Comparing the properties of the host- and the IP-multicast

- **Deployment cost:** The IP-multicast requires additional knowledge in the routers to the basic unicast communication and extra work from the administrators of the routers; the ALM needs the traditional unicast IP infrastructure, only.
- **Flexibility:** The host- and the IP-multicast are flexible, and it is easy to change the topology of the multicast tree.
- **Speed of delivery:** The ALM theoretically cannot be more optimal than the IP-multicast tree, in such a way that the delivery of the ALM has higher delay than the IP-multicast.
- **Robustness:** In case of the ALM, the hosts are responsible to maintain the tree; in case of the IP-multicast, the routers define the tree. Since the routers operate safely, non-stop, but the user can switch off a host anytime, in such a way the IP-multicast is more robust.

Figure 5. A typical TMC scenario



its more reliable nature. Another side of the problem is that independently from the usage rate of the IP multicast, its sophisticated routing and transporting methods are adapted in the ALM, too.

In the future, new applications as well as methods will emerge in the field of multicasting in order to more efficiently use the existing network.

CONCLUSION

The emerging media applications use multicast technology to efficiently deliver large media data to the receivers. The fundamentals of the network-level IP-multicast and the application-level host-multicast are presented. The main fields of research are the wide-area routing and the reliable multicast transport protocols in the IP-multicast, and a novel application-level routing protocol and communication concept in the host-multicast. The advantages and the drawbacks of the two basic multicast technologies are compared. Selecting the most beneficial technology to apply depends on the requirements of the actual media application.

KEY TERMS

ALM (Application-Layer Multicast): A novel multicast technology that does not require any additional protocol in the network routers, since it uses the traditional unicast IP transmission.

Application-Level Multicast: Alternative name of the application-layer multicast.

AS (Autonomous System): A network where the main routers are in common administration. The Internet is composed of peering ASs.

Host-Multicast: Alternative name of the ALM.

IETF (Internet Engineering Task Force): A voluntary association for developing Internet standards.

IP-Multicast: Network-level multicast technology, which uses the special Class-D IP-address range. It requires multicast routing protocols in the network routers.

Multicast Routing Protocol: In order to forward the multicast packets, the routers have to create multicast routing tables using multicast routing protocols.

Multicast Transport Protocol: To improve the reliability of the multicast delivery, special transport protocols are used in addition to the widely used unreliable UDP.

Reliability: The improved quality of data transmission; different types of reliability exist, including data accuracy or real-time delivery.

RFC (Request for Comments): The IETF publish them as de facto standards of the Internet.

TTL (Time-to-Live): A field in the IP packet header. Its value is the allowed hop-count, the number of routers, which can forward the packet before delivery or dropping out.

Unicast: The one-to-one communication way, where only one host transfers data with another host. In the traditional IP the unicast is applied.

Deployment Cost: The IP-multicast requires additional knowledge in the routers to the basic unicast communication and extra work from the administrators of the routers; the ALM needs the traditional unicast IP infrastructure, only.

Flexibility: The host- and the IP-multicast are flexible, and it is easy to change the topology of the multicast tree.

Speed of Delivery: The ALM theoretically cannot be more optimal than the IP-multicast tree, in such a way that the delivery of the ALM has higher delay than the IP-multicast.

Robustness: In case of the ALM, the hosts are responsible to maintain the tree; in case of the IP-multicast, the routers define the tree. Since the routers operate safely, non-stop, but the user can switch off a host anytime, in such a way the IP-multicast is more robust.

IP-Style Semantics: Similarly to the traditional (unicast) IP communication, a source can send data at any time; for this it does not have to join to the group of hosts.

Open Groups: The source does not have to know the members of the groups for sending data and the receivers (members of the group) do not have to know the source.

Variable Groups: The hosts can create, join to or leave any group at any time. The communication does not need any control center to coordinate the activity of the hosts.

Current Network Security Systems

Göran Pulkkis
Arcada Polytechnic Helsinki, Finland

Kaj Grahn
Arcada Polytechnic Helsinki, Finland

Peik Åström
Arcada Polytechnic Helsinki, Finland

INTRODUCTION

Network security is defined as "a set of procedures, practices and technologies for protecting network servers, network users and their surrounding organizations" (Oppliger, 2000, Preface). The need for network security is caused by the introduction of distributed systems, networks, and facilities for data communication. Improved network security is required because of the rapid development of communication networks. Network security is achieved by using software based tools, that is, network security software (Pulkkis, Grahn & Åström, 2003).

BACKGROUND

This article gives a topical overview of network security software, that is, the topics are not covered in detail, and most topics are briefly introduced and left for further study. The main objective is to present "state-of-the-art" of network security software and to stimulate discussion about related skills and education needed by network users, IT professionals, and network security specialists.

PROTECTION AGAINST MALICIOUS PROGRAMS

Malicious software exploits vulnerabilities in computing systems. Malicious program categories are (Bowles & Pelaez, 1992):

- *Host program needed*
    - **Trap door**
    - **Logic bomb**
    - **Trojan horse**
    - **Virus**
- *Self-contained malicious program*
    - **Bacteria**
    - **Worm**

The ideal protection is prevention, which still must be combined with detection, identification and removal of such malicious programs for which prevention fails. Protection software is usually called antivirus software (Stephenson, 1993):

- **First Generation**
  Simple scanners searching files for known virus "signatures" and checking executable files for length changes.
- **Second Generation**
  Scanners using heuristic rules and integrity checking to find virus infection.
- **Third Generation**
  Memory resident "activity traps" identifying virus actions like opening executable files in write mode, file system scanning, and so forth.
- **Fourth Generation**
  Antivirus software packages using many different antivirus techniques in conjunction.

Examples of recent advanced antivirus techniques are *generic decryption* (*GD*) and *digital immune system (DIS)* technology (Stallings, 2000, Chap. 9).

Protection levels of modern antivirus software are:

- **Gateway level protection** consists of mail server and firewall protection. Viruses are detected and removed before files and scripts reach a local network.
- **File server level protection** consists of server software. Viruses are detected and removed even before network users access their files/scripts.
- **End user level protection** consists of workstation software. Viruses undetected in outer defense lines are detected and removed.

All levels should be combined to achieve depth in antivirus defense. Virus definition databases should be automatically and/or manually updated.

FIREWALL SOFTWARE

Firewalls protect computers and computer networks from external security threats. Firewall types are:

- **Packet-filtering router**, which applies a software and/or hardware implemented filtering rule set to each incoming/outgoing IP packet and then forwards or discards the packet. Most TCP/IP routers support basic user defined filtering rules. A packet-filtering firewall can also be a stand-alone network link device, for example, a computer with two network cards.
- **Application-level gateway (proxy server)**, which acts as an application level traffic relay. A typical application level gateway is a protocol oriented proxy server on a network link, for example, an HTTP proxy, a SMTP proxy, a FTP proxy, and so forth. An HTTP proxy is also a Web page cache for Web usage through the proxy.
- **Circuit-level gateway**, which typically relays TCP packets from one connection to another without examining the contents.

CRYPTOGRAPHIC SOFTWARE

Cryptographic network security software consists of secure network applications and secures network system software.

Software for Secure Network Level Data Communication

Secure network level data communication is based on the Internet Protocol Security (IPSec) protocol. Two computers in the same TCP/IP network implement end-to-end security through the network, when IPSec software is installed and properly configured in both computers. IPSec provides two operation modes:

- **Transport mode**, where original IP headers are used
- **Tunnel mode**, where new IP headers are created and used to represent the IP tunnel endpoint addresses. IPSec is usually embedded in Virtual Private Network (VPN) software. VPN provides secure LAN functionality in geographically distributed network segments and for Internet connected computers. Fundamental VPN types are:
- **Access VPN**, a secure connection to a LAN through a public TCP/IP Network
- **Connection VPN**, a secure remote connection between two logical LAN segments through a public TCP/IP network.

IPSec and VPN functionality is included in Windows 2000/XP. Commercial VPN software products are F-Secure VPN+™, Nokia VPN, Cisco Security VPN Software, and so forth. Open source IPSec and VPN software is also available (Linux, 2003).

Middleware

Middleware is a software layer between the network and the applications for providing services like identification, authentication, authorization, directories, and security (Internet2 Middleware, 2004). Shibboleth (2004) is an example of open source authentication and authorization middleware. Commercial security middleware based on the SHH protocol is presented in SSH Tectia Solution (2004).

Software for Secure Transport Level Data Communication

Many network applications are based on the IETF Transport Layer Security (TLS) standard. The TLS/SSL protocol is based on an established client-server TCP connection. Then both computers execute the SSL Handshake Protocol to agree on the cryptographic algorithms and keys for use in the actual data communication (Stallings, 2000, p. 214). TLS/SSL versions of common application level TCP/IP protocols are available (see Table 1).

VPN solutions can also be implemented using the TLS/SSL protocol and executed on the transport level. This technology, called SSL-VPN provides VPN functionality to geographically distributed network segments and for Internet connected computers using a standard Web browser. A commercial SSL-VPN software product is presented in Symantec™ (2004).

Web Security

Basic Web security features are access level security and transaction level security. Access level security is provided with firewalls which guard against intrusion and unauthorized use. Transaction level security requires protocols for protecting the communication between a

Table1. Secure application level protocols based on TLS/SSL (Oppliger, 2000, p.135)

Secure protocol	Port	Description
HTTPS	443	TLS/SSL protected HTTP
POP3S	995	TLS/SSL protected POP3
IMAPS	993	TLS/SSL protected IMAP4
SMTPS	465	TLS/SSL protected SMTP
NNTPS	563	TLS/SSL protected NNTP
LDAPS	636	TLS/SSL protected LDAP

Web browser and a Web server. Proposed protocols are HTTPS, S-HTTP, and PCT (Pulkkis, Grahn & Åström, 2003, p. 14). HTTPS was originally introduced by Netscape for the Netscape Navigator browser. Presently, HTTPS is an accepted standard supported by practically all Web browsers, while S-HTTP and PCT are seldom used.

E-Mail Security

E-mail traffic to and from e-mail servers is protected, when the SMTPS protocol is used. Sessions with e-mail client programs can be protected

- by using the mailbox access protocols POP3S and IMAPS, and
- by embedding an e-mail client program in a HTTPS Web page.

E-mail content security requires e-mail client program extensions for signing and/or encrypting outgoing messages as well as for decrypting and/or signature checking incoming messages. The most widely used e-mail client security extensions are PGP and S/MIME, see Stallings (2000, Chap. 5).

Secure E-Commerce

Secure electronic transaction (SET), originally introduced by MasterCard and Visa, is an open security specification designed to protect credit card transactions on Internet (Stallings, 2000, Chap. 7). SET provides

- secure communication,
- trust based on X.509v3 certificates, and
- privacy based on strictly controlled access to sensitive information.

Secure Shell (SSH)

The Secure Shell (SSH), a secure remote connectivity protocol in TCP/IP networks, is a de-facto standard being further developed by one of the IETF Security Area Working Group. Two SSH versions have hitherto been developed: SSH1 and SSH2. Commercial as well as open source SSH implementations are available (SSH Communications Security, 2003; OpenSSH, 2003).

Secure Network Management

A protocol for secure network management, SNMPv3, was introduced in 1998 by IETF to address the lack of security in earlier SNMP versions. SNMPv3 incorporates authentication and encryption features to SNMP managers and access control features to SNMP agents (Stallings, 2000, Chap. 8).

Secure DNS (DNSSEC)

The absence of trust in DNS host name resolution is a security hazard in all TCP/IP applications. To address this problem IETF formed a working group to develop the DNSSEC standard. The objective is to provide both authentication and integrity to DNS information. DNSSEC uses public key cryptography to sign DNS information (Securing the Domain Name System DNSSEC, 2003).

Secure Routing Software

Routing protocols and their hardware/software implementations in computer networks are usually open and functionally unprotected. A manifestation of an emerging recognition of routing security in the Internet community is the recently formed IETF Routing Area Working Group "Routing Protocol Security Requirements (rpsec)", which in December 2003 published the Internet Draft "Generic Threats to Routing Protocols" (Barbir, Murphy, & Yang, 2003).

Security Token Access Software

The required randomness in cryptographic key generation may cause security problems, if secret or private keys are used in the main memory of network connected computers. Intruders may identify keys as random areas, since code and data are usually structured. For this reason, a secret key should be changed after some time interval, and a private key should be stored and used in a separate hardware token together with the code of the cryptographic operations using it. Usually, this token is a computer chip on a smartcard. Private keys on a smartcard are protected by pin codes or biometrically by digital fingerprint comparison and/or by digital voice recognition. A numerical smartcard reader dedicated keypad is necessary for pin code security. Software required for accessing cryptographic tokens on smartcards is:

- Device driver for communication with the smartcard through the used smartcard reader.
- PC/SC, a specification set released by an international consortium (PC/SC Workgroup, 2003) for integration with the operating system. In PC/SC, a device manager keeps track of the cards and card readers connected to a computer.
- An Application Programming Interface (API) like PKCS#11, also called CrypTokI, or Microsoft Crypto API.

Wireless Security Software

A radio interface is by nature easy to access. Security threats are either passive or active attacks. Active attacks involve altering data streams and passive attacks, on the other hand, include snooping on transmission. The most important security features are authentication, authorization, confidentiality, integrity and denial of service. The corresponding software is included in the network.

WLAN security is built-up around 802.11i/WPA (Wi-Fi, 2003) or VPN/IPSec. In Bluetooth, there are three security modes handled by the security manager (Grahn, Pulkkis, & Guillard, 2002). A bonding process including pairing and authentication, and encryption based on the SAFER+ algorithm are implemented. Also, a concept of trusted devices is applied.

The security features in a GSM network can be divided into three subparts, subscriber identity authentication, user and signaling data confidentiality, and subscriber identity confidentiality. In 3G systems, security is based on what was implemented in GSM. The encryption algorithm is stronger, the application of authentication algorithms is stricter and subscriber confidentiality is tighter. The security principles are all incorporated into the Authentication and Key Agreement (AKA) procedure (Grahn et al., 2002).

SECURITY ADMINISTRATION SOFTWARE

Security administration uses intrusion detection software, vulnerability checking software, and software for security software management.

An Intrusion Detection System (IDS) monitors traffic in a network and/or user behavior in a host computer to identify possible intruders and/or anomalous behavior and/or misuse (Stallings, 2000, Chap. 9).

Major vulnerabilities are too short, easily guessed or cracked passwords. A potential intruder could run a password cracker on the encrypted passwords stored in a network. System administrators can use cracking to disable usage of bad passwords.

Intrusion prevention requires regular scans for unnecessary open ports and other vulnerabilities like missing security patches.

Network security software in host computers and in other network nodes like routers is often software managed. Management software examples are:

- F-Secure® Policy Manager™for management of “not only antivirus solutions, but all critical network security solutions on all tiers of the network” (F-Secure, 2003).
- Symantec™Gateway Security 5400 Series with firewall, antivirus protection, intrusion prevention/detection, and vulnerability check features managed from a centralized console (Symantec™, 2003).

SECURITY SOFTWARE DEVELOPMENT

Antivirus protection programming skills require knowledge about self-modifying programs/scripts and of virus sensitive operating system features.

Firewall software programming skills are based on detailed knowledge of TCP/IP protocol stack implementation software.

The open source toolkit OpenSSL is available for TLS/SSL application design (The OpenSSL Project, 2003). OpenSSL is installed as a C function library. Also, commercial development tools are available (Certicom, 2003; RSA BSAFE, 2003).

S/MIME e-mail extensions can with special toolkits be added to existing network software and be embedded in network software being developed. Freeware S/MIME v3 toolkits are (S/MIME Freeware Library, 2003) and the Mozilla S/MIME Toolkit. Phaos S/MIME Toolkit is a Java package (Phaos S/MIME, 2003) for secure messaging in Java applications.

IPSec software development is usually VPN software development. IPSec can be integrated in the networking software and/or hardware of a router/a computer node. Commercial IPSec developer toolkits such as SSH QuickSec™and SSH IPSEC Express™are available (SSH Communications Security, 2003).

Toolkits for SSH protocol integration during network software design are also available (SSH Communications Security, 2003).

In smartcard application development usually some development kit is used. Microsoft offers a Smartcard Toolkit to be used together with visual programming tools.

RSAEuro is an open source cryptographic toolkit providing C functions for the use of digital signatures, data encryption and for creating cryptographically safe random numbers. RSAEuro can be downloaded from public FTP servers in European university networks.

DESIGN OF SECURE SOFTWARE

Network security software implements security features. Other network software implements functionality and other features like usability, efficiency, simplicity, safety, dependability, reliability, and so forth. Security requirements for any network software include:

- absence of vulnerabilities and security holes; and
- secure interfaces.

Security should be integrated in the network software life cycle starting from the specifications. The need to assess vulnerability and to react on security incidents should be proactively minimized before network software is used. A recent handbook for secure software design is available (Viega & McGraw, 2002).

FUTURE TRENDS

IPSec is a mandatory part of the new version of the IP protocol, IPv6 (IP version 6 Working Group, 2004). Thus IPSec is automatically included in the IP software in all nodes in future TCP/IP networks. Also DNSSEC and secure routing protocols will be included in the system software of future TCP/IP networks.

New wireless network protocols emerging are among others Wireless USB (WUSB) (Kolic, 2004) and ZigBee™ (2004). WUSB will offer the same functionality as standard wired USB devices. ZigBee is a low-power, short-range, wireless technology. Both technologies will be used in networking solutions for home/industrial automation.

Wi-Fi Protected Access version 2 (WPA2) includes full 802.11i support in a WLAN (WPA Specification Documentation, 2003). WPA2 will replace RC4 with AES. It will also include the CCM protocol. The new standard implementation is hardware accelerated and will require replacement of most access points and some NIC's (Network Interface Cards).

Session key agreements in future wired network, will be based on absolutely secure quantum cryptography protocols (Bennett & Brassard, 1984), which are physically implemented by transmission of randomly polarized laser pulses in optical fibers (Stucki, Gisin, Guinnard, Ribordy, & Zbinden, 2002). Absolutely secure means that verified reception of a session key is also a proof that the same key has not been eavesdropped. Commercial Quantum key distribution technology is already available (Quantum Key Distribution, 2004).

CONCLUSION

Software solutions and tools are network security cornerstones. Today, network security software is a large and complex rapidly expanding area. Network security software skills are a needed by every computer and computer network user. This has profound implications on all education, since use of computer networks is inevitable.

Education for professional network security software skills should include:

- installation, configuration, and test use of all categories of available network security software solutions and products,
- source code inspection exercises of open source network security software solutions,
- programming exercises and projects with TLS/SSL application development environments and cryptographic toolkits.

Network security software development skills are important in upper level network security education.

KEY TERMS

E-Mail Protocols: Simple mail transport protocol (SMTP) is a set of commands for transport of ASCII encoded e-mail messages. Post office protocol (POP3) retrieves new messages from a mailbox to a remote e-mail client. A remote e-mail client can simultaneously access several mailboxes on different mail servers with the Internet message access protocol (IMAP).

Internet Engineering Task Force (IETF): An open international community engaged in Internet architecture evolution (IETF, 2003). Working Groups in several topical areas develop technical drafts and Internet standards.

Internet Protocol Security (IPSec): Developed by an IETF Security Area Working Group. IPSec introduces a new TCP/IP protocol stack layer below IP. IPSec adds authentication and optionally encryption to transmitted data packets. Authentication ensures that packets are from the right sender and have not been altered. Encryption prevents unauthorized reading of packet contents.

Pretty Good Privacy (PGP): An e-mail extension used to encrypt/decrypt and cryptographically sign e-mail as well as to verify e-mail signatures. Verification of a signature is a proof of sender identity and message authenticity.

Secure Multipurpose Internet Mail Extensions (S/MIME): A secure e-mail standard based on MIME. S/MIME, being further developed by an IETF Security Area Working Group, accomplishes privacy and authentication by using encryption/decryption, digital signatures and X.509 certificates

Simple Network Management Protocol (SNMP): An application layer TCP/IP protocol for management information exchange between network devices. SNMP includes two main software entity types: managers and agents.

Virus: Malicious code added to an executable file loaded to a computer and executed without the user's knowledge and consent. Computer viruses often copy and spread themselves to other computers in the same network.

X.509 and PKI: A X.509 certificate is a standardized data structure for proving the ownership of a public cryptographic key with a cryptographic signature of a trusted third party, a certification authority (CA). A public key infrastructure (PKI) is hardware, software, people, policies and procedures needed to issue, manage, store, distribute and revoke X.509 certificates.

Curriculum Development in Web-Based Education

Johanna Lammintakanen
University of Kuopio, Finland

Sari Rissanen
University of Kuopio, Finland

INTRODUCTION

A paradigm shift has taken place in the last decade, with a move from traditional to Web-based education at different educational levels (Harasim, 2000; Karuppan, 2001; Kilby, 2001). Web-based education (WBE) has moved on from the delivery of educational content to Web-based sites with interactive functions (Carty & Philip, 2001). Concurrently, new innovative kinds of pedagogical experiments have shifted the paradigm from teaching to learning (Pahl, 2003). As summarised by Armstrong (2001), what educators have in fact realised is that a good Web-based education theory and good education theory are one and the same; the only difference is that WBE transcends the barriers of space and time. The paradigmatic shift has occurred as part of planned educational policy, while at the same time good international or national experiences have also supported the growth of WBE. In addition, there have been attempts to have more coherent and cohesive educational systems and degrees especially in the European context (The Bologna Declaration, 1999.)

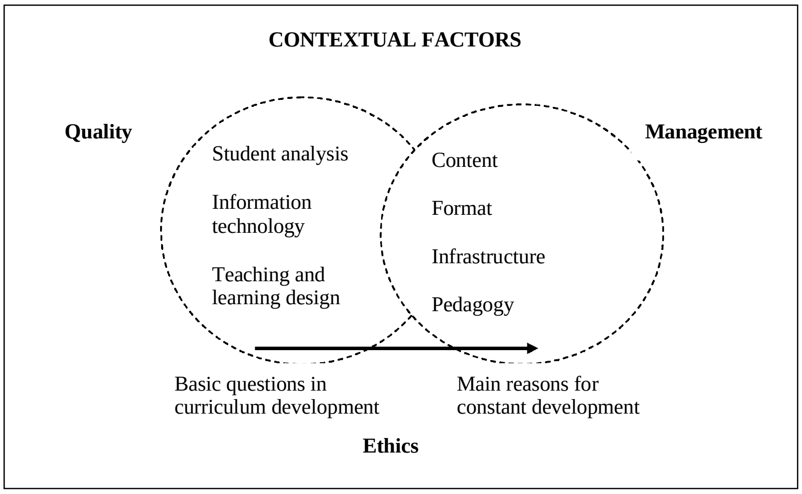
The aim of this article is to pursue the discussion of some essential issues and promoting factors facing Web-based curriculum development (Figure 1). At the beginning, the main concerns in curriculum development are quite often related to students, new technology and pedagogical issues. However, the curriculum development is a process due to constantly evolving information technology and changes in course contents. The second part of this article focuses on this. Additionally, curriculum development does not happen in a vacuum. Therefore, quality, ethics and management are briefly summarized as important contextual concerns in WBE curriculum development.

BACKGROUND

Curriculum Development in Web-Based Education

Basic questions at the first phase of the WBE curriculum development have been summarized in this review into

Figure 1. Curriculum development as a continuous process



three overall themes: 1) student analysis; 2) information technology; and 3) teaching and learning design (adapted from Alexander, 2001).

Student Analysis

One crucial component in curriculum development is the identification of potential users, and analysis of their needs (Karuppan, 2001; Lammintakanen & Rissanen, 2003). Variables such as age, gender, being employed or unemployed are premised as having an effect on computer use (Karuppan, 2001; compare to Lu, Yu, & Liu, 2003). Furthermore, learning materials should support the student's particular learning style in order to facilitate learning (Karuppan, 2001). At best, Web-based education encourages the student to take control over his or her own learning. In turn, curriculum development should support this by promoting a completely new way of thinking in students: from what they hope to acquire from the course to what they themselves contribute to the creation of knowledge (McFadzean & McKenzie, 2001).

Although Web-based learning is said to be a flexible way of learning in terms of availability (anywhere and anytime), it is crucial to take into consideration the place from where the students participate, for example, the home or work place, and also the kind of skills that they have.

The following reasons have been recognized as major obstacles in students' use of information and communication technology (ICT): 1) a lack of student workstations; 2) students' lack of time; 3) students' ICT skills; 4) course overlap; 5) insufficient course hours; and 6) teachers' lack of time (Sinko & Lehtinen, 1999). Careful consideration of these aspects provides an idea of what kinds of learner support systems are needed from the educational institution (e.g., tutoring, technical support; Lammintakanen & Rissanen, 2003). In sum, support from the educational organization and other students, as well as the individual's experience of technology have a major influence on the student's learning experiences (Alexander, 2001).

Information Technology

Similarly, fundamental questions exist concerning the technology used in education. One of the problems concerns the interaction between the equipment used, for example, is technology available to students, and is it accessible especially if interactive text, video and voice are combined? What does the technology cost learner? This is something that should especially be taken into consideration in those countries where tuition fees are not implemented (e.g., Lammintakanen & Rissanen, 2003). Web-based education is supposed to be cost-effective from the organizational side (e.g., Karuppan, 2001), although hardware, software and labour costs are somewhat expensive. Similarly, it would be imperative that the equipment be available for both the students and educators "just on time" because of the rapid development of information technology (IT).

Teaching and Learning Design

Although the choices made during the planning process determine whether the Web-based education is based on constructivism or other learning theories, constructivism is usually closely related to WBE (Jefferies & Hussain, 1998). Web-based education is believed to promote a constructivist approach by allowing all-round interaction, transferring the responsibility of learning to the student, and enhancing the construction of knowledge by interaction. During the curriculum development stage, a careful evaluation is needed on whether or not the chosen technology supports teaching strategies that encourage active involvement, critical thinking, and fosters relationships between learners (Armstrong, 2001). It has, however, been shown that although teachers have adopted the model of constructivist epistemology in principle, they have not always implemented it in the ways they organize the learning situations (Sinko & Lehtinen, 1999).

The changing roles of teachers are obvious in WBE. Previous research has shown that the role of the teacher is not diminished, however, traditional teacher duties, such as instructing the learners and information communication, are. The teacher's new role can be described as a learning catalyst and knowledge navigator, or as tutor acting as a facilitator for learning and group processes (see Volery & Lord, 2000). Moreover, the tutor's duty is to maintain a safe environment for learning, and encourage novel problem solving processes (McFadzean & McKenzie, 2001). Web-based learning forces teachers to become course designers who make decisions based on their understanding of the probable needs, expectations and behaviors of students on their own campuses (Blythe, 2001).

To briefly summarize, previous studies have shown that the technology affects learning in many ways (e.g., McFadzean & McKenzie, 2001; Sinko & Lehtinen, 1999). Curriculum development is a time-intensive requiring adequate financial resources in order to develop tightly organised courses. In addition, it is to be expected that the faculty workload would increase (Armstrong, 2001; Carty & Philip, 2001). Unfortunately, too many WBE applications are still mere tutorials or online books (Kilby, 2001).

C

Table 1. The factors of change promoting curriculum development (Pahl, 2003)

Content	The course subject evolves Changes in content to improve the material
Format	Changes in • Staff • Student body (qualifications, numbers, mode of learning) • Timetable (where and when the course takes place) • Syllabus (the content and organization of the course) • Curriculum (level, extent, prerequisites) • Legal and/or financial environment
Infrastructure	Improvements in hardware technology Systems and language technology face constant minor changes Learning devices are developing
Pedagogy	Knowledge acquisition, modeling of and access to educational knowledge Active learning in terms of engaging the student through interactive systems Collaborative learning supportive systems Autonomous learning Evolving instructional design

Curriculum Development as a Constant Process

The focus of the Web-based education and especially curriculum development has taken a step forward during the last years. However, while a substantial body of research has focused on this new teaching medium, the results have been mixed and with no significant improvement over traditional methods. Additionally, there is a lack of systematic and scientific knowledge, especially with regard to the effects and outcomes of WBE (Karuppan, 2001; Lu et al., 2003; Reisman, Dear, & Edge, 2001). Still, the use of WBE has rapidly increased.

Previously, the challenges of curriculum development focused merely on the lack of skills and suitable equipment for WBE. Often flexibility and maintenance aspects have been neglected in the design and development of new technologies. In fact, while in previous stages, the main concerns were in the planning processes (i.e., how to begin with WBE); nowadays, important questions are how to update the curriculum and develop it further. The curriculum development can be based on students' evaluations, experiences of others as well as previous studies (e.g., Lammintakanen & Rissanen, 2003). But, there exits also factors that "force" us to develop the curriculum. For example, Pahl (2003) has summarized both internal and external reasons why the curriculum needs to be constantly evolved (Table 1). The evolvement of the design of a Web-based course can be due to four dimensions: content, format, infrastructure, and pedagogy.

FUTURE TRENDS

The Context of Curriculum Development

In previous sections, the WBE curriculum development has been described from the pragmatic perspective. However, some existing and concurrently future challenges that have not been mentioned yet have become more important during the curriculum development process. These themes have been summarized into three interrelated categories: 1) ethical and legal issues; 2) quality assurance and accreditation; and 3) managerial and organizational issues. The challenges arose partly from the literature, and partly from practical experiences (e.g., Alexander, 2001; Kilby, 2001; Roffe, 2002), and concern both national and international curriculum development, since a more global perspective in design and courseware provision is expected (Kilby, 2001; see e.g., MIT Open Courseware, Potts, 2003).

Ethical and Legal Issues

Web-based education provides good opportunities to make use of the many information sources available via the Internet (Jefferies & Hussain, 1998). The problem is, however, the quality of knowledge: how to select appropriate information from among the mass, and how to avoid the use of misinformation (Calvert, 1999). At its worst, the Internet is a tool towards fabrication, falsification and plagiarism, which leads to copyright considerations. In addition, from the ethical perspective, students' privacy and confidentiality, and their respectful and dignified treatment on the Web-based environment are imperative (Armstrong, 2001).

Quality Assurance and Accreditation

Quality is a crucial concern in WBE: there are no common quality standards for course design, delivery and evaluation, nor is there is an accreditation system. Some institutions and countries (e.g., the UK) have developed quality assurance protocols that demonstrate that the online programmes are of equal quality to those delivered by traditional methods (Roffe, 2002). From the students' point of view, the important question is how the courses can be accepted as part of the curriculum; how different educational institutes recognise the courses offered from other institutions nationally and internationally.

One quality issue concerns the lack of information bases (portals, registers), which include information on Web-based courses, learning materials or tools for learning that are available on the Internet. In terms of curriculum development, this kind of meta-knowledge would be very useful, and could potentially even reduce the teacher's workload. But, teachers are not very keen to share material, which they themselves have made, and experiences with colleagues across the educational institutions. However, MIT Open Courseware is an exception, and it is open and available all over the world. MIT offers a standardized process for course modelling and encourages extending collaboration and interdisciplinary teaching (Potts, 2003). Registers would also provide students with the information on the available Web-based courses.

Managerial and Organizational Issues

The tradition of individualism in teaching is still part of the organizational culture at different educational institutions. At best, the organizational culture can support both Web-based curriculum development and joint teaching. The allocation of both human and technical resources, and a clear strategic decision from managers are requirements for faculty development, and the incorporation of WBE into the curriculum (Carty & Philip, 2001). As well as time and resources, it is essential that the organization and its managers have a positive attitude to WBE, and that they promote its implementation (e.g., Alexander, 2001). However, the managerial approach to lead teaching and curriculum development work is not yet visible in different educational organizations.

CONCLUSION

In conclusion, there is no consistent paradigm for WBE, rather there are multiple ways of making use of the Web in education, and these will vary depending on the subject being taught and the needs of the learner. Curriculum development requires a great deal of effort from different stakeholders, and therefore, motivation and commitment for long-term WBE development strategies are also needed at organisational level. In addition, Web-based education appears to support cultural cohesion and more rapid information transformation. Standardization and registers are an essential part of future steps towards the improved utilization of WBE requiring international cooperation (see ISO/IEC, which has developed standards for information technology for learning, education and training, http://jtsc36.org).

KEY TERMS

Asynchronous Mode: A non-real-time education where students and teachers interact with each other but no at same time, e.g., by using bulletin board or email.

Computer and Information Literacy: The abilities to perform computer operations at a skill level high enough to meet the demands of the society, and to use the tool of automation in the process of accessing, evaluating and utilizing information (Carty & Philip, 2001).

Learning Style: The way in which individuals acquire and use information, strategies to process information in learning, and problem solving situations (Karuppan, 2001).

Learning Tools: Included in web-based learning environments for managing the course and are geared to facilitating student learning in the environment.

Portal: Acts as a channel between the content creator and end user. It does not typically have a content of its own.

Synchronous Mode: Real-time education where students and teachers can have a dialogue simultaneously, e.g., by using chat.

Web-Based Education (WBE): Differs from traditional classroom teaching in two essential elements: 1) physical distance and 2) time, allowing more flexibility to the learner. The most basic form of WBE is to deliver syllabi, lecture notes, reading materials and assignments via the Internet. The more advanced level includes computer conference facilities, a help desk, linkage of conferencing and web page assignment, testing and course management tools and evaluation (Karuppan, 2001).

Web-Based Learning Environment: A specially developed programme using Internet technology for the design and development of teaching and learning purposes. Trademarks are, for example, WebCT, WebBoard, Top Class, Virtual – U.

Web-Based Misinformation: Used to describe information found in the Internet that does not fit normative patterns of "truth", i.e., it is incomplete, out-of-date, confused, or low consensus "knowledge" (Calvert, 1999).

Data Collection Methodologies for Web-Based Experiments

Stu Westin
University of Rhode Island, USA

INTRODUCTION

Experimental studies involving the use of the World Wide Web (WWW) are becoming increasingly common in disciplines such as management information systems (MIS), marketing, and e-commerce. The focus of these studies is varied and may involve issues of human factors and interface design (Otto et al., 2000; Koufaris, 2002; Liang & Lai, 2002; Palmer, 2002), issues of information processing and search strategies (Spence, 1999; Johnson et al., 2000; Xia & Sudharshan, 2000; Chiang et al., 2004), issues of vendor trustworthiness (Grazioli & Jarvenpaa, 2000; Jarvenpaa et al., 2000; Norberg, 2003), or a myriad of other topics. Regardless of the issue being studied, data collection for online Web research often proves to be a vexing problem, and ideal research designs are frequently sacrificed in the interest of finding a reasonable data capture mechanism. In this article, we discuss some of the methodological complexities that arise when conducting Web-based experiments. We then describe an innovative, software-based methodology that addresses these problems.

BACKGROUND

Despite the difficulties involved, the research community has recognized the importance of Web-based experimental research (Saeed et al., 2003; Gao, 2003).

Server-side data collection approaches based on active server page (ASP) scripts or the like can prove useful in some circumstances. Consider, for example, the situation where one wants to investigate the impact of download time. This has been studied, for example, as a factor affecting user satisfaction (Otto et al., 2000), and Web site success (Palmer, 2002). Using ASP scripts, a delay mechanism can be easily built into a Web page so that the server will delay serving the requested page to the client until some precise, predetermined time has passed. Different experimental treatment levels are accomplished by merely manipulating the delay time that is scripted into the Web page. Here, the experimental subject, using an ordinary browser, will have the perception that the page is slow to download because of the delay between when the page is requested (e.g., by clicking a hyperlink) and when the page is available in the browser.

As another scenario, consider the situation where the researcher wants to study the end user's Web search strategy (e.g., Jansen et al., 2000; Johnson et al., 2000; Chiang et al., 2004) by considering which pages are accessed, along with the sequence of page access. In this case, we can analyze the so-called *click-stream data*. The research community has, in fact, called on investigators to exploit "non-intrusive means of collecting usage and exploration data through click streams" (Gao, 2003, p. 31) in future Web studies. Here again, ASP scripts in the Web pages can provide a simple data collection mechanism by logging each page request (page ID, server time stamp) in a server database. In both of the above research scenarios, standard Web browser software such as Internet Explorer (IE) can be used in the experiment.

In considering these research situations, it is obvious that client-side data collection mechanisms can be constructed just as easily. In both cases, Java applets, Java scripts, or VB scripts can be embedded into the HTML pages to handle the required tasks, and, again, standard browser software can be used. The only difference in this client-side approach is that the data collection is being handled by the client rather than by the server machine. Neither approach provides any obvious benefits over the other, although in the client-side approach, the Web pages could be stored locally, and thus WWW, or even network access, is not required.

One flaw in all of these research scenarios lies in the fact that experimental access must be restricted to a limited set of Web pages that have been appropriately scripted for data collection. If the experimental subject is allowed to "wander" beyond this limited set of pages (an activity that is fundamental to the nature of the Web), then these actions will not be recorded, and the validity of the experiment will be nullified; there will simply be no data collection scripts to execute. Related to this is the fact that all Web pages used in the experiment must be developed and maintained by the investigator—a task that can be labor intensive if a large number of pages are to be made available. Obviously, the experimental pages should be large in number and professional in appearance if external validity is to be maintained.

In some situations, the research data can be collected without the use of client- or server-side scripting. Click-stream data, for example, can often be gleaned through the use of standard network management software, or through *network sniffers* that can be configured to monitor Internet requests and page downloads. In this case, the experimental treatment can involve pages other than those created specifically for the research study, and, again, standard browser software can be used for the experiment. The problem here can be in the precision or in the format of the data, as the software was not designed for this purpose. Pages containing multiple frames, for example, may be logged as individual (frame) downloads in some circumstances and as a single-page download in others. Client requests that are satisfied through the local cache may not be logged at all.

A problem with all of the data collection methodologies discussed thus far is that they suffer from a lack of experimental control. This lack of control comes from the fact that the instrument with which the experimental subject is interacting (a standard Web browser such as IE) was not designed to be used as a research tool.

Consider the situation in which we wish to study WWW use behavior through analyzing click-stream data. There are ways of gathering data on page requests or page downloads, as noted above. However, there is no means, short of direct visual observation, of recording how a particular page was requested. The page request could have come in the form of a click on a hyperlink, but the request could just as likely have been generated automatically through a dynamic action on the page (e.g., *meta refresh*), or through the *Back* or *Forward* buttons in the browser interface. Normal click-stream data will not distinguish between these circumstances, so the precise behavior or intentions of the experimental subject cannot be determined.

Another problem has to do with the occurrence of multiple windows. Many Web sites open hyperlinks in new browser windows. The problem here is that the data collected cannot reflect which of the open windows is active when actions occur, or even that there are multiple windows in use. Again, the data cannot capture or misrepresents the behavior in question; true *streams* cannot be traced.

A CLIENT-SIDE SOLUTION

As noted earlier, the methodological problems, for the most part, stem from a lack of experimental control. Logic and research experience suggest that, for maximum experimental control, the experimental manipulations (treatments) and the data collection mechanisms should be as close to the experimental subject as possible. That is, they should be embedded in the browser. This leads to the development of a custom IE-lookalike browser for use in Web-based experiments. The creation of such a software application is feasible with currently available programming tools and software techniques. The numerous benefits of this approach certainly outweigh the software development costs. The benefits are greatest when research designs are complex and when precision is of prime importance. This particular methodology has been employed in several research studies, including Norberg (2003) and Chiang et al. (2004).

With custom browser software, there is no need to depend on scripts or applets in experiment-specific Web pages to administer experimental treatments or to record user actions. Consequently, there is no need to restrict the experimental domain to a limited set of custom Web pages. With this approach, the experimental domain can include the entire Web. The custom software can be built with the ability to precisely record user activity and to preempt or modify actions that could be harmful or inappropriate in the experimental context. Experimental control and experimental manipulation can be integrated into the browser.

The software that we know as Internet Explorer is essentially a software interface surrounding a set of dynamic link libraries (DLLs) that provide the requisite Internet processing functionality. Microsoft, in its *Visual Studio* suite of software development products, provides a software object called the *WebBrowser Control* (see Microsoft Corporation, 2004a). This control can be used in Visual Basic (VB) or in C++ applications to add Web browsing functionality to software applications. The *WebBrowser Control* can be thought of as an object wrapper around the Internet-processing DLLs noted above. The *WebBrowser* object works with the standard event-based model of Windows computing.

With the *WebBrowser* control, event handlers are provided for all of the major occurrences in an Internet session, such as *request to navigate to a page*, *page download complete*, or *request for a new window*. Key data such as URL, Target Frame, and Page Title are available with the events. In some cases, actions can be preempted through a *Cancel* argument in the event handler. One important example of this is the *BeforeNavigate* event handler. This routine is triggered after a navigation has been requested by the client, but before the request is fulfilled. This allows the custom software to inspect and evaluate the situation and to possibly modify or cancel the request before it is allowed to proceed.

Properties and methods of the *WebBrowser* object can be used to dynamically emulate all of the features of the IE interface, such as the status bar, the browser window caption, and the standard buttons (Back, Forward, Stop,

Table 1. Sample Web browser members

Event/Method	Behavior/Details	Possible Use
BeforeNavigate2 event	Triggered after page request, but before navigation begins; provides target URL and frame information; allows cancellation of navigation	Can analyze URL request and covertly cancel or redirect inappropriate requests; software can contain a list of irrelevant URLs or heuristic rules (e.g., requests containing forbidden protocols or Web domains can be halted) (e.g., no returns to prior pages)
Navigate2 method	Forces browser to navigate to a new location (URL)	Can be used to covertly modify target for (cancelled) navigation request; can be used to covertly effect programmatic delay between user's request and download activity
DocumentComplete event	Triggered when a page has been successfully downloaded and is available for browsing; provides full URL details	Can be used to capture click-stream data (record URL); can be used to time stamp click-stream data and to determine and record page-viewing time
GoForward/*GoBack* methods	Forces navigation to subsequent (or previous) page in system-maintained URL history list	Can emulate full behavior of IE Forward (and Back) buttons, but this behavior can be modified if needed; note that button action can be included in click-stream data record

Refresh, Home, etc.). In short, an emulation of IE can be built with the inclusion of as few or as many features of the IE interface as are needed in the experimental context.

Table 1 describes selected events and methods of the *WebBrowser* object that are pertinent to this discussion. See Microsoft Corporation (2004b) for a full list and description of the members of this object.

Table 2 provides a sample structure of click-stream data that has been generated with this methodology. This represents one of several system-generated data tables analyzed in Chiang et al. (2004). This data table holds one record per subject per URL visited (i.e., one item in a stream). Fields 1 and 2 were generated automatically by the software and provide primary and secondary sort fields for click-stream analysis. Field 3 provides data for frame-based pages and is derived from the *BeforeNavigate2* event. Field 4 (captured in *BeforeNavigate2* event) records the time at which a page was initially requested (e.g., user click). Field 5 records the duration for which the page was available to the user (*DocumentComplete* event for current page → *BeforeNavigate2* event for next page). Field 6 indicates how this page was requested ("Automatic" indicates a redirect, as by a script action or a meta refresh). Field 7 was captured by the *DocumentComplete* event handler. By writing the data record within the *DocumentComplete* event routine, unsuccessful or aborted downloads were culled from the stream. Sequence gaps in Field 2 indicate such.

In this particular study, randomized assignment of subjects to treatment cells, as well as experimental session duration were managed completely by the software application. (After a fixed duration, the browser was programmatically disabled, and the user was shown a "thank you" page.). A second data table holding Subject_ID and experimental treatment information was later merged with the above table for analysis.

Table 2. Data record structure

	Field	Details
1	Subject_ID	Auto generated by application
2	URL_Sequence#	Auto generated by application
3	Target_Frame	If any
4	URL_Start_Time	Since session began (sec./1000)
5	URL_Duration	Sec./1000
6	User_Action	Click, Back-Button, Forward-Button, Home-Button, Automatic
7	Full_URL	Can be parsed if needed

CONCLUSION

By developing software to host a custom browser research instrument, the investigator is free to include (covertly) all of the requisite mechanisms of experimental control and data capture into the software; no external scripting or network monitoring is needed. Timers to control the duration of the experiment or the occurrence of experimental treatments can be embedded into the application. Experimental treatment randomization can also be built in. User activity down to the keystroke or mouse-click level can be monitored and recorded with millisecond accuracy if needed. Certain events can also be blocked or modified, if necessary. For example, an attempt to open a page in a new window can be intercepted and the page redirected to the initial window. No special (i.e., scripted) Web pages are needed, but attempts to "wander" to irrelevant sites or inapposite protocols (e.g., *mailto*, *ftp*) can easily be halted if desired. The cache can be controlled programmatically through calls to the Windows API. Once the basic system is developed, modifications and new features are fairly simple to put into effect.

The above discussion and summary tables touch on the basic advantages and capabilities of this custom software approach. Many of the complexities, such as the need to develop a custom, preemptive keyboard handler for the browser, are ignored here. Also beyond the scope of this discussion are many of the advanced capabilities, such as how to gain access to an additional rich source of experimental data through use of the document object model (DOM). A more thorough presentation can be found in Westin (2003).

KEY TERMS

ASP (Active Server Page) Scripting: A simple server-side scripting approach where script code (usually VBScript or Jscript) is mixed with HTML code on a Web page. The script code is processed by a script engine before the page is rendered by the server. This can be used to create dynamic Web pages and to share data within or between Web sessions. This is a predecessor of ASP.NET technology.

Click-Stream: In Web research, the click-stream is the sequence of Web pages that is visited by the experimental subject. A click-stream data record can be as simple as URL and sequence number, or a time stamp can be added. This latter approach allows for analysis of page viewing time.

Client-Side/Server-Side Scripting: In a Web environment, this term relates to the fact that scripted tasks can be handled by the browser software (client side) or by the Web server software (server side). A single Web page may contain both client-side and server-side scripts. The script host is determined by the *RUNAT* attribute of the *SCRIPT* tag.

Event Handler: A procedure (subroutine) that executes in response to an event. The event may represent a specific user action (e.g., a mouse click) or may be a manifestation of a system process (e.g., page has finished loading). Details surrounding the event are provided as arguments of the procedure.

Meta Refresh: A special HTML tag that redirects the visitor to a new page. The result is that the final destination of the navigation is different from the initial target.

Method: In object-oriented programming, methods are the actions or behaviors that an object can perform. At the coding level, a method is created by including a procedure (function or sub) within the class.

Network Sniffer: A hardware or software mechanism that monitors, and possibly records, data traffic on a network.

Object Wrapping: Adding code to convert an existing set of software procedures into an object class. The procedures can then be used as methods in an object-oriented software environment.

Data Communications and E-Learning

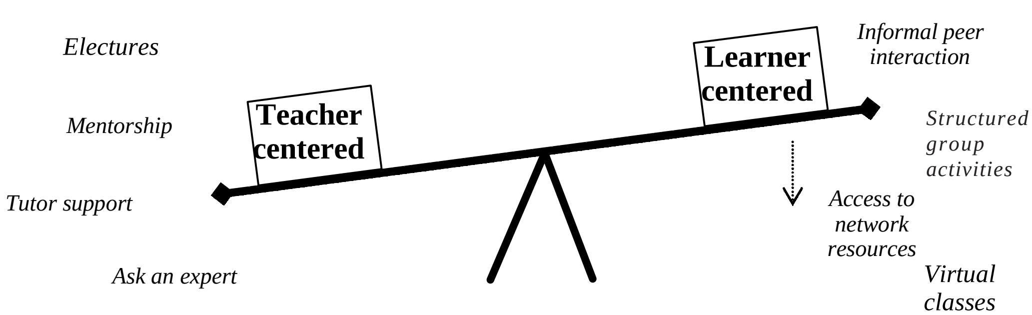
INTRODUCTION

Information and communications technology (ICT) has increasingly influenced higher education. Computer-based packages and other learning objects provide a useful supplement to students studying conventionally by illustrating aspects of the curriculum. Other packages are directed at aspects of course administration such as automated assessment (for example, see Randolph et al. (2002)). Initially such software and materials played only a supplementary role in course offerings, but this has changed rapidly. For example, Coleman et al. (1998) describe a successful early attempt to replace all lecturing with computer-aided learning. Remote delivery of courses also became a viable option because of the advent of the WWW. For example, Petre and Price (1997) report on their experiences conducting electronic tutorials for computing courses. Online education of various sorts is now routinely available to vast numbers of students (Alexander, 2001; Chen & Dwyer, 2003; Peffers & Bloom, 1999). Various terms have been used to label or describe forms of education supported by information technology. These include e-learning (e.g., Alexander, 2001; Campbell, 2004), Web-based learning (e.g. Huerta, Ryan & Igbaria, 2003; Khosrow-Pour, 2002), online learning (e.g., Simon, Brooks & Wilkes, 2003), distributed learning and technology-mediated learning (e.g., Alavi & Leidner, 2001); with e-learning probably the most commonly used term used to describe education and training that networks such as the Internet support.

E-learning has become of increasing importance for various reasons. These include the rise of the information and global economy and the emergence of a consumer culture. Students demand a flexible structure so that they can study, work and participate in family life at the same time (Campbell, 2004). This flexibility is reflected in alternative delivery methods that include online learning and Internet use. We have also become more sensitive to cultural and gender differences, and to the learning needs of the challenged. These needs may be addressed by e-learning (Campbell, 2004).

A number of studies have compared student learning and satisfaction between e-learning and traditional classroom teaching. In an early study, Hiltz and Wellman (1997) found that mastery of course material was equal or superior to that in the traditional classroom and that e-learning students were more satisfied with their learning on a number of dimensions. In particular, they found that the more students perceived that collaborative learning was taking place, the more likely they were to rate their learning outcomes as superior to those achieved in the traditional classroom. They did however identify some disadvantages to e-learning. These included ease of procrastination and information overload. More recently, Piccoli,

Figure 1. Categories of online activities



Ahmad and Ives (2001) found that the academic performance of students in the two environments was similar, but that while e-learning students had higher levels of self-efficacy, they were less satisfied with the learning process. Alexander's comment that "the use of information technology does not of itself improve learning" (Alexander, 2001, p. 241) perhaps highlights the fact that e-learning can be many things and that the intention to introduce e-learning is no guarantee of success.

The different types of teaching and learning activities that are made possible by the Internet are shown in Figure 1. Harasim and Hiltz (1995) divided these activities into two categories: learner or teacher centered. There is, however, no common agreement about which category is the best and many researchers argue for a mixture of learning activities, emphasizing group learning (Bento & Schuster, 2003; Klobas & Renzi, 2003). At the moment there still seems to be an overemphasis on teacher centered approaches, which hopefully will slowly change as a better knowledge of e-learning develops.

BACKGROUND

This article provides an illustration of blended e-learning by describing how we deliver and manage courses in a postgraduate degree in telecommunications management. We aim to foster learner centered education while providing sufficient teacher centered activities to counter some of the known concerns with entirely learner centered education. We use the Internet as the communication infrastructure to deliver teaching material globally and Lotus LearningSpace to provide the learning environment. While the primary aim of our approach is to enhance the student learning process, there are also other incentives that are consistent with this. The university is able to attract a more diverse range of students – those requiring flexibility of study and the other benefits of e-learning. Thus initiatives of this type can benefit the university while meeting the additional needs of students that are discussed in the introduction.

The use of learning and content management systems (LCMS) such as Blackboard, WebCT and Lotus LearningSpace have made e-course development less onerous for faculty. These systems provide a set of tools for publishing, communicating, and tracking student activity. Various guidelines have been suggested for evaluating and choosing software for e-learning (Klobas & Renzi, 2000). After establishing our requirements for a software tool for developing and delivering courses online, we evaluated various alternatives. The requirements that we identified included:

- Instructors should not have to program and debug HTML code;
- All courses should have the same professional look and feel without having to hire computer programmers to write special software, and students should always be presented with the same interface for all their courses;
- The software should be fully integrated (one software package should allow the instructor to do everything required, such as course development and course management);
- Professional support.

After evaluating various alternatives we choose Lotus LearningSpace (LS). Successful use of LS by instructors proved to be significantly less dependent on the technical knowledge of the instructor than was the case with some other popular LCMS. It allows the instructor to focus on the learning of the students rather than on creating and debugging HTML.

LS provides instant feedback to the students and instructor, and enables progress and problems that students encounter as they go through the curriculum to be monitored. Students also have a discussion area where they can ask questions and communicate with the instructor as well as with other students.

LS allows us to create distributed courses that students and instructors can access whether they are online or off-line. Students are able to download material for a course onto their machine so they can go through the curriculum without having to have a direct Internet connection. Using the offline access method makes it easier for students to learn wherever they are located and for instructors to develop and manage course material and reduce critical network bandwidth requirements. Features that facilitate flexible student centered learning include:

- Schedule - provides students with a structured approach to assignments, materials, and assessments. Through the schedule, students can link to everything required to complete their course.
- MediaCenter - allows immediate and searchable access to all materials for the course as the instructor makes them available.
- CourseRoom - provides a discussion group facility, which hosts collaborative interchange between student groups and/or students and instructors.
- Profiles - helps students and instructors get to know their classmates to form productive teams and to network outside the course.

Features that facilitate course management include LS Central for course management and the Assessment

Manager for setting up and tracking of students' progress in their courses.

USING LOTUS LEARNINGSPACE TO ENHANCE LEARNING OF DATA COMMUNICATIONS

Depending on course content and pedagogy the migration to e-learning can be more or less laborious. We have chosen one course in a telecommunication management degree to provide an example of how e-learning was implemented. Appropriately, this course is about networking technology.

The Data Communications Systems course provides an introduction to networking and networking devices focusing on Local Area Networks (LANs) and Wide Area Networks (WANs). Network design, Ethernet, ISDN, Frame Relay, and TCP/IP are introduced, including IP addressing and router protocols. There is a strong practical context that provides students with the opportunity to build, configure and problem solve in a multi-router network environment. This course also includes the first part of the Cisco Certified Network Associate (CCNA) curriculum. The Data Communications Systems course provides a good example of a difficult class to integrate with LS because of the external curriculum, which is contained on a separate Web server, and the external assessment requirement for students.

Students are required to log in to LS once they have selected the course. Students can access LS with a Lotus Notes Client or through a Web browser. The Lotus Notes Client allows students to work off-line by placing an image of what is on the LS server on their laptop or PC at home. This allows students to work while they travel and can reduce the amount of time they are required to be connected to the Internet. When they connect up to the Internet they can resynchronize their copy with the master copy located on a Lotus Notes Server; this flexibility is a major goal of e-learning. The students then use LS schedule to follow the schedule for the course (see Figure 2). Through the schedule, students can access the external curriculum, which resides on a separate Web server.

The course takes a blended learning approach with both face-to-face classes and online learning. This enables us to take advantage of the benefits of technology mediated learning, but does not risk losing the strengths of face-to-face teaching. Theory is presented to students in the form of online topics (Web-based), mini lectures, and laboratories. LS is used to integrate course material from a variety of sources, for example, the Cisco material that contributes to the CCNA. This kind of external mate-

Figure 2. Sample schedule screen

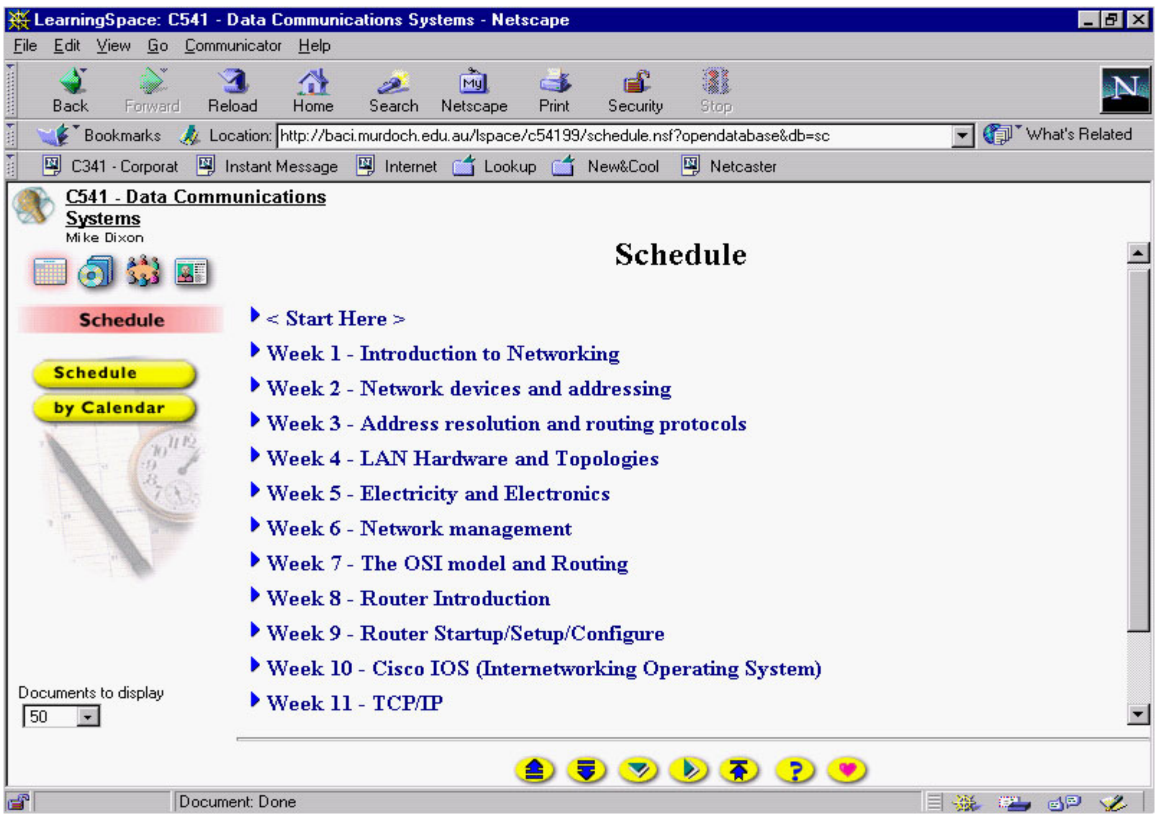


Figure 3. Sample course material screen

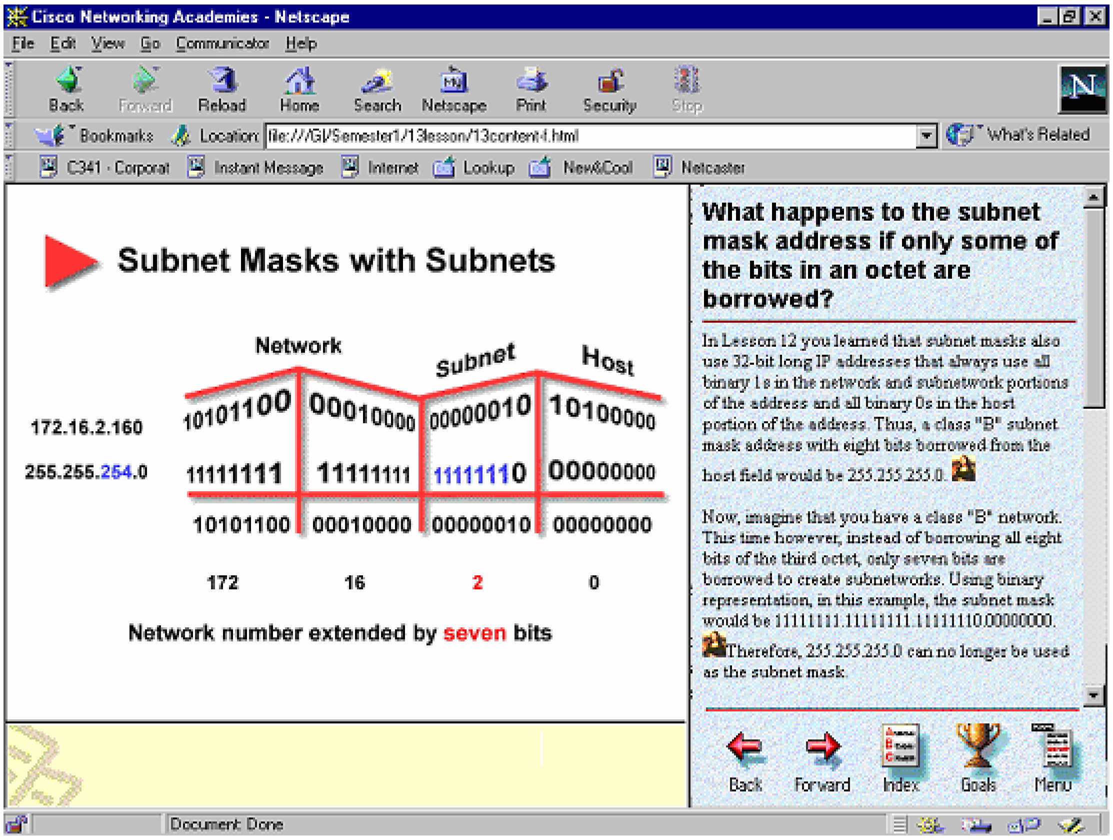

rial must be integrated seamlessly with local content so that students see a totally integrated system when it comes to the delivery of each course. The online teaching material combines Web based text and graphics to explain concepts (see Figure 3 for a sample screen). Short movies are also used to illustrate concepts that are difficult to communicate with just static text and graphics. The students are given aims and objectives at the start of each topic. The teaching material covers these topics in detail and at the end of each topic students have optional self-assessment quizzes that allow them to gauge their understanding of the material. The multiple modes of content delivery cater to different cognitive styles of students.

Instructors also use these online quizzes to measure the understanding of the students before they attend classes. The instructor is able to identify students who are not keeping up to date with their work and also areas that students are having problems with. The mini lectures can then focus on the areas where students are having problems. The instructor can also discuss problem areas in the discussion group. Assignments are submitted online, graded locally and returned with the instructor's personal comments and grade.

There are two Cisco online exams for the course and students are required to pass these exams with a minimum score of 80%. Students are allowed to take the exam more than once. All students must also take a separate supervised written final exam to meet University requirements. The online Cisco exams are done on separate assessment servers, as they are part of the certification process. The Cisco Networking Academy results of all the students around the world are maintained in a database in Arizona so that instructors can analyze how their class has answered questions and compare the results of their students with those of students in other institutions around the world. The final exams for each course are taken locally in a more traditional way.

The course also includes on-campus practical work to prepare students to solve real-world networking problems. Students work in groups during the practical lab sessions. Students are given timed individual and group practical exams at the end of each major component. Students are allowed to take these exams as many times as they like but are required to pass all these exams.

These factors all contribute to facilitating student learning. Faster and more frequent feedback on the material keeps students more in touch with their progress. Testing and checkpoints with built in repetition are important for long-term retention and understanding of the material. The facility to continue to work with the teaching material until an 80% pass is achieved enhances performance. Students see important material multiple times so that their learning is reinforced and students are able to study wherever they are and still be part of the student community. The use of a virtual discussion group enhances the sense of community among the students and teachers. Combining a learner centered approach with LS allows us to achieve a quality course online.

FUTURE TRENDS

E-learning will continue to play an increasing role in education and training. Greater broadband access will enable delivery of richer content and greater interactivity. Convergence of information technologies such as notebooks, phones and television and the development of pervasive computing will provide even greater flexibility to students. Educators and students are coming to understand that learning is lifelong and that technology is a valuable tool in supporting it.

CONCLUSION

E-learning is changing the face of university education. This article discussed an approach used to adopt a learner centered environment within an Internet based degree. As the course used to illustrate the issues in the article is about telecommunications, the Internet is a very appropriate medium for instruction. Students learn about telecommunications while accessing information through the Internet. Technology can provide flexibility of learning and hence enrich the learning experience and diversify the student mix.

KEY TERMS

Blended Learning: E-learning used in conjunction with other teaching and learning methods.

Cisco Certified Network Associate (CCNA): A data communications industry certification.

Distributed Learning: Using a wide range of information technologies to provide learning opportunities beyond the bounds of the traditional classroom.

E-Course: Another term for an online course.

E-Learning: The use of new multimedia technologies and the Internet to improve the quality of learning.

Learning and Content Management Systems (LCMS): These systems provide a set of tools for publishing, communicating, and tracking student activity.

Learning Objects: Small (relative to the size of an entire course) instructional components that can be reused in different learning contexts. Learning objects are generally considered to be digital materials deliverable over the Internet.

Online Learning: An inclusive term for any form of learning supported by computer based training.

Pervasive Computing: Technology that has moved beyond the personal computer to everyday devices with embedded technology and connectivity. The goal of pervasive computing is to create an environment where the connectivity of devices is embedded in such a way that the connectivity is unobtrusive and always available.

Technology-Mediated Learning: Learning where the learner's interactions with learning materials, other students and/or instructors are mediated through information technologies.

Web-Based Learning (WBL): Use of Internet technologies for delivering instruction.

Data Dissemination in Mobile Databases

INTRODUCTION

The development of wireless technology has led to *mobile computing*, a new era in data communication and processing (Barbara, 1999; Myers & Beigl, 2003). With this technology, people can now access information anytime and anywhere using a portable, wireless computer powered by battery (e.g., PDAs). These portable computers communicate with a central stationary server via a wireless channel. Mobile computing provides *database applications* with useful aspects of wireless technology known as mobile databases.

The main properties of mobile computing include mobility, severe power and storage restriction, frequency of disconnection that is much greater than a traditional network, bandwidth capacity, and asymmetric communications costs. Radio wireless transmission usually requires a greater amount of power as compared with the reception operation (Xu, Zheng, Zhu, & Lee, 2002). Moreover, the life expectancy of a battery (e.g., nickel-cadmium, lithium ion) was estimated to increase time of effective use by only another 15% (Paulson, 2003). Thus, efficient use of energy is definitely one of the main issues.

Data dissemination (can also be called *data broadcasting*) is one way to overcome these limitations. With this mechanism, a mobile client is able to retrieve information without wasting power to transmit a request to the server. Other characteristics of data dissemination include: scalability as it supports a large number of queries; query performance which is not affected by the number of users in a cell as well as the request rate; and effective to a high-degree of overlap in the user's request. In this article, the terms data dissemination and data broadcasting are used interchangeably.

The ultimate challenge in data dissemination is to minimize *the response time* and *tuning time* of retrieving database items. Response time is the total of elapsed time required for the data of interest to arrive in the channel and the download time, while tuning time is the amount of time that a client is required to listen to the channel, which is used to indicate its energy consumption. In some cases, the response time is equal to the tuning time.

This article describes a state-of-the art development in data dissemination strategies in mobile databases. Several strategies for improving the query performance by disseminating data to a population of mobile users will be explained.

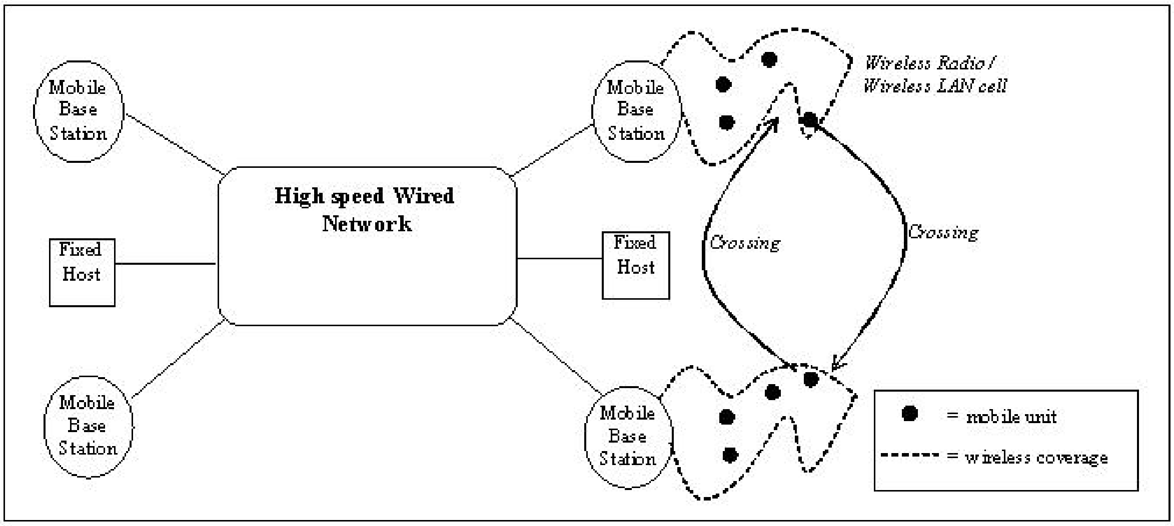
BACKGROUND

In general, each mobile user communicates with a mobile base station (MBS) to carry out any activities such as a transaction and information retrieval. MBS has a wireless interface to establish communication with the mobile client, and it serves a large number of mobile users in a specific region called a "cell". The number of mobile clients in a cell can be infinite. In mobile environment architecture, each MBS is connected to a fixed network as illustrated in Figure 1.

Mobile clients can move between cells while being active and this intercell movement is known as the handoff process (Trivedi, Dharmaraja, & Ma, 2002). Each client in a cell can connect to the fixed network via wireless radio, wireless local area network (LAN), wireless cellular, or satellite. Each of the wireless networks provides a different bandwidth capacity. However, this wireless bandwidth is too small compared with the fixed network such as asynchronous transfer mode (ATM) that can provide a speed of up to 155Mbps (Elmasri & Navathe, 2003).

Data dissemination refers to the periodic broadcasting of database items to mobile clients through one or more wireless channels (or also called broadcast channels), and the clients filter their desired data on the fly. Access to data is sequential. The behavior of the broadcast channel is unidirectional which means the server disseminates a set of data periodically to a multiple number of users. This mechanism is also known as the *push-mechanism* (Malladi & Davis, 2002; Yajima, Hara, Tsukamoto, & Nishio, 2001). It must be noted that data dissemination is different from the data replication mecha-

Figure 1. Mobile environment architecture



nism. Conventional data replication distributes a set of database items to one or more identified clients according to a pre-determined requirement. However, data dissemination broadcasts the database items periodically to an unbounded number of mobile clients, and the clients filter the data on air based on individual interest.

Figure 2 shows the mechanism of data dissemination. In this article, the term data item corresponds to database record or tuples, and data segment contains a set of data items. A complete broadcast file is referred to as a broadcast cycle. The terms mobile client, mobile computer, mobile unit, mobile user and client are used interchangeably.

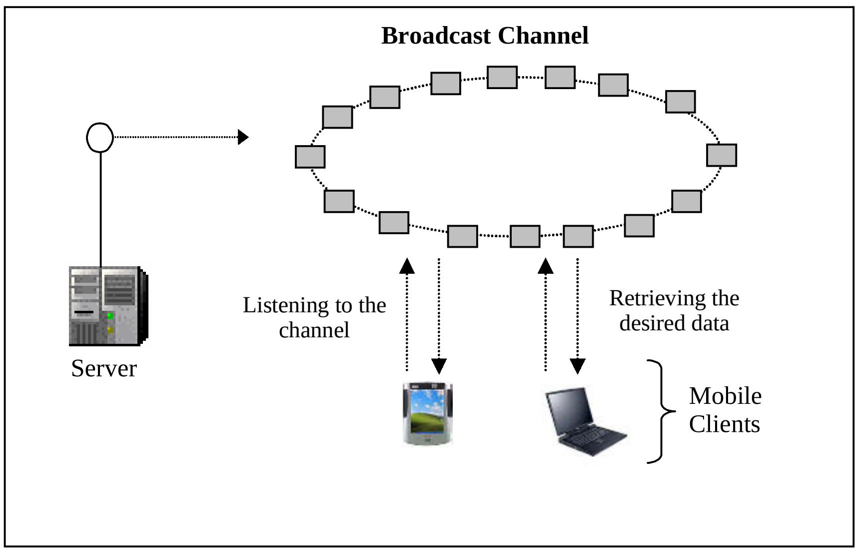
DATA DISSEMINATION

Data dissemination schemes are classified into two categories: one is to minimize query response time, and the other minimizes tuning time.

Minimizing Query Response Time

There are several data dissemination schemes, which include:

Figure 2. Data dissemination mechanism



(i) Selection of Data Items to be Broadcast,
(ii) Non-Uniform Frequency Distribution of Broadcast Data Items,
(iii) Distribution of Data Items over Multiple Channels, and
(iv) Organization of Data Items.

These schemes aim to minimize the query response time by either reducing the waiting time for the desired data to arrive, or, both waiting and download time.

a. Selection of Data Items to be Broadcast

A selection mechanism is designed to reduce the broadcast cycle length, which eventually reduces the query response time. During each broadcast cycle, additional items might be qualified as hot and some previously hot items might cool down, and therefore need to be replaced depending on the size of the cycle. A replacement algorithm is required to replace the cold data items with the new hot items. The server determines a set of appropriate database items to be broadcast, using information from queries received. Since hot items are those accessed by most clients, the access pattern of each client on the database items has to be derived from the clients back to the server. Finally, statistics will be compiled and the desired data items can be broadcast appropriately.

There are at least three replacement algorithms namely *Mean Algorithm*, *Window Algorithm*, and *Exponentially Weighted Moving Average* (*EWMA*) *Algorithm* (Leong & Si, 1997). These algorithms maintain a score for each database item to estimate the access probability of the next broadcast cycle. The scores are defined by measuring the cumulative access frequencies of each database item over the length of the observation period.

However, as the size of the database increases, the number of broadcast items may also increase accordingly. This situation will lead to an increase in response time. The next scheme can be used to improve the response time of the majority requests by manipulating the frequency of hot items to be broadcast.

b. Non-Uniform Frequency Distribution of Broadcast Data Items

The difference in bandwidth capacity between the downstream communication and upstream communication has created a new environment called the *Asymmetric Communication Environment*. In fact, there are two situations that can lead to communication asymmetry (Acharya, Alonso, Franklin, & Zdonik, 1995). One is raised as a result of the capability of physical devices. For example, servers have powerful broadcast transmitters, while mobile clients have little transmission capability. The other is due to the patterns of information flow in the application, such as the situation where the number of servers is far less than the number of clients. It is asymmetric because there is not enough capacity to handle simultaneous requests from multiple clients.

Broadcast Disk is an information system architecture, which utilizes multiple disks of different sizes and speeds on the broadcast medium. This architecture is used to address the above situations (Acharya et al., 1995). The broadcast consists of chunks of data from different disks on the same broadcast channel. The chunks of each disk are evenly scattered. However, the chunks of the fast disks are broadcast more frequently than the chunks of the slow disks. This is the opposite of a flat broadcast where the expected delay before obtaining an item of interest is the same for all broadcast items. With this differing broadcast frequency of different items, hot items can be broadcast more often than others. The server is assumed to have the indication of the clients' access patterns so that it can determine a broadcast strategy that will give priority to the hot items.

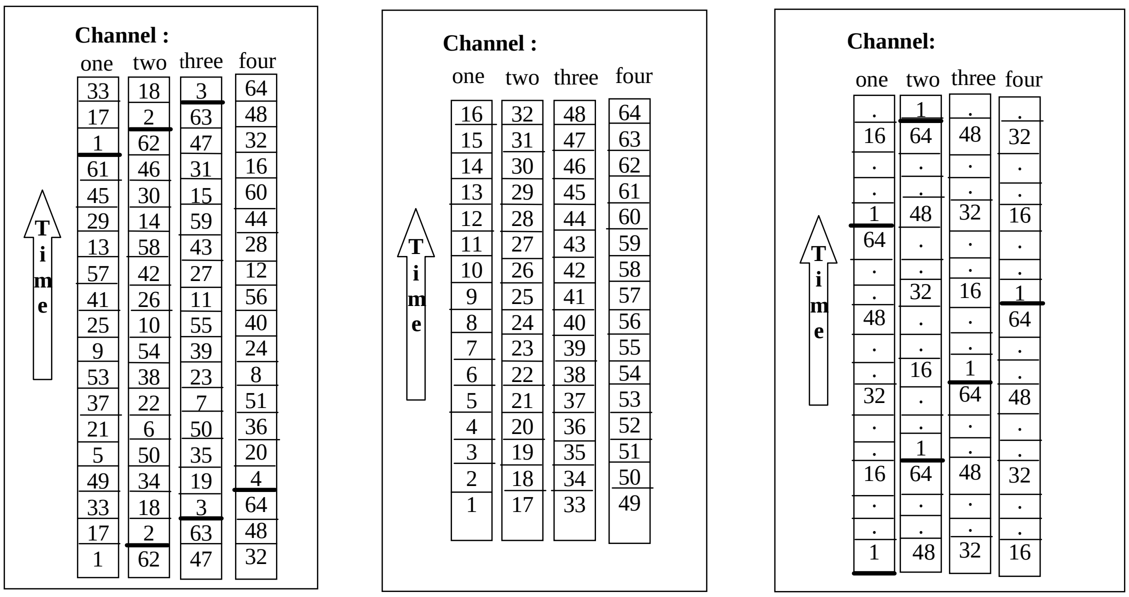
c. Distribution of Data Items over Multiple Channels

An alternative strategy to improve query response time is to distribute the broadcast data over more than one broadcast channel. Moreover, a certain pattern of distribution such as Data Stripping, Data Replication, and Data Replication can be used to handle obstacles like noise and signal distortion that may affect wireless transmission (Leong & Si, 1995). Figure 3 illustrates the three mechanisms.

As shown in Figure 3(a), the data stripping mechanism broadcasts consecutive data items over a multiple channel array and the data items are broadcast at certain intervals to allow the client sufficient time to switch from one channel to another. The data partitioning mechanism in Figure 3(b) allows the database to be partitioned into a number of data segments, and each data segment is placed in a different channel. In Figure 3(c), the database is replicated across all channels, and is therefore called the data replication mechanism.

To avoid the effect of too large data items in a channel, a strategy to determine the optimum number of database items to be broadcast in a channel is needed (Waluyo, Srinivasan, & Taniar, 2003a). In this strategy, the query response time over an on-demand channel is used as a threshold point. Subsequently, the length of the broadcast cycle is split, and broadcast over multiple channels.

Figure 3. Data stripping, partitioning, and replication mechanism



(a) Data Stripping Mechanism

(b) Data Partitioning Mechanism

(c) Data Replication Mechanism

d. Organization of Data Items

The previous schemes are concerned with retrieving a single data item. However, in most cases multiple data items are involved. Organizing database items over the broadcast channel can be applied to reduce waiting time as well as download time. Traditional semantic query optimization is employed to reduce the download time when the application involves multiple entity types, and the query accesses related entities from different entity types (Si & Leong, 1999). The organization of broadcast data is designed to match the query access pattern from mobile clients as closely as possible. As the query initiated by each client varies, this problem is sometimes considered an NP-hard problem.

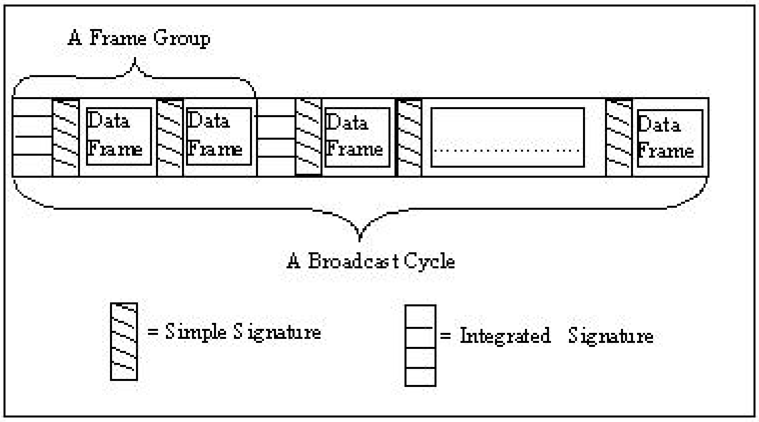
The difficulty is to decide the broadcast order in advance, even without much knowledge of any future query. In general, an access graph is needed to identify the optimal organization of database items over a channel. The access graph is used to represent the dependency of data items. Once the access graph is built, a certain algorithm is utilized to determine the best broadcast program. A cost model called the Semantic Ordering Model (SOM) can be used to determine the most efficient access graph (Si & Leong, 1999). SOM is defined into two models: namely, Simple and Extended SOM. Simple SOM considers only the relationship among entity types while Extended SOM incorporates historical query access patterns. The branch and bound like algorithm (Si & Leong, 1999), Heuristics algorithm (Hurson, Chehadeh, & Hannan, 2000), randomized algorithm (Bar-Noy, Naor, & Schieber, 2000), and Genetic algorithm (Huang & Chen, 2002, 2003) are some algorithms that can be used to identify the most effective organization of broadcast data items. The final broadcast program can be distributed over either a single or multiple channels.

Minimizing Tuning Time

A broadcast indexing scheme is needed to reduce the tuning time by providing accurate information for a client to tune in at the appropriate time for the required data (Lee, Leong, & Si, 2002). In this scheme, some form of directory is broadcast along with the data, and the clients obtain the index directory from the broadcast and use it in subsequent reads. The information generally also contains the exact time of the data to be broadcast. As a result, mobile clients are able to conserve the energy of their unit by switching to "*doze*" mode and back to "*active* mode" when the data is about to be broadcast.

In general, a broadcast indexing technique involves a trade-off between optimizing the client tuning time and the query response time. The consequence of minimizing one of them is the increase of the other. For instance, to minimize the response time is to reduce the length of broadcast cycles. In this case, the index can be broadcast once in each cycle but it will make the tuning time suffer since the client will have to wait for the index to arrive which happens only once in each broadcast cycle. On the other hand, when the index directory is frequently broad-

Figure 4. Multi-level signature



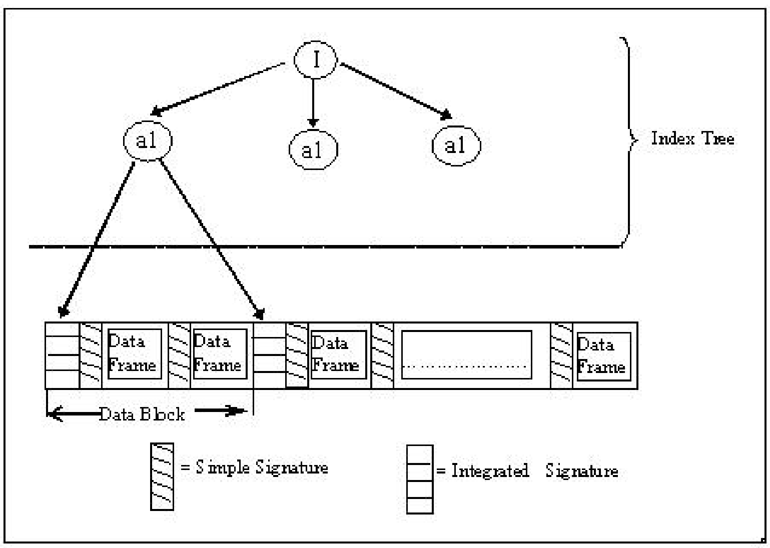
cast in each broadcast cycle to reduce the tuning time, the response time will be greatly affected due to the occupancy of the index in the cycle. Thus, it is necessary to find the optimal balance between these two factors.

Clustering index, non-clustering index, and multiple index methods are used to determine the index distribution over a broadcast channel (Imielinski, Viswanathan, & Badrinath, 1997). Clustering index refers to clustering of a record's attribute whenever all records that belong to the attribute have the same value consecutively. Non-clustering index defines a method for indexing the non-clustering attributes by partitioning each non-clustered attribute in the broadcast cycle into a number of segments called *meta segments*. In multiple indexes, a second attribute is chosen to cluster the data items within the first clustered attribute.

Broadcast indexing can be *tree-indexing* based, *signature* based, or *hybrid indexing* that is the combination thereof. Tree-indexing based such as Global Index structure is utilised to minimise the index response time (Taniar & Rahayu , 2002; Waluyo, Srinivasan, & Taniar, 2003b). The design of the global index model is based on *B*+ tree structure; it incorporates an index channel, and the data items are broadcast separately in data channels.

A signature based index is derived by hashing the attribute values into bit strings followed by combining them together to form a bit vector or signature (Lee & Lee, 1996). The signature is broadcast together with the data on every broadcast cycle. This mechanism is also applied to the query initiated by the client. To process the query, mobile clients need to tune into the broadcast channel and verify the query signature with the data signature by performing a certain mathematical operation such as the "AND" operation. If the signature is not matched, the client can tune to the "doze" mode while waiting for the next signature to arrive. The main issue with this method

Figure 5. Hybrid indexing



is to determine the size of the signature as well as the number of levels of the signature. There are three different signature-based index algorithms, namely *simple signature*, *integrated signature* and *multilevel signature* (Lee & Lee, 1996).

In simple signature, the signature frame is broadcast ahead of each data frame. This makes the total number of signature frames the same as the data frames. An integrated signature is applied for a group of data frames and the signature is calculated accordingly. Figure 4 shows a combination of these two algorithms, forming a multi-level signature. This technique is designed to interleave with data items in a single channel.

A hybrid indexing technique made up of index tree and signature is expected to outperform the single indexing techniques by integrating the advantages of the two techniques into a single operation (Lee, Hu, & Lee, 1998; Hu, Lee, & Lee, 1999). This technique is shown in Figure 5.

CONCLUSION

The inherent limitations and characteristics of mobile computing such as power, storage, asymmetric communication cost, and bandwidth, have become interesting challenges and research opportunities in the field.

This article describes main issues, and several approaches in data dissemination in mobile databases that have been derived from literature. We classify each scheme into two categories: one is to minimize query response time, and the other is to minimize tuning time. Broadcasting schemes that aim to minimize response time include:

(i) Selection of Data Items to be broadcast,
(ii) Non-Uniform Frequency Distribution of Broadcast Data Items,
(iii) Distribution of Data Items over Multiple Channels, and
(iv) Organization of Data Items.

To minimize the tuning time, broadcast indexing of data items is applied. Hybrid schemes that integrate the advantages of these approaches are also of great potential. These techniques can certainly be improved in a number of ways and a vast amount of research is continuing for this purpose.

KEY TERMS

Broadcast Channel: Unidirectional wireless channel to disseminate a set of database items periodically to multiple numbers of mobile users.

Broadcast Cycle: A complete broadcast file.

Data Dissemination/Broadcasting: Periodical broadcast of database information to mobile clients through one or more wireless channels.

Data Item: Database record or tuples.

Data Segment: A set of data items.

Mobile Base Station (MBS): Fixed host that has wireless interface for communicating with mobile clients.

Mobile Computing: The ability of mobile users to keep connected to the wireless network while traveling, and to access information such as news, weather forecast, email, and query to central database server.

Mobile Database: Mobile users connected to the wireless network and equipped with database application to conduct activity like transaction and information retrieval from central database server.

Query Response Time: The total elapsed time while waiting for the data of interest to arrive in the channel and downloading the data.

Tuning Time: The total time a mobile client must listen to the channel, which is used to indicate its energy consumption.

Data Mining and Mobile Business Data

Richi Nayak
Queensland University of Technology, Australia

INTRODUCTION

Research and practices in mobile (m-) business have seen an exponential growth in the last decade (CNN, 2002; Leisen, 2000; McDonough, 2002; Purba, 2002). M-businesses allow users to access information, perform transactions and other operations from anywhere at anytime via wireless networks. Consequently, m-business applications are generating a large volume of complex data (Magic-sw, 2002). Monitoring and mining of this data can assist m-business operators to make sound financial and organisational decisions.

Data mining (DM) or knowledge discovery in databases is the extraction of interesting, meaningful, implicit, previously unknown, valid and actionable information from a pool of data sources (Dunham, 2003). This valuable and real-time information inferred from the data can be used for decision-making. For example, common use of mobile phones and personal digital assistance (PDAs) has increased the number of service providers. The DM technology can help providers to develop services and sales strategies for future benefits. An example of existing applications of data mining in m-business is MobiMine (Kargupta, Park, Pittie, Liu, Kushraj, & Sarkar, 2002), which enables a user to monitor stock prices from a handheld PDA.

BACKGROUND: PROCESS OF KNOWLEDGE DISCOVERY

Data mining - an interactive, iterative, non-trivial process - is usually divided into many subtasks (Figure 1). Prior to commencing the mining process, businesses should identify and define their goals, objectives and limitations. Accordingly, data is gathered and collated from multiple sources as each source may send data in different formats. The next phase is to ensure quality of the data by removing noise, handling missing information and transforming to an appropriate format. A reduced volume of the data set " representative of the overall processed data " is also derived by applying data reduction techniques.

Once the data is pre-processed, an appropriate data mining technique or a combination of techniques is applied for the type of knowledge to be discovered (Table 1). The discovered knowledge is then evaluated and interpreted, typically involving some visualization techniques. When the mined results are determined insufficient, an iterative process of performing preprocessing and mining begins until adequate and useful information is obtained. Lastly, the information is presented to user to incorporate into the company's business strategies.

Figure 1. The data mining process

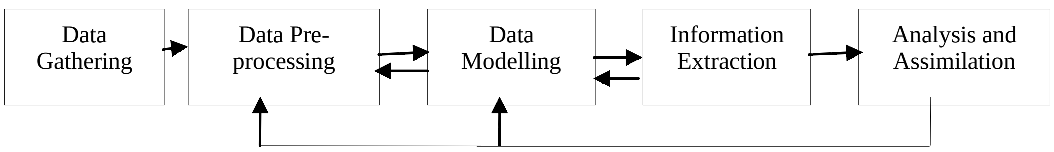

Table 1. Various data mining tasks

Mining Task	Goal	Approaches
Predictive Modelling	To predict future needs based on previous data	Decision tree, Neural networks
Clustering	To partition data into segments	Demographic, Neural networks
Link Analysis	To establish association among items	Counting occurrences of items such as Apriori Algorithms
Deviation Detection	To detect any anomalies, unusual activities	Summarization and Graphical representation

DATA MINING OPPORTUNITIES IN M-BUSINESS DOMAIN

Taking Advantage of Location Information

With the Global Positioning System (GPS) mobile technology, it is possible to identify the location of users (Cousins & Varshney, 2001; Duri, Cole, Munson, & Christensen, 2001). Based on the locations that a person frequents most and the personal information given, it is possible to classify the user in a pre-defined category with data mining techniques. For example, if a person is most often sighted in supermarkets, department stores and at home, and is seen shuttling between sales events, then this person can be classified as a possible homemaker interested in sales events. In terms of a business-to-consumer relation, such information allows businesses to provide the appropriate marketing information to the specific category of users.

In terms of a business-to-business relation, the ability to track the location of the employees is ideal to determine the work efficiency of the employees. Analysis of employee's time spent on the duty will determine the employee who is performing best and most suited for the next pay increment and promotion. Businesses like courier companies are dependent on the information regarding the locations of the transported parcels. Data mining techniques are able to analyse various routes and time spent in receiving parcels over a period. The outcome determines the efficiency of the business processes and factors behind their failure or success.

Personalization of M-Business Applications

Due to the limited screen space provided on mobile devices, it is difficult for mobile users to browse the product or service catalogues on the devices. It is important for vendors to provide only the products or services that match the needs of individual users. Short message service (SMS) is used primarily for simple person-to-person messaging. Information obtained from analysing the user data about previously accessing these services can be used to create personalized advertises to the customer delivered by SMS (Mobilein.com, 2002).

Relevant services can be offered based not only on the personal profile of the device holder, but also on the device holder's location and time factor. For example, m-business applications used in the travel industry can assist users to find attractions, hotels and restaurants of their preference on requested location and time. The *clustering data mining* technique groups the customers with similar preferences. When a new customer mentions his preferences, a recommendation can be made based on the previous similar preferences. *Associative data mining* can be used to indicate which places a person is most likely to visit in a single trip or in two consecutive trips, with having inputs such as location and time of visits to attractions for each user. This provides great convenience for users as these services can be used while driving, for example, a suggestion can be made based on the association rule that if the user is on place A then the user should visit the place B, previous 80% visitors have done so.

Predicting Customer Buying and Usage Patterns

Service providers can analyse the consumer behaviour data (e.g., by analysing gateway log files and content server log files on WAP) and predict the consumers buying and usage patterns, or to understand how mobile subscribers use their wireless services. Using the stored data, companies can apply data mining to identify customer segments using *clustering data mining techniques*, to distinguish customers' consumption patterns using *deviation detection techniques*, and transaction trends using *associative data mining techniques*. This information can then be used to provide better services to the customers or to attract potential customers.

Predicting Future and Better Usage of Mobile Technology

Data, about the number of mobile phones in the market, the number of users subscribing a service, the amount of usage measured in currency, the users' satisfaction and feedback, can be extracted and analysed with data mining. The resulting information can be used to predict the trends and patterns of usage of mobile phones and services. For example, some of the popular services bought through m-commerce technology are mobile ringing tones, logos and screensavers. The most common used interface for these kind of transactions are short message service (SMS) and the standard e-commerce interface, the Internet. An example is Nokia's focus on screensavers, logos and ringing tone availability. This is most likely to be a result of previous research on their users' trends, by capturing the data on the users' demands and needs, and then analysing the users' feedbacks. This information helped Nokia to develop a new market product where the product is no longer just a mobile phone, but also provides extra features like SMS, logos and additional ringing tones and screensavers (Nokia, 2002).

Trend Analysis of Costs versus Benefits

Any m-business constantly analyses whether the profits derived from the business is sustainable. Data mining can assist to do a trend analysis of the business over a period. A possible way to analyse the data collected from the profit derived from the business is the use of linear regression (a *value prediction technique* of the DM). A graph based on average returns versus average investment into the business can be plotted. Analysis of graph indicates whether the amount of investment incurred is greater or smaller than the returns derived. Many other business factors can also be considered during regression analysis.

Optimisation of Delivery Content

A mobile commerce platform should integrate with existing backend databases and businesses applications to deliver data via all the channels such as WAP, VoxML, TruSync, BlueTooth or any wireless protocol. Data mining can also be used to match which channel is best at a time to deliver the information. Data mining techniques can optimise the amount and format of the content for delivery based on the connection speed of the device requesting the information. Data mining techniques help to decide what tasks, activities and transactions are most economical and beneficial to use at the time.

Fraud Detection in M-Business

The analysis of the types of fraudulent activities in telecommunication systems is one of the applications that data mining can assist in a mobile environment. The dynamic nature of different fraudulent activities and the changes of the normal usage can lead in the detection of fraudulent through observing behavioural patterns. A data mining system will have plenty of examples of normal usage and some examples of fraud usage. Based on these previous examples, a *predictive data mining* system establishes facts about fraudulent activities. Whenever a change in the normal usage is detected, the system analyses the change, and is able to predict whether the change is a fraud or not.

DATA MINING CHALLENGES

In order to apply data mining efficiently in m-business, certain requirements have to be met. Ideally, the methods used for mining mobile data should be able to: (1) mine different kinds of knowledge in databases; (2) deal with diverse type of data types such as relational, temporal and spatial types of data; (3) mine information from heterogeneous databases and global information systems; (4) handle noise and incomplete data that is mostly the case in m-business domain; (5) perform the mining tasks efficiently regardless of the size and complexity of the data set; (6) support interactive mining of knowledge at multiple levels of abstraction; (7) support integration of the discovered knowledge with existing knowledge; and (8) deal with the issues related to applications of discovered knowledge and social impacts such as protection of data security, integrity and privacy.

Distributed Environment

In m-business environment, data can reside in many different geographical locations. Most data mining systems are currently based on centrally-located data; data is stored in a single database and the mining techniques are focused on this data set. XML is proving to be an essential way to perform data exchange not only on the Web but also wirelessly between applications or between users and applications. XML has provided the facilities to integrate data and documents to allow for data communication in "a flexible and extensible representation" (Graves, 2002). If every mobile device is able to transmit XML documents that can be read and processed, regardless which platform the mobile device is running on, data integration from multiple sources becomes easier.

But, as a result of convergence between computation and communication, the new data mining approaches have to be concerned with distributed aspects of computation and information storage. A distributed data mining approach typically works by: (1) analysing and compressing local data for minimisation of network traffic; and (2) analysing and generating global data models after combining local data and models (Park & Kargupta, 2002).

Clickstream Data

Users of mobile devices are highly restricted on the Web pages that they can visit, due to small display screen. On a WAP phone, the average number of links it has to other Web site is an average of five links, while a standard Web page has an average of 25 links. If a user is to have three clicks on the Web via a WAP phone, there are only 5^3 (= 125) pages that are accessible to the user, compared with the standard Web page having 25^3 (= 15625) accessible pages (Barnes, 2002). It is quite unlikely that the user will be going to the site that he really wants from the links available. As a result, the usage of data mining to analyse clickstream data collected from users of mobile devices to predict the user's interest is not going to be accurate.

Security and Privacy

With the technology of sending personal messages to mobile users, it has become possible for users to specify the types of information that they prefer, and for businesses to provide those information only. For example, if the user indicates that his preference is a particular brand of product above a particular price, then it can be analysed that the user may also be interested in another similar brand of the same standard. This opens data mining possibilities such as classifying the users based on their reported needs; finding correlations between various needs.

Unfortunately, some users who do not believe in the security of mobile data might inaccurately declare their personal information and preference. This will result in incorrect data mining output. Thus, although data mining results have classified the user as a potential person to send information to, but in reality, it can add expense to incur cost in conducting data mining and including the irrelevant people into the mobile service. A possible solution is use of XML that allows documents to be complex and tagged with unmeaningful names in data transfer. The document is not useful to an unauthorized person without the knowledge of how to transform (decrypt) the document appropriately.

Cost Justification

With the issue that a data mining application is usually computationally expensive, there is always a concern whether the benefits of data mining justify the cost incurred in the process. Also, there is a difficulty to strike a balance between the security and privacy of data transferred versus the computational cost required to process the "encrypted" documents. The more complex the communication document is with the concern of security and privacy, the more computational power is needed to process these documents.

Technological Limitation

Although there are a number of mobile technologies available, there exist several limitations and constraints of the technologies adversely affecting the performance of data mining in m-business domain. Some of the limitations are low bandwidth, limited battery power, unreliable communications that result in frequent disconnections. These factors increase the communication latency, additional cost to retransmit data, time-out delays, error control protocol processing and short disconnections (Madria, Mohania, Bhowmick, & Bhargava, 2002). These limitations pose significant problems in collecting data for mining purposes. For example, the present low bandwidth means that the data transfer is slow. This implies that data mining processes have to be delayed until most data transfers have been completed and received.

Furthermore, the potential of gathering knowledge about a user's location is appealing in terms of m-business and data mining, this potential is not yet realized until present technologies improve to provide adequate and up to standard location.

FUTURE TRENDS AND CONCLUSION

The success of an m-business depends on the ability to deliver attractive products or services that are personalized to the individual user at the right time on the right location. These information intensive services can only be obtained by collecting and analysing combined demographic, geographic, and temporal data. This data can not be transformed into useful information with traditional reporting techniques and tools. Data mining enables the user to seek out facts by identifying patterns within data. Data mining can give businesses the edge over other businesses by offering marketing that is more focused on particular consumer groups or with suggesting the better use of mobile technology. An investment in data mining to m-business data is an extra expense, but can still help m-businesses to provide the right services to the right people at the right time, and that can make a vital difference.

KEY TERMS

Clustering: This data mining task is to identify items with similar characteristics, and thus creating a hierarchy of classes from the existing set of events. A data set is partitioned into segments of elements (homogeneous) that share a number of properties.

Data Mining: Data mining (DM) or knowledge discovery in databases is the extraction of interesting, meaningful, implicit, previously unknown, valid and actionable information from a pool of data sources.

Link Analysis: This data mining task establishes internal relationship to reveal hidden affinity among items in a given data set. Link analysis exposes samples and trends by predicting correlation of items that are otherwise not obvious.

Mobile Business Data: Data generating from mobile business activities such as accessing information, performing transactions and other operations from anywhere anytime via wireless networks.

Predictive Modelling: This data mining task makes predictions based on essential characteristics about the data. The classification task of data mining builds a model to map (or classify) a data item into one of several predefined classes. The regression task of data mining builds a model to map a data item to a real-valued prediction variable.

D

Data Mining for Combining Forecasts in Inventory Management

Chi Kin Chan
The Hong Kong Polytechnic University, Hong Kong

INTRODUCTION

The traditional approach to forecasting involves choosing the forecasting method judged most appropriate of the available methods and applying it to some specific situations. The choice of a method depends upon the characteristics of the series and the type of application. The rationale behind such an approach is the notion that a "best" method exists and can be identified. Further that the "best" method for the past will continue to be the best for the future. An alternative to the traditional approach is to aggregate information from different forecasting methods by aggregating forecasts. This eliminates the problem of having to select a single method and rely exclusively on its forecasts.

Considerable literature has accumulated over the years regarding the combination of forecasts. The primary conclusion of this line of research is that combining multiple forecasts leads to increased forecast accuracy. This has been the result whether the forecasts are judgmental or statistical, econometric or extrapolation. Furthermore, in many cases one can make dramatic performance improvements by simply averaging the forecasts.

BACKGROUND OF COMBINATION OF FORECASTS

The concept of combining forecasts started with the seminal work 35 years ago of Bates and Granger (1969). Given two individual forecasts of a time series, Bates and Granger (1969) demonstrated that a suitable linear combination of the two forecasts may result in a better forecast than the two original ones, in the sense of a smaller error variance. Table 1 shows an example in which two individual forecasts (1 and 2) and their arithmetic mean (combined forecast) were used to forecast 12 monthly data of a certain time series (actual data).

The forecast errors (i.e., actual value – forecast value) and the variances of errors are shown in Table 2.

From Table 2, it can be seen that the error variance of individual forecast 1, individual forecast 2, and the combined forecast are 196, 188 and 150, respectively. This shows that the error variance of the combined forecast is smaller than any one of the individual forecasts and hence demonstrates an example how combined forecast may work better than its constituent forecasts.

Bates and Granger (1969) also illustrated the theoretical base of combination of forecasts. Let X_{1t} and X_{2t} be two individual forecasts of Y_t at time t with errors:

Table 1. Individual and combined forecasts

Actual Data (Monthly Data)	Individual Forecast 1	Individual Forecast 2	Combined Forecast (Simple Average of Forecast 1 and Forecast 2)
196	195	199	197
196	190	206	198
236	218	212	215
235	217	213	215
229	226	238	232
243	260	265	262.5
264	288	254	271
272	288	270	279
237	249	248	248.5
211	220	221	220.5
180	192	192	192
201	214	208	211

$$e_{jt} = Y_t - X_{jt}, \qquad j = 1,2$$

such that

$$E[e_t] = 0, \qquad E[e_{jt}^2] = \sigma_j^2 \qquad j = 1,2$$

and

$$E[e_{1t}e_{2t}] = \rho\sigma_1\sigma_2$$

where σ_j^2 is the error variance of the j^{th} individual forecast and ρ is the correlation coefficient between the errors in the first set of forecasts and those in the second set.

Consider now a combined forecast, taken to be a weighted average of the two individual forecasts:

$$X_{ct} = kX_{1t} + (1-k)X_{2t}$$

The forecast error is

$$e_{ct} = Y_t - X_{ct} = ke_{1t} + (1-k)e_{2t}$$

Hence the error variance is

$$\sigma_c^2 = k^2\sigma^2 + (1-k)^2\sigma_2^2 + 2k(1-k)\rho\sigma_1\sigma_2 \qquad \textbf{(1)}$$

This expression is minimized for the value of k given by:

$$k_0 = \frac{\sigma_2^2 - \rho\sigma_1\sigma_2}{\sigma_1^2 + \sigma_2^2 - 2\rho\sigma_1\sigma_2}$$

and substitution into equation (1) yields the minimum achievable error variance as:

$$\sigma_{c0}^2 = \frac{\sigma_1^2\sigma_2^2(1-\rho^2)}{\sigma_1^2 + \sigma_2^2 - 2\rho\sigma_1\sigma_2}$$

Note that $\sigma_{c0}^2 < \min(\sigma_1^2, \sigma_2^2)$ unless either ρ is exactly equal to σ_1/σ_2 or σ_2/σ_1. If either equality holds, then the variance of the combined forecast is equal to the smaller of the two error variances. Thus, a priori, it is reasonable to expect in most practical situations that the best available combined forecast will outperform the better individual forecast—it cannot, in any case, do worse.

Newbold and Granger (1974), Makridakis et al. (1982), Makridakis and Winkler (1983), Winkler and Makridakis (1983), and Makridakis and Hibbon (2000) have also reported empirical results that showed that combinations of forecasts outperformed individual methods.

Since Bates and Granger (1969), there have been numerous methods proposed in the literature for combining forecasts. However, the performance of different methods of combining forecasts varies from case to case. There is still neither definitive nor generally accepted conclusion that sophisticated methods work better than simple ones, including simple averages. As Clemen (1989) commented: *In many studies, the average of the individual forecasts has performed the best or almost best.* Others would agree with the comment of Bunn (1985) that the Newbold and Granger (1974) study and that of Winkler and Makridakis (1983) "demonstrated that an overall *policy* of combining forecasts was an efficient one and that if an *automatic* forecasting system were required, for example, for inventory planning, then a linear combina-

Table 2. Forecast errors and variances of errors

Errors of Individual Forecast 1	**Errors of Individual Forecast 2**	**Errors of Combined Forecast**

tion using a 'moving-window' estimator would appear to be the best overall".

DATA MINING AND COMBINATION OF FORECASTS IN INVENTORY MANAGEMENT

Data mining is the process of selection, exploration, and modeling of large quantities of data to discover regularities or relations that are, at first, unknown with the aim of obtaining clear and useful results for the owner of the database.

The data mining process is deemed necessary in a forecasting system, and it is particularly important in combining forecasts for inventory demands. Errors in forecasting demand can have a significant impact on the costs of operating and the customer service provided by an inventory management system. It is therefore important to make the errors as small as possible. The usual practice in deciding which system to use is to evaluate alternative forecasting methods over past data and select the best. However, there may have been changes in the process, generating the demand for an item over the past period used in the evaluation analysis. The methods evaluated may differ in their relative performance over sub-periods of the method that was best only part of the time, or in fact never the best method and perhaps only generally second best. Each method evaluated may be modeling a different aspect of the underlying process generating demands. The methods discarded in the selection process may contain some useful independent information. A combined forecast from two or more methods might improve upon the best individual forecasts. Furthermore, the inventory manager typically has to order and stock hundreds or thousands of different items. Given the practical difficulty of finding the best method for every individual item, the general approach is to find the best single compromise method over a sample of items, unless there are obvious simple ways of classifying the items, by item value or average demand per year, and so forth. Even if this is possible, there will still be many items in each distinct category for which the same forecasting method will be used. All of the points made on dealing an individual data series, as previously noted, apply with even more force when dealing with a group of items. If no one individual forecasting method is best for all items, then some system of combining two or more forecasts would seem *a priori* an obvious approach, if the inventory manager is going to use the same forecasting system for all items.

The need for data mining in combining forecasts for inventory demands comes from the selection of sample items on which forecasting strategy can be made for all items, the selection of constituent forecasts to be combined and the selection of weighting method for the combination.

The selection of the sample items is a process of exploratory data analysis. In this process, summary statistics such as mean and coefficient of variation can be investigated so that the sample selected could represent the total set of data series on inventory demands.

The selection of constituent forecasts to be combined is the first stage of model building. The forecasts methods might be selected from popular time series procedures such as exponential smoothing, Box-Jenkins and regression over time. One could include only one method from each procedure in the linear combination as the three groups of methods were different classes of forecasting model and thus might contribute something distinct, while there was likely to be much less extra contribution from different methods within the same class. It might also be useful to attempt to tailor the choice of methods to particular situations. For example, Lewandowski's FORSYS system, in the M-competition (Makridakis et al., 1982), appears to be particularly valuable for long forecast horizons. Thus it might be a prime candidate for inclusion in situations with long horizons but not necessarily in situations with short horizons. It is also important to note that combining forecasts is not confined to combination utilizing time series methods. The desire to consider any and all available information means that forecasts from different types of sources should be considered. For example, one could combine forecasts from time series methods with forecasts from econometric models and with subjective forecasts from experts.

The second stage of model building is to select the weighting method for the combination of forecasts. The weighting method could be simple average or "optimal" weighting estimated by a certain approach, for instance, the constrained OLS method (Chan, Kingsman, & Wong, 1999b). Furthermore, the "optimal" weights obtained could either be fixed for a number of periods (fixed weighting) or re-estimated every period (rolling window weighting) (Chan, Kingsman, & Wong, 1999a, 2004). The selection process can then be done by comparing the different weighting methods with an appropriate performance measure. In the case of inventory management, the carrying of safety stocks is to guard against the uncertainties and variations in demand and the forecasting of demand. These safety stocks are directly related, or made directly proportional, to the standard errors of forecasts. If, as is usually the case, a stock controller is dealing with many items, it is the performance across the group of items that matters. Hence, the sum of the standard errors of the forecasts, measured by the sum of the root mean squared errors over all the items, can be used to compare the results between the different weighting methods. The ultimate aim is to find the one best overall method for the weighting process to use for all the items.

FUTURE TRENDS AND CONCLUSION

The usual approach in practical inventory management is to evaluate alternative forecasting methods over a sample of items and then select the one that gives the lowest errors for a majority of the items in the sample to use for all items being stocked. The methods discarded in the selection process may contain some useful independent information. A combined forecast from two or more methods might improve upon the best individual forecasts. This gives us some insights in the process of data mining. There are a number of well-known methods in data mining such as clustering, classification, decision trees, neural networks, and so forth. Finding a good individual method from our tool kit to handle the data is clearly an important initial step in data mining. Then we should always bear in mind the power in combining the individual methods. There are two kinds of direction to do the combination. The first one is basically a direct combination of the individual methods, such as simple average or "optimal" weighting. The other one is to classify our data first, and then select the weighting method. Classification is always an important aspect of data mining and combination of forecasts sheds some new light on this. Another important message is that if we are dealing with large data sets, then it is not very worthwhile to find the "best" individual method. Obviously, there may not be any best individual at all. A viable alternative is to find several sensible individual methods and then combine them as the final method. This approach will usually relieve much of our effort in finding the best individual method, as justified by the law of diminishing return.

KEY TERMS

Combination of Forecasts: Combine two or more individual forecasts to form a composite one.

Constrained OLS Method: A method to estimate the "optimal" weights for combination of forecasts by minimizing the sum of squared errors as in a regression framework, and the weights are constrained to sum to one.

Data Mining: The process of selection, exploration, and modeling of large quantities of data to discover regularities or relations that are at first unknown with the aim of obtaining clear and useful results for the owner of the database.

Fixed Weighting: "Optimal" weights are estimated and are used unchanged to combine forecasts for a number of periods.

Highest Weighting: Use the individual forecast procedure that is given the highest weight in the fixed weighting method. This is not a combination. This method is equivalent to choosing the forecasting technique which is the best on the weight estimation period.

Rolling Window Weighting: "Optimal" weights are estimated in each period by minimizing the errors over the preceding *m* periods, where *m* is the length in periods of the "rolling window". The weights are then used to combine forecasts for the present period.

Simple Average Weighting: A simple linear average of the forecasts, implying equal weights for combination of forecasts.

Data Mining for Supply Chain Management in Complex Networks

Mahesh S. Raisinghani
University of Dallas, USA

Manoj K. Singh
i2 Technologies, USA

INTRODUCTION

Supply chain comprises the flow of products, information, and money. In traditional supply chain management, business processes are disconnected from stock control and, as a result, inventory is the direct output of incomplete information. The focus of contemporary supply chain management is to organize, plan, and implement these flows. First, at the organizational level, products are manufactured, transported, and stored based on the customers' needs. Second, planning and control of component production, storage, and transport are managed using central supply management and replenished through centralized procurement. Third, the implementation of the supply chain involves the entire cycle from the order-entry process to order fulfillment and delivery. Data mining can create a better match between supply and demand, reducing or sometimes even eliminating the stocks.

Data mining thus has become an indispensable tool in understanding needs, preferences, and behaviors of customers. It is also used in pricing, promotion, and product development. Conventionally, data mining techniques have been used in banking, insurance, and retail business. This is largely because of the fact that the implementation of these techniques showed quick returns. Data mining is being used for customer profiling where characteristics of good customers are identified with the goals of predicting new customers and helping marketing departments target new prospects. The effectiveness of sales promotions/ product positioning can be analyzed using market-basket analysis to determine which products are purchased together or by an individual over time, which products to stock in a particular store, and where to place products in each store (Groth 2000; Kopanakis & Theodoulidis, 2003; Weir, 1998). In addition, data mining is used in a variety of other industries such as the financial, healthcare, and telecommunications industry, among others.

There are a lot of opportunities and applications of data mining even beyond the obvious. One of the potential areas is "Supply Chain Management." One of the realities of the demand and supply in the manufacturing industry is that no matter how well balanced a system is, there is an element of uncertainty that creates a mismatch between demand and supply. The objective of this article is to identify those areas in the supply chain where most of the uncertainty exists and to determine suitable data-mining methods to accurately predict uncertainty. The underlying assumption of this paper is that a data warehouse has been implemented before the data-mining techniques can be applied.

A KEY BUSINESS PROBLEM: UNCERTAINTY

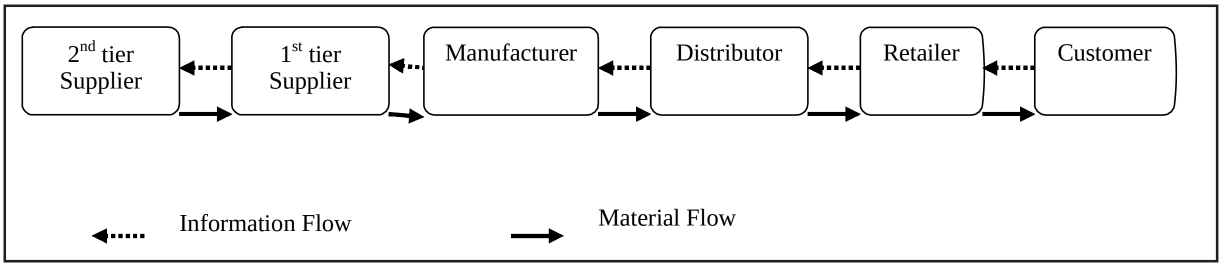
There are two issues that plague supply chain management—variation in the demand and supply and variation in the speed and extent of communication within the supply chain. Variation in demand and supply is due to the inherent uncertainty also present in the processes. Accurately predicting the uncertainties in demand, supply, and processes and then formulating action plans around the prediction is the essence of supply chain management (SCM).

Before we can address the problem of uncertainty in supply chain and explain the use of data-mining techniques, we need to understand the basic process of SCM and where uncertainty exists. In its most simplified form, a supply chain can be depicted as the flow of information from a customer's customer to a supplier's supplier and then the flow of material in the reverse direction, as shown in Figure 1.

The whole supply chain can be conceptually broken down as Supply – Process – Demand. Traditional forecasting planners of supply chains use demand and supply forecasting as a means of controlling uncertainty. However, there are three major drawbacks in those methods, namely:

1. Incorrect forecasting model
2. Incorrect number of parameters
3. Incorrect coefficients values of these parameters.

Figure 1. Information and material flows in the supply chain



Each of these three problems can be solved using data mining. The models are chosen from a finite set of predefined models in data mining. The model can be recreated as many times as needed in order to extract previously unknown patterns and relationships in data. When forecasting using data-mining techniques, the program can detect even minor effects of some parameters.

DATA MINING: METHODS AND PROCESS

Data mining is the process of extracting ideas in data. It can also be defined as "a decision support process that tries to discover patterns and relationships that are beyond the realm of human experience and imagination in the large database and present them to a knowledgeable user for review and examination" or "as the process of extracting previously **unknown, valid,** and **actionable** information from large databases and then using the information to make crucial business decisions" (Groth, 2000).

Data mining not only uses a discovery-based approach in which pattern matching and other algorithms are employed to determine the key relationships in the data but also describes the steps that must be taken to ensure meaningful results.

DATA-MINING METHODS

Data mining is used to build six types of models aimed at solving business problems: classification, regression, time series, clustering, association analysis, and sequence discovery.

Classification

A predictive model is generated based on the historical data. These models are used to assign instances to a group or class by calculating the value of a categorical variable. The value of this categorical variable is generally binary in nature. It can include multiple but discrete values.

Regression

Regression is used to predict values for categorical variables. The values are continuous, real numbers, i.e., it has decimal values, and it has no fixed range in which the values of the variables are fitted.

Time-series forecasting

This method uses a series of existing values and their attributes to forecast future values, except that the values of the categorical variables are dependent on time. Using various data-mining tools, the distinctive features of time can be exploited.

Clustering

Clustering is used to segment a database into clusters, with the members of each cluster sharing a number of interesting properties. These clusters are not predefined and have two basic uses: 1) summarizing the contents of the target databases; and 2) as inputs to the other methods s like supervised learning.

Association

Association is used to describe behavior that is captured in the database. This method relates the occurrences of various events by identifying patterns or groups of items.

Sequencing

Sequencing defines items that are likely to occur together on a sequence basis. This could help marketers in timing their promotions to correlate with the sequential buying order exhibited by their customers.

Data-Mining Process

Robert Grossman, Director of the National Center for Data Mining at the University of Illinois at Chicago, classifies the data-mining process into four phases. Each of these phases is described below:

Phase 1: Data Warehousing

Data warehousing is the foundation for successfully applying data-mining techniques and other analytical and predictive tools. Data warehousing involves the transfer, conversion, and integration of data from legacy systems to a central repository where data is stored and made available to clients.

The downside of data warehousing is the high cost of implementation and the time it takes to complete the process. Data warehouses can cost in excess of $10 million to build and take anywhere from one to three years to complete (Peacock, 1998). This is a very expensive and time-consuming effort.

An alternative is the use of a data mart, which is a functional or departmental data repository. It can constructed as individual components, usually costs between $10,000 and $1 million to build, and can be brought online in less than six months. Data marts can be inconsistent with the data warehouse. To correct this, data may also be enriched with additional attributes. This may be accomplished by adding data extracted from other internal databases or purchased from third-party sources (Asbrand, 1997).

Data-mining provides more meaningful data when it uses large databases extracted into data warehouses. Data-mining technology is more commonly used in large, consumer-oriented businesses such as banking and the retail industry because of the extremely high cost of implementation.

Phase 2: Data Mining Tools

Algorithms are applied to the data in order to produce predictive models. The selection of tools depends on the proper identification of a business problem and analysis to determine the correct technique to use. Some common types of problems and the technique used in data mining are illustrated in Table 1 (META Group, 1997):

The key to using these tools is to understand that it requires a team effort between the analysts, the marketing experts, and information technology experts.

Phase 3: Predictive modeling

During this phase, the predictive models are analyzed and combined to produce a single aggregate model. These techniques may be mixed sequentially or in parallel. Sequentially, the user picks a technique to produce a model and then applies another technique to the results. In parallel, the user chooses different techniques and applies them all to the initial dataset.

Phase 4: Predictive Scoring

Here, the predictive models are applied to score operational data (Grossman, 1998). For instance, a bank could analyze the attributes and habits of its checking account customers for clues that might reveal an acceptable minimum balance in order to retain profitable customers. The bank can use data mining to develop profiles of customer groups inclusive of members consistently hav-

Table 1. Problem types and techniques used in data mining

Example	Problem Type	Technique
What are the top three characteristics of customers who have switched to my competition?	Classification	Neural Networks Decision Tree
What are the largest buckets within my customer base to which I should be marketing a new service?	Clustering	Neural Networks Decision Tree
What is the likelihood a given individual who opens a bank account will also open an IRA within the next three months?	Association and Sequencing	Statistical Techniques Rule Induction
What will the average exchange rate be over the next three months?	Regression and Forecasting	Neural Networks Statistical Techniques

ing trouble maintaining minimum balances. This helps the bank identify profitable customers and predict the minimum balance needed to retain them. As a result, the percentage of profitable customers can rise by a significant percentage (Fabris, 1998).

APPLICATIONS OF DATA MINING IN SUPPLY CHAIN MANAGEMENT

Manufacturers, airlines, banks, insurance companies, credit card companies, and retailers have successfully used data-mining technology. Data mining works best as a supplement to the existing tools and can be used with decision support systems (DSS) to improve the overall result of the system. Zdanowicz (2004) discuss the detection of money laundering and terrorist financing via data mining. Data-mining tools can be used to provide the most accurate picture of the capacity, maintenance, and factory scheduling problems. DSS can take this information as input to provide the planner with an optimal factory scheduling solution.

The supply chain model for any industry will have suppliers, manufacturers, distributors, retailers and customers. Next, we look at each segment of the supply chain to understand the application of data mining.

Retailers

At this point of the supply chain, retailers receive the forecast from primarily two sources, one directly from the individual customer and the other from small- and medium-size organizations. Actual consumption by the individual customers and medium and small organizations is added. The difference between the forecast and the actual consumption is the variation in the demand. The difference between the request and the supply accounts for the variation in the supply.

Data mining can be used at this point in the following ways:

- Market segmentation based on service needs of distinct groups;
- Market basket analysis - retailers can understand the buying behavior of the customers; and
- Target promotion with the use of a computerized approach and an extensive database.

Distributors

At this point in the supply chain, distributors receive the forecast from retailers and large organizations. They pair this data with the actual consumption by the retailers and large organizations. The difference between the forecast and the actual consumption is the variation in the demand. The difference between the promise and the actual supply accounts for the variation in the supply.

Data mining can be used at this point in the following ways:

- Predictions of supply uncertainties to predict the supply uncertainties at the supplier level and at the item level;
- Predictions of process uncertainties can be loss and item obsolescence;
- Predictions of demand uncertainties - market segmentation for retailers and big customers based on factors such as volume of demand, periodicity, variations, etc.;
- Stock out prediction at the warehouse; and
- Strategic implications - logistics becomes a tool to help accomplish corporate strategic objectives.

Manufacturers

At this point, manufacturers receive the demand from distributors or directly from retailers. Manufacturers pass on the demand of retailers to alliance partners and try to fulfill only the demand of distributors. The difference between the forecasted demand from distributors and the actual consumption by the distributors is the variation in the demand. The difference between the promise and the actual supply from component suppliers accounts for the variation in the supply for manufacturers.

Data mining can be used at this point in the following ways:

- Predictions of supply uncertainties - predict supply uncertainties for manufacturers at the supplier level and at the item level;
- Predictions of process uncertainties due to machine breakdown, poor performance, and maintenance schedules;
- Predictions of demand uncertainties based on distributor, item, location, etc.; and
- Predicting future trends in demand - discover trends in the demand of the product.

Mass Customization

Another area where data mining can be used is in identifying the products for "mass customization" at the delivery end. Companies implement mass customization by putting together unique customer orders from a large number of products, while minimizing the inventory of product components. Data mining helps in identifying these permutations and also in identifying the demand pattern for these permutations.

DATA-MINING IMPLEMENTATION ARCHITECTURE

A data-mining application can be an effective tool only when implemented along with some existing decision support system and an enterprise resource planning (ERP) system. The difference between a decision support system (DSS) and a data-mining application is that, unlike data-mining applications, DSSs do not perform queries or analysis of data. Figure 2 illustrates the manner in which this marriage between DSS and data mining affects the implementation architecture.

An ERP system integrates the processes of an organization. Data related to these processes are scattered throughout the system. This large amount of unorganized data cannot be used as it is for data-mining applications. A data warehouse has to be built that organizes ERP data so that it is easily accessible and organized for online analysis.

The smooth flow of information from an ERP to a data-mining tool through a data warehouse will require open metadata integration. Information describing the ERP data, the target data warehouse schema, and the data mappings and transformation rules need to be stored in an open relational metadata repository and be easily accessible to the data- mining tools used in the architecture. This facilitates changes made to the underlying warehouse. It then passes these changes to the analysis tools and makes complete information available to end users, such as the source of the data flows and frequency of updates (Coombs, 1999). Some of the issues in implementing data mining include result interpretation, data selection and representation, and system scalability considerations.

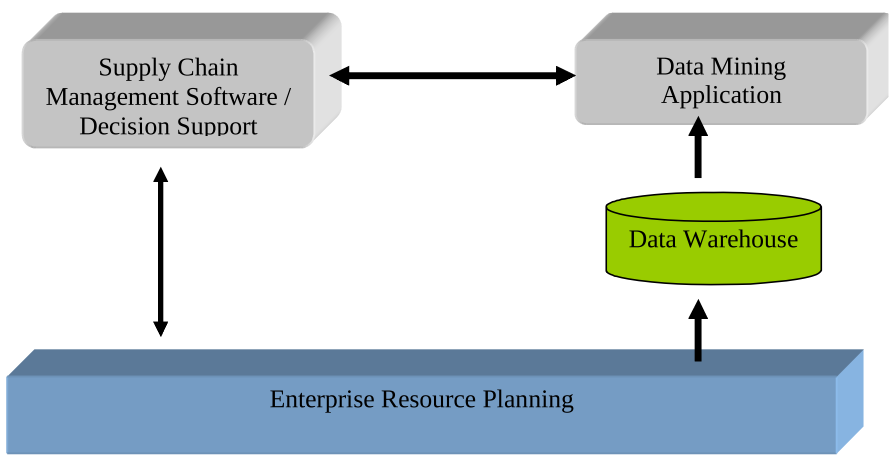
IMPLICATIONS FOR MANAGEMENT

Data mining creates fertile ground for the invention of new tools, analytical methods, and data management to add value to an organization's most valuable asset—its data. Organizations have experienced paybacks of 10 to 70 times their data warehouse investment after data-mining components are added (Chen, Sakaguchi, & Frolick, 2000). But it is not meant to be used for simple querying or reporting purposes, nor complex queries where the parameters are known. It is ideal for cases where only the problem is known, and neither the parameters nor the values of the parameters are known.

It is more important to formulate the business problems and opportunities rather than to start at the technology side. A company should ask the following questions:

1. What are the main business problems and opportunities in the supply chain?
2. What knowledge does a company need to solve these problems or explore opportunities?
3. *Can a company use this knowledge to take appropriate action?*
4. Does a company have the necessary (historical) data available on demand, supply and process behavior to make an analysis potentially successful?
5. *Given a company's knowledge need, what would be the appropriate technique to analyze the available data?*

Figure 2. The data mining implementation architecture



After answering all these questions, a company may decide whether data mining is an appropriate technology.

CONCLUSION

A common characteristic shared by the industry users of data-mining technology is the data intensive. The benefits of data mining have been sufficiently proven in a wide variety of business sectors; it's time to expand the horizon of the application of data mining to other potential areas such as supply chain management. This article makes an initial effort to explore the possibility of using data mining in supply chain management. There is a huge potential for improvement using the techniques of data mining. If small areas can be identified and an incremental approach followed to studying supply chain management, the early adopters of this technology will reap major benefits. Considering the capabilities of today's data-mining software, the power of hidden patterns and relations in supply chain data will lead to important differentiating factors in the competitive global business environment.

KEY TERMS

Data Mining: Process of extracting ideas from data.

Data Warehouse: System for managing data for decision support.

Induction Techniques (Decision Trees and Rule Induction): Assign the largest portion of the discovery process to machine (Nelson, 1998).

Logistics: The art of moving goods within the supply chain.

Neural Networks: Build internal representations of the patterns (Nelson, 1998).

Statistics: High level of user involvement to build models describing the behavior of the data (Nelson, 1998).

Data Mining in Franchise Organizations

Ye-Sho Chen
Louisiana State University, USA

Bin Zhang
Louisiana State University, USA

Bob Justis
Louisiana State University, USA

INTRODUCTION

Franchising has been a popular business approach given the high rate of business failures (Justis & Judd, 2002; Thomas & Seid, 2000), and its popularity continues to increase in today's e-business-centered global economy. For example, *Entrepreneur* magazine¾well known for its Franchise 500 listing¾in early 2001 included a category called Tech Businesses into its Franchise Zone which contains subcategories of Internet Businesses, Tech Training, and Miscellaneous Tech Businesses. At the time of this writing, 35 companies are on the list of Entrepreneur.com. Netchising, combing the power of the Inter*net* for global demand-and-supply processes and international fran*chising* arrangements for local responsiveness, seems to rise as an effective global e-business growth strategy (Beck & Morrison, 2000; Morrison, Beck & Bouquet, 2000). The Netchising business model "offers potentially huge benefits over traditional exporting or foreign direct investment approaches to globalization" and is "a powerful concept with potentially broad applications" (Davenport, 2000, p. 52).

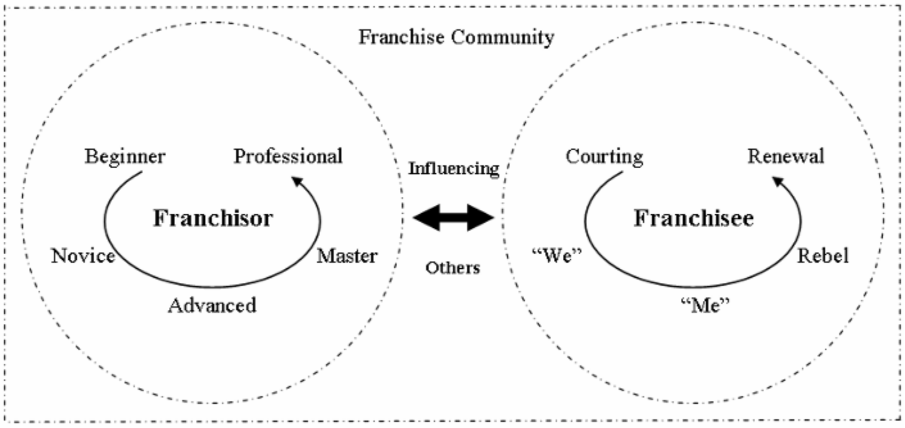
In his best seller, *Business @ the Speed of Thought*, Bill Gates (1999) wrote: "Information technology and business are becoming inextricably interwoven. I don't think anybody can talk meaningfully about one without talking about the other" (p. 6). Gates' point is quite true indeed when one talks about data mining in franchise organizations. Despite its popularity as a global e-business growth strategy, there is no guarantee that the franchising business model will render continuous success in the hypercompetitive environment. This can be evidenced from the constant up-and-down ranking of the Franchise 500 by Entrepreneur.com. Thus, to see how data mining can be "meaningfully" used in franchise organizations, one needs to know how franchising really works. In the next section, we show that (1) building up a good "family" relationship between the franchisor and the franchisee is the real essence of franchising, and (2) proven working knowledge is the foundation of the "family" relationship. We then discuss in the following three sections the process of how to make data mining "meaningful" in franchising. Finally, future trends of data mining in Netchising are briefly described

FRANCHISING: THE FRANCHISOR/ FRANCHISEE RELATIONSHIP

Franchising is "a business opportunity by which the owner (producer or distributor) of a service or a trademarked product grants exclusive rights to an individual for the local distribution and/or sale of the service or product, and in return receives a payment or royalty and conformance to quality standards. The individual or business granting the business rights is called the *franchisor*, and the individual or business granted the right to operate in accordance with the chosen method to produce or sell the product or service is called the *franchisee*" (Justis & Judd, 2002, pp. 1-3). Developing a good "family" relationship between the franchisor and the franchisee is believed to be the most important factor for the success of a franchise (Justis & Judd, 2002). Figure 1 describes how such a "family" relationship is built in the franchise community.

In Figure 1, the franchisor has to learn to deal with many issues to increase the business. The learning process is incrementally developed through the following five stages (Justis & Judd, 2002): (1) Beginner¾learning how to do it; (2) Novice¾practicing doing it; (3) Advanced¾doing it; (4) Master¾teaching others to do it; and (5) Professional¾becoming the best that you can be. At a higher stage of the development, most of the problems in the previous stages have been dealt with. However, more complicated and challenging questions will arise as the franchise continues the expansion. This is especially true when the system reaches the stage of

Figure 1. Understanding how the franchisor/franchisee "family" relationship works



Professional, when many unforeseen and difficult problems could happen all of sudden. Bud Hadfield (1995), the founder of Kwik Kopy franchise and the International Center of Entrepreneurial Development, aptly stated: "The more the company grows, the more it will be tested" (p. 156). To capture the learning process, a counter-clockwise round arrow surrounding the franchisor is used to depict the increasing intensity of learning as the franchisor continues surviving and thriving.

To understand how the "family" relationship is developed, one needs to know the five phases of franchisee life cycle (Schreuder, Krige & Parker, 2000): (1) Courting: both the franchisee and the franchisor are excited with the relationship; (2) "We": the relationship starts to deteriorate, but the franchisee still values the relationship; (3) "Me": the franchisee starts to question the reasons for payments-related issues with the attitude that the success so far is purely of his/her own work; (4) Rebel: the franchisee starts to challenge the restrictions being placed; and (5) Renewal: the franchisee realizes the "win-win" solution is to continue teaming up with the franchisor to grow the system. Similar to the franchisor, a counter-clockwise round arrow surrounding the franchisee is used in Figure 1 to depict the increasing intensity of franchisee life cycle as the franchisee continues learning and growing in the franchise system.

While the franchisee progresses through the life cycle, the "family" relationship is gradually developed through a process of influencing others (Justis & Vincent, 2001), as depicted in Figure 1 with a bi-directional arrow: (1) working knowledge, proven abilities of expanding the franchise system profitably; (2) positive attitude, constructive ways of presenting and sharing the working knowledge; (3) good motivation, providing incentives for learning or teaching the working knowledge; (4) positive individual behavior, understanding and leveraging the strengths of the participants to learn and enhance the working knowledge; and (5) collaborative group behavior, having the team spirit to find the best way to collect, dissimilate, and manage the hard-earned working knowledge. By going through the processes of learning and influencing, both the franchisor and franchisee gain the working knowledge in the franchise community progressively. The franchisor, the franchisee, and the franchise community in Figure 1 are surrounded with dashed lines, meaning there is no limit to the learning process.

MANAGING FRANCHISE ORGANIZATIONAL DATA

There are many contact points within the franchise community where the franchisor and the franchisee can influence each other; in business these contact points are sometimes called "touchpoints." Based on the Customer Service Life Cycle (CSLC) model developed by Ives (2004), Chen, Chong, and Justis (2002) proposed a framework (see Table 1) to harness the Internet to serve the customers for the franchising industry. The 11 sub-stages in Table 1 are based on two well-known franchising books by Justis and Judd (2002) and Thomas and Seid (2000). The model in Table 1 may be used as a comprehensive guide for a franchise system to develop its Web site, especially at the stages of Requirements and Acquisition.

Table 1 also is a comprehensive framework for a franchise organization to model the data needed to serve its customers, that is, franchisees and their customers. A well-designed Internet strategy shall empower the franchisor and the franchisees to collect, use, renew, store, retrieve, transmit, and share the organizational data needed to do the collaborative work in different phases of the CSLC model. Specifically, three types of data are needed:

- *Operational data:* the daily activities at (1) the franchisor headquarters, including six major entity types: employees; business outlets owned by franchisees or companies; prospective franchisees; product development; suppliers (e.g., marketing agents, accountants, insurance providers, attorneys, real estate agents); and government offices, (e.g., taxes and worker compensation); and (2) the franchisee business outlet, including six major entity types: customers, employees, contacts with the headquarters, product inventory, suppliers, and government offices.
- *External data:* the relationship management activities in the franchise community, including three major entity types: the relationship with customers, the relationship with partners and suppliers, and the performance benchmarks in the industry.
- *Legacy data:* the activities that have been working well or gradually adapted since the franchise system came into existence. Examples include (1) rewarding activities to the top performers among the franchisees; (2) efficient procedural activities for the employees at the headquarters supporting the franchisees; and (3) effective and friendly face-to-face activities for the field representatives to serve the franchisees at their outlets.

MANAGING FRANCHISE ORGANIZATIONAL INFORMATION

An architecture, adapted from Inmon (1996), of data mining in franchise organizations with respect to the franchisor/franchisee relationship management depicted in Figure 1 is shown in Figure 2. The architecture consists of four levels: (1) data collection, holding operational, external, and legacy data collected from the franchise

Table 1. The customer-service-life-cycle model in franchising

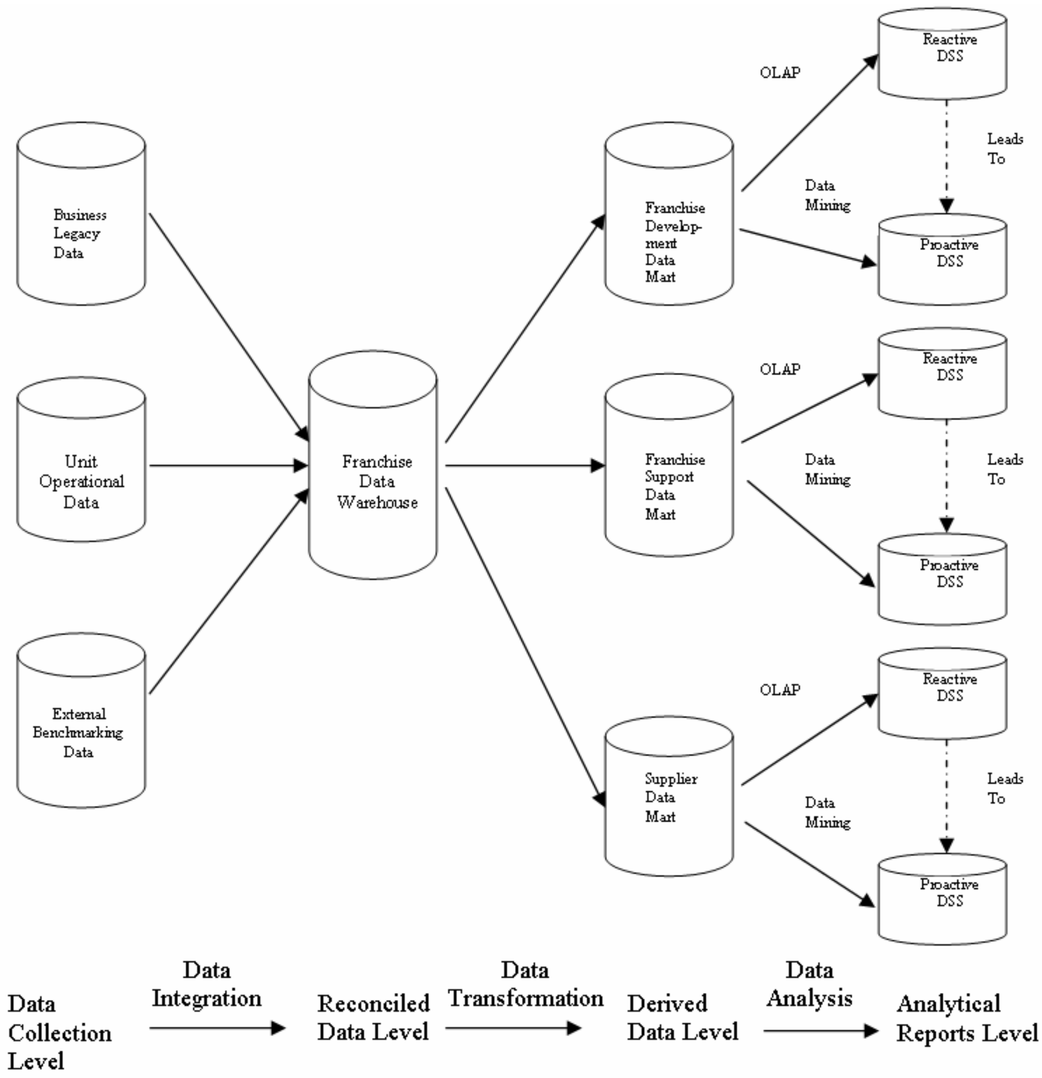
CSLC	Sub-stages	Example: Technology Strategies of WSI Internet (www.wsicorporate.com)
Requirements	Understanding How Franchising Works	Internet
	Investigating Franchise Opportunities	Internet • Global Gateway • Internet Solutions • Portfolio & Technologies • About Us • Franchise Opportunities • Experts Online • Interactive Online
	Obtaining Franchisee Prospectus	Internet • E-mail
	Making the Choice	Internet
Acquisition	Preparing Business Plan	Internet
	Financing the Franchised Business	Internet
	Signing the Contract	Internet
Ownership	Marketing & Promoting the Franchise Products/Services	Internet/Intranet/Extranet • Need a Website? • Live Call • Employment @ WSI • Hot News • WSI ICE Flash • Message from the President
	Managing the Franchise System	Internet Intranet • Serving Franchisees' Customers Extranet
	Building the Relationship between the Franchisor and the Franchisee • The Courting Phase • The "We"-Phase • The "Me"-Phase • The Rebel Phase • The Renewal Phase	Internet Intranet • Knowledge Centre • Training at Headquarters • Newsletter • Meetings • Toll-free Phone Line Extranet • Purchasing Cooperatives
Renewal or Retirement	Becoming a Professional Multi-unit Franchisee or Retiring from the Franchise System	Internet Intranet Extranet

business environment; (2) reconciled data, holding data warehouse data that are subject-oriented, integrated, time-variant, and non-volatile (Inmon, 1996); (3) derived data, containing several data marts (e.g., franchisees, customers, competitors, and suppliers) derived from the data warehouse based on various franchisee/customer-centered segmentations; and (4) the analytical reporting level, producing various relationship performance reports (e.g., business outlet periodical summary, financial, scorecards, and mysterious shopping) for the decision makers using the decision support systems (DSS) for their decision making. To move from the data collection level to the reconciled data level, data integration is needed. It is a very time-consuming process that involves the activities such as cleansing, extracting, filtering, conditioning, scrubbing, and loading. To move from the reconciled data level to the derived data level, data transformation is needed which involves the activities such as replication, propagation, summary, aggregate, and metadata. To move from the derived data level to the analytical reporting level, data analysis is needed which involves two major activities¾online analytical processing (OLAP) and data mining.

A typical OLAP analysis consists of pre-defined multi-dimensional queries. Some examples in franchising are shown below:

- Show the gross margin by product category and by franchise outlets from Thanksgiving to Christmas in the last five years.

Figure 2. An architecture of data mining in franchise organizations



- Which franchise outlets are increasing in sales and which are decreasing?
- Which kinds of customers place the same orders on a regular basis at certain franchise outlets?
- How many franchisees did we lose during the last quarter of 2001, compared to 2000, 1999, and 1998?

Other OLAP activities include spreadsheet analysis, data visualization, and a variety of statistical data modeling methods. Since the query activities are pre-defined, we call the supporting systems reactive DSS.

Data mining, on the other hand, is used to identify hidden relationship patterns of the data residing in the data marts. Typical data mining modeling analysis can be classified into the following three categories:

- Classification and Prediction, using techniques such as RFM (recency, frequency, and monetary), regression, decision tree, and neural network
- Association Rules, using techniques such as market basket analysis, correlation analysis, cross-sell analysis, and link analysis
- Cluster Analysis, using techniques such as partition, hierarchy, outlier, and density analysis

Table 2, adapted from Delmater and Hancock (2001), shows that data mining techniques can be used to help serve franchisees' customers at the different stages of the CSLC model.

Since the data mining queries and related activities are not pre-defined, we call the supporting systems proactive DSS. A major drawback of proactive data mining is that without careful preliminary examination of the data characteristics, the mining activities may end in vain (Delmater & Hancock, 2001). In order to achieve a higher success rate of data mining, we suggest (on the right side of Figure 2) that OLAP-based queries need to be conducted first. For example, one may find, through daily OLAP queries, that certain segments of customers buy certain products frequently. This pattern may lead us to do more in-depth proactive analysis of the customers and products relationships. The result may help the company serve customers better and generate higher profits.

Table 2. Franchisees' customers data mining using the CSLC approach

CSLC	Explanation	Data Mining Activities (and Techniques Used)
Requirements	Finding and reaching the customers	• Lead Generation • Market Analysis & Segmentation (Classification and Prediction) • Mining Web Site Visitors (Association Rules) • Text Mining Usenet Newsgroups (Cluster Analysis)
Acquisition	Selling to the customers	• Customer Acquisition Profiling • Customer Segmentation Strategy (Classification and Prediction) • Online Shopping Tracking (Association Rules) • Pricing Strategy (Association Rules) • Customer-centric Selling (Association Rules) • Text Mining Contact E-Mails (Cluster Analysis) • Scenario Notification (Association Rules)
Ownership	Satisfying the customers after the sales	• Customer Service • Inquiry Routing (Association Rules) • Text Mining E-Mails & Inquiries (Cluster Analysis) • Scenario Notification (Association Rules) • Staffing Level Prediction (Classification and Prediction)
Retirement or Renewing	Retaining the customers so that you can continue coming back	• Customer Retention • Sharper Customer Focus through Loyalty Program (Classification and Prediction) • Detecting Customer Complaints through Text Mining (Cluster Analysis) • Detecting Inappropriate Customer Services (Cluster Analysis) • Individual Customer Profiles (Classification and Prediction) • Scenario Notification (Association Rules)

MANAGING FRANCHISE ORGANIZATIONAL KNOWLEDGE

As was mentioned in the discussions of Figure 1, the key for building the franchisor/franchisee "family" relationship is in the franchise organizational learning. In addition, there are five vital factors for a successful learning program: knowledge, attitude, motivation, individual behavior, and group behavior. Thus, working knowledge is the real foundation of a successful franchise "family" relationship. The working knowledge is structured in many forms of profiles that are embedded in the operational manuals of the franchise business processes. Table 3 gives some examples of those working knowledge profiles with respect to the CSLC business processes associated with the sub-stages in Table 1.

A working knowledge profile is developed when a certain task of the CSLC process is repeated many times with good results. Consider the Site Profile used at the "Marketing & Promoting the Franchise Products/Services" sub-stage in Table 3. The Site Profile is used to help the new franchisee to find a good business site, and typically it is the real estate department at the franchisor headquarters which is responsible in developing the profile. The Site Profile is continuously being tested and enhanced. Various OLAP/Data Mining analytical reports monitoring the performance of the sites are generated at the Analytical Reports Level shown in Figure 2. Based on those reports, the real estate experts and their teams are able to fine-tune the attributes and the parameters within the Site Profile. Most often, the corresponding data collection procedures in the CSLC sub-stage also need to be revised and perfected so that better report scorecards can be generated.

This process of enhancing the working knowledge profile will achieve its high peak when both the franchisor and the franchisees are arriving at the Professional and Renewal stage of growth. A significant phenomenon of being a Professional franchisor and a Renewal franchisee are their ability to leverage the assets of the hard-earned working knowledge profiles into dynamic capabilities and high-business-value-creation completive-advantage strategies. The new products or services coming out of the process of leveraging the working knowledge profiles may transform the franchise business into a more, sometimes surprisingly, profitable enterprise. The capability of leveraging the assets of franchise working knowledge into profitable products or services is at the heart of a successful franchise.

Consider as an example the site selection working knowledge at McDonald's. The Franchise Realty Corporation real estate business, a result of site selection asset leveraging, is the real money-making engine at McDonald's. This can be evidenced from the following speech of Ray Kroc, founder of McDonald's, to the MBA class at the University of Texas at Austin in 1974: "Ladies and gentlemen, I'm not in the hamburger business. My business is real estate" (Kiyosaki, 2000, p. 85), In the book *McDonald's: Behind the Arches* (Love, 1995, p. 152), Kroc commented further: "What converted McDonald's into a money machine had nothing to do with Ray Kroc or the McDonald brothers or even the popularity of McDonald's hamburgers, French fries, and milk shakes. Rather, McDonald's made its money on real estate…." McDonald's makes money out of real estate by leasing properties from landlords and then subleasing the stores to the franchisees. The Professional franchisees, many of them are multi-unit operators, can then focus on expending the business without worrying about finding good locations for the growth. This money-making real estate strategy is what separates McDonald's from other fast-food chains (David, 2003).

Knowledge repository systems, consisting of working knowledge profiles such as the one shown in Figure 3, can be linked into the franchisor headquarters and the franchisee outlets for knowledge sharing and learning. Such a repository has two dimensions. First, there is a working knowledge level for the collaborative team, the franchisee outlet, the franchisor headquarters, and the franchise community. Second, there are user skill levels, including Beginner in the Courting Phase, Novice in the "We"-Phase, Advanced in the "Me"-Phase, Master in the Rebel Phase (since the rebel ones tend to be those who know the system very well and are capable of influencing others to follow them), and Professional in the Renewal Stage of the franchisee life cycle. The foundation of the framework is the working knowledge of the five crucial elements—Knowledge, Attitude, Motivation, Individual Behavior, and Group Behavior—used by the collaborative team, to effectively influence others in building the franchise "family" relationship. The working knowledge profiles at the franchisee outlet, the franchisor headquarters, and the franchise community can be modularized according to the user's level. An intranet-based curriculum of working knowledge modules can then be designed for the users to learn the working knowledge profiles effectively.

FUTURE TRENDS

The third industrial revolution, combining Internet technology with globalization, produces various new data mining opportunities for the growth of franchise organizations. For example, knowledge network applications, using data mining techniques such as social network analysis (Wasserman & Faust, 1994), can be developed to connect Professional franchisees in the world. The goal

Table 3. The CSLC model of franchise working knowledge

CSLC Sub-stages	Examples of Working Knowledge Profiles
Understanding How Franchising Works	• Lead Generation Profile • Website Visitor Profile
Investigating Franchise Opportunities	• Benchmark Profile • Successful Franchisee Profile
Obtaining Franchisee Prospectus	• Prospectus Profile
Making the Choice	• Competitor Profile
Preparing Business Plan	• Business Plan Profile
Financing the Franchised Business	• Financing Institute Profile • Non-traditional Franchising Profile
Signing the Contract	• Franchisee Profile
Marketing & Promoting the Franchise Products/Services	• Site Profile • Customer Profile • Product Profile
Managing the Franchise System	• Support Team Profile • Employee Profile • Supplier Profile
Building the Relationship between the Franchisor and the Franchisee	• Event Management Profile • Best Practices Profile • Crisis Management Profile
Becoming a Professional Franchisee or Retiring from the Franchise System	• Multi-unit Franchisee Profile • Co-branding Profile • Opportunities Profile • Social Network Profile

is to enable the franchise system to venture into new global emerging markets¾ for example, China¾ through international franchising, and develop innovative products/services through asset leveraging. This could be done because franchise capabilities, structured in the working knowledge repository shown in Figure 3, enable the Professional franchisees to work with the franchisor to continuously improve and leverage the current franchise working knowledge. An example of knowledge networks of Professional franchisees can be illustrated in Figure 4. There are six Professional franchisees (A-F) in the figure, with three clusters (A-C, D-E, and F) of knowledge networks. Each Professional franchisee (a dot) has his/her personal knowledge network (arrows pointing out of the dot) tested and built over the years while doing day-to-day problem solving at the franchisee outlet. The knowledge network may include the customers' likes and dislikes, the kind of employees to hire, the competitors' and suppliers' pricing strategies, and the social needs in the local community. Each Professional franchisee is surrounded with a circle with dashed lines, meaning there is no limit to the personal knowledge network. In order to solve the problems more effectively, Professional franchisees may share with each other their approaches. Thus, clusters (connected dots) of knowledge network are formed for solving various problems more effectively.

CONCLUSION

Franchising has been popular as a growth strategy for small businesses; it is even more so in today's global and e-commerce world. The essence of franchising lies in managing the "family" relationship between the franchisor and the franchisee. In this article we showed data mining plays an important role in growing and nurturing such a "family" relationship. Specifically, we discussed: (1) how franchise organizational data can be managed effectively using the methodology of Customer Service Life Cycle; (2) how franchise organizational information is deciphered from the customer-centered data using OLAP and data mining analytical techniques; and (3) how the franchise organizational knowledge is leveraged to grow the franchise system. The ability to continue leveraging the

KEY TERMS

Customer Service Life Cycle: Serving customers based on a process of four stages: Requirements, Acquisition, Ownership, and Retirement. Many companies are using the approach to harness the Internet to serve the customers.

Data Mart: A small database with data derived from a data warehouse.

Data Mining: Analytical techniques used to find out the hidden relationships or patterns residing in the organizational data.

Data Warehouse: A database that is subject-oriented, integrated, time-variant, and non-volatile.

Franchisee: The individual or business who receives the business rights and pays the royalties for using the rights.

Franchisee Life Cycle: The stages a franchisee goes through in the franchise system: Courting, 'We,' 'Me,' Rebel, Renewal.

Franchising: A business opportunity based on granting the business rights and collecting royalties in return.

Franchisor: The individual or business who grants the business rights.

Franchisor/Franchisee Learning Process: The stages of learning, including Beginner, Novice, Advanced, Master, and Professional.

Franchisor/Franchisee Relationship Management: The vital factor for the success of a franchise, including: Knowledge, Attitude, Motivation, Individual Behavior, and Group Behavior.

Data Mining in Practice

Sherry Y. Chen
Brunel University, UK

Xiaohui Liu
Brunel University, UK

INTRODUCTION

There is an explosion in the amount of data that organizations generate, collect, and store. Organizations are gradually relying more on new technologies to access, analyze, summarize, and interpret information intelligently and automatically. Data mining, therefore, has become a research area with increased importance (Amaratunga & Cabrera, 2004). Data mining is the search for valuable information in large volumes of data (Hand, Mannila, & Smyth, 2001). It can discover hidden relationships, patterns, and interdependencies, and generate rules to predict the correlations, which can help the organizations make critical decisions faster or with a greater degree of confidence (Gargano & Raggad, 1999).

There is a wide range of data mining techniques that has been successfully used in many applications. This paper is an attempt to provide an overview of existing data-mining applications. The paper begins by building a theoretical background to explain key tasks that data mining can achieve. It then moves to discuss applications domains that data mining can support. The paper identifies three common application domains, including bioinformatics data, electronic commerce, and search engines. For each domain, how data mining can enhance the functions will be described. Subsequently, the limitations of current research will be addressed, followed by a discussion of directions for future research.

BACKGROUND

Data mining can be used to achieve many types of tasks. Based on the types of knowledge to be discovered, it can be broadly divided into supervised learning and unsupervised learning. The former requires the data to be preclassified. Each item is associated with a unique label, signifying the class in which the item belongs. In contrast, the latter does not require preclassification of the data and can form groups that share common characteristics (Nolan, 2002). To achieve these two main tasks, four data mining approaches are commonly used: classification, clustering, association rules, and visualization.

Classifications

Classification, which is a process of supervised learning, is an important issue in data mining. It refers to discovering predictive patterns where a predicted attribute is nominal or categorical. The predicted attribute is called the class. Subsequently, a data item is assigned to one of predefined sets of classes by examining its attributes (Changchien & Lu, 2001). One example of classification applications is to analyze the functions of genes on the basis of predefined classes that biologists set (see "Classifying Gene Functions").

Clustering

Clustering is also known as *Exploratory Data Analysis* (EDA; Kohonen, 2000). This approach is used in those situations where a training set of preclassified records is unavailable. Objects are divided into groups based on their similarities. Each group, called a cluster, consists of objects that are similar between themselves and dissimilar to objects of other groups (Roussinov & Zhao, 2003). From a data mining perspective, clustering is unsupervised learning of a hidden data concept. One of the major applications of clustering is the management of customers' relationships, which is described in "Customer Management."

Association Rules

Association rules, which were first proposed by Agrawal and Srikant (1994), are mainly used to find out the meaningful relationships between items or features that occur synchronously in databases (Wang, Chuang, Hsu, & Keh, 2004). This approach is useful when one has an idea of the different associations that are being sought out. This is because one can find all kinds of correlations in a large data set. It has been widely applied to extract knowledge from Web log data (Lee, Kim, Chung, & Kwon, 2002). In particular, it is very popular among marketing managers and retailers in electronic commerce who want to find associative patterns among products (see "Market Basket Analysis").

Visualization

The visualization approach to data mining is based on an assumption that human beings are very good at perceiving structure in visual forms. The basic idea is to present the data in some visual form, allowing the human to gain insight from the data, draw conclusions, and directly interact with the data (Ankerst, 2001). Since the user is directly involved in the exploration process, shifting and adjusting the exploration goals is automatically done if necessary (Keim, 2002). This approach is especially useful when little is known about the data and the exploration goals are vague. One example of using visualization is author co-citation analysis (see "Author Cocitation Analyses").

DATA-MINING APPLICATIONS

As mentioned in the aforementioned discussion, data mining can be used to achieve various types of tasks, such as classification, clustering, association rules, and visualization. These tasks have been implemented in many application domains. The main application domains that data mining can support include bioinformatics data, electronic commerce, and search engines.

Bioinformatics Data

In the past years, bioinformatics has been overwhelmed with increasing floods of data gathered by the Human Genome Project. Consequently, a major challenge in bioinformatics is extracting useful information from these data. To face this challenge, it is necessary to develop an advanced computational approach for data analysis. Data mining provides such potentials. Three application areas, which are commonly presented in the literature, are described below.

Clustering Microarray Data

Unsupervised learning produces clustering algorithms, which are being applied to DNA microarray data sets. The clustering algorithms are often incorporated into the analysis software of microarray images and are therefore frequently used to visualize local and global relationships among hybridization signals captured by the array. Currently, hierarchical clustering is the most popular technique employed for microarray data analysis. Basically, this approach is based on similarity or dissimilarity to proceed successively by either merging smaller clusters into larger ones or by splitting larger clusters (Moller-Levet, Cho, Yin, & Wolkenhauer, 2003). The results of the algorithm are a tree of clusters called a *dendrogram* (Liu & Kellam, 2003). One disadvantage of this approach is that clustering algorithms are very sensitive to noisy data and errors in the data set.

Classifying Gene Functions

Biologists often know a subset of genes involved in a biological pathway of interest and wish to discover other genes that can be assigned to the same pathway (Ng & Tan, 2003). Unlike clustering, which processes genes based on their similarity, classification can learn to classify new genes based on predefined classes, taking advantage of the domain knowledge already possessed by the biologists. Therefore, the classification approach seems more suitable than clustering for the classification of gene functions. To conduct the classification, we need supervised learning to assign pathway memberships that correspond well to the true underlying biological pathways.

Identifying Phenotype Data

In the two aforementioned approaches, the genes are treated as objects while the samples are the attributes. Conversely, the samples can be considered as the objects and the genes as the attributes. In this approach, the samples can be partitioned into homogeneous groups. Each group may correspond to some particular phenotype (Golub, et al., 1999). A phenotype is the observable and physical characteristics of an organism. Over the past decade, growing interest has surfaced in recognizing relationships between the genotypes and phenotypes. Tracing a phenotype over time may provide a longitudinal record for the evolution of a disease and the response to a therapeutic intervention. This approach is analogous to removing components from a machine and then attempting to operate the machine under different conditions to diagnose the role of the missing component. Functions of genes can be determined by removing the gene and observing the resulting effect on the organism's phenotype.

Electronic Commerce

The widespread use of the Web has tremendous impact on the way organizations interact with their partners and customers. Many organizations consider analyzing customers' behavior, developing marketing strategies to create new consuming markets, and discovering hidden loyal customers as the key factors of success. Therefore, new techniques to promote electronic business become essential, and data mining is one of the most popular techniques (Changchien & Lu, 2001). Data mining applications in electronic commerce include customer management and market basket analysis.

Customer Management

For analyzing customers' behaviors, a frequently used approach is to analyze their usage data in order to discover user interests, and then recommendations can be made based on the usage data extracted. Wang et al. (2004) have developed a recommendation system for the cosmetic business. In the system, they segmented the customers by using clustering algorithms to discover different behavior groups so that customers in the same group have similar purchase behavior. For each group's customers, they used the association-rules algorithm to discover their purchase behavior. In addition, they scored each product for each customer who might be interesting in it with the collaborative filtering approach and content-based filtering. They found that this approach could not only recommend the right product to the right person, but also recommend the right product to the right person at the right time.

Market Basket Analysis

Market basket analysis is a typical example among the various applications of association rules, and it aims at identifying associations between consumers' choices of different products (Giudici & Passerone, 2002). The data analyzed in a market basket analysis usually consists of all buying transactions carried out by the consumers in a certain unit of time. The market basket analysis refers to the application of data-analysis techniques to databases that store transactions from consumers buying choices of different products. The aim of the analysis is to understand the association structure between the sales of the different products available. Once the associations are found, they may help in planning marketing policies. For instance, if there is a relationship between two products over time, then retailers can use this information to contact the customer, decreasing the chance that the customer will purchase the product from a competitor. This is the type of data typically analyzed with association rules.

Search Engines

Data mining is of increasing importance for search engines. Traditional search engines offer limited assistance to users in locating the relevant information they need. Data mining can help search engines to provide more advanced features. According to current applications, there are three potential advantages: (a) ranking of pages, (b) improvement of precision, and (c) author co-citation analysis. These advantages are described below.

Ranking of Pages

Data mining identifies the ranking of the Web pages for a particular topic by analyzing the interconnections of a series of related pages. PageRank (Kamvar, Haveliwala, Manning, & Golub, 2003) applies this approach to find pertinent Web pages. In PageRank, the importance of a page is calculated based on the number of pages that point to it. This is actually a measure based on the number of back links to a page. A back link is a link pointing to a page rather than pointing out from a page. This measure is used to prioritize pages returned from a traditional search engine using keyword searching. Google applies this measure to rank the search results. The benefit is that central, important, and authoritative Web pages are given preferences. However, the problem is that it only examines the forward direction. In addition, a much larger set of linked documents is required.

Improvement of Precision

The problem of PageRank is that it is a purely link structure-based computation, ignoring the textual content. Therefore, the precision is low. On a narrowly focused topic, it frequently returns resources for a more general topic. The IBM Almaden Research Centre continues to develop the Clever search engine (Chakrabarti et al., 1999). The main approach is to promote precision by combining content with link information, breaking large hub pages into smaller units, and computing relevance weight for pages. Users' logs are the other source that can be used to improve precision. Zhang and Dong (2002) developed a Chinese image search engine named eeFind by using the matrix analysis on search engine log (MASEL). The basic idea of MASEL is to use the query log to find relations among users, queries, and clicks on results. The relation between pages chosen after a query and the query itself provides valuable information. After a query, a user usually performs a click to view one result page.

Author Co-Citation Analyses

Author co-citation analysis (ACA) has been widely used as a method for analyzing the intellectual structure of science studies. It can be employed to identify authors from the same or similar research fields. Chen and Paul (2001) used visualization to perform such an analysis, and a 3D virtual landscape was applied to represent author co-citation structures. The most influential scientists in the knowledge domain appear near the intellectual structure's center. In contrast, researchers who have unique expertise tend to appear in peripheral areas. The virtual landscape also lets users access further details regarding a particular author in the intellectual structure, such as a list of the author's most cited papers, abstracts, and even the full content of that author's articles.

FUTURE TRENDS

The above three application domains demonstrate that data mining is a very useful technology that opens new opportunities for data analysis. However, there are still many limitations that we need to be aware of and that should be investigated in further work.

Preparation of Data

It is important to know that the effective implementation of data mining methods depends on a large extent on the availability and quality of the data. Therefore, a cleaning and data-transformation step before analysis is usually needed. In addition, we have to understand the characteristics of each application and set clear data mining targets so that truly useful information can be produced with appropriate data mining techniques.

Good Communication

Data mining is an interdisciplinary research area, which involves experts from different domains. One of the significant problems of interdisciplinary research is the wide range and levels of domains of expertise that are present among potential users, so it can be difficult to provide access mechanisms appropriate to all (Kuonen, 2003). Therefore, it is important to have good communications between data mining technologist and users, and among users from different domains.

Multimedia Mining

Basically, Web content consists of a variety of media types such as text, image, audio, video, and so forth. Multimedia mining is engaged to mine the unstructured information and knowledge from these online multimedia sources. However, most current research in the area of data mining still focuses on text data; multimedia mining has received less attention than text mining (Kosala & Blockeel, 2000) and opens a new window for future research to explore.

Evaluation of Effectiveness

As previously described, data mining enhances the functions of the applications in different domains. However, the effectiveness of these applications is still a question. Certainly, there is a need to conduct more empirical studies to verify the effectiveness and evaluate the performance of these applications. In particular, we need more evaluation from user points of view. Better and more detailed evaluation can lead to better understanding of users' needs, and help to develop more effective applications.

CONCLUSION

In summary, data mining can search for interesting relationships and global patterns from various types of resources. These relationships and patterns represent valuable knowledge about the objects that are reflected by many applications in the real world. In this paper, we have given some background to data mining and have provided an overview of three application domains, including bioinformatics data, electronic commerce, and search engines. It should be noted that data mining has also been applied to other application domains, such as digital libraries, Web-based learning, health care, and so forth. It is another direction for future research to investigate what major functions are required for each application domain and to develop concrete criteria for the evaluation of their effectiveness. These works can be integrated together to generate guidelines, which can be used for commercial and research communities to select suitable data mining techniques. The ultimate goal is to enhance the functions and performance of these applications by exploiting the full potential of data mining techniques.

KEY TERMS

Author Cocitation Analysis: The analysis of how authors are cited together

Bioinformatics: An integration of mathematical, statistical, and computational methods to organize and analyze biological data

Collaborative Filtering: A technique that is used for making recommendations by computing the similarities among users

Content-Based Filtering: A technique that involves a direct comparison between the content or attributes of a user's profile and the document to make recommendations

Dendrogram: A graphical procedure for representing the output of a hierarchical clustering method. It is strictly defined as a binary tree with a distinguished root that has all the data items at its leaves.

Electronic Commerce: Commercial activities that facilitate the buying and selling of goods and services over the Internet

Microarrays: A high-throughput technology that allows the simultaneous determination of mRNA abundance for many thousands of genes in a single experiment

Multimedia Mining: A new field of knowledge discovery in multimedia documents, dealing with nonstructured information such as texts, images, videos, audio, and virtual data

Noisy Data: Errors in the data due to the nature of data collection, measurement, or sensing procedures

Search Engines: Web services that help search through Internet addresses for user-defined terms or topics

INTRODUCTION

The concept of data warehouse first appeared in Inmon (1993) to describe a "subject oriented, integrated, non-volatile, and time variant collection of data in support of management's decisions" (31). It is a concept related to the OLAP (online analytical processing) technology, first introduced by Codd et al. (1993) to characterize the requirements of aggregation, consolidation, view production, formulae application, and data synthesis in many dimensions. A data warehouse is a repository of information that mainly comes from online transactional processing (OLTP) systems that provide data for analytical processing and decision support.

The development of a data warehouse needs the integration of data that come from different sources, mainly legacy systems. The development of a data warehouse is, like any other task that implies some kind of integration of preexisting resources, complex. This process, according to Srivastava and Chen (1999), is "labor-intensive, error-prone, and generally frustrating, leading a number of warehousing projects to be abandoned mid-way through development" (118). OLTP and OLAP environments are profoundly different. Therefore, the techniques used for operational database design are inappropriate for data warehouse design (Kimball & Ross, 2002; Kimball et al., 1998).

Despite the obvious importance of having a methodological support for the development of OLAP systems, the scientific community and product providers have paid very little attention to the design process. Models usually utilized for operational database design (like the Entity/Relationship-E/R model-should not be used without further ado for analytical environments design. Bearing in mind just technical reasons, databases obtained from E/R models are inappropriate for decision support systems, in which query performance and data loading (including incremental loading) are important (Kimball & Ross, 2002). Multidimensional paradigm should be used not only in database queries but also during its design and maintenance. As stated in Dinter et al. (1999): "To use the multidimensional paradigm during all development phases it is necessary to define dedicated conceptual, logical and physical data models for the paradigm and to develop a sound methodology which gives guidelines how to create and transform these models during the development process." Wu & Buchmann (1997) claimed for data warehouse design methodologies and tools "with the appropriate support for aggregation hierarchies" and "mappings between the multidimensional and the relational models,"(79).

The next section summarizes existing approaches in data warehouse design. Then, our approach for the development of data warehouses is briefly described. Finally, conclusions are presented.

SUMMARY OF EXISTING APPROACHES

There are several proposals for data warehouse design; in this section, we summarize the most relevant ones.

In Kimball and Ross (2002) and Kimball et al. (1998), an approach based on two points is proposed: the data warehouse bus architecture that shows how to construct a series of data marts that, finally, will allow for the creation of a corporate data warehouse, and the business dimensional life cycle (BDL) with the purpose of development of data marts based on dimensional star schemas starting from the business requirements. It is an iterative methodology in which, after a project planning and a business requirements definition task, different activities are developed. These activities can be categorized into three groups: technology activities, data design activities, and specification and development of final user applications activities.

Last, there are two activities related to data warehouse deployment, maintenance, and growth. It is a detailed methodology and, according to the authors, is widely tested. However, in our opinion, it is focused on the relational model from its initial phases.

In Debevoise (1999), an object-oriented methodological approach is proposed, using Unified Modeling Language (UML) to detail the methodology steps. Use case diagrams are used to describe the tasks that the team has to carry out to complete each phase. Use cases will specify what every team member has to do to complete each project cycle part. This methodology is less detailed than the previous one and is a bit difficult to follow.

Cabibbo and Torlone (1998) presented a logical model for multidimensional (MD) database design, and a design methodology to obtain a MD schema from operational databases. As the starting point, they use an ER schema that describes an integrated view of the operational databases. This schema may contain all information valuable for the data warehouse, but the information is in an inappropriate format for this kind of system. The methodology consists of a series of steps for the MD model schema construction and its transformation into relational models and multidimensional matrices. The methodology is incomplete and starts from an ideal assumption; that is, all information is contained in the ER schema. In our opinion, operational schemas should be simply a support, giving more importance to analytical users' requirements.

Golfarelli and colleagues (Golfarelli & Rizzi, 1999; Golfarelli, Maio, & Rizzi, 1998) outlined a methodological framework for data warehouse design based on a conceptual multidimensional model of the same authors, called dimensional fact model (DFM). The methodology is mainly focused on a relational implementation.

Abelló et al. (2001, 2002) reviewed multidimensional data models and proposed a new one, as an extension of UML. Luján-Mora et al. (2002) also extended UML for multidimensional modeling and proposed a methodology also based on UML for the development of data warehouses (Trujillo & Luján-Mora, 2003; Trujillo et al., 2001).

There are many other partial proposals, focused on issues such as model transformation, view materialization, index, etc. For example, Sapia et al. (1999) proposed using data mining techniques in data warehouse design phases (for example, using data mining algorithms for discovering implicit information on data, for conflict resolution in schema integration for recovering lost values and incorrect data, etc.).

The problem with all these works is that they propose to use a new different methodology for data warehouse design, so organizations must use at least two different methodologies: one for OLTP environments and one for OLAP environments. We think that it is better to integrate data warehouse design in the existing methodologies, modifying and adding new activities, so that the training and learning curve for data warehouse design is less difficult.

OUR APPROACH

Our approach is based on applying the experience and knowledge obtained in relational database system development in the last decade (Structed-Query Language or SQL, ER modeling, Computer Aided Software Enginerring or CASE tools, methodologies...) to multidimensional database (MDDB) design. We propose a MDDB development methodology analogous to the traditional ones used in the relational database systems development. Instead of defining a new methodology, we adapt METRICA, an existing traditional methodology (de Miguel et al., 1998), to the development of data warehouses.

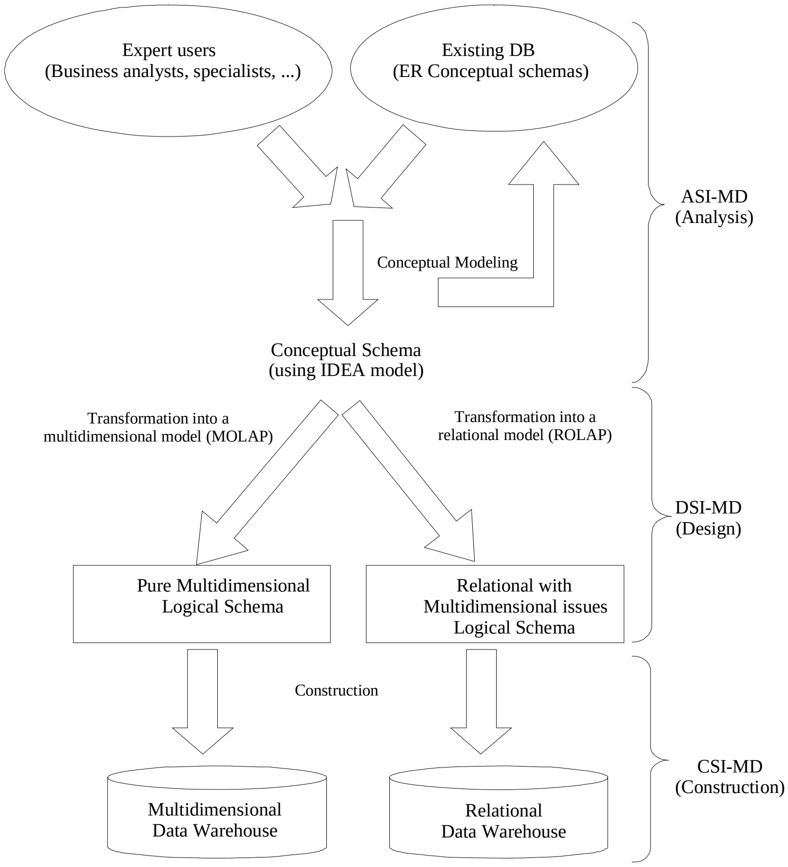
Our methodology (MIDEA) (Cavero et al., 2003) uses as reference framework the Spanish Public Methodology METRICA version 3 proposal (MV3), which is similar to British Structured Systems Analysis Design Method (SSADM) or French Merise. The considered MV3 processes are those that have more influence on the data warehouse development, that is, information system analysis, design, and construction (ASI, DSI, and CSI). The new processes, modified from the original MV3 proposal, have been named as ASI-MD (multidimensional), DSI-MD, and CSI-MD, respectively. Of course, it does not mean that the rest of the processes should not be taken into account on a data warehouse development, but we have considered that the differences should not be significant with respect to any other information system development.

MIDEA uses IDEA, Integrating Data: Elementary-Aggregated, (Sánchez et al., 1999) as a conceptual model. IDEA is a multidimensional conceptual model used to understand and represent analytical users' requirements in a similar manner as the ER model is used to interact with microdata users. Preexisting OLTP system data schema and requirements obtained from analytical data users are the main inputs to the construction of IDEA multidimensional conceptual schema.

This methodology is supported by a CASE tool that incorporates a graphical interface (de Miguel et al., 2000). This tool allows the transformation of a conceptual IDEA schema into a logical schema based on a model supported by some multidimensional or relational products.

Figure 1 presents an overview of the methodology, showing the scope of its three processes: ASI-MD, DSI-MD, and CSI-MD.

Figure 1. Methodology overview



Each process consists of activities, and each activity consists of tasks. The order of the activities does not mean that sequential order is mandatory. The activities can be developed in a different order, or in parallel, overlapping tasks of different activities. However, a process will not be completed until the completion of each of its activities. In every process, a graphic emphasizing its most important activities is included.

One of the activities of the ASI-MD phase is "datawarehouse conceptual modeling." The main purpose of this activity is to obtain, using the IDEA model, the data warehouse multidimensional conceptual schema. It has seven tasks: obtaining preliminary subcell structures, obtaining preliminary dimensions, obtaining preliminary hierarchies, obtaining detailed hierarchies, obtaining detailed subcell structures, obtaining fact schemas, and multidimensional schema verification and validation. For a detailed specification of such tasks, see Cavero et al. (2002).

CONCLUSION

Data warehouse development has turned into a critical success factor for many companies. During this process, some important issues must be taken into account:

1. Integration of OLTP and OLAP database design in a unique methodology
2. Verification and construction of analytical schemas starting from analytical data user requirements, using existing operational schemas as support for the creation of conceptual multidimensional schema

3. Reverse engineering to obtain conceptual schemas from existing specific multidimensional databases
4. Creation or modification of existing operational schemas as a result of analytical users' requirements

KEY TERMS

Conceptual Modeling: High-level modeling; modeling at a high level of abstraction.

Data Mart: A data warehouse focused on a particular subject or department. Data warehouses may consist of several data marts.

Data Warehouse: A repository of information coming mainly from online transactional processing systems that provides data for analytical processing and decision support.

Multidimensional Databases: Databases based on multidimensional models.

Multidimensional Modeling: A modeling technique used in data warehouses, multidimensional databases, and OLAP applications, based on defining the facts of interest in terms of their dimension hierarchies.

OLAP (Online Analytical Processing): A category of tools and techniques that allows online analysis of data, usually by means of multidimensional views of data.

OLTP (Online Transaction Processing): In data warehousing context, this refers to the traditional transaction processing of data, as opposed to the analytical processing provided by OLAP.

Database Integrity

Jorge H. Doorn
INTIA, Universidad Nacional del Centro de la Provincia de Buenos Aires, Argentina

INTRODUCTION

One of the factors that stimulated the development of database technology was the need to guarantee the consistency of the stored data. On the other hand, the demand to process more complex data with more semantic content have also lead to a better understanding of the properties of the data and motivated the evolution of the Data Base Management Systems (DBMS) toward the inclusion of facilities to handle such properties. The handling of data properties within the context of a database engine faces two main difficulties: 1) Properties are hard to identify, especially those obvious in the actual world; 2) Data property presentation varies during the process of design of the software.

The first one falls in the field of the Requirement Engineering (Loucopoulos & Karakostas, 1995). The proper requirements elicitation of a software product is a key factor in the success of the whole software development process. However, these requirements are not easy to deal with. They have different intrinsic natures and they may appear showing different faces. In many cases, some requirements are totally or partially hidden in the information collected by the software developers (Jackson, 1995).

The second one falls in the fields of Conceptual modeling and Earlier Logical Design (Doorn & Rivero, 2002). During these activities, issues concerning data modeling and DBMS paradigms promote changes in the way they are considered. Pragmatic issues such as the degree of adhesion of a given DBMS or others related with performance may introduce additional mutations. The understanding of the evolution from actual world data properties to database world integrity restrictions is another a key factor in the success of the software artifact during its life cycle. This understanding must be accompanied with a well defined traceability mechanism, which must clearly identify the actual world data property behind every database integrity restriction (Pinheiro, 2003). Traceability is also a key factor especially during software maintenance activities.

BACKGROUND

Not every data property must be modeled, but each property must be looked at carefully to see if modeling is needed in the context of the scope and in the objective of the software artifact. A more analytical approach may order the data properties by taking into account their importance (Karlsson, 1996).

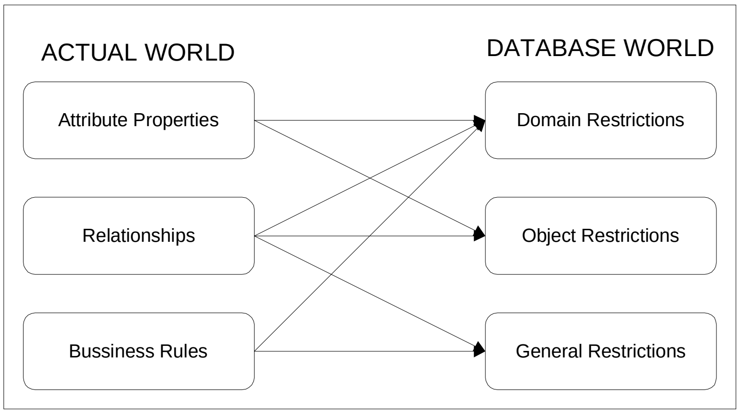
When a data property describes the allowed values for attributes, it is called Attribute Property. Another kind of data property establishes connections among different attributes, known as Relationships. When a data property carries out a semantic that is specific of the Universe of Discourse, not found in other occurrences of the same data, it is called a Business Rule (Ceri et al., 1997; Codd, 1990; Ross, 1997).

Many authors have addressed the restrictions in Databases. In Dey (1999), a profound analysis is done about ternary and higher degree relationships. The authors depict a general framework for the analysis of such constructs and provide generalized rules for their representation in the relational model. Ceri et al. (2000) analyze the order in which triggers, stored procedures, and referential integrity restrictions are executed. Regarding this matter, SQL3 (Cochrane, 1996) has defined a precise execution order and scope of its clauses. A survey of the state of the art of the semantic integrity constraints in some relational and object relational available database systems is done in Rivero et al. (2002).

EVOLUTION OF DATA PROPERTIES

Figure 1 shows all possible mappings from data properties in the actual world to database integrity restrictions. It should be noticed that there are neither arrows from Business Rules to Object Restrictions, nor from Attribute Properties to General Rules. These mappings are extremely hard to find. Also, some other mappings shown in Figure 1 occur very seldom, while others are common. Figure 2 introduces a basic taxonomy of both actual world data properties and database integrity restrictions and gives a more detailed mapping.

Figure 1. Mappings data properties into integrity restrictions



Attribute Properties. Database Engines have a set of built-in data types whose main purpose is to deal with the Attribute Properties of the data to be stored. These data types are useful and have been used for decades, helping users to take care of their data processing needs.

As with all the other Non-Functional Requirements, Attribute Properties are expressed in the Universe of Discourse in declarative ways. An Attribute Property defines the Set of Values that the attribute may have. These sets may be defined by enumeration of the members or by intention. Basically, Attribute Properties defined by enumeration map to Object Restrictions while those defined by intention may map to Domain Restrictions upon the ability of the DMBS to express the restriction (see arrows leaving Attribute Properties in figure 2). When an Attribute Property is defined by enumeration, the list of all possible values for such an attribute should be stored somewhere in the Database. It will become an inclusion dependency when such list is not key of the holding object. Otherwise it will be materialized as a referential integrity constraint.

Relationship Properties. The connection among different attributes is the source of most of the data processing richness and problems. These connections have a scope larger than Attribute Properties since they involve several attributes, at least two, usually belonging to different objects or entities.

When software artifacts are involved, the links among real world things (persons, objects, activities, etc.) are present throughout the whole process of their development. Sooner or later, the links among those things become data Relationships (see arrows leaving Relationships in figure 2). How soon this happens depends upon the software design approach. Some Relationships are binary (cardinalities may be 1:1, 1:N, N:M); however, Relationships may connect three or more real objects. When Relationships must become persistent in the data repository, an obvious issue needs to be analyzed: how are they preserved? Some very old approaches put the linked data together to express the Relationship. These approaches used to have many well-known disadvantages, especially when the Relationship cardinality was not 1:1. This redundancy was also known as the source of a new problem: consistency of data being one of the reasons that pushed towards the creation of the first database models. A Relationship whose cardinality is N:M between entities or objects introduces new problems. Firstly, there may be attributes belonging to the Relationship itself and second, more than one link is needed. The redundancy can be reduced or avoided expressing the links among data in other ways. This implies the inclusion of a special attribute in the data not found in the real world but used to represent the link. This attribute may be either a physical reference telling where the related data is stored, or a logical reference holding a key attribute that permits the related data to be found. In both cases, the redundancy problem is replaced by a referential integrity problem. To sum up, the technique used to store the data in the computer resources will create one or both of the following problems: Data Redundancy or Referential Integrity.

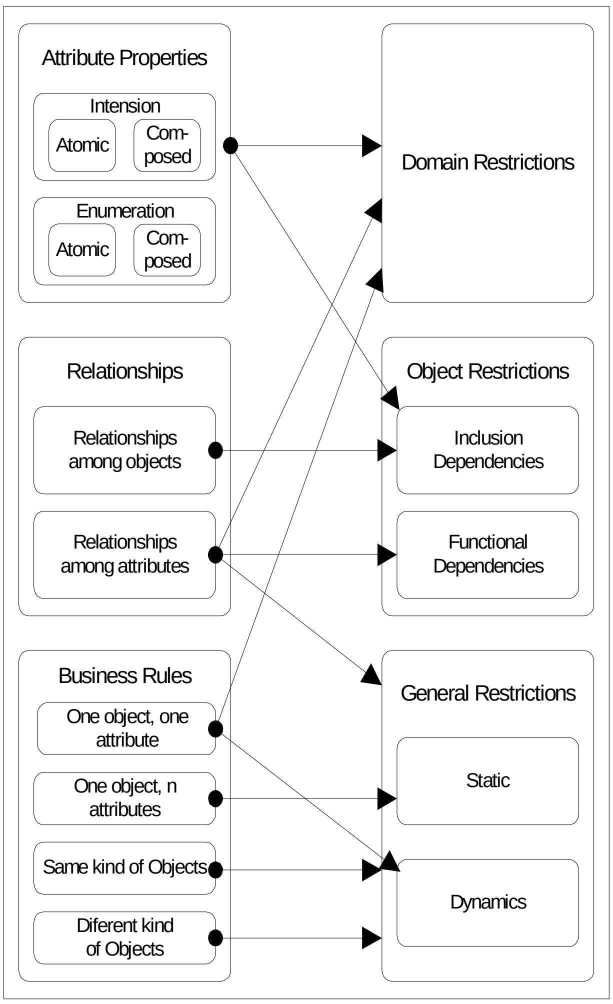
No matter how it is referenced, the referred data should be available every time it is needed. But since the referred data is stored and processed independently from the referring data, the link may become lost. This is called the Referential Integrity problem.

In most cases Relationships maps into Object Restrictions. However, it may happen that Relationships can be reduced to Domain Restrictions when the set of possible values is small. On the other hand, complex Relationships force their implementation by means of General Restriction.

Business Rules. Every organization restrains behavior in some way. This is strongly associated to constraints that define which data may (or may not) be actualized. A Business Rule is a declarative sentence usually describing a correct state of a piece of data.

The process of identifying Business Rules is often iterative and heuristic, where rules begin as general organization statements of policy. Even if the policy is formal and specific, it is typically described in a general and informal fashion, and it often remains for the person responsible to translate it into meaningful specific statements of what to do. These statements are only sometimes originated in a given policy. More often, they arise from the day-to-day operation of the organization. These sentences are sometimes clear, sometimes (perhaps deliberately) ambiguous, and most of the time, contain more than one idea (Ross, 1997).

Figure 2. Detailed mappings



A Business Rule could be confused, due to its appearance, with Attribute Properties and with Relationships. A Business Rule whose scope is only one attribute has in fact the same structure as an Attribute Property sharing all their characteristics. On the other hand, Business Rules involving more than one attribute belonging to the same or different entities or objects may be either similar to or rather different from the Relationships (see arrows leaving Business Rules in figure 2). A General Restriction is dynamic when involve temporal issues. This implies that its evaluation requires some kind of registration of the evolution of the participating data or when the restriction needs the current and the upcoming data.

As mentioned above the need to guarantee the integrity of the stored data was and still is one of the key factors driving the evolution of the Data Base Management Systems (DBMS), creating different Database paradigms. The following paragraphs give a brief summary about how most popular paradigms see the Database integrity problem.

Relational Databases. A rich theory for constraints has emerged in relational databases, mainly based on a fundamental class of constraints called dependencies. Its main motivation is to incorporate more semantics into the relational model.

The term relational model has thus come to refer to the broad class of database models that have relations as the data structure and that incorporate some or all of the query capabilities, update capabilities, and integrity constraints (Abiteboul et al., 1995). Many ideas of other database paradigms already in the scenario (and in their own evolution process) have been borrowed by researchers and vendors, and introduced in current relational products. This fact has created types of incomplete and extended relational engines, which started to be known as postrelational databases. They are incomplete because not all the prescribed issues for the relational model are satisfied, and extended because they go further in some other areas such as active characteristics.

Active Databases. Supporting reactive behavior implies that a database management system may be viewed from a production rule system perspective. These production rules are well known today, in database terminology, as active rules or simply triggers. It is a form of computation, which is motivated by the occurrence of some event, typically a database operation, executing a reaction to that stimulus. Active rules may pose queries to the database to collect information about events and database objects and decide whether events require an action. Then they may execute actions, normally any sequence of database operations (Ceri, 1997). Reactive behavior is seen as an interesting and practical way to check for satisfaction and enforcement of integrity constraints. Nevertheless, integrity constraint maintenance, materialized view maintenance (especially useful in the warehousing area) and implementation of Business Rules, are not the only areas of application of data repositories with reactive behavior. Other interesting applications areas are replication of data for audit purpose, data sampling, workflow processing, scheduling, real-time applications and many others. In fact, practically all products offered today in the marketplace support complex reactive behavior on the client side.

Spatial Databases. Even though there is a very active research area interested in the design of robust and efficient spatial databases, the inability of current GIS regarding the implementation and management of spatial integrity constraints is still evident. This is due to the fact that within the scope of geographic applications, special problems come up due to the locational aspects of data. A modification in a spatial database may cause simultaneous updates in a large number of records in multiple files, making it hard to manage the entire environment. A very sophisticated control is required to avoid redundancy and loss of integrity.

Object-Relational Databases. Object-oriented literature typically uses the term “relationship” to mean, specifically, relationships supported by foreign keys in a relational system. Various levels of support for referential integrity have been implemented in those systems. As in the relational paradigm, triggers are very effective in supporting data integrity in a database, especially for dealing with those restrictions that cannot be expressed declaratively. ORDBMSs demand a system of triggers even more flexible than the relational one.

Object-Oriented Databases. Given that in an OO environment, objects are collected into classes and relationships are established at the class level. A relationship between classes denotes a set of relationships between the objects of the respective classes. Relationships may have attributes. A model is always a compromise to achieve the right amount of expressive power while keeping simplicity and clarity. Domain Restrictions, keys, and referential integrity constraints may all be used straightforwardly in OODBMSs.

Other kinds of constraints are peculiar to OODBMSs, for instance: constraints of the migration of objects between classes (roles); exclusivity constraints between classes; constraints on the definitions of subclasses; and existence dependencies. The last ones are the key to semantic integrity checking since they allow the designers to track and solve inconsistencies in an object-oriented conceptual schema (Snoeck & Dedene, 1998).

Distributed Databases. A distributed database managing system (DDBMS) is a database management system (DBMS) that supports characteristics of a distributed database, that is, the possibility of handling information contained in multiple locations, and preserving data integrity at the same time. A DDB differs from a centralized DB mainly in that data are placed in a number of locations instead of being located in only one site. This characteristic of DDBs causes the control of data integrity to be more complex than for centralized environments. Each transaction can involve more than one location, and it is hard to keep an execution order of the instructions of the transaction to preserve data integrity.

FUTURE TRENDS

The strength of the SQL standards induces one to think that in the future the object relational paradigm will continue to be dominant in the field of DBMS. Improvements to check-and-trigger mechanisms are strongly needed to integrate data properties in a more friendly way with the data itself. Development platforms where data properties become a concern of the engine and the data integrity is fully factorized will form application programs leading to an evolution and the maintenance of less traumatic DBMS-based software artifactss. Naturally, this process will require very active participation on the part of researchers and DBMS producers.

CONCLUSION

Taxonomies of both data properties in the actual world and integrity restriction in the Database world have been given. A mapping of possible evolutions of data properties into the integrity restrictions was also presented. This mapping was always described from the actual world perspective. Its importance can be easily derived from figure 2, where it is shown that merely looking at the integrity restrictions is not enough to know the why’s of their existence. Moreover the actual world to Database world perspective eases traceability, which has been proven to be a key factor in software evolution and maintenance.

KEY TERMS

Conceptual Modeling: A formal or semi-formal description of the actual world elements (objects, persons, organizations) to be included in the future software artifact.

Database Paradigms: The rational and theoretical framework or archetype used to formulate and support a database.

DBMS: Data Base Management Systems. It is a collection of programs that enables users to create and maintain a database.

Logical Design: A formal or semi-formal description produced by the translation of the Conceptual Model into terms of the database structures.

Traceability: The ability to describe the life of a requirement in both backward and forward directions.

Universe of Discourse: The environment in which the software artifact will be used. It includes the macrosystem and any other source of knowledge.

Database Support for M-Commerce

Hong Va Leong
The Hong Kong Polytechnic University, Hong Kong

INTRODUCTION

M-commerce applications have evolved out of e-commerce applications, riding on the rapid advancement in mobile communication technologies in the past decade. The diffusion of applications on the Internet into the mobile computing environment has taken an accelerating pace ever since. Virtually all e-commerce and m-commerce applications rely on the provision of information retrieval and processing capability. In this regard, database systems serve as the information source and repository for these applications, backed by efficient indexing mechanism. Bean (2003) gave a good report on supporting Web-based e-commerce with XML, which could be easily extended to m-commerce. An m-commerce framework, based on JINI/XML and a workflow engine, was also defined by Shih and Shim (2002). Customers can receive m-commerce services through the use of mobile devices, such as pocket PCs, PDAs, or even smart phones. These mobile devices together with their users are often modeled as *mobile clients*. Central to supporting m-commerce applications are three types of entities: mobile device, mobile communication, and database. In particular, we are more interested in providing efficient access mechanisms to mobile-client-enabled database servers, which are often called *mobile databases*. Mobile databases contain the core information to support the underlying m-commerce applications, while the use of mobile devices serves for the hardware platform, with mobile communication providing the necessary connection between mobile databases and mobile devices for interfacing with real users or customers.

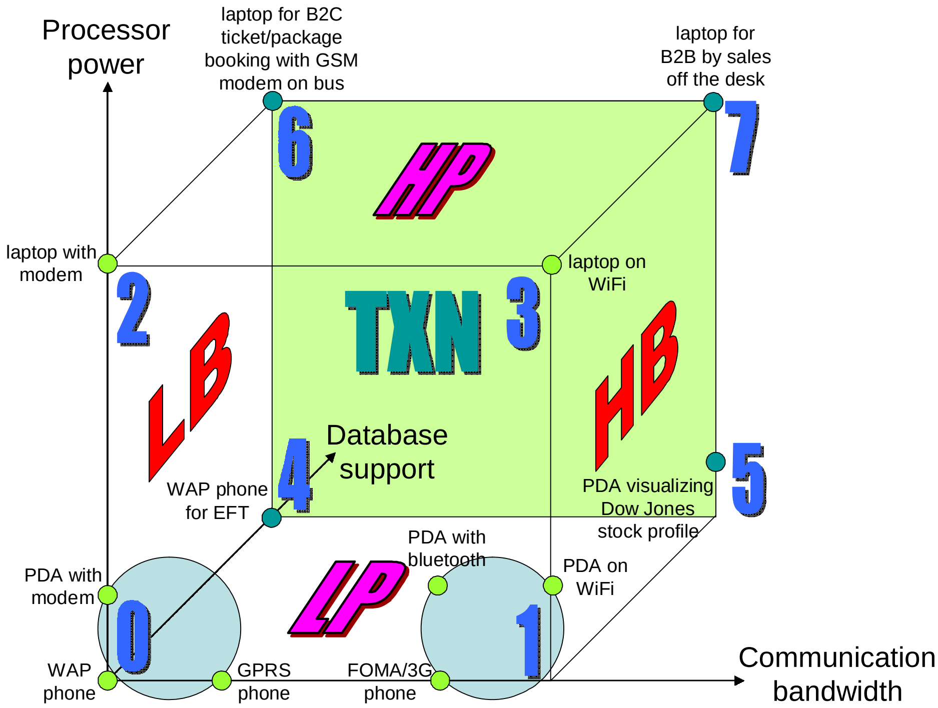
The two major types of data access requirements for a mobile database are data dissemination and dedicated data access. In a mobile environment, data dissemination is preferred, since it can serve a large client population in utilizing the high-bandwidth downlink channel to broadcast information of common interest, such as stock quotations, traffic conditions, special events, or the number of available seats at a performance. On the other hand, dedicated data access is conveyed through uplink channels with limited bandwidth. To disseminate database items effectively, the selected set of hot database items can be scheduled as a broadcast disk (Acharya, Alonso, Franklin & Zdonik, 1995) or the "air storage" (Leong & Si, 1997). The sequence of items to be broadcast is referred to as a broadcast program (Acharya et al., 1995). Proper indexes can be built to facilitate access to database items in the broadcast (Imielinski & Badrinath, 1994). Redundancy can be included to combat the unreliability of wireless communication (Tan & Ooi, 1998).

For dedicated data access, queries and updates to databases are transmitted from the client to the server. Since quite a significant portion of m-commerce services involve location-dependent queries, performance of location-dependent queries should be improved (Madria, Bhargava, Pitoura & Kumar, 2000), dictating effective location maintenance with moving object databases (Wolfson, Sistla, Xu, Zhou & Chamberlain, 1999). This enables efficient execution of common queries such as K-nearest neighbor search. As database systems become more powerful, they can help to process continuous queries (Prabhakar, Xia, Kalashnikov, Aref & Hambrusch, 2002), which are executed continuously, returning possibly location-dependent results.

BACKGROUND

The three fundamental elements in the provision of an m-commerce application, namely, mobile device, mobile communication and database support, can be considered orthogonal. First, the variety of mobile devices differs vastly in computational power, ease of programming, interoperability of operating environments, and support for auxiliary devices. Some mobile clients may be based on a high-end laptop of capacity close to that of a desktop. Other mobile clients may be based on a low-end PDA, or cellular WAP or GPRS phone. Second, mobile communication offers varying bandwidth and reliability, based on low-bandwidth and unreliable GSM connection, medium-bandwidth GPRS or Bluetooth connection, or high-bandwidth 802.11b or 3G/CDMA2000 connection with higher reliability. Third, the database may be as primitive as a file system or simple relational database like MS Access, or as complex as a high-performance Oracle database with transactional support and information retrieval ability. *Transactions* are useful in ensuring a sequence of database operations to be executed consistently without any interference experienced. This leads to a "cube"-like taxonomy as shown in Figure 1.

Figure 1. Taxonomy on m-commerce support



In Figure 1, the taxonomy for m-commerce support is displayed. Planes **LP** and **HP** represent the low computing power equipment and high computing power equipment respectively, whereas planes **LB** and **HB** reflect the availability of low- and high-communication bandwidth. With the availability of transactions in the **TXN** plane, this gives rise to eight different regions, 0 to 7.

Region 0 represents the support of standard file or simple database access from PDA, connecting through low-speed modem or WAP phones. Processing is basically performed at the server, since it is too expensive for clients to support complex mechanism. To combat the low-bandwidth problem, information distillation/extraction (Cowie & Lehnert, 1996) may be performed to reduce the amount of information transmitted. Simple client/server data access paradigm suffices. Region 1 assumes an improved wireless network, with CDMA2000 or WiFi. As a result, data access is more effective, and conventional client/server data processing techniques can be adopted in a rather straightforward manner.

Region 2 corresponds to a mobile client with higher computational power. Information transmitted can be transcoded to reduce the bandwidth consumption. Interactive and intelligent mechanisms such as multi-resolution browsing (Yau, Leong & Si, 2001) can be employed. Data items are cached to combat the low-communication bandwidth, unreliable communication, and frequent disconnection. Research work addressing this issue has drawn much attention in the past, as pioneered by the work on the Coda file system (Mummert, Ebling & Satyanarayanan, 1995). In Coda, frequently accessed files are cached by the clients, and updates made during client disconnection are reintegrated with the file system upon reconnection. Caching in an object-oriented database was studied by Chan, Leong, Si and Wong (1999). Configurations in Region 3 allow easy access to data from the server. With ample bandwidth and processing power, prefetching of data items is done to prepare for potential network disconnection (Jing, Helal & Elmagarmid, 1999). Numerous research works on mobile data access have been conducted with respect to Regions 2 and 3.

Plane **TXN** represents the transactional equivalence of the above-mentioned four regions. Regions 4 and 5 involve the use of PDAs or phones to access databases in a transactional manner. Owing to the low device capability, the only effective mechanism is to execute the transaction at the server. Clients only implement the user interface, supplying the required data and displaying the result sets. Information distillation could be needed for the low-bandwidth configurations in Region 4. The use of a proxy server helps to simplify the client/server design, since the proxy will be responsible for contacting different parties involved in the transaction. Finally, for Regions 6 and 7, there are a lot more research potentials, since the client is more powerful on which more complex algorithms can improve overall system performance. For instance, it would be appropriate to implement on the client a variant of the optimistic concurrency control protocol (Bernstein, Hadzilacos & Goodman, 1987) for Region 6, and two-phase locking with lock caching (Franklin, Carey & Livny, 1997) for Region 7 configurations.

In practical m-commerce applications, clients are moving around and are often far away from their home locations. Research and application focus should therefore be on the low-communication bandwidth, as well as on client mobility. This corresponds to plane **LB**. Under such configurations, a large client population communicates with database servers over wireless communication channels (Alonso & Korth, 1993). Efficient access mechanisms to these mobile databases must be devised after addressing client movement and client location management (Wolfson et al., 1999). This gives rise to a new class of database queries, known as *location-dependent queries* (Madria et al., 2000). A *geographical information system* component enables these queries to be resolved through geo-referencing (Choy, Kwan & Leong, 2000). *Moving object databases* can keep track of the whereabouts of clients (Wolfson et al., 1999).

STRONG DATABASE SUPPORT

M-commerce applications involve access to one or more databases, which are often being accessed concurrently by multiple clients. Transactions are executed to ensure the database consistency despite concurrent access. The correctness criterion of *serializability* on concurrent transactions can be enforced through concurrency control protocols. Concurrency control protocols in a client/server or a mobile environment can be classified according to their nature (Franklin et al., 1997; Jing et al., 1999). In m-commerce applications, simultaneous access to multiple databases, which are managed by different organizations, is a norm rather than an exception. A collection of database systems organized in a coherent way, and functioning in a cohesive and collaborative manner, is referred to as a *federated database system* (Fang, Ghandeharizadeh, McLeod & Si, 1993). Often, it is necessary to provide consistent accesses to those multiple databases with a transaction-like behavior, known as *global serializability* (Breitbart, Garcia-Molina & Silberschatz, 1992). The distributed activity accessing the multiple databases is called a *global transaction*. Tesch and Wäsch (1997) presented an implementation of global transactions on the ODMG-compliant multi-database systems. However, creating a federated database system could involve a lot of coordination efforts, both at the system level and the enterprise managerial level. The execution cost of the global transactions, in terms of concurrency control and atomic commitment, can be high. Thus, global transactions have not been widely adopted, despite their usefulness and convenience. Rather, multiple sub-transactions were commonly executed on individual databases without enforcing global serializability. *Compensating transactions* (Chrysanthis & Ramamritham, 1994) are executed explicitly to undo the effect of failed sub-transactions.

In a mobile environment, it is appropriate to relax serializability, which could be imposing overly restrictive constraints on the execution of transactions. It is often acceptable for a mobile client not to see the updates made by concurrently executing mobile clients, in exchange for a faster execution and a higher probability of committing its transaction. Isolated-only transactions (Lu & Satyanarayanan, 1995) were proposed to reduce the impact of client disconnection. N-ignorance (Krishnakumar & Bernstein, 1994), bounded inconsistency (Wong, Agrawal & Mak, 1997), and update consistency (Shanmugasundaram, Nithrakashyap, Sivasankaran & Ramamritham, 1999) were some of the common weaker forms of correctness criteria. In these approaches, they try to ignore some of the operations in a transaction or allow them to be executed out-of-order in some controlled manner.

Regardless of whether serializability or its weaker form is adopted, transaction processing throughput in a mobile environment can be improved by utilizing the broadcast bandwidth effectively. The database can be broadcast and transactions can be processed against the *broadcast database*. This is very useful for read-only transactions (Pitoura & Chrysanthis, 1999) simply by tuning for a consistent set of database items over the broadcast. To enable update transaction processing, the hybrid protocol by Mok, Leong, and Si (1999) ensures serializability by performing validation for update transactions, and utilizing the uplink channel to request for additional database items not available over the broadcast. Consistency across database items is ensured through the use of timestamps. In update consistency (Shanmugasundaram et al., 1999), a mobile client is only required to see updates made at a server consistent with the values it reads, without having to follow the same serialization order as those observed by other mobile clients; it can be enforced by the cycle-based algorithm.

With the embracement of the Internet computing paradigm, more and more enterprises are willing to publicize their databases as part of their drive towards B2B or B2C e-commerce. Under most cases, these databases can be accessed from outside the enterprise via a Web interface. The ability to access consistent information using global transactions in a federated database system becomes more practical and manageable. Although updates to databases are normally restricted in a non-federated database environment, more and more databases become enabled for the execution of read-only transactions (enquiries) by external parties. The use of global transactions on "loosely" federated databases could become more popular. Furthermore, the presence of a high proportion of read-only transactions even renders the concurrency control for global transactions far more efficient.

Under certain B2B settings, it would be advantageous to automate the workflow process across enterprises (Vonk & Grefen, 2003). It is important to ensure the transactional execution of a low-level workflow process, albeit the more relaxed consistency requirement on higher level processes. Naturally, the overall process can be modeled as a nested transaction, which is destined to be long-lived that global serializability could be too restrictive in delivering good performance. Instead, the adoption of compensating transactions to roll back unintended effects is more appropriate (Tesch & Wäsch, 1997). With respect to the B2C settings, mobile clients would normally only initiate local transactions or simple global transactions spanning across a small number of databases, rather than a long-lived workflow process. The limitation of communication bandwidth and occasional network disconnection implies a longer transaction execution cycle. As a result, existing research works for m-commerce point to supporting global transactions with relaxed correctness criteria, allowing partial transaction commitment and controlled degree of inconsistency, whenever necessary.

FUTURE TRENDS

Owing to the complexity of global transaction processing and the resource limitations of mobile clients, it is sensible to migrate the coordination effort to the proxy server and the Web server, thereby relieving the mobile clients from the complex processing. This is especially true in the context of Regions 4 and 5. As a result, there would be the decoupling of the transaction processing mechanism from the application logic, with basic transactional support at the proxy. The application logic can further be delivered conveniently through the adoption of mobile agents (Yau et al., 2001), preferably intelligent agents that can make sensible decision on behalf of the client, only reporting back the outcome and obtaining confirmation from the client. For instance, mobile agents can act on behalf of the client for event-driven transactions like stock-selling transactions or auctioning. Support for global transactions can be provided primarily on the wired network through the agents. For Region 6 and 7 configurations, more complicated control can be established at the clients, whose higher computing power can also be dedicated to filter for information more effectively, with reference to its local cache, and to provide value-added operations on the data. Now, it is mature to leverage on the computing power of these mobile clients for m-commerce, by engaging in the popular paradigm of peer-to-peer computing (Avancha, D'Souza, Perich, Joshi & Yesha, 2003). Effective visualization of the result set and navigation through the result sequence to decide on the next processing step is also important, since low-end mobile devices normally are only equipped with a relatively small display. This user interface constraint would not change until the penetration of foldable display.

CONCLUSION

Database support is an important and yet fundamental issue in m-commerce applications. With respect to the vast difference in the power and capacity of mobile devices, the varying wireless communication bandwidth, and the new dimension of client mobility and network disconnection, adjustments need to be made to render appropriate database support to these applications. The consistency requirement of accessing multiple databases demands transactional support from database systems. In this article, we gave a generic classification along the three major characteristics for m-commerce environments. The different issues of m-commerce database support were surveyed and discussed. In the future, there should be a division of research efforts, in providing effective transactional support at the server or proxy through agents, while leveraging on the capability of the clients in information organization and presentation, and also in the quest for better value-added computing support and solutions.

KEY TERMS

Broadcast Database: A mobile database whose contents are being broadcast, fully or partially, to a population of mobile clients.

Compensating Transaction: A transaction that is executed to undo the effect of another committed transaction. Unlike ordinary transaction rollback or abort, both original and compensating transactions are visible in the committed projection of the execution history.

Continuous Query: A query that is re-evaluated continuously. For example, the query "*give me the most updated temperature*" will return different readings depending on the current moment. Some continuous queries are also location dependent. For instance, the query "*show me the nearest gas station*" will continually execute a location-dependent query. Advanced query processing technique is needed, in conjunction with moving object databases.

Federated Database System: A network of independent and autonomous databases cooperating in a loosely coupled manner to share and exchange information.

Geographical Information System: An information system that stores and manipulates data for geographical entities such as streets, road junctions, railway, land-use, or even terrain. The data is associated with the location of the entities to allow fast geo-referencing.

Location-Dependent Query: A query whose results depend on the current location of the query issuer. For example, the query "*which is the nearest gas station*?" will return different gas stations depending on the current location of a driver.

Mobile Database: A database accessible to mobile clients. There are appropriate mechanisms to take into account the limitation of the wireless bandwidth, the use of downlink broadcast channel, and the effect of client mobility.

Moving Object Database: A database that maintains efficiently the location information about moving objects, with proper indexing on the object location.

Serializability/Global Serializability: Serializability is the generally accepted correctness criterion for concurrent execution of transactions. The concurrent execution should produce the same effect and lead to the same database state as one possible sequential execution of the same set of transactions. Global serializability is the correctness criterion for concurrent execution of global transactions over many database systems. It is a stronger correctness criterion than serializability.

Transaction/Global Transaction: A transaction is a sequence of operations on a database that should appear as if it were executed non-interfered, even in the presence of other concurrent transactions. A transaction should satisfy the ACID properties, namely, **A**tomicity, **C**onsistency, **I**solation, and **D**urability. A global transaction is a distributed transaction that is executed on two or more database systems.

INTRODUCTION

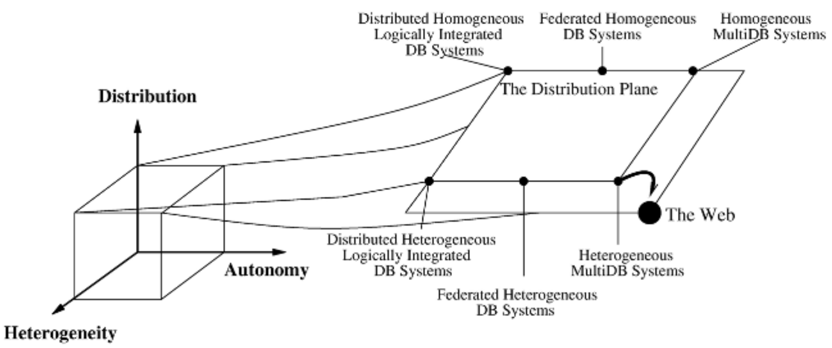
Database community has been seriously disturbed with the Web technologies expansion. Particularly, two reports have produced a special commotion in database field. The first one, the Asilomar report (Bernstein et al., 1998), postulates the new directives in databases tendencies, previewing the Web impact in this field. The second one, Breaking out the Box (Silberschatz & Zdonik, 1996), proposes how database community must transfer its technology to be introduced into Web technology. In this sense, the database box must be broken out into its autonomous functional components, and they must be used to reach a solution for the problem of heterogeneous data sources integration.

BACKGROUND

Thinking about the Web as a huge, highly distributed database, we may consider different dimensions to conceptually describe it. Tamer Özsu and Valduriez (1999) define a classification of database systems with respect to: 1) their distribution; 2) the autonomy of local systems; and 3) the heterogeneity of database systems. The autonomy concept is considered as the distribution of control, not of data. This indicates the degree to which individual DBMSs can operate independently. Whereas autonomy refers to the distribution of control, the distribution dimension deals with the physical distribution of data over multiple sites. With respect to heterogeneity, this can range from hardware heterogeneity, differences in networking protocols, variations in DBMSs, and so forth, to the data model or the policy for managing integrity on the database.

Obviously, the Web is in the distribution plane, and, as shown in Figure 1, we think that "it falls out" of the cube because it presents the highest degree of distribution, heterogeneity, and autonomy. Therefore, traditional distributed database techniques must be further extended to deal with this new environment in order to face Web environment intrinsic problems, such as the management of semi-structured information.

Figure 1. Extending the cube



A lot of work has still to be carried out in the database community to resolve all of the issues related to such a kind of distributed and heterogeneous database, which is what the Web actually is.

Due to space limitations, we only review some related and open issues, such as the integrity problem, query optimisation problem, integration issues in both Web and Semantic Web. But the reader must note that this coverage is not complete. There are some interesting issues uncovered, such as data models, security, transaction processing, and so forth.

THE INTEGRITY PROBLEM IN THE WEB

Some important factors related to this issue include the structure of the underlying database upon which the constraints are imposed, the nature of the imposed constraints, and the method adopted for their evaluation. Traditionally, two restrictions are focused in databases: domain and structural restrictions. So they must be considered in a Web data model.

From a database perspective, XML Schema (2001) provides a new technological standard which enables us to represent data semantics like a database does. We can find a discussion about schema languages in Lee and Chu (2000).

A domain restriction defines the set of values that an attribute may have. XML-Schema provides enhanced data types and user-defined data types. New data types can be created from base data types specifying values for one or more facets for the base data type. Moreover, on XML-Schema we can define subclasses and superclasses of types. We can also disable the restriction or extension of a particular type.

With respect to structural restrictions, in this schema language, we can represent:

1. Uniqueness for attribute. Furthermore, XML Schemas specify uniqueness not only for attributes but also for arbitrary elements or even composite objects.
2. Key for attribute.
3. Foreign key for attribute; using the *key/keyref* mechanism, which complements the *id/idref* one of previous versions of XML Schema and solves its associated problems.

QUERY OPTIMISATION IN THE WEB

Optimisation on regular path queries (Grahne & Thomo, 2000, 2001) and indexing techniques over semi-structured information (McHugh & Widom, 1999) have already been studied. One of the most important studies on XML and semi-structured data optimisation (McHugh & Widom, 1999) has been developed for the LOREL system (Abiteboul, Quass, McHugh, Widom & Wiener, 1997). LOREL not only supports the traditional value index, but also label, edge, and path indexes.

However, other relevant aspects, such as composition reordering, restriction propagations, and more complex and sophisticated techniques, magic rewriting for example (Bancilhon, Maier, Sagiv & Ullman, 1986), are well known in database systems and have yet to be tested in the XML context.

From the XML perspective, constraint propagation cannot be used exclusively for query optimisation, but it can and must be used during new type derivation or inference (Fan, Kuper & Siméon 2001). This is generically called subtyping. One of the main characteristics of XML is that it allows new type extensions and restrictions through inheritance. The computation of this new set of constraints is fundamental in object-oriented systems, and very important in preventing integrity constraints violations in our schema.

Constraint derivation in subtyping is useful with domain and column constraints, but it is also useful with entity and referential constraints (Fan, Kuper, & Siméon, 2001). The existence of physical index associated with keys and references in order to accelerate relationship composition is common.

INTEGRATION ISSUES IN THE WEB

Wrappers were the first building block on Web integration. They act as interfaces to each data source, providing (semi-) structure to non-structured sources or mapping the original data source structure to a common one. The knowledge about evaluating a query over multiple wrappers is encapsulated by mediators. The wrapper-mediator approach provides an interface to a group of (semi-) structured data sources, combining their local schemas in a global one and integrating the information of local sources. So the views of the data that mediators offer are coherent, performing semantic reconciliation of the common data model representations carried out by the wrappers. Table 1 summarizes the most popular wrapper-mediator systems. The next level of abstraction on Web integration corresponds to ontology-based systems. From the data perspective, ontologies enrich the semantic of the schema, resolving synonymy and polysemy problems (Heflin, 2001). The reader can find an excellent review in ontology engineering in (Corcho, Fernández-López & Gómez-Pérez, 2001). Table 2 summarizes the most popular ontology-based systems.

Table 1. A summary of wrapper-mediator systems

Not XML based	• DISCO • GARKIC
XML based	• AMOS • TSIMMIS • MIX • MOCHA

Table 2. A summary of ontology-based systems

INTEGRATION ISSUES IN THE SEMANTIC WEB

Tim Berners-Lee (2000) outlined his vision for the Semantic Web: "In the context of the Semantic Web, the word semantic means machine processable. For data, the semantics convey what a machine can do with that data". He also underlined that the Semantic Web is a declarative environment, where you say what you mean by some data, and not what you want to do with it. The development of the Semantic Web involves the adoption of different technologies (Figure 2), which allow adding meaning to the structure of the XML documents and describing the necessary semantic information in order to be processed by the machines. For a long time, this problem has been dealt with by means of "ontologies" described as documents or files "that definitely define the relationships between the terms". According to the information sources, the ontologies describe the content of the data repositories regardless of their syntactic representation, enabling their semantic integration (Mena, Illarramendi, Kashyap, & Sheth, 2000).

As a means to materialize a conceptualization or ontology, a language to represent that knowledge is required. Traditionally, these languages have been developed in the area of artificial intelligence and concentrate their formal base on paradigms such as: the 1st and 2nd order predicate calculus, description logic or the object-oriented ones. Nowadays, languages based on XML are ideal candidates for the Semantic Web. Thus, first proposals were SHOE, XOL, OML and RDFS, which inherit the labels of XML and incorporate new characteristics that improve the expressiveness of the initial data model. Latter, other languages that extend RDF and RDFS were proposed, such as OIL, DAML+OIL and OWL. This latter are going to become the standard for representing ontologies, due to the efforts of the W3C Semantic Web Group.

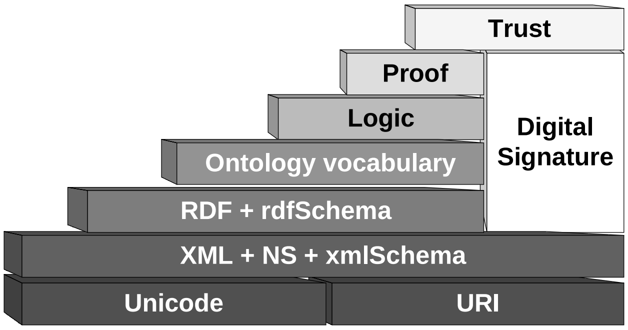
- The most naive setting for the Semantic Web would be the one in which all the data sources commit with a very limited set of well known universally accepted ontologies. It is evident that this scenario is not very realistic because everybody is not expected to commit with a limited group of ontologies. It is easier to imagine that there will be many ontologies and many systems in charge of evaluating specific ontologies. The evaluation should be made in a cooperative way thanks to the interaction of agents or systems, which is essential to respect the interoperability and autonomy of the systems.

CONCLUSION: A DATABASE PERSPECTIVE

Since Codd formally defined the relational model in the early 1970s, it has proved its expressiveness and efficiency, but also has presented limitations. This has motivated the definition of many extensions. Among these, two have shown an unusually high degree of success. Deductive and object-oriented database paradigms are attempts to introduce recursion and object-orientation in databases. XML is a standard based on a semi-structured model that allows structural recursion. Its algebra has functional language characteristics that support both static and dynamic type inference. This means that XML includes and extends the problems of distribution, recursion, and object-orientation in relational models.

It has been shown that there exist several ways to specify integrity constraints in XML, using DTDs or XML Schema, among others. To avoid multiple fetching of constraints expressed in different formats during data management, it would be desirable to choose a unique

Figure 2. Semantic Web (figure by Tim Berners-Lee, http://www.w3c.org/2000/Talks/1206-xml2k-tbl/slide10-0.html)



format of constraints specification. The XML Schema seems to be the best candidate due to its expressiveness, as is shown in recent studies (Lee & Chu, 2000). Nevertheless, other standards, like RDF and RDF Schemas, are complementary and can be used together in a higher abstraction level, as proposed in the Semantic Web. Almost all of the aspects related to maintenance and query optimisation via integrity constraints are open in XML.

Many frontiers are open to research and development. Moreover, we still cannot ensure that the W3C XML query language and algebra recommendations, in its current status, would be valid as a practical query language for data intensive processing. Alternative proposals exist, see the comparative analysis of Bonifati and Ceri (2000), although many of them conform to the W3C's one. A good example is the proposal (Beech, Malhotra & Rys, 1999) developed by three important W3C members: Oracle, IBM, and Microsoft. Together, they have developed a query language and algebra very close to SQL and relational algebra whose results are compatible with XQuery's although these are especially oriented to data intensive processing.

An update semantic model is still undefined revealing the amount of work yet to do. For a complete definition of the data manipulation language, it will be necessary to define new recommendations including the given update commands. Having finished the process of complete formalization of the language, the development of a transactional system for XML would be necessary. It would maintain data integrity under multiple concurrent accesses. This work is mainly related to the logical data schema. Improvements in the physical model will begin later on.

As a result, we may note how many aspects of XML query processing, including integrity constraints management, would have to receive serious attention from the database community. New fields of research are open and in-depth research on all aspects related to this new data model in the Web are of vital interest regarding its application to industry.

The Semantic Web will continue to be a model of growth similar to the Web and its success depends on us being able to elaborate realistic techniques that make this development model feasible. The trade-off adopted among the concepts of expressive power, correctness, completeness and efficiency, for each one of the different mechanisms of inference, will open a wide range of study regarding new evaluation techniques – based on ontologies – for distributed logical programmes within the context of the Semantic Web. On the other hand, the query and efficient management of huge distributed knowledge bases still have many unsolved aspects, related – among other things – with the efficient integration of information and the development of distributed mechanisms of inference.

KEY TERMS

Data Integration: The problem of combining data from multiple heterogeneous data sources and providing a unified view of these sources to the user. Such unified view is structured according to a global schema. Issues addressed by a data integration system include specifying the mapping between the global schema and the sources and processing queries expressed on the global schema.

Domain Restriction: A condition, usually formulated in first order logic, that defines the set of values that an attribute or variable may have. In database terminology, a domain restriction is a kind of integrity constraint.

Integrity Constraint: Properties that the data of a database are required to satisfy and they are expected to be satisfied after each transaction performed on the database. Integrity constraints provide a way of ensuring that changes made to the database do not result in a loss of data consistency. Integrity constraints include key references and cardinality restrictions.

Mediator: Systems that filter information from one or more data sources that are usually accessed using wrappers. The main goal of these systems is to allow users to make complex queries over heterogeneous sources, as if it was a single one, using an integration schema. Mediators offer user interfaces for querying the system, based on the integration schema. They transform user queries into a set of sub-queries that other software components (the wrappers), which encapsulate data sources' capabilities, will solve.

Ontology: A logical theory accounting for the intended meaning of a formal vocabulary , i.e., its ontological commitment to a particular conceptualization of the world. The intended models of a logical language using such a vocabulary are constrained by its ontological commitment. An ontology indirectly reflects this commitment (and the underlying conceptualization) by approximating these intended models.

Query Optimization: A problem that can be stated as follows: Given a query, the set of all execution plans that compute it and a cost function that is defined on the before set, find a execution plan that is of minimum cost using some search strategy.

Semantic Query Optimization: A query optimization process based on knowledge. The knowledge used is usually represented as, but is not limited to, integrity constraints.

Semantic Web: An extension of the current Web in which information is given well-defined meaning, better enabling computers and people to work in cooperation. Berners-Lee said that in the context of the semantic Web, the word "semantic" meant "machine processable". He explicitly ruled out the sense of natural language semantics. For data, the semantics convey what a machine can do with that data.

Structural Restriction: Conditions that relate one attribute or variable value with respect to other possible values of the same attribute or variable or to the value of others' attributes. In database terminology, a structural restriction is a kind of integrity constraint. Some examples of structural restrictions are: uniqueness of an attribute value, key for attribute and foreign key for attribute.

Decision Support Systems Concept

Daniel J. Power
University of Northern Iowa and DSSResources.com, USA

INTRODUCTION

Since the late 1960s, researchers have been developing and implementing computerized systems to support management decision makers. A number of decision support systems (DSS) typologies were proposed in the early 1980s (cf., Alter, 1980; Sprague & Carlson, 1982), but technology developments and new applications led to an expanded DSS framework (cf., Power, 2000a, 2000b, 2001). The expanded DSS framework developed in detail in Power (2002a) helps decision makers and DSS developers explain and categorize potential decision support projects as well as existing DSS.

Many terms are used for specific types of DSS. For example, some vendors and managers use the terms "business intelligence," "collaborative systems," "computationally oriented DSS," "data warehousing," "model-based DSS," and "online analytical processing (OLAP)" software to label decision support software. Software vendors use these more specialized terms for both descriptive and marketing purposes. The terms used to describe decision support capabilities are important in making sense about what technologies have been deployed or are needed. Some DSS are subsystems of other information systems, and this common structural design adds to the complexity of categorizing and identifying DSS. In general, DSS are a broad class of information systems used to assist people in decision-making activities (cf., Power, 2004).

According to Alter (1980), DSS can "take on many different forms and can be used in many different ways" (p. 71). DSS differ in terms of capabilities and targeted users of a specific system, and in terms of how the DSS is implemented and what it is called. Some DSS focus on data, some on models, and some on facilitating communications and collaboration. DSS also differ in scope. Some DSS are intended for one "primary" user and "stand alone" for analysis, and other DSS are intended for many users in an organization.

BACKGROUND

Traditionally, academics and practitioners have discussed building DSS in terms of four major components: the user interface, the database, the models and analytical tools, and the DSS architecture and network (cf., Sprague & Carlson, 1982). This traditional list of components identifies similarities and differences between categories or types of DSS. The expanded DSS framework is primarily based on the differential emphasis placed on the DSS components when systems are actually constructed. The importance of the components in providing decision support functionality is the major differentiating factor among various types of DSS.

The expanded DSS framework focuses on one major dimension, with five categories and three secondary dimensions. The major characteristic in the framework is the dominant technology component that drives or provides the decision support functionality. Five generic categories based on the dominant component are discussed in this section: communications-driven, data-driven, document-driven, knowledge-driven, and model-driven DSS. The following categories (with explanations based on Power, 2001, 2002a, 2004) can classify DSS currently in use:

- Communications-driven DSS include systems built using communication, collaboration, and decision support technologies. These systems were developed first in the late 1980s and are called groupware. Group DSS also involve communications, but many GDSS derive their functionality by providing a group of users with access to quantitative decision models.
- Data-driven DSS include file drawer and management reporting systems, data warehousing and analysis systems, executive information systems (EIS), and some spatial DSS (SDSS). Business intelligence systems are also examples of data-driven DSS. Data-driven DSS emphasize access to and manipulation of large databases of structured data and, especially, a time-series of internal company data and sometimes external data. Simple file systems accessed by query and retrieval tools provide the most elementary level of functionality. Data warehouse systems that allow the manipulation of data by computerized tools tailored to a specific task and setting or by more general tools and operators provide additional functionality. Data-driven DSS with OLAP, drill-down, and scorecards provide the highest level of functionality and decision support

that are linked to the analysis of a large collection of historical data.

- Document-driven DSS integrate a variety of storage and processing technologies to provide complete document retrieval, summarization, and analysis. A search tool that creates text summaries and rates document relevance provides decision support functionality, but the dominant component is the document base. Examples of documents that might be included in a document database include policies and procedures, product specifications, catalogs, and corporate historical information, including minutes of meetings, corporate records, and important correspondence.
- Knowledge-driven DSS can suggest or recommend actions to managers. These DSS contain specialized problem-solving expertise based upon artificial intelligence and statistics technologies. The "expertise" consists of knowledge about a particular domain, understanding of problems within that domain, and "skill" at solving some of these problems.
- Model-driven DSS include systems that use accounting and financial models, representational simulation models, and optimization models. Model-driven DSS emphasize access to and manipulation of a model. A simple algebraic model with "what if?" analysis provides the most elementary level of model-driven DSS functionality.

Table 1 summarizes the five types of DSS and the expanded DSS framework. Data-driven, document-driven, and knowledge-driven DSS need different and specialized database components to provide decision support. A data-driven DSS needs a relational or a multidimensional database of structured data. A document-driven DSS need a specialized document repository and, in some instances, a relational database to assist in document searching. A knowledge-driven DSS needs to store knowledge, including rules, frames, or likelihood data. A model-driven DSS derives functionality from the model component. Finally, the communications and networking component is the key driver for a communications-driven DSS.

FUTURE TRENDS

The number of DSS of each generic type is expanding rapidly. In general, each generic type of DSS can be targeted to the same user group. Also, a given decision process may benefit from implementation of multiple DSS. Each DSS can have a narrow, specific purpose or a more general purpose. DSS of any type can serve multiple, overlapping purposes. For example, to provide business intelligence to managers, more than one DSS may be needed, including both a data-driven DSS and a document-driven DSS. Finally, each category of DSS can be deployed using a Web-based architecture. Today, Web technologies (Linux, Apache server, MySQL, PHP) provide a powerful DSS development environment. DSS can, should, and will be categorized in terms of these three secondary dimensions—user groups, purpose, and the enabling technology.

One can and should use all four dimensions in Table 1 to categorize a specific DSS. Some specific questions for identifying the type of DSS include the following:

Table 1. Summary of D. Power's expanded DSS framework

Dominant Component	User Group	Purpose	Enabling Technology
Communications **Communications-Driven DSS**	Intra- and interorganization users	Conduct a meeting, post on a Bulletin Board	Web-based or LAN
Database **Data-Driven DSS**	Managers, staff, intra- and interorganization	Query a data warehouse, ad hoc analysis	Mainframe, LAN, Web-based
Document-base **Document-Driven DSS**	Specialists, managers	Search Web pages, find documents	Web-based
Knowledge-base **Knowledge-Driven DSS**	Internal users, customers	Management advice, choose products	LAN or Web-based
Models **Model-Driven DSS**	Managers and staff, customers	Crew scheduling, decision analysis	Stand-alone PC, Web-based

Source: Based on Power (2002a)

1. What is the dominant component and driver of decision support?
2. Who makes up the targeted user group?
3. What is the purpose of the DSS?
4. What is the enabling technology used for implementing the system?

The answers to these questions should help classify the proposed DSS or the DSS product a vendor is trying to sell or an existing system that was previously implemented in a company. For example, a manager may want to build a model-driven, interorganizational, product design, Web-based DSS. Or, a company might currently have a data-driven, intraorganizational, ad hoc query, client/server-based DSS. In the future, a checklist of questions will help DSS analysts and managers categorize and describe DSS.

CONCLUSION

This article explained DSS and summarized a broad conceptual framework that should be used for categorizing DSS. Discussion and debate and efforts to use the framework can improve our understanding of DSS and make the framework more useful for both research and development of DSS. One hopes that the expanded framework improves our overall understanding of computerized systems intended to support decision making. The DSS concept has been reinterpreted and broadened over the past 25 years, and technologies have changed and improved. There remain, however, conceptual overlap problems related to terms associated with computerized decision support, and vendors still use too many marketing terms for decision support development software. In general, the basic DSS goal of supporting decision makers using computing technology remains crucial and important for any organization that is in a complex, rapidly changing environment.

KEY TERMS[1]

Business Intelligence (BI): A popularized umbrella term introduced by Howard Dresner of the Gartner Group in 1989 to describe a set of concepts and methods to improve business decision-making by using fact-based support systems. The decision support purpose is to provide managers with information or business intelligence. The term is sometimes used interchangeably with briefing books and executive information systems. A business intelligence system is a data-driven DSS.

Data: Binary (digital) representations of atomic facts, especially from financial transactions. Data may also be text, graphics, bit-mapped images, sound, or analog or digital live-video segments. Structured data are the raw material for analysis using a data-driven DSS. The data are supplied by data producers and are used by information consumers to create information.

Decision Support Systems (DSS): A specific class of computerized information systems that support decision-making activities. DSS are interactive computer-based systems and subsystems intended to help decision makers use communications technologies, data, documents, knowledge, and models to identify and solve problems and make decisions. Five more specific DSS types include communications-driven DSS, data-driven DSS, document-driven DSS, knowledge-driven DSS, and model-driven DSS.

Executive Information Systems (EIS): A computerized system intended to provide current and appropriate information to support decision making for senior managers using a networked workstation. The emphasis is on graphical displays, and there is an easy-to-use interface.

Online Analytical Processing (OLAP): Software for manipulating multidimensional data from a variety of sources that were stored in a data warehouse. The software can create various views and representations of the data. OLAP software provides fast, consistent, interactive access to shared, multidimensional data.

Web-Based DSS: A computerized system that delivers decision support information or decision support tools to a manager or business analyst using a "thin-client" Web browser like Internet Explorer. The computer server that is hosting the DSS application is linked to the user's computer by a network with the transmission control protocol/Internet protocol (TCP/IP). Web-based DSS can be communications-driven, data-driven, document-driven, knowledge-driven, or model-driven.

What If? Analysis: The capability of "asking" the software package what the effect will be of changing input data, decision variables, or independent variables. In a model-driven DSS, a decision variable is a changing factor in the model that is determined by a decision maker. The presence of this capability helps identify a model-driven DSS.

ENDNOTE

Decision Support Systems in Small Businesses

Yanqing Duan
University of Luton, UK

Mark Xu
University of Portsmouth, UK

INTRODUCTION

Decision support systems (DSSs) are widely used in many organisations (Arslan et al., 2004; Belecheanu et al., 2003; Dey, 2001; Gopalakrishnan et al., 2004; Lau et al., 2001; Puente et al., 2002). However, there is a common tendency to apply experience and techniques gained from large organisations directly to small businesses, without recognising the different decision support needs of the small business. This article aims to address the issues related to the development and the implementation of DSSs in small business firms. Our arguments are based on evidence drawn from a large body of DSS literature and an empirical study conducted by the authors in the UK manufacturing sector.

BACKGROUND

Early DSS were developed in parallel with management information system (MIS) in the 1970s. MIS is developed to primarily generate management information from operational systems, whilst DSS as defined by Gorry and Scott Morton (1971) is information systems that focus on supporting people in the unstructured and semi-structured decision-making process. A typical DSS consists of four main components: the database, the model base, the user interface and the users. Central to the DSS are the models and analytical tools that assist managers in decision making and problem solving. Concomitant with advances in the technology of computing, most DSS provide easy access to data and flexible control models with a friendly user interface design; some DSS also incorporate a variety of analytical tools and report/graphic generators. The main purpose of DSS is not to replace managers' ability to make decisions, but to improve the effectiveness of managers' decision making.

DSS in practice can hardly be separated from other types of computer-based systems, as it is often integrated with those systems, for example operational databases, spreadsheets, report generators, and executive support systems. Thus the boundary of DSS has now been extended, and DSS broadly refers to any computer-based information system that affects or potentially affects how managers make decisions. This includes data and model oriented systems, reporting systems, executive support systems, expert systems and group decision support systems.

The success and continued growth of small and medium sized enterprises (SMEs) are critically important to local and national prosperity, but their problems are not always accorded the same importance as those of larger organisations. Compared to the research devoted to large organisations on the use of information systems, SMEs have attracted much less attention. It is also the case that the problems inherent in providing support for small business management are more commonly studied from a social or economic viewpoint. Very few studies indeed have addressed decision support needs in the context of the use of information technology.

Managers of small businesses have often been disappointed with software packages because of the inability of these to adapt well to their needs (Heikkila et al., 1991). There are dangers in seeing small businesses as miniature versions of large businesses; many problems differ, and even similar problems require different solutions. Small enterprises normally have limited resources and less skilled managerial staff. They have higher failure risks and commonly do not have suitable access to the information they need.

DSS IMPLEMENTATIONS

Small business may represent a productive domain for attempts to introduce greater levels of computer-based decision support. Ray (1994) suggests that small business managers and their staff have positive attitudes towards the use of computers in business. Cragg and King (1993) report that many companies have plans to increase their use of computer applications, and found that the wish for better information was the motivating force in all case studies conducted. In the majority of the firms studied by Khan and Khan (1992), managers believed that a computerised system improved their performance in selected areas, but that there is still room for significant further development.

Gordon and Key (1987) point out that if small business managers' problem-solving skills are deficient in any of the critical areas of management decision-making, then they must improve those skills through the use of appropriate educational programmes, consultants, decision support tools, or some combination of these. Unfortunately, the owner-manager (because of involvement in the day-to-day operation of the firm) has not the time, resource or expertise needed to evolve an appropriately analytical approach (Raymond et al., 1989, cited in Naylor & Williams, 1994). There would seem to be as strong a case for the potential benefits of DSS to the smaller business as for its larger counterpart, provided suitable software is available, and it is effectively used by the managers concerned.

Limited research has investigated the success factors for the use of information technology (including DSS) in small businesses (Delone, 1988; Lai, 1994; Raymond & Bergeron, 1992) and the design and development of specific DSSs for SMEs (Chaudhry et al., 1996; Houben et al., 1999). Some work has been done specifically to identify those areas that have not been adapted to DSS, but show potential for its introduction for the small business (Duan et al., 2002). Most research (Levy, 1999) indicates that computer use is still confined to operational activities, although a few studies (Naylor & Williams, 1994) found that some SMEs have realised the value of their information systems as decision support tools and had begun to use them for more complex activities. Other researchers suggest that there are many areas in which DSS can be better developed and utilised to help managers in critical decision-making processes, such as marketing, sales promotion, cash-flow management and customer services. It has been argued that small businesses can improve their organisational performance and increase their competitiveness with appropriate information systems (Levy et al., 1999). The increasing emphasis on competitiveness in small business has led to a new focus on the competitive advantage promised by appropriate use of information technology (Levy et al., 1999; Lin et al., 1993).

A study conducted within the UK manufacturing SMEs by Duan et al. (2002) shows that the extent of DSS use is generally limited and the use of DSS varies considerably among the firms surveyed. However, even where there was a reported low level of DSS use, managers' satisfaction was relatively high. The applications with which managers were most satisfied were: cash management, budget preparation and materials requirements planning. Despite the relatively low usage of DSS generally, the majority of SME managers indicated that they use computers personally to aid business decisions; this suggests that there is, at least, widespread use of desktop computing in managers' offices.

Regarding the inhibitors to the greater use of DSS, lack of staff time to analyse needs and identify solutions is the most significant factor identified. Lack of finance for systems purchase or development, lack of experience of systems development, lack of information on available DSS packages, and unavailability of appropriate software were other factors commonly cited (Duan et al., 2002).

DSS DEVELOPMENT METHODS

DSS for small businesses can be developed and implemented in different ways. Four routes were identified, such as:

- Off-the-peg - purchase of a commercially developed package;
- Bespoke - designed by a software house for the specific application;
- In-house - developed by the firm's own specialist staff;
- User - developed by managers as users.

Research (Duan et al., 2002) shows that the majority of DSS were purchased as commercially developed packages; other systems were developed by managers as users, developed by in-house specialists or developed as bespoke systems by software houses. In view of the normally limited resource base for IT development (Heikkila et al., 1991), it is not surprising that most small firms choose to purchase commercially developed, ready-to-use DSS software. By breaking down the development methods into three decision-making levels, it shows that commercial packages are more commonly used at the operational level (60%) than at the strategic level. In contrast, user-developed DSS are more commonly used at the strategic level than at the operational level.

Research on *in-house* and *user* development methods in small firms is scarce. The evidence from the Duan et al. (2002) survey suggests that small business managers are capable of developing their own DSS, and that a certain proportion do so. Research in Canada by Raymond and Bergeron (1992) found that user-developed DSS in small businesses are more successful than any developed by other means. A study by Lai (1994) in the USA, however, revealed no link between the method of system development and DSS success.

By far the most commonly used DSS in small manufacturing firms are commercial packages purchased off the shelf for operational decision making. The readiness of small business managers to purchase commercial packages, coupled with their recognition that DSS vendors provide valuable support, suggest that small businesses represent a market for software developers that will continue to grow. That many managers are developing their own systems to support strategic decisions might also suggest there to be a market opportunity here.

THE FUTURE NEEDS FOR DSS IN SMES

The research by Duan et al. (2002) attempts to identify the gaps between the current provision of DSS and small business managers' desired levels of DSS support. The findings reveal that:

- the current level of DSS usage is low;
- although DSS usage is limited, managers are generally satisfied with DSS they are using;
- the desired level of support is much higher than the current provision;
- the high standard deviations for current DSS use and desired levels of support indicate high variations among responses. The standard deviation of levels of satisfaction is lower than the other two variables; this suggests that there is less disagreement on this issue.

The study supports the argument that current DSS in small businesses are geared to operational rather than strategic decision making. It is evident that the low-level use of DSS found by Raymond in 1982 has not changed significantly. The desired level of support at the operational level is also much higher than that at the strategic level. Users appear to expect that DSS will provide the most benefit for operational decisions. This is perhaps as well, given the nature of the decision-making tasks at strategic level, involving complex and changing environments, high level of uncertainty and the need to include decision makers' personal intuition and judgement. The lower-level use of DSS and desired support for strategic decision making does not mean that there is no space for further improvement, however. Indeed, the fact that many managers are "going it alone" could mean that professional support will enhance strategic planning. Levy et al. (1998) report that one of their case study firms had been successful in integrating information systems into its business strategy and gained competitive advantages. However, computer support for strategic decisions is still a challenging area for future research and much effort is being expended to overcome the difficulties (Duan & Burrell, 1997; Li et al., 2000), yet again, in the context of the larger business.

CONCLUSION

Decision support systems are designed to assist managers to make more effective decisions. Potentially, they could provide great benefits to SME managers and enhance managers' decision-making capability. However, the extent of DSS implementation in small business is still low in general, although there is significant variation between different firms. The literature review of previous studies indicates that the situation has not changed significantly since Raymond's investigation in 1982, and the present study confirms this. Lack of staff time to analyse needs and identify solutions is the most significant factor holding firms back from adopting, or making further use of DSS. Use of DSS at the operational decision-making level is higher than at the strategic level. Small business managers are generally satisfied with the DSS they are using and are hoping for much better DSS support in the future. DSS development, particularly DSS for strategic decisions in small business, still represents both a challenge and an opportunity for DSS professionals and researchers.

DSS in SMEs are most commonly implemented by purchase of a commercial package, and only rarely by bespoke development. Most DSS are used for operational rather than strategic decision making. Those firms that do use DSS to support strategic decisions rely upon user-developed models.

Although DSS applications in SMEs are still relatively few in number, most DSS users report satisfaction with their systems. To reduce the gaps between current DSS provision and the managers' indicated needs, a greater focus on small business by DSS researchers and practitioners is required. Systems most likely to appeal to small business managers will have to be appropriate to their sector's needs, and capable of implementation with minimal user training. In conclusion, it can be said that the current situation in relation to DSS in small business is full of potential but requiring further professional support.

KEY TERMS

Database: A collection of related information. The information held in the database is stored in an organised way so that specific items can be selected and retrieved quickly.

Decision Support System (DSS): An interactive computer-based system, which helps decision makers utilise data and models to solve semi-structured to unstructured problems.

Executive Information System (EIS): A computer-based information delivery and communication system designed to support the needs of senior managers and executives.

Expert Systems: A computer-based system that performs functions similar to those normally performed by a human expert. It has a knowledge base, an inference engine and a user interface.

Group Decision Support Systems (GDSS): Information systems that support the work of groups (communication, decision making) generally working on unstructured or semi-structured problems.

Management Information System (MIS): A business information system designed to provide past, present, and future information appropriate for planning, organising and controlling the operations of an organisation.

Small and Medium Sized Enterprises (SMEs): The definition of SMEs varies in different countries. It is normally defined as having between 10 and 249 employees in the UK and Europe.

INTRODUCTION

Decision-making support systems (DMSS) are specialized computer-based information systems designed to support some, several or all phases of the decision-making process (Forgionne et al., 2000). They have the stand-alone or integrated capabilities of decision support systems (DSS), executive information systems (EIS) and expert systems/knowledge based systems (ES/KBS). Individual EIS, DSS, and ES/KBS, or pair-integrated combinations of these systems, have yielded substantial benefits for decision makers in real applications.

The evolution of the systems has presented unique challenges and opportunities for DMSS professionals. To gain further insights about DMSS achievements, challenges, and opportunities, we asked recognized leaders in the field for their views. This article overviews the DMSS concepts, presents the expert views regarding achievements, challenges, and opportunities, and examines the implications for DMSS research and practice.

DMSS ARCHITECTURES

Decision-making support systems involve various creative, behavioral, and analytic foundations that draw on a variety of disciplines (Sage, 1981). These foundations give rise to various architectures that deliver the fundamental support concepts to individual and group users. The architectures, which are summarized in Table 1, include: (a) the classic systems (Alter, 1996), which include decision support systems (DSS), expert and knowledge based systems (ES/KBS), executive information systems (EIS), group support systems (GSS), and spatial decision support systems (SDSS) and (b) new systems (Forgionne, 1991; Forgionne et al., 2002; Gray & Watson, 1996; Mora et al., 2003; Power, 2002; Turban & Aronson, 1998), which include management support systems (MSS), decision technology systems (DTS), Integrated DMSS, data warehouse (DW)-based and data mining (DM)-based DMSS (DW&DM-DMSS), intelligent DMSS (i-DMSS), and Web-based DMSS or knowledge management DMSS.

The architectures have been applied to a variety of public and private enterprise problems and opportunities, including the planning of large-scale housing demand (Forgionne, 1997), strategic planning (Savolainen & Shuhua, 1995), urban transportation policy formulation (Rinaldi & Bain, 2002), health care management (Friedman & Pliskin, 2002), decision making in the pharmaceutical industry (Gibson, 2002), banking management (Hope & Wild, 2002), entertainment industry management (Watson & Volovino, 2002) and the military arena (Findler, 2002). The reported, and other applications, draw on advanced information technologies (IT), including intelligent agents (Chi & Turban, 1995), knowledge-based (Grove, 2002) and knowledge-management procedures (Alavi, 1997), synthetic characters (Pistolesi, 2002), and spatial decision support systems (Silva et al., 2002) among others.

DMSS ACHIEVEMENTS AND FUTURE TRENDS

Once created, DMSS must be evaluated and managed. A variety of approaches have been suggested to measure DMSS effectiveness. There are economic theory-based methodologies, quantitative and qualitative process and outcome measures, and the dashboard approach. These approaches suggest various organizational structures and practices for managing the design, development, and implementation effort. Most of these approaches suggest much more user involvement than had heretofore been

Table 1. Decision-making support systems architectures

Classic DMSS Architectures	Description	Main Decision-Making Phase Supported					DMSS' SUPPORT CHARACTERISTICS
		INTELLIGENCE	DESIGN	CHOICE	IMPLEMENTATION	LEARNING	
DSS	A DSS is an interactive computer-based system composed of a user-dialog system, a model processor and a data management system, which helps decision makers utilize data and quantitative models to solve semi-structured problems.			**A**			(A) What-if, goal-seeking & sensitivity analysis.
ES & KBS	An ES/KBS is a computer-based system composed of a user-dialog system, an inference engine, one or several intelligent modules, a knowledge base and a work memory, which emulates the problem-solving capabilities of a human expert in a specific domain of knowledge.	**A**		**B**			(A&B) Symbolic pattern-based recognition; fuzzy data; how and why explanation facilities.
EIS	An EIS is a computer-based system composed of a user-dialog system, a graph system, a multidimensional database query system and an external communication system, which enables decision makers to access a common core of data covering key internal and external business variables by a variety of dimensions (such as time and business unit).	**A**			**B**		(A&B) Key performance indicators (KPIs) in graphs and text tables; data exploring and searching through drill-down, roll-up, slice and dice and pivoting operations; networking communications to internal and external bulletin boards.
GSS	A GSS an integrated computer-based system composed of a communication sub-system and model-driven DMSS (DSS), to support problem formulation and potential solution of unstructured decision problems in a group meeting.		**A**	**B**			(A) Idea generation through brainstorming facilities; pooling and display of ideas; generation of alternatives and criteria. (B) Preference models; voting schemes; conflict negotiation support.
SDSS	A SDSS a computer-based system composed of a user-dialog sub-system, a geographic/spatial database sub-system, a decision model sub-system and a set of analytical tools, which enables decision makers to examine situations based strongly on spatial data.	**A**		**B**			(A) Spatial data searching support; visualization tools for maps, satellite images and digital terrains. (B) What-if analysis of scenarios, goal-seeking analysis, sensitivity analysis of decision variables upon spatial data.

Table 1. Decision-making support system architectures (continued)

Modern DMSS Architectures	Description	Main Decision-Making Phase Supported: INTELLIGENCE	DESIGN	CHOICE	IMPLEMENTATION	LEARNING	DMSS' SUPPORT CHARACTERISTICS
MSS, DTS or I-DMSS	These systems are the result of the triple-based integration (i.e., DSS, EIS and ES/KBS) and have the aim to offer a full support to decision makers in all phases of the DMP.	**A**	**B**	**C**	**D**		(A&D) Visual data exploring through graphs; color codes and tables; data exploration with drill-drown, roll-up, slice and dice, pivoting operations. (B) Intelligent advice through AI-based capabilities to support the models selection task. (C) Numerical modeling through available numerical-based models; what-if, goal-seeking and sensitivity analysis.
DW & DM DMSS	DW&DM-DMSS are computer-based systems composed of a user-dialog sub-system, a multidimensional database subsystem and an online analytical processing (OLAP) component enhanced with knowledge discovery algorithms to identify associations, clusters and classifications rules intrinsic in the data warehouse.	**A**					(A) OLAP capabilities of aggregation, slice and dice; drill-down; pivoting; trend analysis; multidimensional query; graphics and tabular data support. Knowledge discovery patterns using statistical-based, tree-decision or neural networks.
Web-DMSS & KM-DMSS	Web-DMSS & KM-DMSS are computer-based systems composed of an user-dialog sub-system, a text &multimedia document storage subsystem and publishing/retrieval subsystem to preserve and distribute knowledge in the organization using intranets.	**A**				**B**	(A&B) Document publishing and retrieval facilities.
i-DMSS	Computer-based systems composed of a user-dialog sub-system, a multidimensional database and knowledge base subsystem and a quantitative & qualitative processing sub-system, all enhanced with AI-based techniques, designed to support all phases of the DMP.	**A**	**B**	**C**	**D**	**E**	(A&D) Visual data exploring through graphs; color codes and tables; data exploration with drill-drown, roll-up, slice and dice, pivoting operations. (B) Intelligent advice through AI-based capabilities to support the models selection task. (C) Numerical and qualitative modeling through numerical-based or symbolic models; what-if, goal-seeking and sensitivity analysis. (E) Symbolic reasoning through knowledge-based models for explanations about how and why the solution was reached.

practiced, and they also suggest a larger role for specialists outside of traditional information systems practitioners to carry out the technical design, development, and implementation tasks.

The suggested changes and developments present unique challenges and opportunities for DMSS professionals. To gain further insights about DMSS achievements, challenges, and opportunities, a recent study compiled opinions from recognized leaders in the field (Forgionne, Gupta & Mora, 2002). As detailed elsewhere (idem, 2002), the professionals were selected on the basis of their demonstrated accomplishments and reputation within the DMSS community. All experts are long-time professors, consultants, and practitioners with substantial influential publications, leadership positions, and project successes in the DMSS field. The expert verbatim views are summarized in Table 2.

DMSS Achievements

The expert opinion implicitly suggests that DMSS have been recognized as a unique type of information system. Further, the opinions seem to focus on the deployment of new and advanced information technology (IT) to improve the quality of the overall DMSS design. This collective opinion suggests that advanced IT progress can be used to improve DMSS design, development, and implementation. The expert views on core DMSS concepts indicate that distributed DMSS, through Web-based, mobile computing and accessibility concepts, will be a critical factor in maintaining DMSS achievements.

DMSS Challenges

The experts also offered opinions about the next generation of DMSS. In their collective opinion, the next generation of DMSS will involve: (a) the use of portals, (b) the incorporation of previously unused forms of artificial intelligence through agents, (c) better integration of data warehousing and data mining tools within DMSS architectures, (d) creation of knowledge and model warehouses, (e) the integration of creativity within DMSS architectures, (f) the use of integrated DMSS as a virtual team of experts, (g) exploitation of the World Wide Web, (h) the exploitation of mobile IT, and (i) the incorporation of advanced IT to improve the user interface through video, audio, complex graphics, and other approaches. A recent survey on artificial intelligence and DMSS literature (Mora et al., 2003) suggests similar research issues: (a) increasing the processing capabilities of DMSS through intelligent agents, fuzzy systems and neural networks, (b) improving the user-interface capabilities through multimedia and virtual environments, and (c) deploying the potential of distributed knowledge-bases using the Web. In short, the experts and literature on AI and DMSS implicitly recognize the relevance of improving the DMSS user interface, information and knowledge representations schemes and intelligent processing capabilities through the deployment of advanced IT.

Table 2. DMSS achievements, challenges, and opportunities

DMSS Issue	Expert Collective Opinion
Key Achievements	the evolution of DMSS software and hardware; the implementation of DMSS in a variety of organizations; the creation of DMSS tailored design and development strategies
Research Issues and Practical Problems	providing quality data for decision support; managing and creating large decision support databases; model management and model reuse; building knowledge driven DMSS; improving communication technologies; developing a uniform and comprehensive DMSS scheme; developing an effective toolkit; developing and evaluating a synergistic integrated DMSS; collecting insights about the neurobiology of decision support for managers' less structured work; the application of agent and object-oriented methodologies; developing DMSS though well-established methodologies
Core DMSS Architectural Concepts and Opportunities	Web technology; accessibility; security; effective data, idea, and knowledge management, possibly through the use of smart agents; effective model management; effective dialog management; EIS-like features; incorporation of basic and common DMSS functionalities; mobile computing; user-centric design

DMSS Opportunities and Future Trends

Future opportunities, trends and challenges discerned by the experts include: (a) availability of DMSS packages for specific organizational functions, such as customer relationship management, (b) system functional and technical integration, (c) reducing software tool costs, (d) consolidation and innovation, (e) the creation of a technology role for the decision maker through the DMSS application, (f) the integration of the decision maker into the design and development process for DMSS, (g) developing effective design and development tools for user-controlled development, (h) accommodating the structural changes in the organization and job duties created by DMSS use, (i) developing measures of DMSS effectiveness, (j) recognizing the group dimension of organizational decision making, (k) incorporating the cognitive dimension of human decision making, (l) utilization of smart agents and features, (m) distribution of DMSS expertise through collaborative technologies, (n) incorporating rich data, information and knowledge representation modes into DMSS, and (o) focusing user attention on decisions rather than technical issues. Common themes suggested by this disparate expert opinion are: (a) the DMSS should focus decision makers on the decision process rather than technical issues, and (b) DMSS development may require specialized and new IT professionals. However, DMSS success, and in particular large-scale DMSS projects, will be realized in organizations through a systematic and well-managed implementation approach.

CONCLUSION

In some ways, the DMSS field has not progressed very much from its early days. There is still significant disagreement about definitions, methodologies, and focus. Experts vary on the breadth and depth of the definitions. Some favor analytical methodologies, while others promote qualitative approaches. Some experts focus on the technology, while others concentrate on managerial and organizational issues. There does not seem to be a unified theory of decision making, decision support for the process or DMSS evaluation. Furthermore, the achieving of successful implementation of large-scale DMSS is still a complex and open research problem (Mora et al., 2002).

In spite of the diversity, opinions are consistent regarding some key DMSS elements. Most experts recognize the need for problem pertinent data, the role of the Internet in providing some of the necessary data, the need for system integration within DMSS architectures and between DMSS and other information systems, and the importance of artificial intelligence within DMSS processing. The DMSS concept also continues to be successfully applied across a variety of public and private organizations and entities. These applications continue to involve the user more directly in the design, development, and implementation process.

The trends will create DMSS that are technologically more integrated, offer broader and deeper support for decision making, and provide a much wider array of applications. In the process, new roles for artificial intelligence will emerge within DMSS architectures, new forms of decision technology and methodology will emerge, and new roles will be found for existing technologies and methodologies.

As the evolution continues, many tasks that had been assigned to human experts can be delegated to virtual expertise within the DMSS. With such consultation readily available through the system, the decision maker can devote more effort to the creative aspects of management. Support for these tasks can also be found within DMSS. In the process, the decision maker can become an artist, scientist, and technologist of decision making. The DMSS-delivered virtual expertise can reduce the need for large support staff and corresponding organizational structures. The organization can become flatter and more project-oriented. In this setting, the decision maker can participate more directly in DMSS design, development, implementation, and management. Such changes will not occur without displacements of old technologies and job activities, radical changes in physical organizations, and considerable costs. As the reported applications indicate, however, the resulting benefits are likely to far outweigh the costs.

D

KEY TERMS

Data Warehousing–Data Mining (DW-DM) DMSS: Computer-based system composed of a user-dialog sub-system, a multidimensional database subsystem and an online analytical processing (OLAP) component enhanced with knowledge discovery algorithms to identify associations, clusters and classifications rules intrinsic in a data warehouse.

Decision Making Support System (DMSS): An information system designed to support some, several or all phases of the decision making process.

Decision Support System (DSS): An interactive computer-based system composed of a user-dialog system, a model processor and a data management system, which helps decision makers utilize data and quantitative models to solve semi-structured problems.

Executive Information System (EIS): A computer-based system composed of a user-dialog system, a graph system, a multidimensional database query system and an external communication system, which enables decision makers to access a common core of data covering key internal and external business variables by a variety of dimensions (such as time and business unit).

Expert System/Knowledge Based System (ES/KBS): A computer-based system composed of a user-dialog system, an inference engine, one or several intelligent modules, a knowledge base and a work memory, which emulates the problem-solving capabilities of a human expert in a specific domain of knowledge.

Group Support System (GSS): An integrated computer-based system composed of a communication sub-system and model-driven DMSS (DSS), to support problem formulation and potential solution of unstructured decision problems in a group meeting.

Intelligent Decision Making Support Systems (i-DMSS): Computer-based system composed of a user-dialog sub-system, a multidimensional database and knowledge base subsystem, and a quantitative and qualitative processing sub-system enhanced with AI-based techniques, designed to support all phases of the decision making process.

Management Support Systems (MSS), Decision Technology Systems (DTS), or Integrated Decision Making Support Systems (I-DMSS): Systems that integrate DSS, EIS and ES/KBS to offer full support to the decision maker in all phases of the decision-making process.

Spatial Decision Support System (SDSS): A computer-based system composed of a user-dialog sub-system, a geographic/spatial database sub-system, a decision model sub-system and a set of analytical tools, which enables decision makers to analyze situations involving spatial (geographic) data.

Web-DMSS & Knowledge Management (KM)-DMSS: Computer-based system composed of a user-dialog sub-system, a text and multimedia document storage sub-system, and publishing/retrieval subsystem to preserve and distribute knowledge in intranet-supported organizations.

Decision-Making Support Systems and Representation Levels

Jean-Charles Pomerol
Université Pierre et Marie Curie, France

Frédéric Adam
University College Cork, Ireland

INTRODUCTION

The concept of Decision Support System (DSS), which was first coined by Gorry and Scott Morton (1971), was proposed in an attempt to focus the attention of IS researchers and practitioners more closely on the decision-making processes of managers. It sought to acknowledge the importance of decision-making as the key activity that managers must perform in organizations (Huber, 1982).

Even though there are good functional definitions of what DSS should do, a readily understandable definition that takes into account the specificities of human reasoning (e.g., studies by Herbert Simon; Pomerol & Adam, 2004) is still lacking. In this chapter, we try to bridge the gap between human reasoning and the understanding and design of DSSs. We begin with a description of the human process of decision-making, then we give a semi-formal definition of Decision Making Support Systems (DMSS) and conclude with a few words about the architecture of such systems.

BACKGROUND

Human decision-making has its origin in a dissatisfaction commonly referred to as a decision problem. The dissatisfaction arises from the difference between the current state of affairs and another, not yet existing, more desirable state of affair. The notion of state of affair or *state of the world* refers to the seminal work of Savage (1954). As described by Simon, managerial decision-making is characterized by a number of key factors: (1) the personal dimension, which is at the core of the decision-making process, in that what one person wants may not be desirable for another; (2) the issue of uncertainty, whereby the current state of the world may not be known with certainty; and (3) the difficulties inherent in evaluating the desirable state of the world when it includes many different attributes that are not fully compatible (e.g., increasing market share and reducing costs). The process of human decision-making is represented in Figure 1.

In Figure 1, we have sketched what may be regarded as a realistic human decision process, tracking the main components of decision reasoning. For the sake of simplicity, we have divided the process into two main parts: diagnosis and look-ahead. It is, of course, not always easy to separate these two, but from an engineer's point of view, it facilitates the design of systems aimed at supporting the process of decision-making.

DECISION MACHINES, WHAT-IF ANALYSIS, AND LOOK-AHEAD

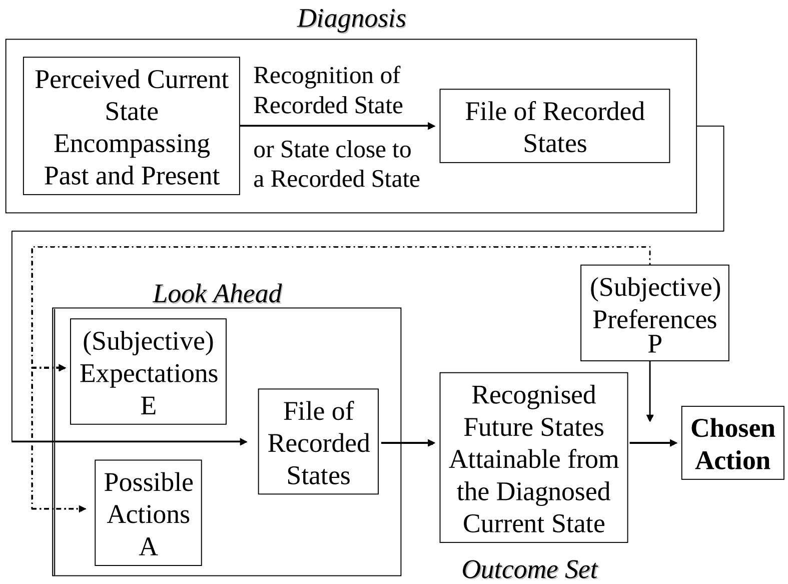
The model presented in Figure 1 can be used to predict what may be the most appropriate systems able to support the decision process. A number of corresponding DMSS designs can be proposed—diagnosis machine (or decision machine), "what-if" analysis machines, and look-ahead machines—which seek to tackle the most difficult and abstract level in human decision-making.

Decision Machines

A decision machine is an automaton adhering to one-to-one correspondence between the diagnosed current state and a proposed action. As said before, the word "decision" is, in this case, improper because the decision has already been made by the designer of the system. However, when people are unaware of the program or when it is so sophisticated that it is impossible to look through its operations, one can refer to these as decision machines. As such, most decision machines are mere classifiers linking a recognised state to an action. Numerous of these machines exist in the context of almost continuous decision (i.e., control of industrial processes, underground train driving, etc.).

With a programmed decision machine relating the current state to an action, one does not capture the full complexity of human decision-making. In addition, in many concrete situations, the set of all the possible current states cannot be described either extensionally or intentionally. Thus, the human decision maker is always

Figure 1. The decision process (adapted from Pomerol, 1997)



indispensable, working in an interactive way with the machine, mainly because unexpected (not programmed) states might occur. Many accidents have resulted from the bad recognition of the current state (wrong diagnosis) by a subject (Boy, 1991). Thus, the designers of decision support systems are confronted with the paradoxical problem of developing systems capable of helping people in situations that neither the user nor the program can foresee. This is one of the most difficult challenges in the development of decision support systems.

"What-If" Analysis

Although various frameworks have been proposed to cope with uncertainty, many decision makers discover that, in real situations, events are either very interdependent or the probabilities remain unknown (e.g., what is the probability that the price of oil will be higher in three months than today?), such that rational decision-making is impossible. Predicting or even identifying all the possible reactions of other agents and competitors is another key difficulty. The ability to envision the future and to anticipate events exists only in most advanced animals. Key components of the intelligent behavior of human beings are the capacity for anticipation, the ability to decide against immediate short-term advantage, and the desire to pursue future gains.. This type of multi-criteria choice can be regarded as a basic expression of rationality. This is consistent with Damasio's view that "will power is just another name for the idea of choosing according to long-term outcomes rather than short-term ones" (Damasio, 1994, p. 175).

In any case, "what-if" analysis or, more accurately, "scenario reasoning," should produce two outputs: all possible outcomes at a given horizon and the probability or plausibility of each outcome. Decision makers exercise their preferences on probabilistic outcomes (preferably multi-attribute), and then make their decisions and implement the resulting actions in accordance with the chosen scenario. Unfortunately for non-aided decision makers, scenario reasoning may lead to a combinatorial explosion such that it is often impossible to handle long, precise, and diverse scenarios (Pomerol, 2001). This is the very reason why support from machines is necessary.

Look-Ahead Machines

Two capabilities appear to be necessary in a look-ahead machine: (1) the ability to combine many actions and events (with their probabilities); and (2) the ability to imagine the possible actions and to anticipate all possible reactions of other agents and/or nature. According to Figure 1, this "imagination" ability is simply provided by the file of recorded states, such that for a given subject, all possible events and reactions of the other agents are drawn from a set of memorised items. However, forecasts never predict what is really new (Hogarth & Makridakis, 1981; Makridakis, 1990). It is, therefore, unlikely that look-ahead machines can escape this weakness. Another reason for using recorded states is that human forecasts are often too optimistic because human beings remember success more easily than failures (Kahneman & Lovallo, 1993). The intrinsic difficulty in forecasting is the main weakness of many formalised planning processes. This is particularly true for long-term or strategic planning (Mintzberg, 1994). Bearing in mind that the basis for scenario building is often restricted to the set of recorded actions, events, and situations (i.e., states), there are two types of look-ahead machines: simulators and decision-making support systems (DMSS).

A simulator is a machine in which a real industrial or social process has been modelled on a reduced scale. Then, some initial data and parameters are fed into the simulator and the user observes the evolution of the variables in which he or she is interested.

When it is possible to develop at least a partial model of the given process, it is possible to exploit it by developing a DMSS. Research and development conducted by one of the authors in the DMSS area over a period of many years led to the conclusion that DMSSs are look-ahead machines designed to perform an exploration at several cognitive levels. At the data level, it is called "what-if" or sensitivity analysis. Roy (1998) has also described another type of "what-if" analysis called robustness analysis. In robustness analysis, the question raised by the decision maker is, "What input modifications can a decision endure before really becoming bad?" It differs from sensitivity analysis, which looks for the largest modification of some input that leaves a decision unchanged.

DECISION-MAKING SUPPORT SYSTEMS

A Functional Definition for DMSS

There are many ways to conceive of and technically describe a DMSS, but most typical "textbook" definitions are not really helpful for the purpose of teaching students what DMSSs are about or for the purpose of developing better systems. Keen and Morton (1978) present a comprehensive sample of the definitions and ideas relying upon functional views put forward by IS researchers in the 1970s. These ideas are suitably summarised in the following quote.

Decision support implies the use of computers to: (1) assist managers in their decision process for semi-structured tasks, (2) support rather than replace managerial judgement and (3) improve the effectiveness of decision making rather than its efficiency.(Keen & Morton, 1978, p. 1)

The obvious drawback of such definitions is that, while they clearly describe what a DMSS is meant to do, they are weak at describing how it should do it and do not provide any clear guidelines for DMSS development or usage. According to Naylor (1982), this lack of formal theorisation of what a DMSS should do greatly contributed to the relative lack of success of the DMSS concept. During the 1980s, many authors attempted to go beyond the limitations inherent in such definitions and to put forward new ideas about the design and development of DMSS applications (Bonczek et al., 1981; Lévine & Pomerol, 1989; Sprague & Carlson, 1982). These new definitions were more or less inspired by Artificial Intelligence (AI), while the functional perspective was changed by the introduction of the concept of EIS. Since then, other concepts have been proposed either on the technological (i.e., OLAP, data warehouse) or conceptual side (I.e., Groupware, drill down, exception reporting, etc.), but this does not fundamentally change the nature of decision-making support nor does it change the difficulties inherent in the design of executive systems with clear decision-making relevance.

DMSS as Information Processing System

Bonczeck et al. (1981) were the first authors to introduce the idea of AI in DMSS theory and to regard a DMSS as a special kind of Information Processing System (IPS) as described by Newell and Simon (1972). This novel vision of DMSS amounts to viewing DMSS applications as essentially problem solving applications. Their vision of DMSS, as illustrated in Figure 2, shows the typical structure of a DMSS application.

In conformity with Newell and Simon's (1972) model, the IPS features a processor (the PPS), memories (the KS) and an input/output device (the LS). Sprague and Carlson (1982) extended this vision of a DMSS based on representation, operations, memory aids, and control mechanisms. The main contribution of Sprague and Carlson was to emphasise the importance of two additional factors: (1) the role of the representation—a certain structure applied to the data; and (2) the methods available to the decision maker to use and control the DMSS (i.e., how the DMSS supports the decision-making process).

In a simplified diagram, Sprague (1987) illustrates his vision of DMSS as a system with memories (a database), an operation performed according to programmed models, and a dialogue device (see Figure 3).

It is worth noting that the all-important concept of control has disappeared from this diagram, despite the acknowledgement of its importance for the successful use of the DMSS application. Lévine and Pomerol reintroduced the control aspect of DMSS in their vision of DMSS (1989, 1995). They proposed that using a DMSS amounts to performing a heuristic search up to the moment where the decision maker feels that he or she has gathered sufficient knowledge to make a decision.

Figure 2. Structure of a DSS according to Bonczek et al. (1981)

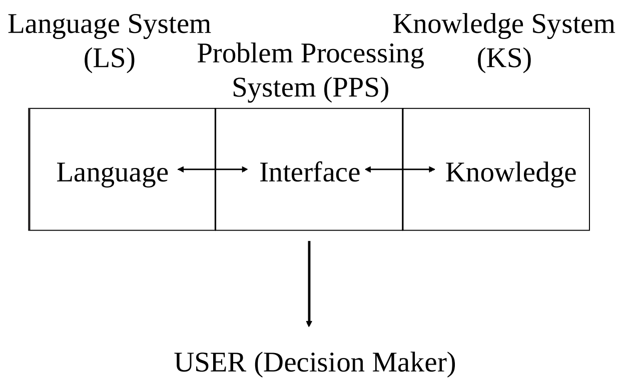


Figure 3. A DSS according to Sprague (1987)

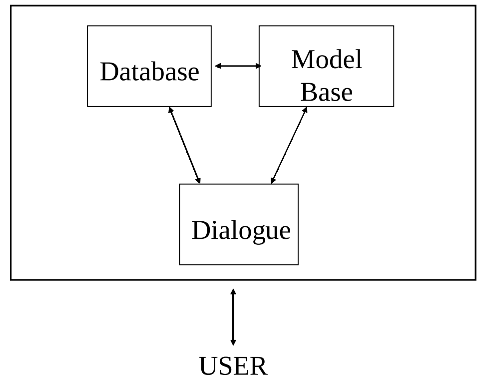

Levine and Pomerol (1995) suggested that this heuristic search occurs at different levels. These representation levels initially described by Humphreys and Bekerley (1985) are characterised by their level of abstraction and a specific way of thinking that corresponds to the degree of formalisation of the problems. Humphreys (1989) later described how problem solving involves passing through the five levels from the highest to the lowest level of abstraction as described below.

(1) At the highest level, representations are mainly cultural and psychological; managers are more or less aware of what a problem involves, but its expression is mostly beyond language. It is at this level that the problem is shaped.
(2) At this level, representations become explicit, and the problem can be broken down into a number of sub-problems, some of which can be formalised. The structuration of the problems is still partial rather than detailed, and managers will refer to the "marketing function" or the "marketing process" without being able to formalise processes in greater details.
(3) At this level, decision makers are able to define the structure of the problems they must solve. They are able to put forward models that can be used for the investigation of the alternatives they will pursue.
(4) At this level, the decision makers will perform sensitivity analysis with the models they have defined in the previous stage in order to determine which input values are the most suitable.
(5) At the lowest level, managers decide upon the most suitable values, and the representation of the problem they must solve is stable and fully operational.

The process described by Humphreys is a top-down process whereby the structuration of the concepts investigated is refined from one level to the next until decisions can be made. Levels 1 and 2 are generally considered strategic levels of reflection handled by top executives, whereas the remaining three levels correspond to more operational and tactical levels. The top level is obviously a very important stage of the decision-making process, as the only factors limiting the horizon of the decision maker are either psychological (unconscious) or cultural (e.g., one's educational background). In human decision making, this step of shaping the framework for further studying the problem appears under the name "setting the agenda" (Simon, 1997) or "problem setting" (Checkland, 1981). The role of the person who shapes the problem, the "problem owner" in Checkland's words, is very important for the follow-up of the decision and action. This stage is all the more important in that it conditions the outcome of the decision-making process. Avenues that are not envisaged at that stage are unlikely to be explored at a later stage. The manager's vision of the problem is then considerably refined at the second level to prepare for the formalisation of the third level, where the manager enters the realm of "hard system thinking" and where representations and computational models must be fully stabilised. At the remaining levels, the manager will define the processing to be applied to the data and identify the most appropriate input values of the model. The refining process from top cognitive level to lower ones also can be interpreted as a decision process in which high-level decisions shape the decision framework, and within which smaller decisions are then made leading to actions, which is the ultimate level.

Based on this view of DMSS, we can conclude that existing DMSS applications often cover levels 3, 4, and 5 and neglect the two initial levels that, admittedly, are much more problematic to handle.

FUTURE TRENDS – TOWARDS A CONTINGENCY VIEW OF DMSS

The definition of DMSS we have proposed addresses four key problems:

(1) It takes into account the problem of representation levels.
(2) It accounts for the continued success of spreadsheet-based DMSS applications, which are still the most used DMSSs.
(3) It helps researchers understand the classical "what-if" analysis as a heuristic search for better insights (generally of a look-ahead type).
(4) It provides some insights into the reasons why the human decision maker is so important in the decision-making process (i.e., to express his or her preferences and to evaluate the outcomes generated by the DMSS).

This definition envisions the DMSS as an Information Processing System (IPS) designed so that the decision maker can perform a heuristic search at any representation level. At the lower levels (3,4, and 5), the model in the DMSS is virtually complete, and the system may be able to deliver a complete solution ready to be implemented. By contrast, at the higher levels (1 and 2), the model, only present in the manager's mind and in an incomplete form, is not available for modeling, and the decision-making process must be enacted as a dialogue between the DMSS and the decision maker. An important consequence is that the interaction that takes place between the DMSS and the manager is fundamentally different at the lower levels than at the higher levels. At the lower levels of abstraction, the exchanges between the IPS and the manager are limited to data entry and output of results; at the higher levels, they must enable the control of often abstract, heuristic searches.

Naturally, the development of DMSS applications aimed at the first and second levels is very ambitious. The support that decision makers get from their DMSS comes mainly from the ability of the underlying models to accurately represent and simulate reality. However, models are, at best, incomplete and can only provide partial support to the decision maker. In the future, developers of DMSS must address the challenges inherent in designing applications able to handle interaction with their users at the five different levels of abstraction.

CONCLUSION

In this chapter, we provide a technical definition of DMSS, taking into account the specificities of human decision making, particularly the look-ahead process often illustrated by scenario thinking and multi-attribute choice. The arbitration process required between short-term desires and long-term advantages can be supported by tools allowing a heuristic search at different cognitive levels. The search stops when a satisfying trade-off has been attained. This introduces the DMSS as a look-ahead machine and paves the way to a better understanding and a better design of future DMSS.

KEY TERMS

Decision-Making Process: Process whereby managers make decisions, including the stages described by Herbert Simon: intelligence, design, choice, and review.

Decision Support System: A computer system that enables managers to solve a given problem in their own personalised way.

Look-Ahead: Ability of human decision makers to anticipate all potential future scenarios and the likelihood that they will come to pass.

Representation Level: Degree to which the problems faced by managers are well formalized in their own minds and can be represented for the purpose of DSS development.

Robustness Analysis: A form of "what-if" analysis that seeks the maximum variation of a parameter that keeps a decision within acceptable values.

Sensitivity Analysis: A form of "what-if" analysis that seeks the largest variation of an input value into a model input that leaves the outcome of the decision unchanged.

Structure: Characteristic of a decision situation that determines whether the problem it involves can be programmed or described in specific terms (i.e., for the purpose of developing a relevant DSS).

Defining and Understanding ERP Systems

David Sammon
University College Cork, Ireland

Frédéric Adam
University College Cork, Ireland

INTRODUCTION

The last 15 years have seen the emergence on the software market of a category of software called Enterprise Resource Planning systems or ERP, which has become the focus of both researchers and practitioners in the information systems area. At this time, the ERP software market is one of the fastest growing markets in the software industry with long-term growth rates of 36-40%. Some estimates put the eventual size of the market by the year 2010 at US$1 trillion (Bingi et al., 1999). Since these estimates have been put forward, the ERP market has slowed down, but the overall growth of the enterprise-wide application market is still quite strong, thanks to a number of additional segments, such as Customer Relationship Management (CRM) and Supply Chain Management (SCM). Also, more recently, a new trend is emerging in the market: the re-implementation and extension of ERP, referred to as ERP II (Humphries and Jimenez, 2003).
Fundamentally, ERPs are all integrated "mega packages" (Gable et al., 1997) which provide support for several or all functional areas of the firm depending upon the configuration purchased by the client. Their complexity is reflected in the complexity of their implementation and deployment in organisations where they have been observed to have a substantial impact on everyday activities in both the short term and the long term. This has led to many reports of unsuccessful implementation, which are however matched by many reports of substantial benefits accruing to implementing firms. Thus, managers look upon ERP software as necessary evils and much research has been carried out in order to increase the success rate of ERP implementations and to ensure that benefits materialize.

THE EMERGENCE OF ERP

The historical origin of ERP is in inventory management and control software packages that dictated system design during the 1960s (Kalakota and Robinson, 2001). The 1970s saw the emergence of Material Requirements Planning (MRP) and Distribution Resource Planning (DRP), which focused on automating all aspects of production master scheduling and centralised inventory planning, respectively (Kalakota and Robinson, 2001). During the 1980s, the misnamed MRPII (Manufacturing Resource Planning) systems emerged to extend MRP's traditional focus on production processes to other business functions, including order processing, manufacturing, and distribution (Kalakota and Robinson, 2001). In the early 1990s, MRPII was further extended to cover areas of Engineering, Finance, Human Resources, Project Management, etc. MRPII is a misnomer, as it provided automated solutions to a wide range of business processes, not just those found within a company's manufacturing and distribution functions (Kalakota and Robinson, 2001). However, although MRP II systems overcame some of the drawbacks of MRP systems they became less relevant because:

- Manufacturing is moving away from a "make to stock" situation and towards a "make to order" ethos where customisation is replacing standardisation. This has lead to a far more complex planning process.
- Quality and cost are only minimum requirements for organisations wishing to compete in the marketplace. Competition has moved to a basis of aggressive delivery, lead-times, flexibility and greater integration with suppliers and customers with greater levels of product differentiation.

As a result, MRPII was further extended and renamed ERP (Kalakota and Robinson, 2001). An ERP system differs from the MRPII system, not only in system requirements, but also in technical requirements, as it addresses technology aspects such as graphical user interface, relational database, use of fourth generation language, and computer-aided software engineering tools in development, client/server architecture, and open-systems portability (Russell and Taylor, 1998; Watson and Schneider, 1999). Also, while "MRP II has traditionally focused on the planning and scheduling on internal resources, ERP strives to plan and schedule supplier resources as well, based on the dynamic customer demands and schedules" (Chen, 2001). This brief evolutionary definition of ERP is depicted in Figure 1.

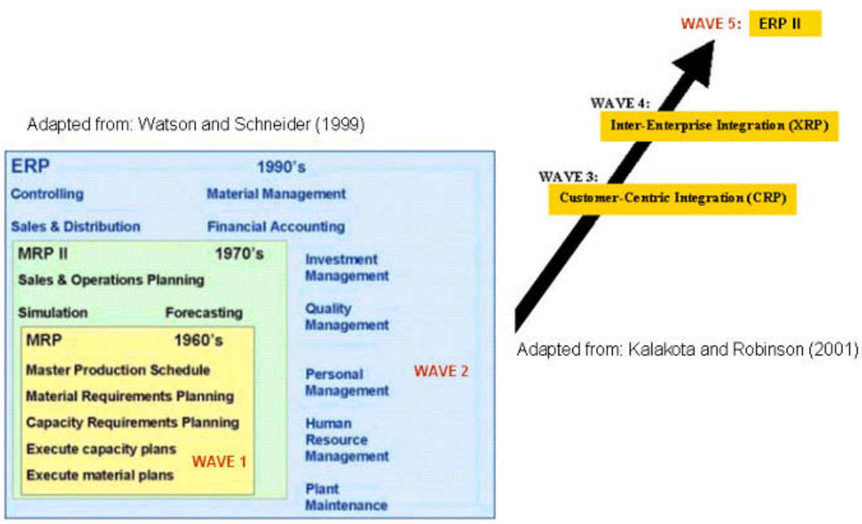
Kalakota and Robinson (2001) position ERP as the second phase in the "technology" and "enterprises internal and external constituencies" integration process, as illustrated in Figure 1. According to Kalakota and Robinson (2001), *Wave 1* of the evolution of ERP addresses the emergence of Manufacturing Integration (MRP), while *Wave 2* relates to Enterprise Integration (ERP). The combined impact of "key business drivers" (replacing legacy systems, gaining greater control, managing globalisation, handling regulatory change, and improving integration of functions across the enterprise) forced the "structural migration" from MRP to ERP (Kalakota and Robinson, 2001). Another significant factor in the second wave of ERP development was Y2K preparation, which was often cited as the major reason for ERP adoption (Brown et al., 2000; Kalakota and Robinson, 2001; Themistocleous et al., 2001). A new wave, *Wave 5*, now exists and positions ERP II as the new approach to enterprise integration.

ERP DEFINED

Although there is no agreed-upon definition for ERP systems, their characteristics position these systems as integrated, all-encompassing (Markus and Tanis, 2000; Pallatto, 2002), complex mega packages (Gable et al., 1997) designed to support the key functional areas of an organisation. The American Production and Inventory Control Society (APICS) defines ERP as, "an accounting-oriented information system for identifying and planning the enterprise-wide resources needed to take, make, ship, and account for customer orders" (Watson and Schneider, 1999). As a result, by definition, ERP is an operational-level system. Therefore, an Enterprise Resource Planning (ERP) system is a generic term for an integrated enterprise-wide standard information system (Watson and Schneider, 1999) that impounds deep knowledge of business practices accumulated from vendor implementations throughout organisations (Shang and Seddon, 2000).

ERP can be further defined as a strategic business solution that integrates all business functions, including manufacturing, financial, and distribution (Watson and Schneider, 1999). ERP systems are also being referred to as "enterprise systems" (Davenport, 1998; Chen, 2001) and "enterprise-wide Information Systems" (Al-Mashari, 2000; Milford and Stewart, 2000). It is a customised, packaged, software-based system that handles the majority of an enterprise's information systems' requirements (Watson and Schneider, 1999). It is a software architecture that facilitates the flow of information among all functions within an enterprise (Watson and Schneider, 1999). As a result, ERP systems are traditionally thought of as transaction-oriented processing systems (Davenport, 1998; Chen, 2001) or transactional backbones (Kalakota and Robinson, 2001). However, they are continually redefined based on the growing needs of organisations. Therefore, various definitions point to ERP systems as being enterprise-wide information systems that accommodate many features of an organisation's business processes. They are highly complex, integrated systems, which require careful consideration before selection, implementation, and use. Neglect of any of these areas can lead a company down the path to failure already

Figure 1. Evolution of ERP Systems



worn by FoxMeyer, Unisource Worldwide Inc., etc. (Adam and Sammon, 2004).

INSIDE ERP SYSTEMS

ERP systems use a modular structure (i.e., multi-module) to support a broad spectrum of key operational areas of the organisation. According to Kalakota and Robinson (2001), the multiple core applications comprising an ERP system are "themselves built from smaller software modules that perform specific business processes within a given functional area. For example, a manufacturing application normally includes modules that permit sales and inventory tracking, forecasting raw-material requirements, and planning plant maintenance." Typically, an ERP system is integrated across the enterprise with a common relational database, storing data on every function. ERP are widely acknowledged as having the potential to radically change existing businesses by bringing improvements in efficiency, effectiveness, and the implementation of optimised business processes (Rowe, 1999). One of the key reasons why managers have sought to proceed with difficult ERP projects is to end the fragmentation of current systems, to allow a process of standardisation, to give more visibility on data across the entire corporation and, in some cases, to obtain competitive advantage (Adam and Sammon, 2004).

ERP systems have expanded to include "back office" functions, such as operations, logistics, financials or human resources and "non-transaction-based systems" (Davenport, 1998) or "front office" functions, such as sales, marketing, customer services as an integral component (Davenport, 1998; Chen, 2001). This inclusion is a result of the emergence of Supply Chain Management (SCM) (Chen, 2001; Turban, et al., 2001) and Customer Relationship Management (CRM) strategies and systems (Chen, 2001), as illustrated in Figure 2.

While the names and numbers of modules of the ERP systems available on the market may differ, a typical system integrates all its functions by allowing modules to share and transfer information freely and by centralizing all information in a single database (Chen, 2001). Figure 3 provides an overview of such an ERP system.

ERP packages force an organisation to implement a proven set of business processes, which means that there is no need for the organisation to "reinvent the wheel." ERP packages encapsulate reusable "best practice" business processes. As state of the art technology and processes move forward, purchasers of packaged software move with them (Weston, 1998; Krumbholz et al., 2001; Stefanou, 2000). ERP packages give the foundation to the business, thus the management can concentrate on "grabbing market share" (Weston, 1998). Kalakota and Robinson (2001) stress that the popularity of ERP systems stems from the fact that they appear to solve the challenges posed by portfolios of "disconnected, uncoordinated applications that have outlived their usefulness."

These "legacy systems" provide one of the biggest drags on business productivity and performance because maintaining many different computer systems leads to

Figure 2. ERP Extended

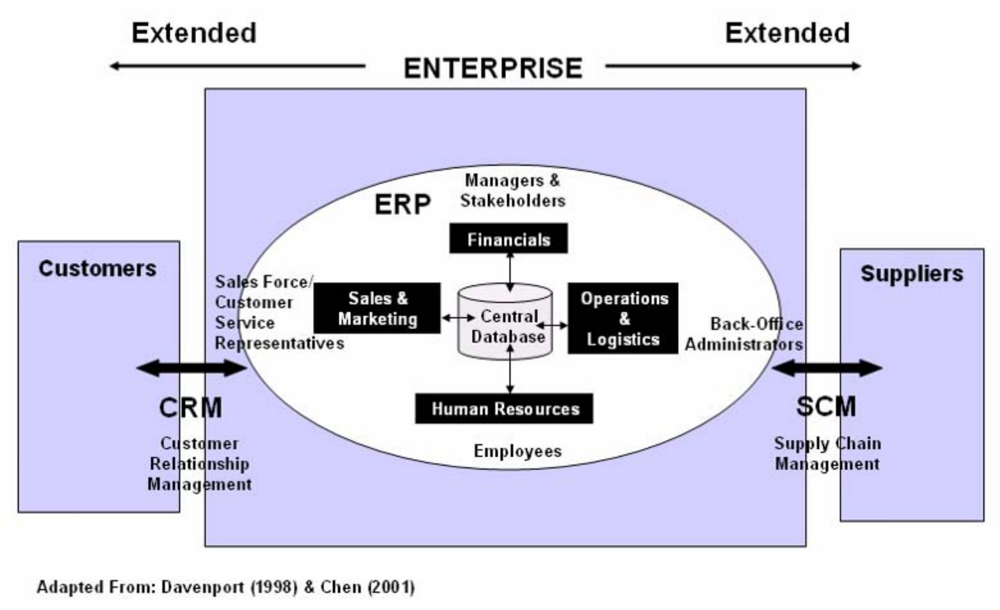


Figure 3. Module Overview of an ERP System

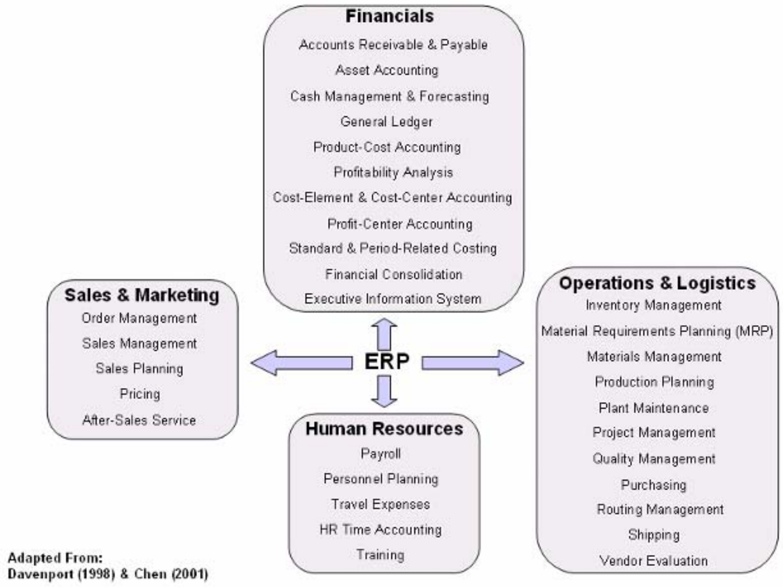

enormous costs. These include: direct costs such as rationalisation, redundancy, re-keying, reformatting, updating, debugging, deleting, etc., but more importantly, include indirect costs such as a company's purchasing and sales system which cannot communicate with its production/scheduling systems, leading manufacturing productivity and customer service to suffer. Crucially, management may be left to make vital decisions based on information from incompatible systems, thereby relying on instinct rather than sound business rationale.

MacVittie (2001) identified three goals behind the implementation of an ERP system:

1. Integration of Financial Data: When managers depend on their function's or unit's perspective of financial data, conflicting interpretations will arise (e.g., Finance will have one set of sales figures while Marketing will have another). Using an ERP system provides a single version of sales.
2. Standardisation of Processes: A manufacturing company that has grown through acquisitions is likely to find that different units use different methods to build the same product. Standardising processes and using an integrated computer system can save time, increase productivity, and reduce head count. It may also enable collaboration and scheduling of production across different units and sites.
3. Standardisation of Human Resource Information: This is especially useful in a multi-site company. A unified method for tracking employee time and communicating benefits is extremely beneficial because it promotes a sense of fairness among the workforce as well as streamlining the company as a whole.

BENEFITS OF ERP

Clearly, a properly implemented ERP system can achieve unprecedented benefits for business computing (Watson and Schneider, 1999). However, some companies have difficulty identifying any measurable benefits or business process improvements (James and Wolf, 2000; Donovan, 2001). For example, Pallatto (2002) observed that some vendors and consultants are presently "soft-peddling" the term ERP due to bad experiences and management frustration, when original business goals and benefits were not achieved, with their ERP implementations.

Rutherford (2001) observed that only around 10% to 15% of ERP implementations deliver the anticipated benefits. According to James and Wolf (2000) companies that were able to identify benefits thought that they could have been realized without the implemented ERP system. They felt that most the benefit they got from their ERP came from changes, such as inventory optimization, which could have been achieved without investing in ERP (James and Wolf, 2000). Therefore, ERP systems can be considered as a catalyst for radical business change that results in significant performance improvement (Watson and Schneider, 1999). According to James and Wolf (2000), reporting on an instance of an ERP implementation, "many of the benefits that we are able to achieve today could not have been predicted at the time that we started work on ERP. In fact, in hindsight it appears that much of the value of these large systems lay in the infrastructure foundation they created for future growth based on Information Technology."

Shang and Seddon (2000) presented a comprehensive framework of business benefits that organisations might be able to achieve from their use of ERP systems. They present 21 ERP benefits consolidated across five benefit dimensions (operational, managerial, strategic, IT infrastructure, organizational). Shang and Seddon (2000) analyzed the features of ERP systems, literature on IT benefits, Web-based data on 233 ERP-vendor success stories, and interviews with 34 ERP cases to provide a comprehensive foundation for planning, justifying and managing the ERP system. The focus and goal of the Shang and Seddon (2000) framework is "to develop a benefits classification that considers benefits from the point of view of an organisation's senior management" and that can be used as a "communication tool and checklist for consensus-building in within-firm discussions on benefits realisation and development" (Shang and Seddon 2000).

Shang and Seddon (2000) also commented that there were few details of ERP-specific benefits in academic literature and that "trade-press articles" and "vendor-published success stories" were the major sources of data. However, they warned that, "cases provided by vendors may exaggerate product strength and business benefits, and omit shortcomings of the products." This was also observed in Adam and Sammon's (2004) study of the "ERP Community" and the *sales* and *needs* discourse that characterise it. It is therefore extremely important to be able to assess the suitability of the ERP system for any organization. A study conducted by Sammon and Lawlor (2004) reiterates this argument, highlighting that failure to carry out an analysis of the mandatory and desirable features required in a system with an open mind will lead to the blind acceptance of the models underlying the ERP packages currently on sale on the market, with detrimental effects on the organization and its operations.

The justification for adopting ERPs centres around their business benefits. However, Donovan (1998) believes that to receive benefit from implementing ERP there must be no misunderstanding of what it is about, or underestimation of what is involved in implementing it effectively, and even more importantly, organisational decision makers must have the background and temperament for this type of decision making (Donovan, 2001).

CONCLUSION

Kalakota and Robinson (1999) put forward four reasons why firms are prepared to spend considerable amounts on ERP systems:

1. ERP systems create a foundation upon which all the applications a firm may need in the future can be developed.
2. ERP systems integrate a broad range of disparate technologies into a common denominator of overall functionality.
3. ERP systems create a framework that will improve customer order processing systems, which have been neglected in recent years.
4. ERP systems consolidate and unify business functions such as manufacturing, finance, distribution and human resources.

Thus, despite the slowdown of ERP package sales from 1999 on (Remy, 2003), there is evidence that the trend towards ERP and extended ERP systems is well established (Stefanou, 2000). Some segments of the ERP market maybe saturated, but powerful driving forces including e-commerce (Bhattacherjee, 2000), Enterprise Application Integration (EAI) (Markus, 2001), Data Warehousing (DW) (Inmon, 2000; Markus, 2001; Sammon et al., 2003) and ERP II (Pallatto, 2002) will further push this market to new heights in years to come. This will mean that considerable proportions of the IT investment of many firms will converge towards ERP-type projects and that IS researchers need to pursue their efforts at developing better frameworks and better methodologies for the successful deployment of Enterprise Systems in firms.

KEY TERMS

APICS: The American Production and Inventory Control Society was founded in 1957 and is a global leading provider of information and services in production and inventory management.

ERP Community: A model defining the collective relationships and interactions between the three *de facto* actors (the ERP vendor, the ERP consultant, the implementing organization) within the ERP market.

ERP II: ERP II is understood to mean the re-implementation and expansion of ERP. It is an extended, open, vertical, and global approach to systems integration and can be understood as an application and deployment strategy for collaborative, operational, and financial processes within the enterprise and between the enterprise and key external partners and markets, in an effort to provide deep, vertical-specific functionality coupled with external connectivity.

Extended Enterprise: Understood as the seamless Internet-based integration of a group or network of trading partners along their supply chains.

Legacy Systems: Mission-critical "aging" systems that supported business functions for many years. However, they are no longer considered state-of-the-art technology and have limitations in design and use. Within organisations, the vast majority were replaced pre-Y2K with ERP systems.

Modular System Design: An ERP system can be broken down by functional area (e.g., sales, accounting, inventory, purchasing, etc.). It increases flexibility in terms of implementing mutli-module (from one or many vendors), or single-module ERP functionality.

Return On Investment (ROI): A technique used for measuring the return on an investment and is often used in the justification of new ERP systems, or to measure how well an ERP system has been implemented, or for implementing new or additional functionality.

D

Delineating Knowledge Flows for Enterprise Agility

Mark E. Nissen
Naval Postgraduate School, USA

INTRODUCTION

The practice of knowledge management (KM) purports to take the power of knowledge to the group, organization and even enterprise level (Davenport & Prusak, 1998). Although this potential benefit of KM is not viewed universally (Gore & Gore, 1999; McDermott, 1999), many scholars (e.g., Drucker, 1995) assert that knowledge represents one of the very few sustainable sources of competitive advantage. Hence, the knowledge-based organization—one that competes on the basis of its differential knowledge (e.g., see Grant, 1996, for discussion of the knowledge-based view of the firm)—appears to offer great promise in terms of performance and capability.

Drawing from Nissen (2004), the knowledge-based organization must be able to apply substantial knowledge, when and where it's needed, to affect organizational goals. However, knowledge is not distributed evenly through the organization, so rapid and efficient knowledge flow is critical to enterprise performance. The larger, more geographically dispersed, and time-critical an enterprise (e.g., global manufacturing firms, telecommunication and software companies, military forces), the more important knowledge flow becomes in terms of efficacy. Unfortunately, our collective knowledge of how knowledge flows is quite primitive (Alavi & Leidner, 2001; Nissen, 2002). Lacking knowledge-flow theory and application for guidance, even enterprises with multimillion-dollar KM projects have difficulty seeing past *information* technologies such as intranets and Web portals. Further, Nissen, Kamel, and Sengupta (2000) note such KM projects rely principally upon trial and error, one of the least effective approaches known.

BACKGROUND

This section draws heavily from Nissen (2004) to summarize key background pertaining to knowledge flow. It focuses in particular on important concepts from the emerging literature on knowledge management and augments current work on knowledge flows (e.g., Baumard, 2002; Echeveria-Carroll, 1999; Fang, Lin, Hsiao, Huang, & Fang, 2002; Foss & Pedersen, 2002; Gupta & Govindarajan, 2000; Schulz & Jobe, 2001; Zhuge, 2002). For the purposes of this article, three important concepts from the KM literature are summarized: 1) knowledge hierarchy, 2) knowledge management life cycle, and 3) current knowledge-flow theory.

Knowledge Hierarchy

Many scholars (e.g., Davenport & Prusak, 1998; Nissen et al., 2000; von Krogh, Ichijo, & Nonaka, 2000) conceptualize a hierarchy of knowledge, information, and data. As illustrated in Figure 1, each level of the hierarchy builds on the one below. For example, data are required to produce information, but information involves more than just data (e.g., need to have the data in context). Similarly, information is required to produce knowledge, but knowledge involves more than just information (e.g., it enables action). We operationalize the triangular shape of this hierarchy using two dimensions—abundance and actionability—to differentiate among the three constructs.

Briefly, data lie at the bottom level, with information in the middle and knowledge at the top. The broad base of the triangle reflects the abundance of data, with exponentially less information available than data, and even fewer chunks of knowledge in any particular domain. Thus, the width of the triangle at each level reflects decreasing abundance in the progress from data to knowledge. The height of the triangle at each level reflects actionability (i.e., the ability to take appropriate action, such as a good decision or effective behavior). Converse to their abundance, data are not particularly powerful for supporting action, and information is more powerful than data. But knowledge supports action directly, hence its position near the top of the triangle. Curiously, there is current speculation as to one or more additional levels "above" *knowledge* in such hierarchies (e.g., *wisdom*; cf. Spiegler, 2000). The present article does not attempt to address "wisdom flow."

Knowledge Management Life Cycle

Nissen et al. (2000) observe a sense of process flow or a life cycle associated with knowledge management. Integrating their survey of the literature (e.g., Davenport &

Figure 1. Knowledge hierarchy (adapted from Nissen, 2002)

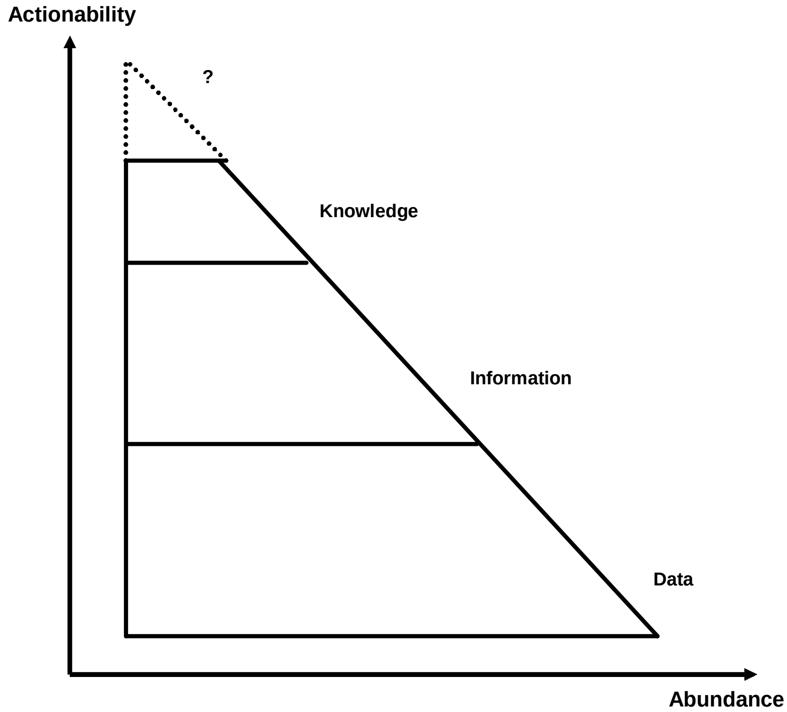

Table 1. Knowledge management life cycle models (Adapted from Nissen et al., 2000)

Model	Phase 1	Phase 2	Phase 3	Phase 4	Phase 5	Phase 6
Despres and Chauvel	Create	Map/ bundle	Store	Share/ transfer	Reuse	Evolve
Gartner Group	Create	Organize	Capture	Access	Use	
Davenport & Prusak	Generate		Codify	Transfer		
Nissen	Capture	Organize	Formalize	Distribute	Apply	
Amalgamated	Create	Organize	Formalize	Distribute	Apply	Evolve

Prusak, 1998; Despres & Chauvel, 1999; Gartner Group, 1999; Nissen, 1999), they synthesize an amalgamated KM life cycle model as outlined at the bottom of Table 1.

Briefly, the creation phase begins the life cycle, as new knowledge is generated within an enterprise; similar terms from other models include *capture* and *acquire*. The second phase pertains to the organization, mapping, or bundling of knowledge, often employing systems such as taxonomies, ontologies, and repositories. Phase 3 addresses mechanisms for making knowledge formal or explicit; similar terms from other models include *store* and *codify*. The fourth phase concerns the ability to share or distribute knowledge in the enterprise; this also includes terms such as *transfer* and *access*. Knowledge use and application for problem solving or decision making in the organization constitutes Phase 5, and a sixth phase is included to cover knowledge refinement and evolution, which reflects organizational learning—and thus a return to knowledge creation—through time. It is important to note, as in the familiar life cycle models used in IS design (e.g., System Development Life Cycle), progression through the various phases of this Life Cycle Model is generally iterative and involves feedback loops between stages; that is, all steps need not be taken in order, and the flow through this life cycle is not necessarily unidirectional.

Current Knowledge-Flow Theory

This section summarizes the dynamic model developed by Nissen (2002). It begins by building upon Nonaka's (1994) work to conceptualize an extended model of knowledge-flow dynamics. This extended model is intended to help managers to understand better how enhancing knowledge flow can increase enterprise intelligence. The first step is to augment Nonaka's two-dimensional framework by incorporating a third dimension, the *KM life cycle*. We operationalize the construct using the life cycle stages from the Amalgamated Model presented in Table 1.

The second step requires relabeling the epistemological and ontological dimensions. Because the terms *epistemological* and *ontological* can be confusing when used in the present context, we relabel them as *explicitness* and *reach*, respectively, to target directly the principal focus of each dimension (i.e., differentiating explicit vs. tacit knowledge; indicating how broadly knowledge reaches through an enterprise).

In Figure 2, we note a few notional vectors for illustrating and classifying various dynamic patterns of knowledge as it flows through the enterprise. For example, the simple linear flow labeled "P&P" (i.e., Policies & Procedures) depicts the manner in which most enterprises inform, train, and attempt to acculturate employees: explicit documents and guidelines that individuals in the organization are expected to memorize, refer to, and observe. As another example, the cyclical flow of knowledge labeled "KMLC" (i.e., KM life cycle) reflects a more complex dynamic than its simple linear counterpart. This flow describes a cycle of knowledge creation, distribution, and evolution within a workgroup, for example.

Further, Nonaka's dynamic model of knowledge flow can also be described in this space by the curvilinear vector sequence corresponding to the processes labeled "SECI" (i.e., socialize, externalize, combine, internalize), "externalize", "combine", and "internalize". Thus, our model subsumes the one proposed by Nonaka and shows a complex dynamic as knowledge flows along the life cycle. Moreover, examination of this space suggests also including (and connecting) the "create" and "refine" vectors, which are not part of Nonaka's theory but represent key elements of the empirically derived Life Cycle Model (e.g., the key to knowledge generation and evolution). Clearly, a great many other flows and patterns can be shown in this manner.

APPLICATION EXAMPLE – NEW PRODUCT DEVELOPMENT

Drawing concepts from Nissen (2004) in this section, we know the business environment now changes very rapidly, and the frequency of such changes is only expected to increase through time. Business processes must change even more rapidly for the knowledge-based organization to anticipate—not simply react to—new competitive requirements and market opportunities. Hence, the days of fixed business rules (e.g., embedded in static workflow or ERP systems) are long gone, as enterprises must be able to reconfigure processes quickly to capitalize on often-ephemeral advantages. To accomplish such agile reconfigurability, enterprise knowledge must flow quickly and efficiently across space, time and organizational units as process changes dictate. Again, enterprise knowledge flow is critical to performance.

To help ground in practice our knowledge-flow model previously described, we illustrate its application through an example of new product development in 21st century.

Figure 2. Notional knowledge-flow vectors (adapted from Nissen, 2002)

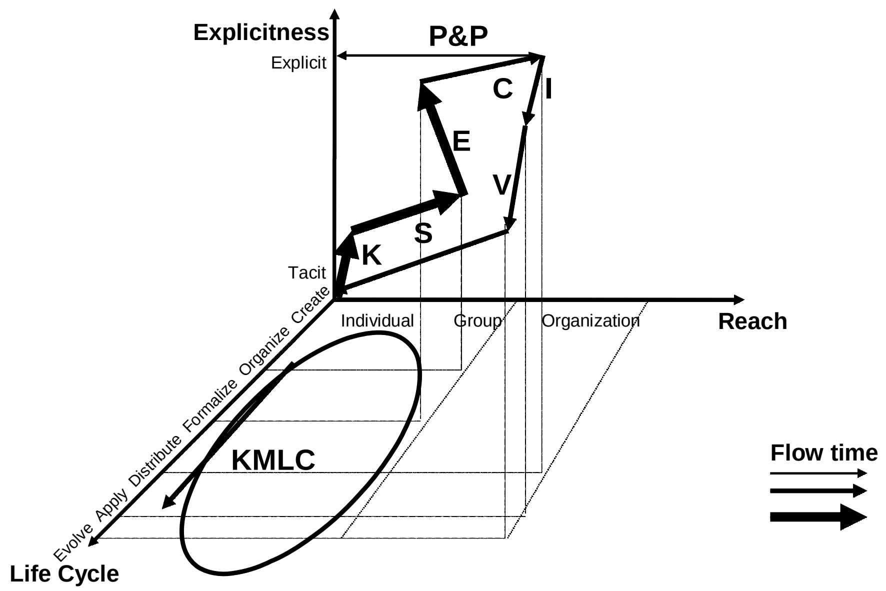

Figure 3. Current enterprise knowledge (adapted from Nissen, 2004)

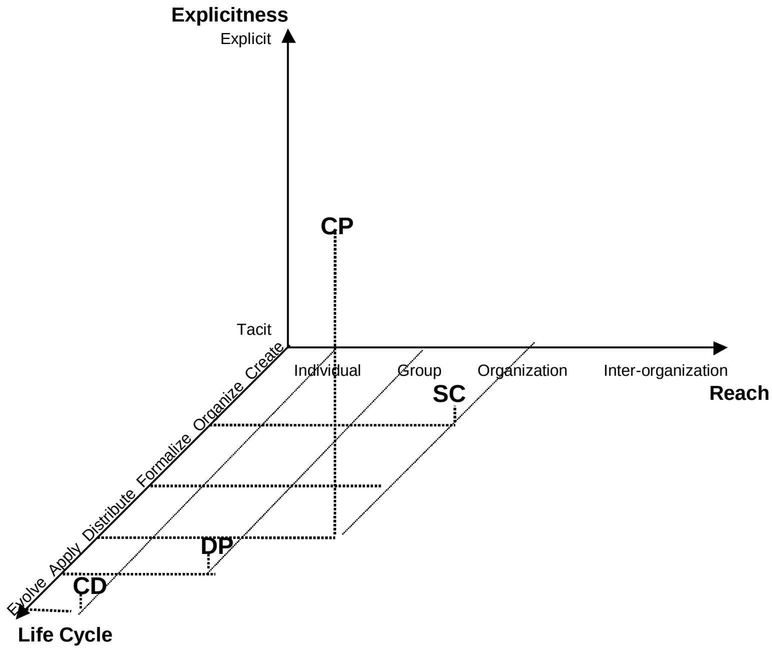

Figure 4. Required knowledge flows (adapted from Nissen, 2004)

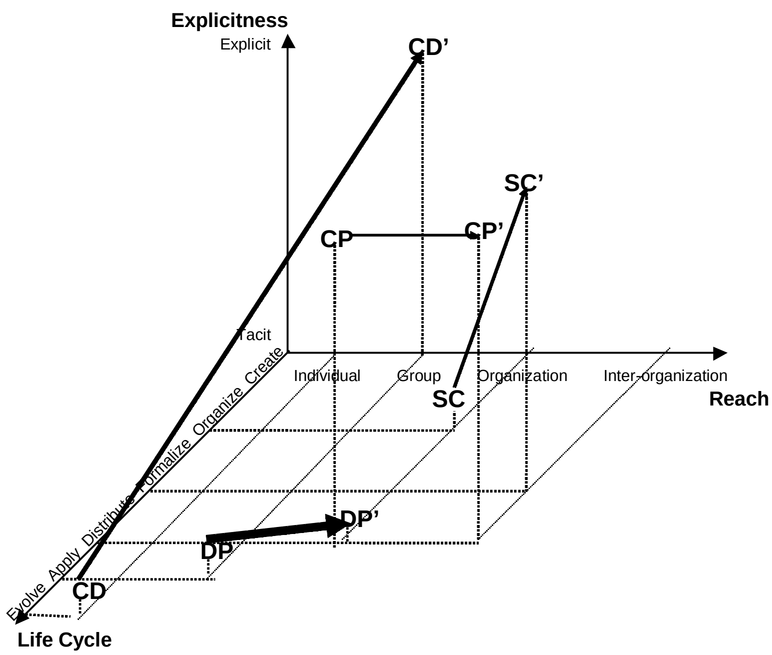

We can similarly ground the knowledge-flow model in other application domains (e.g., banking, consulting, manufacturing, telecommunications)—in which some of the specifics vary, but the principles hold constant. However, this example should convey clearly the key ideas. Typically heavy investments in plant and equipment for new product development confine most physical capital to specific geographical locations, and processes based upon such plant and equipment are very resistant to short-term changes. Yet global customer markets and supplier bases demand just such short-term changes. This represents a challenging context in terms of knowledge flow. Further, increasingly global markets and operations cause the demand for specific products to be unpredictable and to shift continually. New product design cycles can barely keep up with such demand shifts, and dynamic supplier networks change with each new product offering.

Here we discuss four areas of knowledge that appear to be critical: 1) customer demands, 2) competitor products, 3) design processes, and 4) supplier capabilities. In Figure 3, we use our multidimensional model to depict and examine such critical knowledge. Beginning with customer demands, the three-dimensional plot point corresponding to such knowledge is labeled "CD" in the figure. Notice it is plotted at the tacit end of the explicitness axis (e.g., future customer wants are generally not explicitly stated), the individual level in terms of the reach dimension (e.g., customer preferences are developed by individuals), and evolve stage of the life cycle (i.e., customer tastes evolve through time).

Even with this single step of classifying and plotting customer-demand knowledge in terms of our multidimensional model, we have identified a critical knowledge element, and can compare and contrast it visually with other key elements of knowledge. In similar fashion, knowledge of competitor products (i.e., labeled "CP" in the figure), internal design processes (i.e., labeled "DP") and supplier capabilities (i.e., labeled "SC") are also plotted in this figure. This set of points provides us with a view of the firm's critical knowledge as it exists today. We explain below how such knowledge is *not flowing* to where (and when) a knowledge-based organization needs it to be, even though it is deemed critical. This motivates the need for inducing knowledge flow.

In Figure 4, we plot these same four points along with their counterparts depicting how knowledge in each area needs to flow in terms of our three model dimensions. For instance, customer-demands knowledge needs to be made explicit, and its reach must extend at least to the level of a marketing group within the firm. The question of where along the life cycle depends upon how agile and proactive the firm wishes to be; as depicted in the figure (i.e., point CD'), ideally the firm would want to *create* customer demand through new-product innovation and brand loyalty. A vector connecting the current and desired knowledge points (i.e., CD-CD') is shown to delineate the corresponding knowledge flow requirement. Here we understand now what knowledge is critical, the state of such knowledge, and how it must flow to enable new product innovation.

Points and vectors corresponding to necessary knowledge flows in terms of competitor products (i.e., CP-CP'), supplier capabilities (i.e., SC-SC'), and design processes (i.e., DP-DP') are classified, identified, and plotted in similar fashion in Figure 4. For instance, unlike (tacit) customer demands, knowledge of competitor products is already explicit and distributed, but the requisite knowledge flow shows such knowledge must also be made explicit *across* organizations (i.e., within our firm as well as the competitors'); this requires business intelligence to identify what competitors are doing in relevant marketspaces.

The knowledge flow corresponding to supplier capabilities is similar (e.g., required to flow beyond the supplier and into our firm), except such capabilities (e.g., in terms of new product development) must also be made explicit (i.e., not left as unarticulated potential) through formalization; this requires competitive sourcing to identify and help develop promising suppliers. Finally, design-process knowledge is required to flow beyond a specific design group, which suggests organization-wide distribution, however, distributing tacit knowledge as such remains a difficult undertaking, as it is often referred to as "sticky" in the product-development context (Szulanski, 1996; von Hippel, 1994).

FUTURE TRENDS

What kinds of future trends are suggested by inducing knowledge flows in the analysis described previously? For one, this particular analysis provides insight into the reality that one size does not fit all in terms of KM and IT. Rather, the key lies in focus on how the requisite knowledge associated with each vector can be induced to flow in situations where it is currently "clumped" or "constricted" (e.g., the marketing flow described previously). For another, to induce knowledge flows, the extant tools and processes employed by most successful firms can be integrated and targeted to focus specifically on the corresponding knowledge. Using knowledge-flow induction as outlined previously, the manager can ask what is preventing this specific knowledge from flowing today, and reconfigure the enterprise's tools and processes to obviate the problem.

The analysis described previously also points to future trends in terms of new IT. For instance, we now know better than to focus IT on information and data, and such knowledge can be used to focus research and development specifically upon classes of technologies that can address knowledge directly. Some such technologies such as those of data mining and artificial intelligence are known relatively well, whereas others such as "knowledge amplifiers" and "knowledge engines" have yet to be invented. Finally, inducing knowledge flows as described previously has implications in terms of research. Despite the progress reflected in this article, our level of ignorance pertaining to knowledge-flow dynamics remains high. Nonetheless, having a multidimensional model and representational method to depict knowledge flows can help guide such research.

CONCLUSION

The knowledge-based organization appears to offer great promise in terms of performance and capability. This article summarizes the current state of the art pertaining to knowledge flow, and provides an overview of a model to help induce the flow of knowledge through an organization. Using a global manufacturing firm as an example to illustrate how the knowledge-flow model provides practical guidance, we identify knowledge elements that are critical to effective performance in an unpredictable, dynamic business environment, and we use the multidimensional model to illustrate how to identify specific knowledge flows required for success. This enables managers to analyze the knowledge flows of their organizations, and provides insights both in terms of future trends and directions for research and development.

KEY TERMS

Competitive Advantage: Employing organizational resources in an advantageous manner that cannot be imitated readily by competitors.

Extended Model of Knowledge-flow Dynamics: A four-dimensional model used to classify and visualize flows of knowledge in the organization.

Knowledge-based Organization: An organization that competes on the basis of its differential knowledge.

Knowledge Flow: The movement or propagation of knowledge across space, time, people and organizations.

Knowledge Hierarchy: The hierarchical relationship between knowledge, information and data, with each level building upon the one below.

Knowledge Management: Capitalizing on intellectual assets in the organization.

Knowledge Management Life Cycle: The cycle of activities associated with managing knowledge.

Delivering Web-Based Education

Kathryn A. Marold
Metropolitan State College of Denver, USA

INTRODUCTION

A decade of hindsight allows us to examine the phenomenon of Web-based course delivery and evaluate its successes and failures. When Web-delivered courses mushroomed from campuses in the 1990s, they were embraced by students, faculty, and administrators alike. The prospect of "electronic tutelage" (Marold, 2002), which allowed students through Web interface to take college courses for credit any time, any place (ATAP), was immediately popular with students. The interruptions of job and schedule changes, relocation, childbirth, failed transportation to campus, and so forth no longer necessitated an interruption in progress toward a degree. Likewise, faculty saw online teaching as an opportunity to disseminate knowledge and assess student progress according to their personal preferences, and to communicate personally with their students, albeit virtually. Administrators saw the revenue without physical classroom allocations as an immediate cash cow. In the beginning, there was satisfaction all around. Although this state of affairs was not necessarily universal, generally it could be concluded that Web-based education was a very good thing.

The Evolution Of Web-Based Course Delivery

Web-based education is a variation of distance learning: the content (college courses from an accredited North American institution, for purposes of this chapter) is delivered via the World Wide Web. The Web course content covers a quarter or semester of curriculum that the student must complete and prove a level of mastery within a given timeline. For the most part, Web-based courses use existing college curriculum and timelines. Web-based education is currently the most popular form of distance education. As educators are inclined to do, it was not long before they wanted to stand back and evaluate what they had created and determine the success of Web-delivered courses as a form of distance education. With McLuhanesque procedures, a glance in the "rear view mirror" was in order (McLuhan, 1964.) The results of many measures of success show that for *some* of the students, *some* of the time, in *some* situations, Web-based education is quite successful. Likewise, for many persons in many situations and in many phases of their formal education, Web-delivered education is *not* the answer.

BACKGROUND

The advent of the World Wide Web in the early 1990s promised a more effective, user-friendly form of Internet distance education. The graphical hypertext and, indeed, the hypermedia nature of the Web could enhance course delivery. Almost immediately, Web courses began to flourish. A new mode of delivery was firmly established.

Web-Based Education's Successes and Failures

Numerous publications have exposed problems associated with the Web-based form of distance education. The population taking the courses was sometimes the problem (Haga, 2001). The attrition and failure rate of Web-delivered courses was higher than the classroom arena (Terry, 2001). The content of the course could be problematic (Haga, 2002). The credibility of course credit achieved online was sometimes suspect (Moreno, 2000). The level of courses offered online was sometimes suspect (Marold, 2003). Research findings suggest the following conclusions concerning Web-based education (see Table 1).

There are almost as many reports of success with Web-based education as there are reports of failures. Students who are successful with Web courses tend to take more of them, sometimes as many as 90 hours of the 120 hours required for a bachelor's degree. There are now entire degrees offered online. The earliest research on Web-based education reported no statistical difference in final grades between Web-based groups and classroom groups (Mawhinney, 1998; Schulman, 1999).

The conclusion that Web-delivered education, like all distance education, is only appropriate for some students cannot be denied. It is obvious that Web courses are not going to go away. It is also undeniable that regardless of how enrollments in Web-based courses are screened, there will be students who enroll in Web courses that should not be in them. It has been shown time and again that some Web students enroll for all of the wrong reasons

Table 1. Successes and failures of Web-based education

Positive	Negative
Survey level courses are the most successful.	The attrition and failure rates for upper level, analytical Web-based courses often reach 50%.
Courses at the 1-2 level of Bloom's taxonomy (Bloom, 1956) of learning immersion are more successful than those at the 3-5 level.	Students at the B and C level (the vast majority of students in any institution) are the most at risk for not completing and not passing Web-delivered courses.
Students with GPA of 3.5 or better are the most successful at completing and excelling in Web-delivered courses.	Web-delivered courses are a disaster for the passive learner without time management and independent study skills.
Graduate level Web-delivered courses are more successful.	Both students and faculty alike indicate time spent on an Internet delivered course is more than it would be on its classroom equivalent.
Courses delivered via a 3rd party distributor or a portal (such as *WebCt* or *Blackboard*) are more successful than self-hosted Web courses	
Internet students generally do better than their classroom counterparts on exams. Internet students generally do worse on projects than their counterparts on assigned projects.	
Analytical and problem solving courses are least successful.	
Web-delivered courses are a godsend for the highly motivated, independent learner.	
Final grades on Web-based education courses generally do not differ significantly from those earned in the classroom. Web-based courses are here to stay. They are an accepted, credible method of course delivery	

(Haga, Marold, & Helms, 2001). It is equally obvious that Web courses fill an enormous need for many students and are, therefore, very successful in many instances.

While the students who are at risk for failure in Web-based courses that are analytical and require problem solving are those students who are generally classified as mid-level achievers, taking prerequisite courses online seems to alleviate the risk slightly (Pence, 2003). The student group at the greatest risk is the mid-level achieving group, which in a normal distribution is the largest number of students in the class (Marold & Haga, 2004). Pence suggests some alleviating factors, such as taking the prerequisite course online from the same institution. This suggests that as students become more accustomed to the requirements and idiosyncrasies of online learning, the risk decreases. Experience makes a difference. In addition, the majority of students taking online courses indicate that they would take another online course, even though they perceive them to be more work than an equivalent classroom course. Despite attrition and failure rates that sometimes reach 50%, Web-based education is clearly a student favorite.

Tables 2 and 3 show some of the research results of a decade of Web-based education.

In the above research of two separate Web-based required computer information systems junior level courses in the same department of a large urban state school, student tests were higher in the Internet version, but their project scores (application of learning) were lower.

In Table 2, there were three different courses at freshman, sophomore, and junior levels, offered online as well as in the classroom, from the same department of a large urban institution. All three courses were survey-type

Table 2. Comparing Internet scores with classroom scores (Haga, 2001)

Telecommunications	**Internet**	**Classroom**
Projects average	60.8	83.5
Exams average	64.2	62.7
Visual Basic Programming		
Projects average	69	73.3
Exams average	72	71.3

Table 3. Comparing Internet scores with classroom scores (Marold, Larsen, & Moreno, 2002)

Introduction to Computers 1010	**Internet**	**Classroom**
Projects average	92.4	92.4
Exams average	78.2	73.5
Computer Applications for Business 2010	**Internet**	**Classroom**
Projects average	90.3	91.8
Exams average	77.5	70.01
Micro-based Software 3270	**Internet**	**Classroom**
Projects average	87.5	93.8
Exams average	77.7	67.8

** Revised classroom exams average for 2010*

Table 4. Successful Web-course characteristics

• More is not better. Simplicity, organization, and clarity are paramount.
• Frequent communication is important, both synchronous (chat, messaging) and asynchronous (e-mail, forum, discussion boards).
• Smaller modules and units work better.
• More frequent, less intricate assignments are better than complex comprehensive assignments due at the end of the course.
• Student uploaded projects and assignments work better than hard copy submissions.
• Individualized assignments are more likely to be submitted.
• The more choices in assignments and projects, the better.
• Proctored exams and secure quizzes are essential for course acceptance in the community and the workplace.
• Courses shorter in duration are more successful than ones that span semesters or quarters.
• Electronic grade books and regular feedback to student assignments submitted are essential.
• Samples of student work communicate expectations for assignments.
• Profiles or student Web pages for class members build community.
• Web links to helpful course content and enrichment material are appreciated, although not used extensively.
• More than one route to the same location in a course individualizes the course.
• Calendars of due dates and course announcements provide quick reference.

courses with a heavy skills component. This research was done earlier than the study shown in Table 2. The test scores were also higher for the Internet sections, and the projects lower.

Although Web-based grades differ from classroom grades on individual projects and exams, generally over a decade of looking back, we see that final grades on courses completed on the Internet and in the traditional classroom do not differ significantly (Haga, 2002; Marold, 2002; Moreno, 2000; Presby, 2001).

DESIGNING AND DELIVERING WEB-BASED EDUCATION

It is heartening to know that the success of a Web-delivered course is not directly related to the faculty's skill in instructional design and Web publication (Marold, 2002). Templates and Web design software suffice for course design. Simple courses are just as successful as complex ones. Studies that count visits to various pages in Web courses show that many of the available pages are infrequently (and sometimes never) used by a majority of online students (Haga, 2001). The same is true for extensive instructions on how to take an online course, or lists of Web links available for extra information supplementing the course material. Factors that contribute to successful Web-delivered course are shown in Table 4. These are general conclusions based upon a decade of studies of Web-based education.

For every individual characteristic listed here, one undoubtedly can find research contradicting it. From their inception, Web delivered courses have been examined and reexamined. However, in general, these are factors that have been found to make a positive difference for faculty and designers of Web-based courses.

FUTURE TRENDS

As Web courses become more common and educators become more proficient at designing and deploying them, undoubtedly their success rate will improve. As students become more accustomed to taking Web courses, they will become more proficient at completing them. As McLuhan (1964) noted, it takes a period of adjusting to a new medium before we are entirely comfortable with it. Once Web courses become part of the "every day" of our existence, Web-based education may take its legitimate place alongside other modes of delivery.

CONCLUSION

In conclusion, Web-based education is working—for some. Entire degrees are obtainable online; students, faculty, administrators, and organizations accept credits earned online. For better or for worse, Web-based education is firmly entrenched in all areas of higher education. While Web-based education has not yet achieved the same level of success as classroom delivered instruction, it is part of most institutions' programs. The fact that Web-based education is truly working in a cost-effective manner for some of the student population some of the time, assures its continuance. Like the printing press of the late 1400s for mass distribution of knowledge, Web-based education provides mass distribution of knowledge in a new, effective way.

KEY TERMS

ATAP: Any time, any place learning. A basic characteristic of Web-based education courses in that they are available to the student on a 24-7 basis.

Bloom's Taxonomy of Learning: A scale that represents an organization of learning levels (five levels) that are characterized by the student's immersion into the theory and application of principles of a course content.

Chat Sessions: Live discussions online with a variable number of participants in a Web-based class. They can be formal and led by the instructor, or they can be leaderless informal conversations. Chat sessions are synchronous.

Electronic Gradebooks: Maintaining a record of a student's progress in a Web-based education class by posting grades on the course Web pages. General gradebooks show all enrollees; personalized gradebooks can only be viewed by the individual student.

Electronic Tutelage: Learning of new complex concepts (sometimes called *scientific* concepts), not with the intervention of a physical tutor, but via electronically delivered materials; the basic theory behind Web-based education.

Synchronous and Asynchronous Communication: Synchronous communication via the Web is immediate communication, such as in chat or instant messaging. Asynchronous communication is delayed communication via the Web, such as threaded discussions, forums, or e-mail messages, where each participant does not have to be online at the same time.

Web-Based Education: A variation of distance learning; the content (college courses from an accredited North American institution, for purposes of this chapter) is delivered via the World Wide Web. The Web course content covers a quarter or semester of curriculum that the student must complete within a given timeline in return for course credit.

Web Links: Hyperlinks (hot links) to other Web sites that are embedded in the active pages of a Web-based education course.

Web Profiles: Short biographies of students enrolled in a Web-based education course. The profiles may contain Web links to students' own home pages and digitized photos of the students.

Democratic E-Governance

Ari-Veikko Anttiroiko
University of Tampere, Finland

INTRODUCTION

The changing role of the state and a managerialist view of the operations of public-sector organizations gave rise to the idea of new public governance. Gradually, more citizen-centered views of governance also emerged, reflecting a need to strengthen the role of citizens and communities in governance processes at different institutional levels. This development, especially since the mid-1990s, has been affected by new technologies, leading to a kind of coevolution of institutional arrangements and technological solutions that have paved the way for a better understanding of the potentials of democratic e-governance.

BACKGROUND

Discussion about governance has acquired new dimensions since the early 1990s due to the gradual erosion of the hierarchical, mainly state-centric, bases of political power. Among the core topics has been the decline of the nation state and the rise of the regions and local governments as the new key players in coping with external challenges and imposing a political will within territorial communities. Also, after the Second World War, and the 1980s in particular, international organizations and regional institutions started to gain more power in the international arena (Pierre, 2000, p. 1). Another widely discussed aspect of public governance relates to the functioning and ways of working of public-sector organizations. In fact, this theme has dominated much of the recent discourse around governance. In all, the entire institutional landscape and the overall understanding of the role of public-sector organizations has gradually changed practically everywhere in the world, thus fueling the discussion about governance. One important governance agenda-setter was the Organisation for Economic Cooperation and Development (OECD) Public Management Committee (PUMA), which carried out work on this topic during the first half of the 1990s, and as a synthesis, published a policy paper entitled *Governance in Transition* in 1995 (OECD, 1995).

OECD's policy lines have been more or less neoliberal, which means that governance issues were discussed and still are, to a large extent, within the framework of New Public Management (NPM). In essence, its message is that the approach to the management of public organizations and services needs to be based on managerialism and market-based coordination (Walsh, 1995). After a gradual widening of these NPM perspectives, some people have referred to this area as new governance or new public governance. Yet, it is important to keep in mind that new governance attempts to widen the horizons inherited from the original market-oriented NPM doctrine.

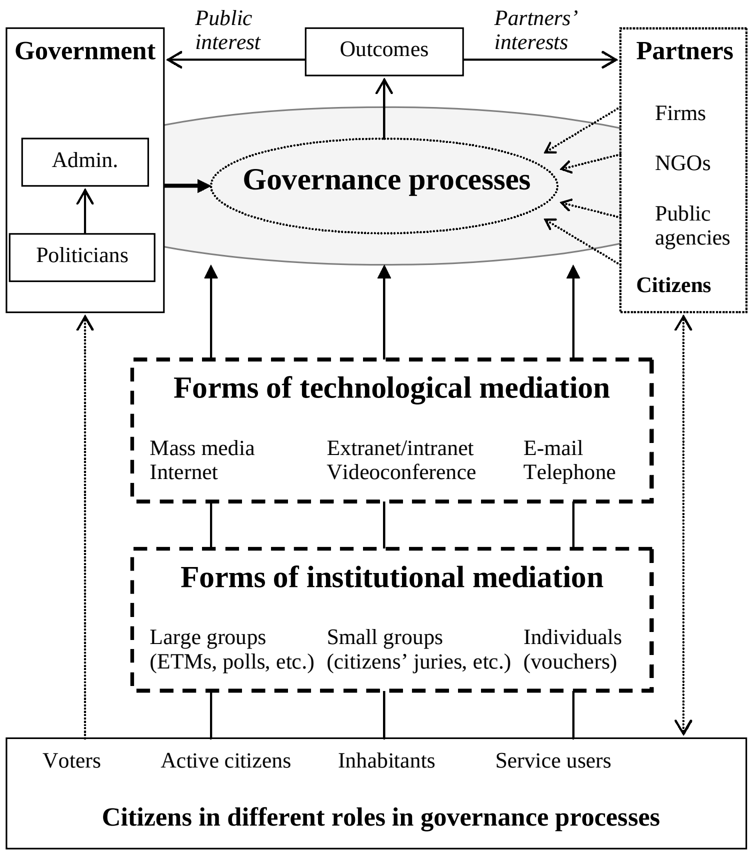
As presented above, contemporary understanding and use of the concept of governance have their roots in the changing role of the state and in a managerialist view of the operations of public organizations. These two discourses have been challenged by another approach that could be called democratic governance. It emphasizes the interactions between citizens, political representatives, and administrative machinery, providing a special view of citizens' opportunities to influence and participate in governance processes.

DEFINITION OF GOVERNANCE

One of the reasons behind the revival of the concept of governance was the need to distinguish between the traditional, institutionally oriented conception of "government" and more dynamic and network-based ways of thinking and working in policy processes. *Government* refers to the institutions and agents that perform the governmental functions, i.e., to formal institutions of the state or those of decentralized territorial governments and their ability to make decisions and take care of their implementation, whereas *governance* as a process concept refers to the new modes and manners of governing within policy networks and partnership-based relations (Stoker, 1998, p. 17; Jessop, 1998, pp. 30–31; see also Kooiman, 1993). In spite of the common root of these two terms, they should not be used as synonyms. The role of government in public governance may vary considerably, with two basic models being state-centric and society-centric models of governance (Pierre & Peters, 2000, p. 29).

The way the concept of governance is used here can be specified as "public governance," which aims to pursue collective interest in the context of intersectoral stakeholder relations. In this sense, governance refers to the coordination and the use of various forms of formal or

Figure 1. Aspects of democratic e-governance (cf. Anttiroiko, 2004, p. 40).



informal types of interaction and institutional arrangements in the policy-making, development, and service processes to pursue collective interest (Anttiroiko, 2004, p. 28).

One essential aspect of recent discussions about governance is to identify how to maintain the "steering" role of political–administrative institutions despite the internal and external challenges to them. The other element causing one of the core dilemmas of governance is the tension between public and private interests, which, in turn, pose a challenge to the democratic control of public governance.

E-TRANSFORMATION IN DEMOCRATIC GOVERNANCE

E-Transformation in governance processes refers to the fact that the information society development profoundly affects the relationships of different actors, forms and channels of communication and interaction, and the entire fabric of network and partnership relations. The transformational aspect of governance leads us back to the issue of the information society, which forms a background for understanding a wider transformative nature of information and communication technologies (ICTs).

The introduction of ICTs in the public sector in the 1960s in most of the advanced countries started to reshape their data-processing activities, such as record keeping and financial administration. Electronic systems started to replace old manual systems. This picture started to change dramatically in the 1990s. At the core of this revolution was the Internet (Seneviratne, 1999, pp. 44–45). Along with this new wave, the democratic potential of ICTs became a global issue.

Since the 1990s, a need for reconstruction of technology along more democratic lines has become apparent. New ICTs have the potential to restructure government and to strengthen democracy, and to create a closer relationship between public administration and citizens, in particular (Pardo, 2002, p. 95; see also Becker & Slaton, 2000). It has even been said that new ICTs applied by government contribute to the emergence of a different type of governance, i.e., more "direct" government, as concluded by Pardo (2002, pp. 90–91).

Figure 2. Continuum of citizen influence (applied from Bishop & Davis, 2002, pp. 20–21).

Democratic e-governance combines three conceptual elements: governance as a core activity area and manner of governing, democracy as a kind of basic principle applied in governance, and ICTs as a tool. As to a formal definition, we may conclude that democratic e-governance is a technologically mediated interaction in transparent policy-making, development, and service processes in which political institutions can exercise effective democratic control and, more importantly, in which citizens have a chance to participate and effectively influence relevant issues through various institutionally organized and legitimate modes of participation (Anttiroiko, 2004, pp. 40–41). At a practical level, democratic e-governance requires both institutional and technological mediation of civic and community interests in formal governance processes, as illustrated in Figure 1.

METHODS OF DEMOCRATIC E-GOVERNANCE

There is nothing inherently "democratic" in governance. It can be, and historically has been, performed in various ways that cannot be called democratic in the true sense of the word. In the history of the institution of community governance, the early modern times represent the era of elite control that since the 19th century began to transform into a conventional democratic mold having expression in the form of civic rights and a representative system of government. This was followed by the rise of professionalism and managerialism in the 20th century. The new phase emerging has, in some descriptions, been called the era of citizen governance (Box, 1998, p. 30; see also Hirst, 2000). Democratic governance requires that political institutions be capable of steering governance processes and affecting their outcomes, that citizens be given a chance to influence and participate in these processes in principle whenever they see fit, that governance processes be made transparent, and that key actors be held accountable for their actions to political institutions and ultimately to society as a whole.

Institutional mediation tools of democratic governance are needed to facilitate civic involvement. A fundamental aim is to supplement the representative system that is considered by many to be too hierarchical, inflexible, and distant from the point of view of ordinary citizens. Gross (2002, p. 250) summarized the basic requirements of e-democracy in the following way: citizens need to be able to access information, to discuss political issues, and to make decisions by voting electronically.

Conventional ways of political influence and participation in modern democracies include voting and campaigning in elections and being an active member of a political party or pressure group. Another category includes memberships of advisory committees or other bodies with a stake in policy processes and also various forms of client or customer involvement in implementa-

Table 1. Methods and forms of democratic e-governance.

1. Facilitating information processes
• *Presenting, disseminating, and sharing information (Web sites, e-BBS, etc.)*
• *Collecting and processing data (e.g., database management tools and e-document management)*
• *Facilitating communicative or two-way information processes (e-mails and e-feedback systems)*
2. Supporting communication and negotiation
• *Facilitating discussion and interaction (electronic discussion forums, e-mails, etc.)*
• *Generating understanding and awareness (idea-generating tools, simulations, etc.)*
• *Facilitating citizen–expert interaction (e.g., consensus conferences)*
3. Citizen consultation and involvement in preparation and planning
• *Consultative referendum*
• *Moderated deliberative polling (scientific deliberative polling, electronic town meeting, etc.)*
• *Other forms of citizen consultation (e-citizens' juries, standing e-panels, etc.)*
• *Participatory planning*
• *Modeling decisions and advising on possible consequences (expert systems, decision support systems, etc.)*
4. Community-based deliberation and participation
• *Virtual communities and cyberassociations*
• *Community networks and local associations*
• *Local and neighborhood governments*
5. Political transactions and decision making
• *Making proposals and initiatives (e-initiatives, e-petitions, etc.)*
• *Participating and voting in elections (e-electioneering, e-voting, etc.)*
• *Making decisions (initiative and referendum processes, including e-referendums)*
6. Implementation and service processes
• *Various forms of user democracy (e-feedback systems, e-vouchers, etc.)*

tion of public policies. More direct forms include voting in referendums and participating in the consultative or advisory bodies set up on an ad hoc basis. Last, there are various types of community group actions as well as political demonstrations that aim at changing public policy, and even various forms of civil disobedience (Birch, 1996, p. 81). One way to systematize these forms on the basis of the degree of citizen influence is presented in Figure 2.

Figure 2 systematizes citizen influence within a continuum: the two extreme ends being a chance to obtain information and a direct political decision making. The idea behind this is originally an old concept of eight rungs on a ladder of citizen participation that proceeds from nonparticipation through a certain degree of tokenism to the exercise of direct citizen control (Bishop & Davis, 2002, p. 17).

Methods of democratic e-governance are based on the functions they serve in policy processes. On the basis of the functions of institutional and technological mediation tools, the methods applicable in e-governance can be presented as in Table 1 (Anttiroiko, 2004; see also Grönlund, 2002; Gross, 2002; 6, 2001; Becker & Slaton, 2000; Barber, 1984).

Since the 1970s, small groups of academics, community organizers, activists, government officials, and media professionals have been experimenting with electronic media and ICTs. Since then, new democratic practices have emerged, and many experiments have been conducted in different parts of the world. Almost all of these have shown how interested ordinary people have been in the opportunity to participate, and how much they have appreciated being consulted and included in these processes (Becker & Slaton, 2000, p. 95; see also Tsagarousianou et al., 1998).

FUTURE TRENDS

Democratization of governance is conditioned by such pervasive changes as globalization, technological development, new forms of social organization, and increased individualism. It may be that a hybrid model of democratic governance is in the making, in which the new technology employed is evolving along with the societal and governmental structures. Becker and Slaton (2000, p. 210) have claimed that despite some setbacks, genuine democracy will increase in degree and scope. This development is supported by such factors as greater influence of social movements, new methods of direct democracy, wider use of consensus-building mechanisms, and new forms of e-enabled democratic political organization. New technological mediation tools and the Internet, in particular, may prove vital in rethinking conceptions of democratic governance. However, only modest democratic gains can be achieved through electronic means, unless a radical redesign of democratic institutions is accomplished, which is not foreseeable in the immediate future (Anttiroiko, 2003).

CONCLUSION

A new discourse about democratization of public governance reflects a gradual transition from both the state-centric model of governance and managerial and market-based views of new public management to the politically oriented coalition-building and stakeholder-involving new governance model that is rooted in the values of authentic democracy (cf. Reddel, 2002; Becker & Slaton, 2000; Barber, 1984). In this sense, democratic e-governance is a technologically mediated interaction in governance processes in which special attention is paid to citizens' chances to participate and influence relevant public policies. New forms of democratic e-governance are expected to pave the way for a greater citizen self-governance that matches the requirements of a changing society.

KEY TERMS

E-Democracy: Electronic democracy (e-democracy) as a tool-oriented conception of democracy refers to new democratic practices in which ICTs and innovative institutional arrangements are utilized (cf. teledemocracy).

E-Governance: Most commonly, the concept of governance is associated with "public governance," which refers to coordination, interaction, and institutional arrangements that are needed to pursue collective interest in policy-making, development, and service processes in the context of intersectoral stakeholder relations. Electronic governance (e-governance) is technologically mediated communication, coordination, and interaction in governance processes.

E-Government: Electronic government (e-government) refers to those aspects of government in which ICTs are or can be utilized, the basic functions being to increase efficiency in administrative processes (e-administration), to guarantee easy access to information for all, to provide quality e-services, and to enhance democracy with the help of new technological mediation tools (e-democracy).

Multilevel Governance: A governance system comprising various institutional levels: local, regional, national, macroregional, and international or global levels. For example, the European Union forms a multilevel governance system with municipalities, regions, member states, and the EU-level institutions, as does any federal system of government, like those in the United States or Germany.

Network: A new form of organization. Networks are loose sets of actors who work together in order to promote their interests within a common operational framework that is held together by some shared interests, reciprocity, and trust. In their most characteristic form, networks are flexible ways of organizing activities that require the competences of several independent actors.

New Public Management (NPM): Neoliberally oriented public management doctrine based on a market-oriented view stating that, instead of direct political control and hierarchies, public organizations should rely on indirect control—that is, market-based coordination—in the interaction between public organizations and their environments. It emphasizes the efficiency and effectiveness of public organizations, customer focus in provision of public services, and market-based conditioning frameworks, such as privatization, competition, and contracting out.

Teledemocracy: A normative theory on democracy that is dedicated to greater, improved, and more direct citizen participation and influence in all aspects of government. It is based on the notion of transformational politics that emphasizes the necessity to fine-tune a democratic system to meet the requirements of an increasingly complex information society. This is evident in how it favors the utilization of new ICTs in democratic processes, in such forms as electronic town meeting, scientific deliberative polling, and new democratic use of the Internet. The most prominent academic developer and advocate of teledemocracy is Professor Ted Becker, Auburn University, Alabama.

Departure of the Expert Systems Project Champion

Janice C. Sipior
Villanova University, USA

INTRODUCTION

This article discusses the expert system (ES) project champion by examining the experiences of Ciba-Geigy Corporation with an ES project, impeded by the departure of the project champion. The OpBright Expert System, developed to support the identification of appropriate optical brightener products by sales representatives, was intended to provide a competitive advantage through superior customer service. With the promotion and transfer of the vital force committed to the project's success, the ES encountered a stalemate. The difficulties in maintaining momentum for the ES without a project champion are discussed. Finally, suggestions are presented to guide organizations away from the same fate.

BACKGROUND

The role of project champion has been recognized as vital to successful project development since the time of Schon's (1963) seminal work. A project champion for information systems is defined as "a key *individual*, whose *personal* efforts in support of the system are critical to its successful adoption" (Curley & Gremillion, 1983, p. 206). The project champion, for ES projects in particular, is recognized as critical to the successful application of this technology (Hayes-Roth & Jacobstein, 1994; Sipior, 2000: Wong, 1996). Champions of ES projects differ from those of other projects due to the necessity to identify, document, and distribute knowledge and expertise, facilitating knowledge-sharing. The characteristics of project champions are discussed in the next section.

Formal Position

A project champion is frequently an executive from the area of application (Willcocks & Sykes, 2000), but may come from external organizations, such as a consultants or vendors (Thomas, 1999). Champions may be managers (Beath, 1991); or hold other formal positions (Mayhew, 1999; Pinto & Slevin, 1989; Thomas, 1999). Surprisingly, champions rarely come from formal IT functions (Martinsons, 1993; Willcocks & Sykes, 2000) and may even view IT managers as too conservative, adversaries to technological innovations, and even inept (Beath & Ives, 1988). Rather than being assigned to the role, interest and personal conviction to a project compel the champion to emerge (Pinto & Slevin, 1989; Schon, 1963). Formally appointing an individual could actually lead to his demise (Howell & Higgins, 1990). Once convinced, the champion exhibits an entrepreneurial spirit (Bolton & Thompson, 2000; Pinto & Slevin, 1989; Schon, 1963).

Leadership Qualities

The champion tends to go well beyond job responsibilities, and may even go against management directives (Beath, 1991; Curley & Gremillion, 1983). Champions are characterized as more than ordinary leaders. They exhibit transformational leadership behaviors (Howell & Higgins, 1990). Such leadership is particularly valuable for implementing systems intended to bring about organizational change (Beath, 1991; Landers, 1999), such as redefining responsibilities, realigning lines of authority, shifting power centers, and adjusting reward schemes. As knowledge repositories, ES certainly has the potential to invoke change of this nature.

Base of Power

Some level of power is held by champions (Mayhew, 1999; Pinto & Slevin, 1989), attributable to formal position or personal relationships. Diminished power can result in project failure (Scott & Vessey, 2002). Champions are perceived as influential or prestigious by organizational members (Curley & Gremillion, 1983). This perception by others may be the result of a planned influence strategy to attract followers (Schon, 1963). Such influence strategies include impression building, rational justification, assertion, or persuasive communication (Howell & Higgins, 1990). Although activities of champions may be intentionally fostered, their influence tactics are not always regarded in a positive light (Beath, 1991).

Visionary Perspective for Change

The champion is willing to put himself on the line, risking his reputation, to complete the project. The champion serves as a visionary and directs his energies to bring about change to achieve that vision (Landers, 1999; Willcocks & Sykes, 2000). Primary among the influence strategies is persuasive communication (Sumner, 2000). The vision must be clearly communicated in order that others understand and support the vision (Kotter, 1995). An unrealistic or misunderstood vision can result in failure well after the project is underway (Royer, 2003).

A CASE STUDY OF THE PROJECT CHAMPION AT CIBA-GEIGY

Ciba-Geigy Corporation, an international chemical manufacturing firm headquartered in Basel, Switzerland, continually strives to gain market position by fostering their progressive image. Ciba-Geigy emphasizes customer service, especially important to the Dyestuffs and Chemicals Division. This division produces over 2,000 products including fabric dyes, optical brighteners, and industrial chemicals, representing approximately 20% of corporate sales. The OpBright Expert System, developed to support the identification of appropriate optical brightener products, was championed by the vice president (VP) of the division as providing benefits realizable from managing internal knowledge. The VP was convinced, as was found in previous research, that effective knowledge management can impact business performance (Alavi & Leidner, 1999; Hansen, Nohria, & Tierney, 1999; Zack, 1999). Included among the anticipated benefits of OpBright are gaining competitive advantage, faster response to customers, consistent quality customer service, training new salespeople, and managing product expertise, as discussed in the following sections.

Gain Competitive Advantage

As a leading dyestuffs and chemicals producer, Ciba-Geigy recognizes the value of IT as an important means for gaining competitive advantage. Continually striving to gain market position by fostering their progressive image, Ciba-Geigy has emphasized the need to utilize IT in direct marketing. The use of laptops by the sales force, championed by the VP, provides a highly visible means for projecting this image as well as enhancing sales force performance.

Respond More Quickly to Customers

Improved communication between the sales force and the division office, in terms of such factors as speed, receipt and response, and content completeness, was realized through the use of laptops by the sales force. For example, access to the online order processing inventory and sales service system enables sales representatives to complete a sales transaction more quickly, increasing employee productivity and providing more responsive and effective customer service. This taste of success led the VP to seek further improvement. In informal meetings with the corporation's computer vendor, IBM, the VP became convinced that customer support could be enhanced through the implementation of an ES, a recognized benefit of expert system applications (Mattei, 2001).

Provide Consistent Quality Customer Service

The VP had the insight to identify the importance of offering fast, expert advice regarding the appropriate use of optical brighteners for individual customer's applications at the time of on-site sales calls. Optical brighteners are used for a wide variety of end-products. For textiles, paper products, and detergents, optical brighteners are applied to enhance coloring, that is, to make "whites whiter and brights brighter." Non-textile applications include testing for leaks, such as those in automotive parts. Salespeople are thus challenged to make appropriate and specific recommendations concerning a wide range of applications, wherein the factors to consider can vary widely. The inability of a salesperson to answer customers' questions can result in delayed or lost sales. Recognizing this impact, the VP championed the expert system as a means of increasing sales profitability. Individual customer questions could be addressed on the spot while maintaining consistency and quality in responses.

Train the Sales Force

By managing and distributing knowledge about optical brightener product features, areas of application, and troubleshooting solutions, the sales force is able to develop a greater understanding of the optical brightener product line and technical characteristics. New salespeople benefit by having unconstrained access to a "technical expert". Sales force training is thereby enhanced during formal training sessions and while on the job.

Manage Critical Product Expertise

The VP envisioned an entire family of ES, for all optical brightener applications, would be developed in the future. The domain for the first ES was appropriately narrowed to include the application of optical brighteners to fabrics only. An expert in this area of application was identified. This individual has extensive experience with the optical brightener product category, having served as a customer support technician and troubleshooter for over 15 years. His knowledge about customer requirements, properties of fabrics, and application processes enabled him to recommend appropriate optical brightener products based on features of those products. This critical product expertise was captured, documented, and can be distributed through OpBright. Such astute management can preclude the loss of valuable corporate knowledge and expertise resulting from normal turnover or absence (Mattei, 2001), promotion (Prietula & Simon, 1989), or retirement.

Momentum without a Project Champion

The VP classified the development of the ES as a research and development (R&D) effort. No formal cost/benefit analysis was performed. Even for R&D projects, a formal analysis is recommended (Brenner & Tao, 2001). However, the cost of this first-time project was viewed as an investment in experience to be applied to future areas of application, an argument commonly made by champions in securing funding (Sharpe & Keelin, 1998). The VP was convinced that the impact of this technology would far outweigh the initial investment.

OpBright encountered a stalemate shortly after its completion. The VP was promoted and transferred to another division. The incoming VP reviewed the OpBright expert system project and restated the objective to develop a *prototype* ES. The objective was met as the prototype had been developed. Without a replacement project champion, OpBright remains at a standstill.

FUTURE TRENDS

Lessons learned, from the Ciba-Geigy case study, to avoid pitfalls attributable to the departure of the champion are discussed in the following sections. These insights may serve to guide future research; focusing on identifying strategies organizations may employ to nurture the continuation of the role of project champion.

Incorporate Expertise Management in Strategic Planning

An assessment of areas of expertise critical to organizational processes and the potential for applying ES technology, should be included within the strategic planning process. Expertise management thereby becomes a formalized managerial activity (Sipior & Garrity, 1990). Incorporating expertise management in strategic planning is clearly unique to ES in particular, differentiating ES project champions from champions of technological innovations in general.

Secure the Support of Top Management

It is well recognized that securing the support of top management is a prerequisite to the long-term success of ES projects (Sipior & Volonino, 1991; Wong, 1996). Broad support for technological innovation from the top individual alone is insufficient unless it is translated into support for specific applications of ES technology by management levels below him.

Top management support is more likely if the ES fits with corporate strategy. By incorporating expertise management within strategic planning, this fit becomes more likely (Zack, 1999). In turn, this fit will garner broader organizational commitment (Meador & Mahler, 1990). To gain the necessary support, a results-oriented approach is preferable since it enables management to buy into the impact ES can have, rather than focusing on the technology itself (Sipior & Volonino, 1991). For management support to be on-going, the results should have continued benefit.

Secure the Support of the Next Generation of Top Management

Top management support is not sufficient, unless the support of the next generation of top management is secured (Kotter, 1995). If successors are ambivalent about the ES project, as was the case for Ciba-Geigy, they certainly will not take the initiative to understand this technology and maintain project momentum.

Recognize, Support, and Nurture a Project Champion

As discussed, a project champion tends to emerge, rather than be assigned to the role. Evidence suggests both the inability to nurture such individuals as well as instances wherein this individual has been successfully developed

(Schon, 1963). When a champion does not emerge naturally, a company may be able to "*find* or *make* a champion for the system" (Curley & Gremillion, 1983, p. 207).

Formalize Project Measurement, Monitoring, and Follow-up

Formalization of expert system project measurement, monitoring, and follow-up evaluation can improve the probability of project success (Brenner & Tao, 2001). Project measurement should include an evaluation at each phase of the project: (1) the validity of the technology to be employed in terms of delivering its claimed capabilities, (2) the benefits to be derived by its application, and (3) the products and services to be produced by employing the technology (Brenner & Tao, 2001). For each phase, project characteristics should be evaluated. The type of idea that generated the project could be rated from high of three to low of zero for a technological advance, new or novel technology, new twist on a known technology, or no technological advance. Additional characteristics to consider include expertise and capabilities gained, time saved, R&D dollars saved, intellectual property expected from the project, importance of the project objective, commercial impact such as increased sales revenue, technical leverage, and internal and external relationship building. Changes in the project should be monitored as the project advances. At project implementation, the estimates from the initial project evaluation should be compared to actual project performance data. Formalizing measurement, monitoring, and follow-up evaluation forces project accountability in terms of delivering the intended results.

CONCLUSIONS

The experiences of Ciba-Geigy underscore the critical importance of the role of project champion in ES development. Conversely, the loss of this individual can threaten the very existence of a project. Organizations should thus take heed and devote attention to harnessing the enthusiasm and drive of ES project champions for advantage, before it is too late to preclude the loss of momentum generated by these individuals. Future research may be directed toward exploring the reasons for failure of projects supported by champions, and identifying strategies organizations may employ to nurture the continuation of the role of project champion for ES.

KEY TERMS

Assertion: Authoritatively convince others of the project's potential benefits so they dedicate their efforts to the project.

Charismatic Behavior: Captivate others into believing in the project as the champion himself does.

Impression Building: Portray outcomes of endeavors as highly positive achievements to promote an image of competence and success.

Inspirational Behavior: Influence others by using emotional appeals, and vivid and persuasive images, to elevate their performance.

Intellectual Stimulation: Challenge others to aspire to imaginative use of their individual skills.

Persuasive Communication: Rely more on persistence, rather than clear and concise arguments, to attain agreement.

Rational Justification: Analyze how the project advances goals and objectives and upholds values of the organization.

Transformational Leaders: Inspire others, through charisma, inspiration, intellectual stimulation, and individualized consideration, to transcend their own self-interests for a higher collective purpose.

Design Levels for Distance and Online Learning

Judith V. Boettcher
Designing for Learning and the University of Florida, USA

INTRODUCTION

The importance of design for instructional programs — whether on campus or online or at a distance — increases with the possible combinations of students, content, skills to be acquired, and the teaching and learning environments.

Instructional design —as a profession and a process— has been quietly developing over the last 50 years. It is a multidisciplinary profession combining knowledge of the learning process, humans as learners, and the characteristics of the environments for teaching and learning. The theorists providing the philosophical bases for this knowledge include Dewey (1933), Bruner (1963), and Pinker (1997). The theorists providing the educational and research bases include Vygotsky (1962), Knowles (1998), Schank (1996), and Bransford, Brown, and Cocking (1999).

Instructional design offers a structured approach to analyzing an instructional problem and creating a design for meeting the instructional content and skill needs of a population of learners usually within a specific period of time. An instructional design theory is a "theory that offers explicit guidance on how to better help people learn and develop" (Reigeluth, 1999).

BACKGROUND

This entry describes a multi-level design process for online and distance learning programs that builds on a philosophical base grounded in learning theory, instructional design, and the principles of the process of change as reflected in the writings of the theorists listed above. This design model builds on traditional instructional design principles, as described by Gagne (1965), Dick & Carey (1989), and Moore & Kearsley (1996). It integrates the strategic planning principles and the structure of the institutional context as described in Kaufman (1992) and Boettcher & Kumar (1999), and also integrates the principles of technological innovation and the processes of change as described by E. M. Rogers (1995) and R. S. Rosenbloom (1998).

This entry describes a six-level design process promoting congruency and consistency at the institution, infrastructure, program, course, activity, and assessment level. It also suggests a set of principles and questions derived from that framework to guide the instructional design process.

Figure 1. Six levels of design for learning

Six Levels of Design	Design Responsibility	Sponsor/Leader	Design and Review Cycle
Institution	Entire campus leadership and community	Provost, CIO and Vice-presidents	3-5 Years
Infrastructure	Campus and Technology Staff	Provost, CIO and Vice-presidents	2-3 Years
Degree, Program	College/Deans/Faculty	Dean and Chairs	1-3 Years
Course	Faculty	Dept Chair	1-2 Years
Unit/Learning Activity	Faculty	Faculty and or Faculty team	1-2 Years
Student Assessment	Faculty	Faculty and or Faculty team	1-2 Years

SIX LEVELS OF DESIGN

Effective instructional design for online and distance learning benefits from instructional planning at six levels. Figure 1 summarizes these six levels of design, and identifies the group or individuals usually responsible for the design at that level and the length of the design cycle at each level. Ideally, the design at each of these six levels reflects philosophies of teaching and learning that are consistent with the institutional mission and consistent with the expectations of the students and society being served.

Level One: Institutional Design

The design work to be done at an institutional level is similar to the strategic planning and positioning of an institution. Institutional planning generally begins with an institution's current vision and mission statements and then proceeds through a data collection and input process that addresses a set of questions such as the following:

Institutional Questions:

- What programs and services comprise our primary mission? For whom?
- To what societal needs and goals is our institution attempting to respond?
- What life goals are most of our students working to achieve?
- What type of learning experiences are our students searching for?
- What changes in our infrastructure are needed to match our desired services, programs, and students?
- Does our institution have any special core competencies, resources, or missions that are unique regionally or nationally that might form the basis for specialized online and distance programs? What are the strengths of our mature faculty? Of our young faculty?

Level Two: Infrastructure Design

People often think that buildings, classrooms, Web applications, communication services, and servers are neutral as far as having an effect on teaching and learning. Nothing could be more misleading. Design of the infrastructure includes design of all the elements of the environment that impact the teaching and learning experiences of faculty and students and the staff supporting these experiences. It includes design of the following:

- Student services, faculty services, and learning resources.
- Design of administrative services, including admission processes, financial processes, and institutional community life events.
- Design of physical spaces for program launching events, hands-on, lab, or network gathering events, as well as celebratory graduation events.

Physical and Digital Plants

Infrastructure design for online and distance teaching and learning programs focuses on the design of the network and Web infrastructure. Infrastructures for online learning have offices, classrooms, libraries, and gathering spaces for the delivery and management of learning and teaching. However, these offices and classrooms are accessed through Web services, rather than through physical buildings. The good news about online infrastructures is that they support an unparalleled new responsiveness, feedback, and access for learning activities.

After almost ten years of building online campuses, we now know that a "digital plant" infrastructure is needed to support the new flexible online and distance environments. We know that this new digital plant needs to be designed, built, planned, maintained, and staffed. The infrastructure to support the new programs cannot be done with what some have called "budget dust" (McCredie, 2000). It is not nearly as easy or inexpensive as we all first thought. Some experts suggest that, a "full implementation of a plan for technology support on campus costs about the same as support of a library — approximately 5% of the education and general budget" (Brown, 2000).

Components of a Digital Infrastructure

What exactly is a digital plant infrastructure? One way of describing this infrastructure is to think of it in four major categories of personal communication tools, networks, hardware for servers, and software applications. A key component of the digital infrastructure is the group of individuals who make the systems work. This digital plant is shown in Figure 2 (Boettcher and Kumar, 2000).

Some of the questions that might be used to guide the development of the digital infrastructure follow.

Personal communication tools and applications:

- Will all students have their own computer? Their own laptop?
- Do we expect students all to be proficient with word processing applications, mail, Web applications, researching on the Internet? With collaborative

tools and with one or more course management systems?

Networks that provide access to Web applications and resources and to remote, national, and global networks:

- What physical wired or wireless networks are needed to support Web applications, such as e-mail servers, directory servers, and Web application services?
- How often will higher bandwidths be needed for video conferencing for programs? For meetings? For downloading large files? For streaming video?

Dedicated servers and software applications that manage campus services:

- What types of interactive Web services will be provided? What hardware and software will be required?•What type of administrative systems and course management system will we use?
- What do we need to do to assure student, faculty, and staff accessibility from anywhere at anytime?

Software applications and services from external providers, such as research and library services that are licensed to the institutional community, Internet services, and out-sourced services, such as network services:

- What licensed services are required and desired?
- What budget is required to support these services currently and into the future?

Technology decisions for students have always been part of the instructional design process for distance learning. A comforting way of thinking about the technology for the infrastructure design level is in terms of the generations of technologies used in distance learning. (Sherron and Boettcher, 1997). Distance learning was made possible with the widespread availability of technologies, such as the mail, radio, telephone, television, and audio and videocassettes. In the 21st century we simply have more technology and more choices.

Now let's look at the design of programs and courses. Design issues at these levels are principally the responsibility of the institutional academic leadership.

Level Three: Program Design

At the program level of design, instructional planners answer questions about the type of program to be offered, to whom, and over what period of time and at what cost. When venturing into new business areas, the following two guidelines are useful: (1) focus on programs that can leverage institutional core competencies and strengths, (2) plan a phased approach, gaining experience in delivering programs in one or two areas before launching others, and (3) recognize that online and distance learners generally are interested in achieving or completing an instructional goal that can assist in their current or future career path.

It is in the next four levels of design that the principles of Vygotsky are most applied, building on Vygotsky's (1962, 1978) view of the learner as a goal-oriented learner within a specific learning context using specific resources as directed by a teacher. These four core elements of all learning experiences provide a framework for the design process:

- The person doing the learning — the learner
- The person guiding and managing the learning — the faculty/teacher/mentor
- The content /knowledge/skill to be acquired/or problem to be solved
- The environment or context within which the learning experience occurs

Program Level Planning Questions:

Program planning design has four categories of planning — curriculum, design/development process, faculty, and student.

Curriculum questions:

- What is the degree or certificate program to be offered online? Will it be a full master's degree (10 to 16 courses), an undergraduate minor (four to six courses) or a certificate program (two to four courses)?
- What types of courses are envisioned? Will these courses be a fully developed "course in a box" with a minimal amount of interaction or a highly interactive and collaborative course requiring or using many online resources and applications?

Design and development questions:

- Who are the faculty who will design, develop and deliver the courses in the program?
- Who will lead the effort to develop the degree or certificate program for online or distance delivery? Which organization will be marketing the program?
- What course management system or similar Web tool will be used for the content management? What tools and resources will be available and

supported for the interaction and collaboration activities?
- What is the schedule for design and development and delivery of courses and program? For the marketing and recruiting of the students?

Faculty questions:

- What training will be available to faculty as they transition to online teaching and learning programs?
- What tools and resources and support will be available to faculty?
- Will faculty have any released time or budget for teaching and learning resources in the new online or distance environment?
- What type of access to the network is recommended and available? Will dial-up be sufficient, or will DSL or cable access be recommended or required?

Student questions:

- Who are the students who will enroll in this course of study? How will we find them and market the program to them?
- What will our students bring to the program experience?
- What tools and resources will the student in this program or certificate program require or be likely to use?
- Where will the students be doing their learning and with what types of content resources and applications? What level of network access is required or recommended?

The question of technology access for students was particularly important in the mid-1990s, when technology access was relatively scarce. However, the latest data from the Campus Computing Study of 2002 suggests that more than 75% of all students own their own desktop or notebook computer (Green, 2002). If all students have their own computers and access to the Internet, this access greatly impacts the design of communication activities and course experiences.

Course Design — Level Four

Design at the course level is usually considered to be the responsibility of the faculty member. In online and distance courses, however, the stand-alone course is the exception rather than the rule. Most online and distance courses are part of a curriculum, certificate, or degree program. This means course-level design occurs within the context of the larger program and that many of the design decisions are made in collaboration with other faculty within the academic program or department. Faculty at the course level are primarily responsible for design decisions on content, objectives, student goals, learning experiences, and assessment for a particular course. Many of these questions for this design level parallel questions at the program level design. The following questions are more specific to a single course:

Course questions:

- Where does this course fit within the context of the degree or certificate program to be offered online? Is it an early course focused on core discipline concepts, peer discussions, and standard problems or a later course focusing on applications and complex scenarios?
- What is the core set of knowledge, skills, and attitudes/values to be acquired by the students?
- What is the set of content resources required and recommended? What content resources will students use to customize the learning experience for their needs and state of knowledge and personal interests?
- Will students be a cohesive cohort group?

Design and development questions:

- What types of instructional activities and experiences will support student learning of the knowledge, skills, and attitudes of the students?
- What course management system or similar Web tool will be used for the content management? For the interaction and collaboration activities?
- What is the schedule for design and development and delivery of this course?

Faculty questions:

- What training is needed for a faculty member to transition to online teaching and learning programs?
- What tools and resources and support will be needed to support the delivery of this course?

Student questions:

- Who are the students taking this course? What are their hopes and expectations? What future courses will depend on the knowledge, skills, and attitudes acquired in this course?
- What knowledge and expertise do the students bring to the course? What is their zone of proximal development (Vygotsky, 1978)?

- What types of teaching and learning strategies best suit the students in this course? What are the life style and learning styles of the students?
- When and where will the students be likely to gather for their collaborative work? When and where will they do their more self-study activities?
- Where will the students be doing their learning? What level of network access is required or recommended?

The next two design levels are within the course parameters and generally are the responsibility of the faculty designing the course.

Level Five: Unit/Learning Activity

Many of the design questions for the unit/learning activity level and the student assessment level are derived from a design model that focuses on integrating student life style and learning styles into instructional planning (Boettcher, 2003). Examples of cognitive learning style design questions include: "How do students process information?"; "How do students respond in their minds when challenged with new concepts and rich content structures?", "What knowledge do students bring to the learning experience?"

The life style of the learner is also addressed in these questions. Life style includes all the elements in a learner's current life situation. Where will the learner be working? Will they have a personal space where they can control sound, temperature, disturbances, and network access? Will they have to "ask" their family if they can access the network? A life-style focus encourages analysis of the where, when, with whom, and with what resources the learner is going to be doing their learning work.

Learning work consists of constructing new knowledge, applying and integrating knowledge, and solving problems with that new knowledge. Mobile, wireless technologies enable learners to study anywhere at any time. Initially, the ability to study anywhere seemed to hold the promise of solving many problems associated with access to learning. However, we have not addressed the question of just when and just where this "anytime" is likely to occur.

Learning activity questions:

- What is the knowledge, skill or attitude that is the desired outcome of this learning activity?
- What kinds of problems can students solve now? What kinds of problems do we want students to be able to solve at the conclusion of the experience?
- What instructional strategy or experience will support the learner learning the desired knowledge, skill, or attitude?
- When, where, with whom, and with what resources is the instructional activity envisioned to occur?
- What role will the teacher/mentor/faculty play during this activity? Will the teacher be present physically or at a distance, synchronously or asynchronously?
- When will a learner know that he/she knows? What feedback or result from a problem being solved will make the learner's knowledge evident?

Level Six: Assessment of Student Learning

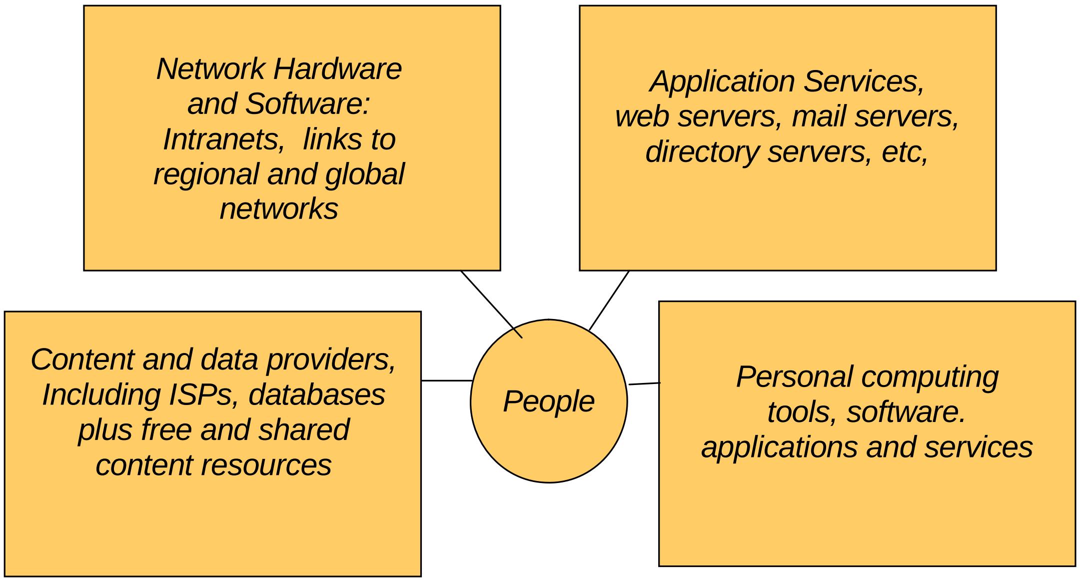
Assessment is fundamental to the design process. Assessment planning helps to balance the goals of learning effectiveness and teaching and learning efficiency. In productive, customized, enriched learning experiences, each learner begins with an existing, personal store of knowledge representation. Learning experiences expand and enrich that knowledge base in individual and personal ways. Productive learning experiences mean that all students complete a learning experience with an expanded, yet different, store of knowledge. The goal is that learners learn core principles so that the core principles can be effectively applied, but the particular way the knowledge base is constructed in individuals is unique.

What we can design into instructional planning is that all learners share some of the same experiences and that assessment focuses on the common learning that is achieved. Assessment can also provide for demonstration of knowledge and skills in more complex environments and for some elements of customized knowledge acquisition. Here are some selected questions for assessing student learning:

Assessment Questions

- How will the learners know the goals and objectives for the learning? It is good to plan for core concepts, practice of core concepts, and customized applications of concepts.
- Will learners be generating a set of their own goals for learning? How will the faculty mentor and learner communicate and agree on goals for learning, particularly for customized applications of concepts?
- In what ways and where will the students be evaluated and graded?
- How will students demonstrate their competency in concept formation? In solving problems?
- If we don't see the students on a regular basis, can we design ways to "see" their minds virtually through conversation and experiences?

Figure 2. Teaching and learning infrastructure - "digital plant"



The portfolio project within the National Learning Infrastructure Initiative (NLII) is also useful as an assessment of complex learning (www.educause.edu/nlii/keythemes/eportfolios.asp).

FUTURE TRENDS

The process of instructional design is a professional task requiring knowledge of educational research, learning processes, and, increasingly, a respect for context, and a comfort level with innovation and instructional technologies. It is a labor-intensive task requiring interaction with content experts and administrators and institutional representatives. Much of the current instructional design processes focus on the analyses of needs and contexts for learning for learners, their tools and their resources — as a group. Future work in instructional design will focus more on the learner as an individual with unique knowledge structures and thus promote the needs for a rich contextual learning environment that is multi-leveled and customizable.

The design of instructional planning will become more of a priority as the demand for effective and efficient learning grows as a result of time pressures, budget pressures, and increasing demands for accountability in education.

CONCLUSION

These instructional design principles reaffirm the iterative nature of design work and the sharing of design work among the hierarchical groups of an institution. Instructional design, when done well, results in delighted and productive learners and faculty pleased with their roles and their work. Consistently applied, instructional design principles keep teaching and learning focused on the who, when, where, how, and why of teaching and learning and help to ensure that the money and time invested in learning programs provide an appropriate return for individuals and for society. Instructional design is a powerful tool that moves teaching and learning into the science of learning and knowing.

KEY TERMS

Instructional Design: The process of analyzing the students, content, and intended context of an instructional program to provide detailed specifications for an instructional program or curriculum to achieve effective and efficient student learning within an affordable and accessible delivery format.

Instructional Design Theory: A "theory that offers explicit guidance on how to better help people learn and develop" (Reigeluth, 1999).

Instructional Strategy: An instructional strategy is a communication activity used to engage the learner in an educational experience and to assist the learner in acquiring the planned knowledge, skill, or attitude. Instructional strategies include lectures, discussions, reading assignments, panel presentations, study and media projects, problem analysis and solutions, field trips and assessment activities.

Learning Infrastructure: The set of physical and digital buildings, applications, services, and people that provide and support the environments for learning.

Learning Theory: A set of hypotheses or beliefs that explain the process of learning or acquiring knowledge and skill.

Online Course: A set of instructional experiences using the digital network for interaction, learning and dialogue. An online course does not require any face-to-face meetings in a physical location. Similar courses such as web-centric courses (also called hybrid or blended courses) are similar to online courses, but require regular scheduled face-to-face classes or meetings.

Zone of Proximal Development: This is a key concept in Lev Vygotsky's theory of learning. The Zone of Proximal Development (ZPD) is the "distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under the adult guidance or in collaboration with more capable peers" (Vygotsky, 1986).

Schenk (Eds.), *Distance learning and university effectiveness: Changing educational paradigms for online learning*. Hershey, PA: Idea Group.

Designing Agents with Negotiation Capabilities

Jana Polgar
Monash University, Australia

SOFTWARE AGENTS TODAY

Agents are viewed as the next significant software abstraction, and it is expected they will become as ubiquitous as graphical user interfaces are today. Agents are specialized programs designed to provide services to their users. Multiagent systems have a key capability to reallocate tasks among the members, which may result in significant savings and improvements in many domains, such as resource allocation, scheduling, e-commerce, and so forth. In the near future, agents will roam the Internet, selling and buying information and services. These agents will evolve from their present day form - simple carriers of transactions - to efficient decision makers. It is envisaged that the decision-making processes and interactions between agents will be very fast (Kephart, 1998).

The importance of *automated negotiation systems* is increasing with the emergence of new technologies supporting faster *reasoning engines* and mobile code. A central part of agent systems is a sophisticated reasoning engine that enables the agents to reallocate their tasks, optimize outcomes, and negotiate with other agents. The *negotiation strategy* used by the reasoning engine also requires high-level inter-agent communication protocols, and suitable collaboration strategies. Both of these subsystems – a *reasoning engine* and a *negotiation strategy* - typically result in complicated agent designs and implementations that are difficult to maintain.

Activities of a set of *autonomous agents have to be coordinated*. Some could be mobile agents, while others are static intelligent agents. We usually aim at decentralized coordination, which produces the desired outcomes with minimal communication. Many different types of *contract protocols* (cluster, swaps, and multiagent, as examples) and *negotiation strategies* are used. The evaluation of outcomes is often based on marginal cost (Sandholm, 1993) or game theory payoffs (Mass-Colell, 1995). Agents based on constraint technology use complex search algorithms to solve optimization problems arising from the agents' interaction. In particular, coordination and negotiation strategies in the presence of incomplete knowledge are good candidates for constraint-based implementations.

SELECTED NEGOTIATION AND REASONING TECHNIQUES

Negotiation space is determined by two components: *negotiation protocol* and *negotiation strategy*. The *negotiation protocol* defines the rules of behavior between the participants in terms of interactions, deals, bidding rules, temporal constraints and offers, as components of the protocol. Two agents must first agree on the negotiation protocol before any interaction starts.

The *negotiation strategy* is a specification of the sequence of actions the agent intends to make during the negotiation. Strategies should be compatible with the negotiation protocol. The focus of any negotiation strategy is to maximize outcomes within the rational boundaries of the environment. The classification of negotiation strategies is not an easy task since the negotiation strategy can be realized by any algorithm capable of evaluating outcomes, computing appropriate actions, and following the information exchange protocol.

The *negotiation mechanism* is the actual implementation of negotiation strategy and negotiation protocol. This field is evolving fast, with emergence of new agent platforms, wireless encounters and extended mobility.

Negotiation is a search process. The participants jointly search a multi-dimensional space (e.g., quantity, price, and delivery) in an attempt to find a single point in the space at which they reach mutual agreement and meet their objectives. The *market mechanism* is used for many-to-many coupling or interactions between participants. *Auctions* are more appropriate for one-to-many negotiations. The market mechanism often suffers from inability to efficiently scale down (Osborne, 1990) to smaller numbers of participants. On the other hand, one-to-many interactions are influenced by strategic considerations and involve integrative bargaining, where agents search for *Paretto efficient* agreements (tradeoffs).

NEGOTIATION STRATEGIES

Analytical Approach (Game Theory)

The principles of bargaining and negotiation strategies in multiagent systems have attracted economists. Early foundations and mathematical models were investigated by Nash (1950), and the field is still very active. The *game theory* is a collection of analytical tools designed to understand and describe bargaining and interaction between decision makers. Game theory uses mathematical models to formally express real-life strategies (Fudenberg, 1991; Osborne, 1994).

The high-level abstraction allows the model to be applied to a variety of situations. The model places no restrictions on the set of actions available to the player. With regard to mathematical models, there already exist many sophisticated and elaborated strategies for specific negotiation problems. The Contract Net Protocol (CNP) (Sandholm, 1993; Smith, 1980) represents the model of decentralized task allocation where agents locally calculate their marginal costs for performing sets of tasks. The pricing mechanism in Sandholm (1993) generalizes the CNP to work for both cooperative and competitive agents. In Zeng (1996), bilateral negotiation based on the Bayesian method is presented. It demonstrates the static nature of the model. The learning effect is achieved by using dynamic updates of a knowledge base, which is consulted during the negotiation process.

Most of the studies assume perfect rationality (flawless deduction, marginal costs are computed exactly, immediately and without computational cost), and the infinite horizon of strategic bargaining. These are not realistic assumptions. More advanced studies deal with coalition formation and negotiation strategies in the environment of multiple self-interested or cooperative agents with bounded rationality (Sandholm, 1993) and bargaining with deadlines.

Analytical approach has the advantage of stable and reliable behavior. The main disadvantage is the static nature of the model, resulting in potential predictability of the outcomes. The other problems are associated with the notion of perfect rationality.

Contracts in automated negotiations consisting of self-interested agents are typically designed as binding (impossible to breach). In cooperative distributed problem solving, commitments are often allowed to be broken based on some local reasoning. Frequently, the protocols use continuous levels of commitment based on a monetary penalty method (Sandholm, 1993). Unfortunately, the inflexible nature of these protocols restricts an agent's actions when the situation becomes unfavorable. The models that incorporate the possibility of decommitting from a contract with or without reprisals (Sen, 1994; Smith, 1980) can accommodate some changes in the environment and improve an agent's status. However, all of these protocols are somewhat restricting with respect to evolving, dynamic situations.

Evolutionary Strategies

With *evolutionary strategies*, the data used as the basis for negotiation, as well as the algorithm operating on the data, evolve. This approach provides more efficient learning, supports the dynamics of the environment, and is adaptable. However, only a few implementations have been attempted, and these have been of only simple negotiation strategies (Aridor, 1998). *Genetic algorithms* are probably the most common techniques inspired by evolution, in particular by the concepts of natural selection and variation. The basic genetic algorithm is derived from the hypothesis that the candidate solutions to the problem are encoded into "chromosomes". Chromosomes represent a solution or instance of the problem hand encoded into a binary string. The algorithm then operates on this binary string. It begins with a randomly generated set of candidate solutions. The set of candidate solutions is generated as a random string of ones and zeroes. Each chromosome is evaluated and the fitness of the chromosome could be the value of the objective function (or the utility if we want to maximize the outcome). A new population is created by selecting individuals to become parents. A thorough description of the genetic algorithm approach can be found in Goldberg (1989).

A very large amount of research has been carried out in the application of evolutionary algorithms to situations that require decisions. Examples include coalition games, exchange economies, and double auctions. This approach was inspired by the concept of variation and natural selection. The intelligent agents are modeled using classifier systems to select decisions. Although the recent research shows that multiagent systems of classifiers are capable of learning how to play *Nash-Markov equilibrium*, the current limitations of computational resources and the instability of "home-grown" implementations significantly constrain the nature of the strategies. The important question is what design and implementation techniques should be used to ease this conflict and to provide the resources required for genetic learning to operate in an unrestricted way. It is believed that the ability of agents to learn simple games would be beneficial to electronic commerce.

Constraint Agents

The potential of constraint-based agents is still to be fully realized and appreciated. One of the possible frameworks for constraint-based agents is outlined in Nareyek (1998). This framework considers agents as a means for simplifying distributed problem solving. An agent's behavior and the quality of solutions depend on the underlying action-task planning system. The recent results with some constraint planners and constraint satisfaction problems (CSP) indicate the potential advantages of this approach.

Agents operating with only partial knowledge of the surrounding environment are prime candidates for the implementation of reasoning using constraint solvers. Agents can share and exchange knowledge in a distributed fashion. The suggestion-correction process used in negotiation strategies corresponds to mapping constraint satisfaction problems to search algorithms and heuristics (Tsang, 1993). The planning and scheduling systems can be treated as CSPs that allow the use of constraint solvers to support the planning activity of an agent. However, similar to analytical tools, constraint solvers represent static models of CSP. In order to achieve flexibility in the decision-making process, the solver has to be able to incorporate an agent's essential characteristics:

Reactive behavior is characterized by the agent's ability to absorb new information and restrict or relax its actions. When constraint solvers face the relaxation of constraints, they recompute the entire problem. The relaxation in constraint planners and schedulers nearly always results in reduced stability and possibly reduced quality of solutions. Despite the recent implementation of constraint solvers in graphical applications (Borning, 1995; Sadeh, 1995), with real-time computation and stability, the constraint relaxation and adaptive behavior still represent some difficulties for practical applications.

An agent's *rational behavior* and fast reaction to the changes in its environment is difficult to support with constraint solvers. Some scheduling systems incorporate this idea and extend or replace deliberative planning with behavior rules (ILOG, 1996). The majority of existing constraint solvers compute the search for solutions offline. An approach to eliminate this problem is the development of an anytime algorithm (Zilberstein, 1995) and constraint hierarchies (Zanden, 1996). Some CSPs are suitable for iterative local search techniques, such as annealing, taboo search or genetic algorithms (Kautz, 1996). Additional information on suitability can be found in Tsang (1993).

Representation of time in traditional planning systems is based on Allen's model of temporal relations (Allen, 1985). This representation does not seem to be suitable for multi-agent interaction with complex temporal relationships and commitment protocols. Problems arise with respect to concurrency and events that last over a period of time.

Social abilities mean interaction, negotiation, coordination, and/or cooperation among agents. A language or interaction protocol typically supports these social skills. The ultimate goal of cooperation and coordination is to reach a globally optimal solution independent of the language or protocol used. If we map the cooperation goals into distributed problem-solving strategies and let each agent play the role of a cooperating computational unit instead of an autonomous negotiator, it is then possible to deploy distributed constraint satisfaction problem-solving strategies.

Multiagent solutions to the distributed constraint problems require new types of design frameworks based on replaceable components that can accommodate the local autonomy of agents, several negotiation strategies, cooperative problem solving, online search for solution, and support for an agent's rational behavior.

Agent design must accommodate static agents as well as trends in mobile agents. The lightweight architecture required for mobile agents, and an efficient and flexible negotiation strategy, are not mutually exclusive. The main issue is to provide a framework that guarantees that the negotiating agent is not overloaded with the complex intelligence that may not be used. We see an agent as a lightweight core with the ability to "borrow" the intelligence it requires from the hosting environment.

The major problem with this component-based framework in which one or more constraint solvers are used as plug-in components arises from the difficulties associated with the description of the constraint satisfaction problem. The representation of the problem can be either under-constrained or over-constrained. In either case, the agent is dealing with incomplete knowledge and it cannot determine which of the generated solutions is optimal and suitable to use in further negotiation.

One of the most important criteria used to judge constraint solvers is their performance. In order to provide reactive and pro-active behavior, it is important for the solver to generate the solution quickly enough to maintain responsiveness. This becomes more difficult to achieve as the number of constraints and variables becomes larger.

A pre-built constraint solver may be able to maintain constraints efficiently. However, declarative definitions of constraints are difficult to use in high-level agent building tools.

There has been very little work in incorporating constraint solvers into reasoning and negotiation strategies of agent systems. The slow acceptance of constraint solvers seems to have been caused by four reasons:

1. Many constraint solvers only support a limited range of constraints.
2. It is difficult to understand and control constraint solvers. When the programmer sets up a set of constraints, it may not be obvious how the constraint solver will maintain them.

3. If the search space is large then online performance of constraint solvers may not be satisfactory for some application domains (e.g., Eaton, 1997).
4. Multi-agent systems are represented by highly distributed search space (distributed constraint optimization problems (DCOP)).

DCOP have been considered an important subject of research for multi-agent systems and multi-agent cooperative mediation (Mailler & Lesser, 2004). DCOP aim at finding optimal assignment to a set of variables dispersed over a number of agents that have some interdependencies. So far, the descriptions of the problem proposed include distributed partial constraint satisfaction problem (Hirayama & Yokoo, 1997), distributed valued constraint satisfaction problem (Lemaitre & Verfaillie, 1997), and DCOP (Yokoo & Durfee, 1991). Typical problem with these asynchronous protocols is the exponential increase in communication. The protocol suggested in Mailler and Lesser (2004) allows the agents to overlap the context used for their local decision making. During the mediation session, the mediator agent computes a partial solution and recommends the value assignments to other agents.

CONCLUSION AND FUTURE TRENDS

Agents are fairly complex and ambitious software systems. They will be entrusted with advanced and critical applications, such as network administration, database and application monitoring, workflow/business process support, and enterprise integration. As such, agent-based systems must be engineered with valid software engineering principles and not constructed in an ad hoc fashion.

Analytical strategies are tools based on a static mathematical model to evaluate outcomes and generate appropriate action. With *evolutionary* or *genetic approaches*, the learning process is more effective and models are adaptable. The advances in *constraint technology* enable the design and implementation of planning and scheduling tasks to be treated as constraint satisfaction problems. The agent concept then can be used to support dynamic adaptation and collaboration of local or distributed problem-solving modules.

Design and implementation of any reasoning strategies and collaboration protocols can lead to complex systems, and these issues can also lead to computer code that is difficult to maintain. The protocols of interaction are complicated and they typically have many levels or states. If a reasoning engine is very large and complex, it restricts and slows an agent's mobility, rationality, and real-time responsiveness. In recent years, patterns of agent collaboration and negotiation, and some useful components and architectures have emerged. Reusable components and generative patterns can greatly improve the quality of agent designs and implementations.

Any agent, and mobile agents in particular, should have the capability to adapt their negotiation strategy and protocol according to the tasks at hand. In order to match tasks with the appropriate negotiation and collaboration strategies, the agent should have the ability and the means to select a negotiation strategy as a component and then "plug it in" for use.

Nwana (1998) discusses the contradiction between the research in agent coordination and reasoning, and the reality of implementing real applications. He suggests that we should continue with "borrowing and consolidation" using already established AI work. This evolutionary path requires adaptable design techniques to support the trends in AI. Instead of building specific negotiation strategies and protocol cores for each problem domain, we build agents with robust, adaptable core capabilities. The agents' negotiation strategy and protocols are then components or pattern-based building blocks that are "borrowed" and matched with the task at hand.

Future trends in the design of negotiating agents will undoubtedly track those in software engineering in general. Interesting and valuable future developments are expected to appear in the areas of separation of concerns and aspect-oriented programming (AOP). Object-oriented techniques, components and patterns have revolutionized software engineering. However, as software applications get more ambitious and complicated, object technology reaches its limits, especially due to its inability to address behavior and functionality that crosscuts an object hierarchy. Research completed by Kendall (1999) has considered how the separation of concerns and AOP can be used to improve the quality of agent designs. Role modeling is another key area for future research, and this area is also detailed in Kendall (1999).

KEY TERMS

Agent: A program designed to provide specialized and well-defined services. An agent can be *static* – executing on the computer where it was installed, or *mobile* – executing on computer nodes in a network.

Bayesian Method: Means of quantifying uncertainty, based on the probability theory. The method defines a rule for refining a hypothesis by factoring in additional evidence and background information. It uses results of previous events to predict results of future events.

Evolutionary Game Theory: Study of equilibria of games played by population of players where the “fitness” of the players derives from the success each player has in playing the game. It provides tools for describing situations where a number of agents interact. Evolutionary game theory improves upon traditional game theory by providing dynamics describing how the population will change over time.

Genetic Algorithm: Class of algorithms used to find approximate solutions to difficult-to-solve problems, inspired and named after biological processes of inheritance, mutation, natural selection, and generic crossover. Genetic algorithms are a particular class of evolutionary algorithms.

Negotiation Mechanism: The actual implementation of negotiation strategy and negotiation protocol.

Negotiation Strategy: Specification of the sequence of actions the agent intends to make during the negotiation.

Paretto Efficient Agreement: State of things in which no player (in game theory) is worse off than the others. It typically refers to the distribution of resources. The agreement could lead to cooperation of players.

Reasoning Engine: A computer program that enables the agents to negotiate with other agents and that involves negotiation strategy.

Designing High Performance Virtual Teams

Ian K. Wong
Queen's University, Canada

D. Sandy Staples
Queen's University, Canada

INTRODUCTION

In the past several decades, we have seen tremendous advancements in the development of communication technology. Since the invention of the Internet in 1969, there has been rapid development of Internet-based communication tools and technologies. This technology has revolutionized business practices by offering another important and effective channel for communication (Foo & Lim, 1997), and has allowed people to work on projects irrespective of their physical location. One resulting business practice that has been adopted in recent years is virtual teamwork. Virtual teams are groups of individuals who work at interdependent tasks, who share responsibility for outcomes, and who work together from different locations. Recently, the use of teams as fundamental building blocks in organizations is increasing, as is the use of virtual teamwork (Furst, Blackburn & Rosen, 1999). This article identifies the characteristics of high performing virtual teams.

BACKGROUND

In addition to the basic definition of a virtual team, all virtual teams have important characteristics that contribute to their overall success. To analyze the characteristics of a team's situation, Cohen's (1994) model of team effectiveness can be used as an organizing framework. The model identifies strengths and weaknesses that readers can use to inform their own design and operations of effective virtual teams. According to Cohen, there are several broad characteristics that all potentially affect how successful the team will be at meeting its task, and are therefore worthy of examination. These characteristics are listed in Table 1 and will be examined in detail in the following paragraphs. Although Cohen's team effectiveness model is based on traditional teams (i.e., collocated), these characteristics have been found to be very important in empirical research on virtual teams (Staples & Cameron, 2004; Wong & Staples, 2004).

TASK DESIGN

Appropriate task design can be a powerful motivator (Cohen, 1994). Both job characteristics theory (e.g., Hackman & Oldman, 1976, 1980) and sociotechnical theory (e.g., Cummings, 1978) suggest that group task design is critical for employee motivation, satisfaction, and performance. Both theories suggest that to positively impact performance and attitudes, the task should be designed according to the criteria specified in Table 2.

Job characteristics theory, which has fairly strong empirical support, suggests that task attributes influence effectiveness through their impact on critical psychological states such as motivation and satisfaction with the work. For example, in a case study of one particular business development virtual team, team members commented that high satisfaction and motivation levels reflected the high perceived significance of the project (Wong & Staples, 2004). Positive motivation and satisfaction levels have a positive effect on the quality of the work and overall productivity of the team (i.e., an indirect effect exists between task design and productivity and quality) (Cohen, 1994). Also, the team must have autonomy in determining how their work will be done, because autonomy enhances worker attitudes, behaviors, and performance (Cohen & Bailey, 1997). Finally, when a remote worker receives managerial feedback in the form of advice and help, the worker's effectiveness increases (Staples, 2001). This would result in an increase in virtual team performance.

Table 1. Characteristics of virtual teams affecting team effectiveness

- Design of the team's task
- The characteristics of the members of the team
- The processes used by the team
- The organizational context of the team

CHARACTERISTICS OF THE TEAM AND ITS MEMBERS

Team member characteristics that influence the success of a virtual team are listed in Table 3 and are described in more detail below (Cohen, 1994).

The size of the team can affect the ability of the team to do its task (Cohen, 1994). If the team is too big, higher coordination costs result. If the team size is too small, it will not have the resources needed to complete its work, and team members will be less likely to be committed to the team. The size of the team should also correspond to the stage of the project. For example, a virtual team developing a new product may need more human resources as the product moves from the design stage into the manufacturing stage.

Stability of team membership is necessary for team effectiveness. If turnover is high, time and effort will be spent orientating new members, performance norms will not develop, and performance will suffer. However, some turnover can be beneficial, in that it could revitalize a stagnant team and enhance creativity (Cohen, 1994).

The collective knowledge and skills of a team will greatly impact the team's ability to carry out its task. Such skills include technical skills, information systems (IS) skills, and interpersonal skills. Information systems skills are needed to use the information technology tools and systems that are available to communicate virtually and share information virtually, which is the norm given the lack of face-to-face interaction in virtual teams. Effective communication skills among team members are also vital to the effectiveness of a virtual team (Grenier & Metes, 1995).

The degree of virtuality (degree of team geographic distribution) could contribute to team effectiveness. There has been limited empirical evidence to suggest that greater geographic distribution (high degree of virtuality) of a team leads to lower performance (Cramton, 2002). This is presumably due to reduced face-to-face contact, reduced opportunities to build social relationships, and the difficulties of communicating and coordinating virtually using communication technology rather than communicating face-to-face. This implies that higher virtuality could be negatively related to team performance and satisfaction with the work and the team.

Team performance beliefs have been found to be a strong predictor of group effectiveness in previous research (Cohen, 1994). For example, team beliefs, assessed via a concept called group potency, were found to be positively related to the commitment to the team, satisfaction with being part of the team, and motivation with the team's tasks (Staples & Cameron, 2004). Group potency captures efficacy beliefs at the group level. Group potency (sometimes referred to as group efficacy) is "a collective belief in the capability of the group to meet a task objective" (Gibson, Randel & Earley, 2000, p. 71).

TEAM PROCESSES

There are several behavioral characteristics pertaining to team process that positively affect team effectiveness.

Table 2. Task design criteria necessary to positively impact performance and attitudes

The task should be designed such that:

- A variety of skills are required (leadership, communication, different technical skills, etc.) such that a team of people are needed to work together to complete the overall task.
- A whole and identifiable piece of work exists so that members can see the outcome of their efforts.
- It is perceived to have significant impact on the lives of other people so that team members feel their work is important and are motivated to complete the task.
- The team has considerable autonomy and independence in determining how the work will be done so that team members feel empowered and responsible for their actions.
- The team is provided with regular and accurate feedback such that the team can understand how it is performing and make adjustments as needed.

Table 3. Characteristics of the team members that affect team effectiveness

- The size of the team
- The stability of the team, in terms of turnover
- The skills of the members of the team
- The relative locations of the team members (i.e., their virtualness)
- The team members' beliefs about their team's capabilities

These are coordination, caring (i.e., team spirit), sharing of expertise, and effectiveness of communications. According to Cohen and Bailey (1997), how team members coordinate is an important characteristic of a team. Since team members are interdependent on each other to get their work done, coordinating interdependent tasks is critical. Good coordination among team members leads to working together without duplication and wasted efforts. Caring about each other implies working together with energy and team spirit. This can motivate team members and foster commitment to the team goals, resulting in higher performance. Sharing and benefiting from others' knowledge and expertise is also important because it supports effective cross-training and decision making to fulfill interdependencies. Good communication processes are required in order to make this possible. Effective communication processes were important in building a successful virtual team according to 84% of team members interviewed in six case studies of virtual teams (Staples, Wong & Cameron, 2004). Similarly, Cohen (1994) found that most high-performing teams are teams in which members are comfortable sharing information and communicate well. These team process variables are part of most models of team effectiveness and have been found to be associated with group effectiveness in previous research (Cohen, 1994).

ORGANIZATIONAL CONTEXT

Lastly, the organizational context that a team works in can create the conditions for a team to be successful or for it to fail (Cohen, 1994). The team with the best internal processes may still perform poorly if it lacks the resources or information needed to do its task. A team will not be able to make good decisions without proper information, without sufficient training, and without adequate resources. The key variables that potentially interact to create an environment where the employee wants to be involved and can participate to complete their tasks effectively are listed in Table 4 and explained below.

According to Duarte and Snyder (2001), human resource policies must be designed and integrated in such a way that virtual team members are recognized, supported, and rewarded for their work. Cohen, Ledford, and Spreitzer (1996) found that management recognition was positively associated with team ratings of performance, trust in management, organizational commitment, and satisfaction for both self-directed and traditionally managed groups in organizations. As such, it is important that an effective reward system with performance measures is in place to reward results. Grenier and Metes (1995) and Lurey and Raisinghani (2001) also suggest that it is important for the organization to reward high levels of team performance. If rewards are solely at the individual level, this does not stimulate the completion of interdependent tasks and the sharing of information and expertise.

Next, it is important that team members have access to continual online training and technical support (Duarte & Snyder, 2001; O'Hara-Devereaux & Johansen, 1994). Training and team building is important because it ensures that employees develop the knowledge required to contribute to organizational performance (Cohen, 1994). It should be available to enable employees to develop the necessary skills and knowledge required to complete their tasks at hand. In addition, providing training to team members shows management's commitment to continual growth and development for members.

Management support and the power structure are also key variables in attaining virtual team effectiveness. Teams not only need to be well budgeted and resourced, but team members also want encouragement and symbolic gestures of appreciation. Symbolic gestures—such as a pat on the back or having management verbally communicate that the team is doing a good job¾demonstrate respect for the team members; this can positively motivate the members. With respect to power structure, it has been shown that team members must have independence and decision-making capability to be successful in virtual groups (Lipnack & Stamps, 1997). In addition, according to Cohen and Bailey (1997), an organization needs to provide team

Table 4. Organizational context factors that affect team effectiveness

- Human resource policies that emphasize and reward teamwork
- Human resource policies that do not penalize (i.e., overlook) virtual workers
- The availability of training to work virtually, work effectively in teams, and carry out task responsibilities
- The amount of support management provides to the team
- The degree of autonomy the team is given to make decisions and take responsibility for their own actions
- The ability of the organization to share information that is needed to carry out tasks and make effective decisions

members autonomy in their work. Worker autonomy has been shown to have clear benefits because it enhances worker attitudes, behaviors, and performance (whether measured objectively or rated subjectively by team members).

Finally, access to information is necessary for team members to effectively complete their tasks. A practical study of a project-based virtual team suggested that most of the information team members needed was held either by themselves or other team members (Wong & Staples, 2004). Therefore, good communication between team members is essential for information to be easily accessed. In addition, resources need to be available for virtual communication to be possible and effective. These resources include information technology infrastructure and information technology tools that are needed to communicate and share information electronically in the virtual setting.

FUTURE TRENDS

The need to compete in a rapidly changing, hypercompetitive, and global marketplace is prompting many organizations to transform their organizational structures from large, hierarchical structures to agile, flexible, new structures (Morris, Marshall & Rainer, 2001). Business is increasingly being done at an international level, and organizations are responding by creating cross-border teams. Consequently, we will see a continuing trend of virtual teams emerging that have team members less geographically concentrated and more geographically dispersed. It remains to be seen how organizations will deal with the increase in geographic dispersion. As shown in research (Cramton & Webber, 1999), higher team member geographic dispersion may lead to lower team performance. Therefore, future research may focus on how to maintain team performance at a high level for teams that have a high degree of virtualness.

Furthermore, management will be continually trying to adopt new communication tools and technologies that have improvements in quality and capabilities. As such, training to use new technology will become especially important; how well team members can communicate and interact with each other depends very much on their ability to properly use the communication tools. Future research may deal with the effectiveness of new, emerging technologies and how they may positively or negatively affect virtual team performance.

CONCLUSION

The success of a virtual team depends heavily on its characteristics. Specifically, the main characteristics are the team's task design, the characteristics of the team members, the processes used by the team, and the organizational context. Analyzing these characteristics can reveal a great deal about how well a team is functioning, and what potential it has to improve. An organization's management can also use these characteristics to effectively design its virtual teams and thereby give it the best chance possible for success. Therefore, it is in management's best interests when putting together a virtual team to carefully consider the characteristics of the team. This will increase the team's chance of success if the variables that yield positive outcomes are maximized.

KEY TERMS

Group Potency: A collective belief in the capability of the group to meet a task objective.

Job Characteristics Theory: Task attributes influence effectiveness through their impact on critical psychological states such as motivation and satisfaction with the work.

Organizational Context: The conditions within the organization that a team works in that influences the successfulness of the team's activities and the involvement of the team members. Reward systems, level of management support, resources provided, and organizational culture all are important organizational factors that potentially affect a team's ability to succeed.

Task Design: The way key attributes of the task are arranged, in terms of the influence of these attributes on the effectiveness of a team in performing the task. Research has found key design attributes include the need for a variety of skills, the perceived importance of the task, the independence and autonomy given to people to determine how the task will be done, and the way task feedback is provided.

Team Characteristics: The composition of the team and the shared beliefs held within the team about the team. Team composition includes such things as the number of team members, the skills the team members collectively possess, and the stability of team membership.

Team Effectiveness: The ability of a team to perform its tasks on time, on budget, and with acceptable quality, as well as the satisfaction, motivation, and commitment of the team members.

Team Processes: "Members' interdependent acts that convert inputs to outcomes through cognitive, verbal, and behavioral activities directed toward organizing taskwork to achieve collective goals" (Marks, Mathieu & Zaccaro, 2001, p. 357).

Virtual Team: A group of individuals who work at interdependent tasks, who share responsibility for outcomes, and who work together from different locations.

Virtuality/Virtualness: The degree to which team members are geographically distributed such that opportunities for meeting informally and/or face-to-face are reduced.

ENDNOTE

1 As one reviewer pointed out, geographic dispersion is just one type of variety that may affect team performance. Other types of diversity include team member values (reflecting different organizational and/or national cultures), backgrounds, and mental models. Research on the optimal mixes of different types of diversity in virtual teams would be very valuable.

Designing Hypertext and the Web

Yin-Leng Theng
Nanyang Technological University, Singapore

INTRODUCTION

Hypertext and Web technology still continue to excite many, ever since it became popular in the late 1980s. Early visionary thinkers such as Bush (1945), Engelbart (1963), and Nelson (1987) in their own ways believed that hypertext and its underlying philosophy would enable man to locate, retrieve, and easily use the store of human knowledge that lies in books, journals, and associated materials in libraries all over the world.

In hypertext, end users not only benefit from the information they read, but also from the richness of associations supported by the network of nodes and links. Hypertext has affected us directly or indirectly in almost every facet of our lives, ranging from scientific work to business and education needs, to our general way of life. For example, the most widely used hypertext system since 1994 is the World Wide Web (or simply the Web) on the Internet.

Though hypertext systems promise a whole new paradigm and freedom of reading and information retrieval, they are not without problems. Ironically, it is precisely this freedom and power with which hypertext systems equip end users that give rise to many of these problems.

BACKGROUND: BRIEF HISTORY OF HYPERTEXT AND THE WEB

When Vannevar Bush (1945) envisioned his hypertext "memex," he dreamed of a personal microfiche-based system that would help him tackle the problem of information overload at that time. His vision of the "memex" heralded the beginning of a search for a system that mimics the human mind to access information quickly and intuitively by reference. In 1965, Nelson (1987) coined the term "hypertext" and presented it as a radical new way of structuring textual information into non-sequential format, a computer-based incarnation of Bush's dream "memex" (Berk & Devlin, 1991). Even though the technology in the "early" years of the hypertext history (for example, Conklin, 1987; Nielsen, 1995) was not sophisticated enough for many of the ideas to be realized, hypertext pioneers staunchly believed that hypertext technology had something special to offer.

Not surprisingly, as the years roll by, hypertext systems grow more sophisticated and computer is the technology that has enabled the concept of hypertext to be seen and not just heard. The growing popularity of the Internet and advancements in networking saw the birth of networked hypertext systems such as the Web. The Web project initiated in 1990 was originally created as an online information tool for high-energy physics research at CERN (the European Center for Nuclear Physics Research in Geneva, Switzerland). Berners-Lee and colleagues, the originators of the Web, built it based on the hypertext paradigm. Based on its likeness to a spider's web, this world of hypertext links is also called the Web.

Although the Web was first made available in 1991, it was only after the release of Mosaic by the National Center for Supercomputing Applications (NCSA) in January 1993 that it really gained prominence. Mosaic, NCSA's Web client, made the Web accessible to a wide and diverse user community because of its easy-to-use, graphical interface. Mosaic and the Web succeeded in establishing a universal hypertext. With the release of Netscape Navigator in 1994 by a commercial company co-founded by the original author of Mosaic, the number of end users on the Internet escalated to a phenomenal figure. Today, the Web is used by millions across the world. It has changed the Internet to the extent that it has become almost synonymous with the modern use of the Internet.

Since the same usability issues arise in hypertext, hypermedia, multimedia, and the World Wide Web, we will call them all "Web" for conciseness.

CONTINUING DESIGN AND USABILITY PROBLEMS

Since Halasz's seminal paper at the Hypertext'87 Conference, seven design issues in hypertext systems were identified; these issues formed the nucleus of multiple research agendas in: (a) search and query; (b) composites; (c) virtual structures; (d) computation in/over hypertext network; (e) versioning; (f) collaborative work; (g) extensibility; and (h) tailorability.

Although these issues were revisited several times over the intervening 15 years, and many research systems have attempted to address the original seven issues (Whitehead et al, 2002), we are still *not* producing better, usable hypertext applications.

With the exponential growth of the Web in 1994 and 1995, these issues became particularly acute. Nielsen (1996) listed 10 top mistakes in Web design, including: (1) use of frames; (2) bleeding edge technology; (3) scrolling text, marquees, constantly running animations; (4) complex URLs (Uniform Resource Locators); (5) orphan pages; (6) long scrolling pages; (7) lack of navigation support; (8) non-standard link colors; (9) outdated information; and (10) overly long download times. When Nielsen (1999) revisited these mistakes three years later, he concluded that all 10 mistakes were still mistakes. Apart from scrolling long pages, which is causing fewer navigation problems, the other nine mistakes still cause significant usability problems and should be avoided in modern Web sites.

A survey of current work (e.g., Wu, Meng, Yu & Li, 2001) seems to suggest one or more of the following problems still persist in hypertext/Web applications: (a) structured search for documents is not sufficiently supported; (b) proving properties of Web sites is difficult or impossible; (c) maintenance is not supported by formal mechanisms; and (d) personalizing of information, or adaptation to user groups, is difficult or impossible.

The question we want to ask is: Could it be possible that these well-intentioned efforts are not achieving their aims because wrong or inappropriate solutions are being sought based on incorrect or incomplete assumptions?

If it is a *psychological* problem, then it may be entirely due to end users' inability to exploit computer screens, complex information structures, and that nothing in the design is going to ameliorate this. Thus, as a psychological problem, it can be alleviated but not solved by better design (Theng, 1997).

If it is an *engineering* problem, it can be attributable to bad system design, and poor design causes psychological problems. The "blame," therefore, should not rest on end users alone!

NEW DESIGN AND USABILITY PROBLEMS

The world is becoming a global marketplace with end users from across the world. However, according to Galdo and Nielsen (1996), this heightened interest in internationalization and localization has not yet been translated into increased usability for international end users.

Globalization brings with it new issues relating to culture and ethics. With respect to design, standard human-computer interaction (HCI) guidelines may not be adequate. They may need to be modified, extended, or restricted.

Culture and Design

Culture is defined as "learned behavior consisting of thoughts and feelings" (Galdo & Nielsen, 1996). There is little provision in hypertext/Web applications to cater to end users' browsing and inter-cultural needs (Theng, Duncker, Mohd-Nasir, Buchanan & Thimbleby, 1999). One reason for the neglect of cultural aspects may be that usability failure is rather commonplace, and cultural usability issues are hard to recognize as such, more so since designers cannot help but see the world from their particular cultural point of view and may be defensive about their work. Thus, cultural usability issues for system designers may come disguised as illiteracy problems or simply as "user faults," rather than as cultural differences.

Apart from colors (Duncker, Theng & Mohd-Nasir, 2000), cultural factors that can influence the design of interactive interfaces for international end users include the following: spoken and written languages; the reading/writing direction; meanings and preferences of colors; and interpretations of signs, pictures, symbols used (Galdo & Nielsen, 1996).

In order to produce usable and useful interactive systems, designers need to ensure that good design features are incorporated into the systems, taking into consideration end users' cultural preferences.

Ethics and Design

According to the Oxford Dictionary, ethics is the "study of right and wrong in human behavior." The notion of the code of ethics and professional conduct is not new. The general moral imperatives in the ACM (Association for Computing Machinery) code of Ethics and Professional Conduct (adopted by the ACM Council, October 16, 1992) include one's contribution to society and human well-being, avoidance of harm to others, honesty and trustworthiness, fairness and non-discriminate actions, respect for property rights, privacy, and confidentiality. A specific professional responsibility in the ACM Code of Ethics is to "give comprehensive and thorough evaluations of computer systems and their impacts, including analysis of possible risks." "Ensuring that users have their needs clearly articulated during assessment and design of requirements" is one of the organizational leadership moral imperatives.

Apart from ensuring that the technical aspects of the Internet are taken care of, designers need also to consider the ethical and legal issues that may arise, owing to the increase in the use of computer-mediated communication devices (Gringras, 1997).

In recent years, Cyberethics, a growing area of research, explores the application of classical ethics to the latest information communication technologies, including the Internet. The fundamental principles of Cyberethics are privacy, property, access, and accuracy (Barroso, 2001). They imply a new set of responsibilities for both professionals and users of the Internet, and have implications for the design of safe, usable, and useful systems.

Duquenoy and Thimbleby (1999) explore the idea of justice to aid improved design. John Rawls' classic *A Theory of Justice* is used to explain why design needs to consider these two principles: liberty and equality (Rawls, 1972). Applying the Principle of Liberty, designers should ask themselves whether their designs persecute, discriminate, and oppress users (Duquenoy & Thimbleby, 1999).

Berners-Lee (1996) at the British Computer Society, in which he was awarded the Distinguished Fellowship, ended the presentation with a somber thought for designers/developers that they were wrong to ignore ethics "because when you design those protocols, you are designing the space in which society will evolve. You are designing, constraining the society which can exist for the next 10-20 years."

NEW DESIGN APPROACHES

Past solutions to address hypertext problems failed to take into consideration the context of use of the systems. Recent promise of the "Semantic Web" has also raised new expectations in that the Web should be (Marshall & Shipman, 2003): (1) a universal library readily accessed and used by humans in a variety of information use contexts; (2) the backdrop for the work of computational agents completing sophisticated activities on behalf of their human counterparts; and (3) a method for federating particular knowledge bases and databases to perform anticipated tasks for humans and their agents.

We propose a shift in mindset to embrace both a conscientious attempt designing with the *heart* to put end users at the center of design incorporating new issues arising from cultural and ethical perspectives, as well as an engineering approach involving the *mind* working with end users.

DESIGNING WITH THE HEART

To provide multi-cultural interfaces to hypertext/Web applications, we envisage the development of "boundary objects" between different cultures accessing shared information resources. "Boundary objects," from a social science perspective, are used by different communities without presupposing a fully shared definition of an object (Star & Griesemer, 1989). To achieve the emergence of inter-cultural boundary objects in hypertext/Web applications, cooperative and communicative features need to be introduced that allow negotiation and articulation across sites. Some ideas for implementation of boundary objects in three areas to create culturally sensitive user interfaces are (Theng, 2003; Theng et al., 1999): (1) creation of boundary objects as part of the hypertext/Web interface; (2) creation of a learning environment; and (3) creation of opportunities to create learning objects by users.

To enable equal access/opportunity/use, we suggest some ideas for implementation to create ethically sensitive user interfaces (Theng, 2003): (i) provision of adaptive and adaptable interfaces for users; (ii) provision of workspace and equal opportunity for search results; and (iii) integration of technology into the social environment.

To capture explicit and tacit knowledge occurring in a continuous, spiral manner, knowledge management proponents such as Nonaka and Konno (1998) suggest management of both explicit knowledge (information) as well as tacit knowledge. For richer exchange of user interactions in hypertext/Web applications, perhaps hypertext/Web applications should: (1) create opportunities to share experiences; (2) articulate tacit knowledge in some "externalization" form; and (3) create ways to integrate different types of knowledge and re-package them into different forms.

DESIGNING WITH THE MIND

To address limitations in current research in hypertext/Web applications, a systematic, engineering approach addressing fundamental issues that concern the *mind* should be considered (Theng, 2003, 1997):

- **For What Purpose?** It is important that designers identify the goals of hypertext/Web applications from the perspectives of the author/developer as well as from the reader/end user. Author/developer goals refer to authoring strategies to consistently apply basic Web document design principles on every single page in the hypertext/Web applications designers create. Reader/end user goals refer to the tasks readers/end users commonly perform when using hypertext/Web applications.
- **How To?** To design user-centered hypertext/Web applications, we need to involve end users and their needs throughout the different stages in the well-accepted iterative development lifecycle: (i) feasibility study; (ii) conceptual design; (iii) building; (iv) implementation; (v) integration; and (vi) maintenance.
- **With What?** This refers to the resources available for the development and delivery environments. They include: (i) data; (ii) rules; and (iii) authoring

tools. Data refers to digitized objects (e.g., text, images, sounds, videos) used to build hypertext/Web applications. They can also refer to existing collections of related information found, for example, in archives or on the Web. Rules are defined as ways in determining data structures of the digitized objects, that is, how data are to be captured and presented. Authoring tools refer to the authoring help and environment provided for designers/developers of hypertext/Web applications. These tools should make authoring as well as maintenance of hypertext/Web applications as easy as possible.

- **Level of Abstraction?** The essence of hypertext/Web applications is the representation of ideas through chunks of text or other media interconnected by relations, typically navigational links similar to knowledge representations such as frames and semantic nets. Instead of viewing knowledge expression as an all at once event, Shipman, Moore, Maloor, Hsieh, and Akkapeddi (2002) advocate viewing it as a constructive process in knowledge building. Perhaps the description of hypertext/Web applications can be at three levels: (i) *instance* level, which addresses specific application and domain needs; (ii) *modeling* level, which addresses the issues of how models for specific domain are created; and (iii) *meta-modeling* level, which addresses the issues of how to go about creating a model.

FUTURE TRENDS AND CONCLUSION

Many hypertext/Web applications are still poorly designed and built in terms of how information is structured and displayed. We argue for a move from treatment to prevention, from treating the end users' symptoms to avoiding bad design. This article makes several theoretical and practical contributions to address design of hypertext/Web applications with the *heart* and *mind*.

In the conventional iterative design process, there is great emphasis to encompass all activities relating to gathering and analyzing end users' needs, specifying end users' requirements, and building and testing prototypes. This is uncontentious wisdom, but so far, doing this is not easy since using these established usability techniques requires a competent level of "craft skills," and applying them is usually laborious and time consuming.

With more informed and sophisticated end users, there is greater awareness and concern that systems should be user focused. Future developments would see more emphasis on Web usability engineering that focuses on integration of creative and practical-to-use design and usability evaluation aids throughout the traditional iterative design process to help designers and developers.

ACKNOWLEDGEMENTS

The author would like to thank colleagues and friends who had given invaluable feedback and support: Harold Thimbleby, Cecile Rigny, Matthew Jones, Norliza Nasir, Elke Duncker, and Paola Ameldi.

KEY TERMS

Hypermedia: A term used to describe the interlinking of textual information and other forms of media, such as audio, video, and photographic images.

Hypertext: A term conceived and coined by Ted Nelson, who described it as interactive branching of text information structured into non-sequential format into nodes and links. The non-linear nature of hypertext provides freedom to readers who enjoy associational thinking and reading.

Information: Commonly known as a collection of facts or data. In Computer Science, it refers to processed, stored, or transmitted data. In Knowledge Management, it refers to codified knowledge.

Knowledge: Includes but is not limited to those descriptions, hypotheses, concepts, theories, principles, and procedures which to a reasonable degree of certainty are either true or useful. In the growing discipline in Knowledge Management, "knowledge" is divided into explicit (information), implicit, and tacit knowledge.

Multimedia: A term used to reflect diverse platforms for communicating ideas and meaning through a mix of media information that may include text, audio, video, and still pictures.

Usability: ISO 9241-11 defines usability as "the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use." Usability of hypertext/Web is commonly measured using established usability dimensions covering these categories of usability defects such as screen design, terminology and system information, system capabilities and user control, navigation, and completing tasks.

Usefulness: This is debatable. Some make the distinction between usability and usefulness. Although it is impossible to quantify the usefulness of a system, attempts have been made to measure its attainment in reference to system specifications and the extent of coverage of end users' tasks supported by the system, but not on end user performance testing.

World Wide Web: Originally created as an online information tool for high-energy physics research at CERN (the European Center for Nuclear Physics Research in Geneva, Switzerland), information is organized as a series of documents referring to each other with links of search and retrieval of text, images, sound, and video. Based on its likeness to a spider's web, this world of hypertext links is also called the Web.

Designing OMIS-Based Collaboration for Learning Organizations

Kam Hou Vat
University of Macau, Macau

INTRODUCTION

Today, the view that knowledge is a valuable organizational resource has become widely recognized and accepted in the business community. This is largely due to the emergence of the knowledge-based economy (OECD, 1996), characterized by a highly competitive and turbulent business environment. One consequence is the increase in organizations' efforts to deliberately manage knowledge. Organizations are realizing that their competitive edge is mostly the intellectual capital (brainpower) (Stewart, 1997) of their employees, and they are particularly interested in harnessing their human resources in order to stay ahead of the pack, through their soaring attention on specific aspects of knowledge management (De Hoog, van Heijst, van der Spek et al., 1999), which deals with the conceptualization, review, consolidation, and action phrases of creating, securing, combining, coordinating, and retrieving knowledge. Undeniably, with Web-based and intranet technologies (Dunn & Varano, 1999), the connectivity and possible sharing of organizational knowledge (bits and pieces of individual know-how scattered throughout the organization) are greatly enabled to cultivate the knowledge culture of the organization. In a knowledge-creating organization (Nonaka & Takeuchi, 1995), employees are expected to continually improvise and invent new methods to deal with unexpected difficulties, and to solve immediate problems and share these innovations with other employees through some effective communication channels or knowledge-transfer mechanisms. In fact, complete organizational knowledge is created only when individuals keep modifying their knowledge through interactions with other organizational members. The challenge that organizations now face is how to devise suitable information system (IS) support (Vat, 2000, 2002a, 2002b) to turn the scattered, diverse knowledge of their people into well-documented knowledge assets ready for deposit and reuse to benefit the whole organization. This article presents some learning organization perspectives of employee-based collaboration through the design of a specific IS support called the *organizational memory information system*—hence, the term OMIS.

THE BACKGROUND OF A LEARNING ORGANIZATION

The concept of the learning organization took seed several decades ago and gained major recognition with the incredible success of Peter Senge's 1990 book, *The Fifth Discipline*. Senge describes a learning organization as a place where people continually expand their capacity to create the results they truly desire, where new and expansive patterns of thinking are nurtured, where collective aspiration is set free, and where people are continually learning how to learn together. At the core of the learning organization are five essential learning disciplines—personal mastery, mental models, shared vision, team learning, and systems thinking—that may be briefly described as follows. Personal mastery has to do with individual learning and can be seen as the basic building block through the actualization of which the learning organization is typically constructed. Mental models are about how individuals reflect on their own knowledge, using such models to improve the internal understanding of an organization's functions and processes. Shared vision implies a sense of group commitment to a matrix of organizational goals, while team learning describes a sharing and utilization of knowledge involving collective thinking skills. The purpose of systems thinking is to understand relationships and interrelationships, as well as the context and the forces that affect the behavior of a system or organization. For the early half of the 1990s, the idea of learning organization had been criticized as the mere re-incarnation of earlier ideologies, such as organization development and total quality management (Rasmussen, 1997). Nonetheless, as more entities adopt the practices underlying the learning organization, it appears that the learning organization concept is passing from buzzword status to a meaningful expression of best organizational practices. Nowadays, many organizations that are engaged in constantly revamping and retooling themselves may be seen as reaching for that ideal goal of learning organizations. In fact, in this modern age of information technology and swift change, learning has become an integral part of the work of an organization run along principles intended to encourage constant reshaping and change. More importantly, learning organizations can be characterized as the organizations that continuously transform themselves by developing the skills of all their people and by achieving what Argyris (1992) has called *double-loop learning*, which helps transfer learning from individuals to a group, provide for organizational renewal, keep an open attitude towards the outside world, and support a commitment to knowledge. And this is often facilitated by the provision of some organizational knowledge transfer mechanisms, an example of which is the organizational memory information system (OMIS) to bring about the fundamental shifts in thinking and interacting, and the new capabilities needed in the learning organizations.

OMIS: AN ORGANIZATIONAL LEARNING EXPERIENCE

Lately, an organization's ability to learn is often considered a process of development to organizational memory. By organizational memory (Walsh & Ungson 1991), we are referring to various structures within an organization that hold knowledge in one form or another, such as databases and other information stores, work processes, procedures, and product or service architecture. As a result, an organizational memory (OM) must be nurtured to assimilate new ideas and transform those ideas into action and knowledge, which could benefit the rest of the organization (Ulrich, Von Glinlow & Jick 1993). Through understanding the important components of the OM (Vat, 2001), an organization can better appreciate how it is currently learning from its key experiences, to ensure that relevant knowledge becomes embedded within the future operations and practices of the organization. In practice, creating and using an OM is a cooperative activity necessarily involving many members of an organization. If those individuals are not adequately motivated in contributing to the OM initiative, and the organizational culture does not support knowledge sharing (Orlikowski, 1992), it is not likely to turn the scattered, diverse knowledge present in various forms, into well-structured knowledge assets ready for deposit and reuse in the OM. Consequently, it is important to distinguish between the organizational memory (OM encompassing people) and the OMIS that captures in a computational form only part of the knowledge of the organization. The OM captures the knowledge of the organization. The associated OMIS makes part of this knowledge available either by providing direct access to it (for example, codified knowledge assets such as experience reports), or indirectly by providing knowledge maps (for example, tacit knowledge assets such as personnel with specific expertise). Managing the OM deals first of all with the question of "Which knowledge should go into the OMIS?" Answering this question requires determining what knowledge is owned by the members of the organization, what knowledge is needed now, what is going to be needed in the future, and for what purposes. This helps the organization to define not only a strategy for acquiring the needed knowledge, but also to establish validation criteria in relation to the defined goals. Besides, we also need to deal with "who needs the knowledge, when, and why," as well as the policies for accessing and using the OMIS. This contextualization of the OMIS with respect to the organization's ability to learn is essential to implement the mechanisms of organizational knowledge transfer.

FUTURE TRENDS OF DESIGNING OMIS

When designing an OMIS to support an organization to learn (Vat, 2001, 2002a), we consider the following modes of learning: 1) individual, 2) group, and 3) repository. Individual learning is characterized by knowledge being developed, and possibly the result of combining an insight with know-how from other sources in the organization, but it is often not distributed and is not secured for reuse. Group learning is centered around the concept of communication in two possible modes: supply-driven or demand-driven. The former is characterized by an individual who has found a way to improve the work process and communicates this to one's co-workers. The latter refers to a worker who has recognized a problem in the current process and asks fellow workers whether they have a solution for this problem. In each case, knowledge is developed, distributed, and possibly combined with knowledge from other parts of the organization, but it is seldom secured. In repository learning, the communication element is replaced by collection, storage, and retrieval of knowledge items. Namely, it is typified by storing lessons learned in some information repository so that they can be retrieved and used when needed. Overall, in repository learning, knowledge is developed, secured, distributed, and is possibly the result of knowledge combination. It is convinced that the requirements of an OMIS design should be formulated in terms of the following usage scenarios. Namely, an OMIS should facilitate individual workers to access the knowledge required by combination, to submit a lesson learned, and to decide which of the co-workers would be interested in a lesson learned. Also, there should be criteria to determine if something is a lesson learned, how it should be formulated and where it should be stored, and how to distribute some newly asserted knowledge piece to the workers in need. The perceived technical issues, nevertheless, could include the following: How do we organize and index the

OM to enhance its diffusion? How do we retrieve relevant elements of the OM to answer a user request or proactively push relevant elements towards users? How do we adapt the answer to users, in particular to their tasks, according to the knowledge contexts? These problems are largely related to information retrieval, and they are bound to the OM framework for knowledge distribution, whose goal is to improve organizational learning, with the aid of the OMIS support.

CONCLUSION

Much of today's literature (Badaracco, 1991; Hamel & Prahalad, 1994; Quinn, 1992; Pinchot & Pinchot, 1994) supports the supposition that intellectual material in the form of information, knowledge, and any other form of intellectual property, is a valued organizational asset, and organizations are increasingly dependent on information technology (IT) for the transfer of knowledge and information. Conspicuously missing, however, is often a discussion of collaboration (Schrage, 1990) as a regenerative source of ideas that will advance organizations to learn, change, and excel (Menon, 1993; Stewart, 1994). In other words, simply transferring information at accelerated (IT) speeds contributes little added value to knowledge. Organizations must go beyond simple information transfer processes to survive and prosper. Garvin (1993) characterizes organizational learning as a continual search for new ideas. To collaborate is to work in a joint intellectual effort, to partition problem solving to produce a synergy such that the performance of the whole exceeds that of any individual contributor. The central issue in organizational learning is how individual learning is transferred to the organizational level. Here, we are assuming an organization of learners who take ownership for their own development and learning on a self-directed basis. Yet, only with a clear understanding of the transfer process can we manage learning processes consistent with organizational goals, issues, and values. If this transfer process is indeed actualized in the design of the OMIS, we could well have a learning organization which has the capability of capturing learning in its different paths and incorporating that learning into the running of its daily operations.

KEY TERMS

Collaboration: To facilitate the process of shared creation involving two or more individuals interacting to create shared understanding where none had existed or could have existed on its own.

Double-Loop Learning: Together with single-loop learning, describes the way in which organizations may learn to respond appropriately to change. Single-loop learning requires adjustments to procedures and operations within the framework of customary, accepted assumptions, but fails to recognize or deal effectively with problems that may challenge fundamental aspects of organizational culture, norms, or objectives. Double-loop learning questions those assumptions from the vantage point of higher order, shared views, in order to solve problems.

Knowledge Management: The broad process of locating, organizing, transferring, and using the information and expertise within the organization, typically by using advanced information technologies.

Learning Organization: An organization that focuses on developing and using its information and knowledge capabilities in order to create higher-value information and knowledge, to modify behaviors to reflect new knowledge and insights, and to improve bottom-line results.

OMIS: An information system supporting the development of organizational memory, whose design philosophy is often organization specific. An example philosophy is to consider the OMIS as a meaning attribution system in which people select certain resource items out of the mass potentially available and get them processed to make them meaningful in a particular context in order to support their purposeful actions.

Organizational Learning: A process of leveraging the collective individual learning of an organization to produce a higher-level organization-wide intellectual asset. It is a continuous process of creating, acquiring, and transferring knowledge, accompanied by a modification of behavior to reflect new knowledge and insight, and produce a higher-level asset.

Organizational Memory: A learning history that tells an organization its own story, which should help generate reflective conversations among organizational members. Operationally, an organizational memory has come to be a close partner of knowledge management, denoting the actual content that a knowledge management system purports to manage.

Designing Web Applications

Gustavo Rossi
UNLP, La Plata, Argentina

Daniel Schwabe
Departamento de Informática, PUC-Rio, RJ, Brazil

INTRODUCTION

The World Wide Web (WWW) has become the most widely used platform for application development and information delivery. Web applications have evolved from static, read-only Web sites to current, collaborative, mobile, and pervasive information systems. Most companies are automating their core work flows using Web technologies; new businesses supported by the provision of complex Web services appear every day.

These application fields impose new modeling, design, and implementation requirements. Applications must have good performance, but they must also be usable and often adaptable to the individual user, his or her location, preferred interface device, and so forth. The time frame of the development life cycle must be short, which means we must improve design and implementation reuse. Applications evolve constantly and in unforeseen ways, so modularity is a must.

Web applications are different from "conventional" applications mainly because they are based on the hypermedia metaphor and because they allow users to access information by navigating through multimedia nodes that are connected by links. More complex structures, such as hierarchical indexes and landmarks, are often necessary to help the user find his or her way through the ocean of information. Successful Web applications provide good navigation topologies, helping the user to complete tasks without experiencing the "lost in hyperspace" syndrome.

In this context, conventional software engineering approaches fail to fulfill the needs of this application domain, if only because they neglect the navigational dimension of Web applications. They simply consider them just as a particular case of interactive applications; for example, they do not provide meaningful abstractions to model the unique features of this kind of software. In particular, treating a Web application just as any other transactional software, in which queries over data are posed using a browser as an interface, ignores the richness of the hypermedia paradigm for describing information systems. The same is true when considering a Web application just as a kind interactive application, in which the standard MVC (model-view-controller) paradigm (Knight & Dai, 2002) can be applied. While database- and programming-centric approaches can be used in the implementation step, conceptual modeling of Web applications requires a more careful approach.

Fortunately, the Web engineering community has come forth with a brand new set of methods and data models to address these issues. In the following section we survey the most interesting aspects of those methods.

BACKGROUND

The leading methodologies in this field, such as Web Modeling Language or WebML (Ceri, Fraternali, & Bongio, 2000; WebML, 2003), Object-Oriented Hypermedia Design Method, also called OOHDM (Schwabe & Rossi, 1998), UML-based Web Engineering or UWE (Hennicker & Koch, 2000), Object-Oriented Hypermedia or OO-H (Cachero, Gómez, & Pastor, 2000), or W2000 (Baresi, Garzotto, & Paolini, 2001), consider the Web-application-development life cycle as an iterative, incremental process, in which different models are specified before the implementation.

The design space is thus partitioned in basically three data models: conceptual, hypertext, and presentation models. Though each method provides its own primitives for describing each model, there is a general consensus on considering these three aspects separately.

The application or conceptual model describes the underlying application domain using well known design primitives: WebML uses data-modeling languages (such as the entity relationships), while OOHDM, UWE, and OO-H use object-oriented concepts in the syntax of UML (unified modeling language).

The conceptual model can be viewed as the data model in traditional applications. The navigation model, meanwhile, is built as a hypertext view over the conceptual model. There may be different views for different user profiles, providing distinct navigation paths or even navigation objects. Generally speaking, a navigation or hypertext schema describes the items that the user will navigate and the links he or she will follow to traverse those items. The navigation schema is described using nodes and links, which abstract the usual components of a Web site.

To model these aspects, almost all methods use their own proprietary notations; UWE, however, has chosen to use a lightweight UML extension by defining stereotypes for each typical hypertext component such as navigation object, link, and index. In this way, it can benefit from all existing concepts and tools developed in the UML world.

In OOHDM, the high-level navigation structure of the application is described by a navigational contexts schema. A navigational context is a set of nodes sharing some properties (products of a brand, results of a query, etc.), and the navigational context schema describes all meaningful contexts together with indexes for accessing the nodes in a context. Contexts allow specifying the navigation alternatives for all its members at the same time, without having to detail it for each individual item. For example, it is possible to state, "From any given product, one can navigate to any of its related products," instead of having to say, "From product CD-ROM, it is possible to navigate to product CD Blanks," from, "From product Shaver, it is possible to navigate to product Shaving Blades," and so on.

All modeling methods provide a design armoury for describing abstract aspects of the user interface in terms of interface objects. These objects show how pages will look like though avoiding delving into the implementation aspects.

Once the different Web application models have been completely specified, a running Web application can be built. Different methods provide different strategies for mapping models into running applications. In general, implementing the conceptual model is straightforward using either conventional databases or object-oriented tools. The navigational views may be materialized or not, but they can be easily described using current server page technologies; interfaces can be built by using HTML (hypertext markup language) or XML (extensible markup language) and Extensible Stylesheet Language (XSL) tools.

Some methods go further. For example, WebML provides a set of tools for automatically generating the running application by performing a set of transformations on the previously described models (WebRatio, 2003).

The main contribution of these methods to the field of Web engineering has been threefold. First, they posited the idea that modeling Web applications involve more than defining conceptual models, that is, the introduction of the navigational modeling activity is essential to understand the dynamics of these applications (Rossi & Schwabe, 1999).

Second, their notations are based on well-known modeling practices (object orientation and entity relationship), which improve abstraction and reuse capabilities, (see, for example, Koch & Kraus, 2002), and provide a good framework for extending the models. In this sense, these methods have been recently used to specify customized applications (Abrahão, Fons, González, & Pastor, 2002; Matera, Ceri, Dolog, & Nejdl, in press; Rossi, Schwabe, & Guimaraes, 2001) and Web-based business processes (Brambilla, 2003; Schmid, & Rossi, 2004).

Third, they have introduced abstract interface specification (or presentation) as an important activity in the engineering process, factoring out interface technology from the design itself, a crucial aspect in times of continuous, fast technological and standards evolution.

The Web engineering community has also discovered a large set of Web design patterns that record and convey design experience (Garzotto, Paolini, Bolchini, & Valenti, 1999; Lyardet, Rossi, & Schwabe, 2000; Molina, Meliá, & Pastor, 2002; Rossi, Schwabe, & Garrido, 1997). These patterns allow the designer to reuse smart solutions that we (and other people) have found in successful applications while solving recurrent problems. These patterns have generated the architecture of Web frameworks, semicomplete designs in a particular application domain that can be refined and customized to obtain running applications (Fayad, Schmidt, & Johnson, 1999; Schwabe, Emeraldo, & Rossi, 2001). More comprehensive work toward obtaining a complete set of design guidelines from a system of patterns can be read in Van Duyne, Landay, and Hong (2003).

FUTURE TRENDS

Related Work

Since their inception, modeling and design methodologies have evolved quickly, and now we can say that the Web engineering field is entering adolescence. There are many other methods deserving mention, such as Web Site Design Method or WSDM (De Troyer & Leune, 1998), focusing on audience-driven modeling and design, and Web Unified Modeling Language, also called WUML (Kappel, 2001), devised specifically for ubiquitous Web applications.

Coming from a complementary perspective, there are proposals aimed at integrating conventional data models and database management systems with the Web platform. One of the first such approaches is Strudel (Strudel, 2003), which allows building Web sites as queries to a database through a specially designed language. Another example is the Araneus Web-base management system (Mecca, Atzeni, Masci, Merialdo, & Sindoni, 1998). Araneus combines a data model for Web documents, several languages for wrapping, querying, creating, and updating Web sites, and a set of methods for site design and implementation. Araneus has also adapted the three-tier idea of separating the application data model from hypertext (navigation) and presentation specification.

Trends

The emergence of the concept of Web services as a way to deploy and use distributed functionality in the Web and to achieve universal interoperability has led to a new trend: the specification of business processes as a combination of Web services. Business processes can be described by modeling the behavior of an actual participant in the process (the so-called *executable* business processes) or by describing the business protocols, that is, the mutually visible message-exchange behavior of the parties (the *abstract* processes). Business Process Execution Language for Web Services, aslo called BPEL4WS (IBM, 2003) provides a language for the formal specification of business processes and business interaction protocols. Meanwhile, the proposers of WebML have extended their modeling approach to allow specifying Web applications that compose Web services to support arbitrary business processes and work flows (Brambilla, Ceri, Comai, Fraternali, & Manolescu, 2002). In this regard, existing work in the Workflow Management Coalition (WfMC, 2003) can also be mentioned.

Current trends in design methods include the extension of existing approaches to support the construction of semantic Web applications, and the use of modern design principles to build pervasive Web software (Kappel, Pröll, Retschitzegger, & Schwinger, 2003).

The emergence of the semantic Web (Berners-Lee, Hendler, & Lassila,, 2001) envisages the next generation of the WWW as a vast pool of semantically annotated data. Such annotations follow semantic models, which are in many ways equivalent to the design models used by the methodologies previously mentioned. Several initiatives are investigating the design, development, and implementation of applications for the semantic Web, such as Corcho, Gomez-Pérez, López-Cima, López-García, and Suárez-Figueroa (2003), Golbeck, Alford, and Hendler (2003), Jin, Decker, and Wiederhold (2002) and Lima and Schwabe (2003a, 2003b).

CONCLUSION

Web modeling and design approaches are evolving rapidly. A healthy community with people coming from diverse fields such as hypermedia, databases, and conceptual and object-oriented modeling has established the basis of a well-grounded discipline. In the meantime, as implementation approaches for Web applications have also evolved, we can build modular and usable Web applications using solid engineering approaches. Modern architectures such as Java2 Enterprise Edition (J2EE) or the variants of the model-view-controller paradigm for the Web (Knight & Dai, 2002) make the mapping of Web design schemata into running applications feasible and straightforward. Tools for assisting the designer in this process already exist as previously mentioned.

The time in which building Web software was a handcrafted, amateur process is over. The Web community is now adopting good engineering practices by seamlessly combining the wisdom from traditional software engineering with the creativity of hypermedia and interface designers.

KEY TERMS

Customization: Customizable applications are those applications that can adapt themselves to the context in which they execute; applications (in particular, Web applications) can be adapted to the user profile, the location, the network connection, and so forth. Building applications that can adapt themselves to the current context involve many different software and information representation problems. In the context of Web applications, we can adapt the application behavior to the user profile, we can change the hypermedia topology for different users' tasks, or we can adapt the user interface for different appliances.

Hypermedia: Hypermedia is a metaphor for representing and accessing multimedia information. Information is represented as a structured collection of multimedia information items, called nodes. The collection's structure can be represented explicitly or implicitly and is typically seen as a graph, whose nodes are connected by links which represent meaningful relationships among them. The graph is traversed by navigating following links by selecting anchors in nodes. The WWW uses the hypermedia paradigm extensively; nodes are usually Web pages and links indicate the URLs that the user can reach from the current page (Halasz, 1991).

Model-View-Controller: The model-view-controller (MVC) is the most widely used software metaphor for building interactive applications. Originally conceived in the context of the Smalltalk programming environment, it is now currently used in Web applications. The MVC partitions the software space into three modules: the model that contains application objects and behaviors, the view that represents how these objects are presented to the user, and the controller that handles the interaction with the user. Using MVC allows a clear decoupling of concerns that helps building applications in which changes in the look, feel, and the interaction style may be changed without affecting the application core (Knight, & Dai, 2002).

Navigation: Navigation is the usual way of traversing a hypermedia graph. While the user explores a particular node, he or she can click an anchor to follow a link to explore another different node. While navigation is a good metaphor to freely traverse a graph of information when the graph is huge or very dense, the user might get lost. Different tools such as maps, landmarks, and navigation histories may help to overcome this problem (Bieber, 2000).

Patterns: Software patterns represent proven solutions to recurrent design problems. A pattern names and describes a problem that occurs once and again, and presents a good solution (a solution used by many expert designers) in an abstract way so it can be used in different occurrences of the same problem. The core of the solution is usually expressed using UML diagrams showing class and object relationships that serve to solve the recurrent problem. In Gamma (1995), the authors present a good catalogue of design patterns for object-oriented software. The same concept applies to the hypermedia and Web domain when designers recognize that they constantly face similar problems. Web navigation and interface patterns record and convey problems related to Web applications' navigational and interface structures.

Semantic Web: According to its original proponents (Berners-Lee et al., 2001, p. 35), "the semantic Web is an extension of the current Web in which information is given well-defined meaning, better enabling computers and people to work in cooperation." In addition to the currently available data meant for human consumption, the semantic Web provides metadata describing this data, allowing it to be processed by programs, allowing for more effective discovery, automation, integration, and reuse across various applications. The metadata are described using the resource description framework (RDF, 1999). The initiative is led by the World Wide Web consortium (W3C, 2001).

UML: The unified modeling language (UML) is the standard modeling and design notation to build object-oriented applications. UML comprises a set of submodels that allow a designer to easily express both structural and dynamic aspects of object societies. UML and its accompanying process model, the rational unified process (RUP), covers all steps of the software development process by providing different diagrammatic tools such as use-case diagrams, class diagrams, sequence diagrams, state models, and so forth. UML is itself described by a metamodel and possesses its own extension mechanisms to adapt it to specific application domains.

Web-Base: According to Mecca et al. (1998), a Web-base is a collection of data of heterogeneous nature, specifically, highly structured data as in relational or object-oriented databases and semistructured data in the Web style. It incorporates both databases and Web sites. A Web-base management system (WBMS) is a system for managing such Web-bases.

Developing Dynamic Balanced Scorecards

Pallab Saha
National University of Singapore, Singapore

INTRODUCTION

With the advent of scientific management in the late 19th century came attempts to increase worker efficiency by setting standards for various factors in an industrial system. While measuring financial factors of a business was prevalent even during late 19th century, the scientific management ideology heralded the start of an era of formally measuring non-financial factors. This ignited several performance measurement frameworks that were used by businesses.

The most widely used among them included Tableau de Bord, developed in early 20th century in France, which focused on improving production processes. Management by Objectives (MBO) was markedly different and radical as compared to early "command & control" structures advocated by Frederick Taylor. Performance Matrix, first developed in 1986, is a list of performance metrics that are priority weighted. Balanced Scorecard (BSC), first published in the *Harvard Business Review* in 1992 by Kaplan and Norton, is a comprehensive framework that imbibed the good ideas of all the earlier frameworks plus presented some new attributes in a concise and understandable manner that managers found easy to comprehend (Epstein & Manzoni, 1998).

BSC focuses on the need to derive performance measures from strategic goals and objectives (Epstein & Manzoni, 1998; Kaplan & Norton, 1992, 1996a, 1996b; Niven, 2002). The impetus for proposing the BSC was the increasing disillusionment of solely using financial metrics to plan, monitor, control and manage organizational performance (Niven, 2002). The BSC categorizes performance measures into four perspectives, namely: financial, customer, internal business process and learning and growth, with the assumption that these capture an organizational performance in a holistic manner. BSC also recognizes the fact that having isolated and unlinked measures constituting the scorecard does not provide a mechanism for managers to "see" the impact of changes and test business hypotheses (Kaplan & Norton, 2004). A well-architected BSC therefore must describe organizational strategy through a system objectives and measures that are linked (Niven, 2002). These measures are linked together in a chain of cause-effect relationships from the performance drivers in the learning and growth perspective all the way through to financial perspective (Kaplan & Norton, 2004; Niven, 2002). However intuitive cause-effect chains may seem, creating them is perhaps the most challenging aspect in scorecard development (Niven, 2002). The concept of balance central to the BSC performance measurement system specifically relates to (Niven, 2002):

- Balance between financial and non-financial measures
- Balance between internal and external constituents of the organizations
- Balance between lag and lead indicators

BACKGROUND

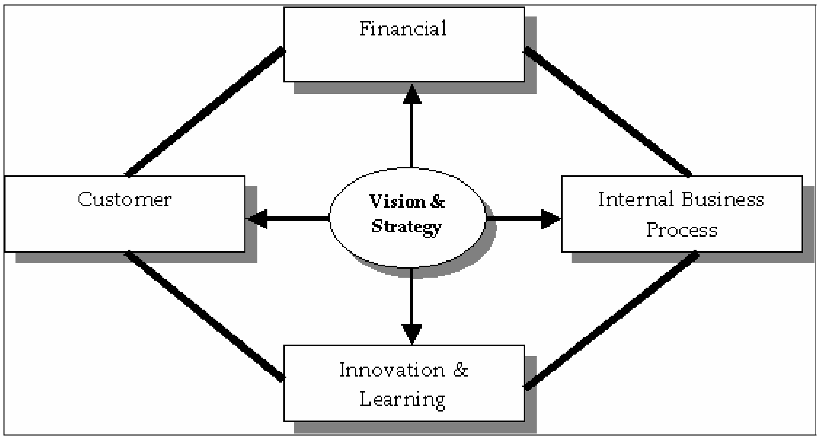
The balanced scorecard framework was selected by the *Harvard Business Review* as one of the most influential management theories of the last 75 years. Driven by its simplicity and power, the BSC framework has been adopted by nearly 50% of Fortune 1000 companies in a Bain & Company Survey in 1999. Notwithstanding its prevalence and industry acceptance, the BSC framework in its classical form as proposed by its founders has certain key deficiencies that often come as obstacles to its effective implementation (Fowler, 2003). These are:

- *Deficiency 1:* A cause-effect diagram used to depict the strategy map expresses the causality in a unidirectional manner.
- *Deficiency 2:* A cause-effect diagram, while showing the cause-effect linkages, does not take into consideration the time varying impact of these influences.
- *Deficiency 3:* A BSC provides no mechanism for validating the performance measures specified.

These key deficiencies have far-reaching implications on the effectiveness of BSC as a strategy implementation framework (Takikonda, 1998; Veen-Dirks & Martin, 2002).

- Cause-effect linkages are viewed as one-way in nature, thus emphasizing one-way thinking.

Figure 1. Basic structure of a BSC performance measurement system



- Unidirectional approach leads to difficulty in reliable simulations.
- While linkages from non-financial to financial measures are shown, feedback loops depicting the impact of financial on non-financial measures is absent.
- It is also assumed that both cause and effect occur in the same place and time, thus not provisioning for delays in causality, thereby missing the temporal/dynamic complexity.
- A static cause-effect diagram makes it difficult to identify "good" predictor metrics.

These five implications necessitate enhancement of the BSC with systems thinking/system dynamics approach to develop the dynamic balanced scorecard (DBSC).

DYNAMIC BALANCED SCORECARD

A broad methodology that combines systems thinking/system dynamics with balanced scorecard theory is shown next. Listed as follows are suggested steps or activities involved that culminate into development of a DBSC.

1. Assessing strategic and organizational landscape.
2. Identifying critical success factors (CSF).
3. Analyzing performance over time for identified CSFs.
4. Developing critical success loops (CSL) for each CSF.
5. Synthesizing individual CSLs into one single global CSL (GCSL).
6. Identifying and defining strategic resources.
7. Specifying strategies and strategic objectives.
8. Building strategy map(s).
9. Identifying performance measures for strategic resources.
10. Specifying targets for performance measures.
11. Identifying initiatives to address strategic objectives and CSFs.
12. Developing Dynamic BSC.
13. Validating DBSC through dynamic simulation.
14. Deploying DBSC as the performance management framework.

While these specific steps can vary from organization to organization, the approach remains largely similar. As the objective of this article is to highlight the use of systems thinking/system dynamics in order to overcome (most) of the deficiencies of the traditional BSC, steps that are specifically different are highlighted and described as follows.

Step 3: Analyzing Performance Over Time for CSFs

Following identification of CSFs that the organization "thinks" is key to its success, analyzing their behavior over time is a good starting point to uncover the underlying systemic structures among interrelated variables. The key here is to select a time horizon that is appropriate for the specific success factor. The "performance over time" graph is a simple graph showing CSFs on one axis and time on the other. Strategic assessment performed earlier identifies the number of other significant variables that might impact specific CSFs. Analysis of CSF performance over time often provides critical input to identify initial linkages between the variables and their impacts on CSFs. This helps in developing testable hypotheses about how variables' behavior might be interrelated (Kim, 1997).

Step 4: Developing Critical Success Loops (CSL) for Each CSF

Representing the systemic structure of each CSF is accomplished using causal loop diagrams (CLD) to develop CSL (Kim, 1997). Drawing CSLs allows the graphical depiction of the structure that exists between the CSF and its impacting variables. The trick here is to identify at least one reinforcing loop for each CSF that would be self-sustaining (Sterman, 2000). Causal loop diagrams used to develop CSLs should clearly identify:

- Linkages between the variables as either reinforcing or balancing (link polarity)
- Feedback loops as either reinforcing or balancing (loop polarity)
- Delays between variables depicting the temporal perspective

Figure 2 shows an illustration of a CSL as a causal loop diagram where *process quality* is the CSF. The diagram clearly identifies link polarities, loop polarities and delays.

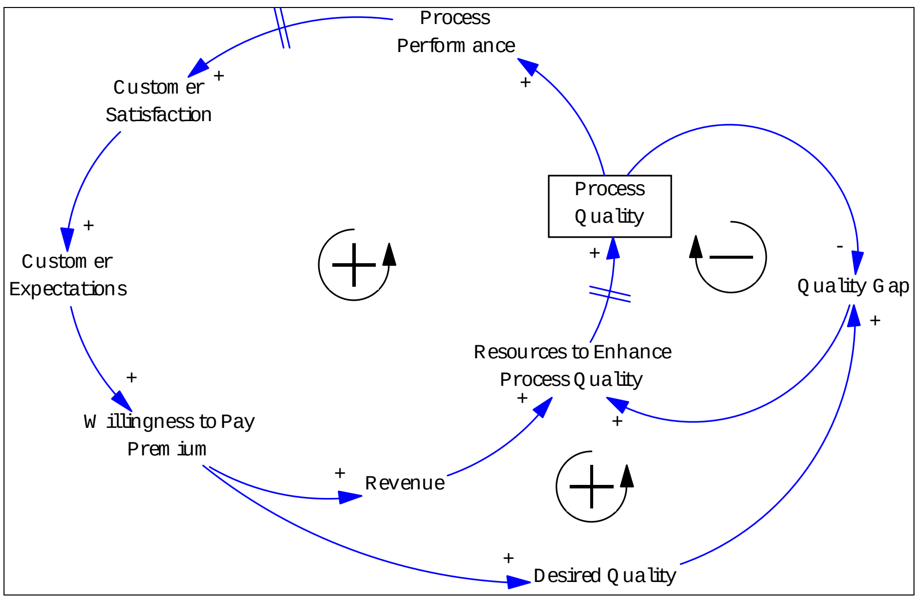
Step 5: Synthesizing Individual CSLs into One Single Global CSL

The next step is to uncover the interplay between the CSFs. This is accomplished by identifying the linkages between the separate CSLs. This involves developing a global critical success loop that logically links all identified CSFs and their impacting variables as a causal loop diagram (Kim, 1997). The global view of the success factors allows depiction of the "big picture" of various variables and their interrelationships. A global CSL is often a starting point to identify policy interventions required to impact CSFs and steer their performance in a manner that an organization desires.

Step 6: Identifying and Defining Strategic Resources

As the primary aim is to identify policy interventions required to impact CSFs and steer their performance in a manner that an organization desires, a critical activity involves identifying the strategic resources that an organization has access to (Warren, 2002). Identifying strategic resources are critical, as the organization "uses" these resources to impact critical success factors. Care must be taken to clearly identify both tangible and non-tangible resources.

Figure 2. Process quality critical success loop



Step 7: Specifying Strategies and Strategic Objectives

Strategic resources are elements that an organization has access to. As resources accumulate or deplete over time, all policy level interventions fundamentally seek to *add*, *increase*, *raise*, *enhance*, *build*, *grow*, *augment*, *boost*, *extend*, *expand* or *develop* either an existing resource or a new resource (Warren, 2002). However in either case, an organization has to work with what is available to it or has access to, which are the strategic resources. In specifying strategic objectives it is imperative to ensure that objectives (and goals) seek to impact resources over time.

Step 8: Building Strategy Map(s)

Figure 3 shows a partial strategy map depicting strategic objectives with linkages. Strategy map is a tool that helps organizations both to communicate their strategies and processes and systems that are needed to implement those strategies (Kaplan & Norton, 2004). In short, strategy maps depict the transformation of various organizational resources into desired outcomes.

Step 9: Identifying Performance Measures for Strategic Resources

It is critical to measure resources in order for them to be controlled, managed and steered. Table 1 lists *resources*, their *typical measures*, *units of resources*, *inflows & outflows*, *units of inflows* and *outflows* and *impacting factors* (Warren, 2002). It is to be noted at this point that a firm is also expected to specify targets for each performance measure (Step 10). Impacting factors are drivers that drive inflows and outflows that accumulate or deplete each resource. Hence when identifying initiatives to impact strategic resources, alignment with impacting factors is essential (McGarvey & Hannon, 2004). The presumption is that strategic initiatives affect impacting factors, which in turn impact the strategic resources.

Step 12: Develop Dynamic Balanced Scorecard

Causal loop diagrams provide an excellent method to capture the dynamics of the problem at a high level, but are not really amenable to simulation in order to fully understand the underlying dynamics of the variables (Sterman, 2000). Hence stock and flow diagrams are used to develop the dynamic balanced scorecard. Strategic resources identified earlier become the "stocks" that accumulate or deplete with time.

Figure 4 shows the partial stock and flow diagram that can be used to validate resources and their performance measures through the use of dynamic simulations. Following validation, measures can then be part of the Dynamic BSC amenable to *what – if* analysis through the development of business dashboards.

FUTURE TRENDS

Organizations are moving toward a service-oriented approach to business operation, which is driving the adop-

Figure 3. Partial strategy map depicting strategic objectives with linkages

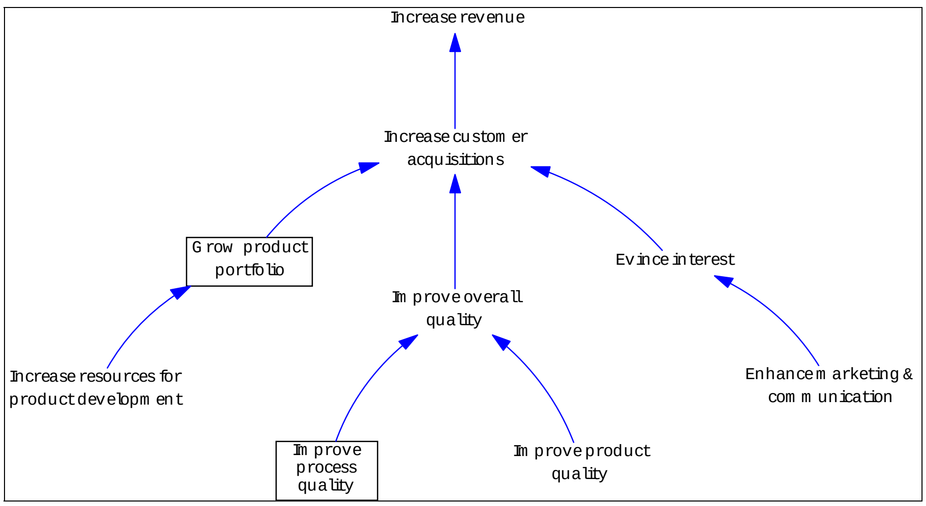


Table 1. Resources, measures, flows and impacting factors

Resources	Performance Measures	Inflows & Outflows	Units of Inflows & Outflows	Impacting Factors (Illustrative)
Revenue	Total revenue (Dollars)	Revenue added Revenue lost	Dollars / quarter	Sales, Competitors performance, New products, Price
Customer base	Individuals (Count)	Customers acquired Customers lost	Individuals / quarter	Sales effort, Price, Demand, Quality, Word of mouth
Products	Number of products (Count)	Products added Products retired	Products / quarter	Development effort, Staff skills, Demand
Overall quality	Defects (Defects Per Million Opportunities)	Increase in defects Reduction in defects	Defects Per Million Opportunities / quarter	Product quality, Process quality, Quality improvement effort
Staff	Number of staffs (Count)	Staffs added Staffs depleted	People / quarter	Salaries, Growth opportunities, Firm performance
Market reputation	Index	Increase in reputation Reduction in reputation	Index value / quarter	Word of mouth, Competitors perception, Customer performance

tion of continuous business process management (Kalakota & Robinson, 2003). However for business process management to be successful, it is imperative for organizations to link process and business performance in an integrated manner to develop an enterprise performance management system (Smith & Fingar, 2003). Development of such management systems depends to some extent on the availability of generic scorecards that organizations can configure based on their specific business needs. Hence future research could focus on two areas:

- Development of dynamic scorecards for industry-specific initiatives like straight-through processing and collaborative planning, forecasting and replenishment.
- Development of dynamic scorecards to monitor and manage compliance to regulatory requirements mandated by law (e.g., the Sarbanes-Oxley Act).

CONCLUSION

The problems of understanding complex system behavior and the challenge of developing models to capture such behavior are apparent in the field of performance measurement. Organizations are faced with conflicting goals of maximizing financial and non-financial returns. Existence of multiple measures in a scorecard addressing such conflicting goals increases the structural complexity of the measurement system and makes it difficult to predict its behavior. Enhanced with use of systems thinking, balanced scorecard practice can be made richer with the incorporation of the dynamic perspective of strategies and performance measures. While BSCs do assume the systemic nature of businesses, they fail to explicitly address the systemic thinking in its original form. This brings forth serious shortcomings in implementation. Synergizing system thinking and balanced scorecards provides a practical way to address these shortcomings.

KEY TERMS

Balanced Scorecard: A selected collection of measures (both financial and non–financial) derived from an organization's strategies. Usually balanced scorecard is considered to be the most prevalent form of performance measurement system.

Causal Loop Diagram: Consists of two or more variables connected by links, which usually take the form of arrows. These diagrams depict three major components: feedback loops, cause-effect relationships and delays.

Collaborative Planning, Forecasting and Replenishment: An industry-wide initiative that involves collaboration between trading (supply chain) partners in the retail industry in order to achieve lower costs, higher efficiency and better customer satisfaction.

Performance Measurement: A management practice that involves specifying and managing a set of metrics addressing business performance, usually in the form of a scorecard. A good performance measurement system is targeted to implement a coherent set of strategies.

Sarbanes-Oxley Act: Requires compliance with a comprehensive reform of accounting procedures for publicly held corporations to promote and improve the quality and transparency of financial reporting by both internal and external independent auditors.

Stock & Flow Diagram: Consists of a set of stocks and flows, stocks representing resources that either accumulate or deplete over time through inflows and outflows. Stock and flow diagrams are largely used in system dynamics and rarely in systems thinking approaches.

Straight-Through Processing: An industry-wide initiative to streamline, transform and automate processes in the financial securities industry in order to achieve lower settlement times and quicker trading.

Strategic Resources: Anything to which an organization has access to that may be strategically useful to it.

Strategy Map: A depiction of strategic objectives with linkages with the aim of showing transformation of various organizational resources into desired outcomes.

System Dynamics: A methodology for modeling and managing complex feedback systems. This includes dynamic simulation models that allow policy formulation and testing.

Systems Thinking: Systems thinking, closely related to system dynamics, is also a methodology to model and analyze dynamic, complex and interdependent nature of systems. However, systems thinking seldom includes developing dynamic simulation models as in system dynamics.

Developing Trust in Virtual Teams

Niki Panteli
University of Bath, UK

INTRODUCTION

During the last few years, there has been an increasing acknowledgment of the importance of trust in business interactions within the management and organizational literatures (e.g., Kramer & Tyler, 1996; Mayer, Davis, & Schorman, 1995; Rousseau, Sitkin, Burt, & Camerer, 1999). Trust, as a positive and confident expectation in the behavior of another party (Cook & Wall, 1980; Currall & Judge, 1995), enables cooperation and becomes the means for complexity reduction, even in situations where individuals must act under uncertainty with ambiguous and incomplete information. Therefore, it is not surprising that in the current age of global and digital economy and virtuality (Shepherd, 2004), there has been an overwhelming interest in trust. Motivated by the need to better understand trust in the digital era, this paper views the case of global virtual teams in commercial business organizations.

BACKGROUND

Trust has received significant recognition as a phenomenon worthy of detailed study in organizational and management studies (Dirks & Ferrin, 2001). In organizations, individuals must often act under uncertainty with ambiguous and incomplete information. This lack of explicit knowledge introduces risk and thus the requirement for trust. Accordingly, trust is defined as the willingness of a party to be vulnerable to the actions of another party (Mayer et al., 1995) based on a state of a positive, confident, though subjective, expectation regarding the behavior of somebody or something in a situation that entails risk to the trusting party (Baba, 1999; Cook & Wall, 1980; Currall & Judge, 1995).

Numerous scholars agree that trust is highly beneficial for the functioning of organizations. Trust "is at the heart of knowledge exchange" (Davenport & Prusak, 1998, p.35). High levels of trust are also key to effective communication (Dodgson, 1993) as they "improve the quality of dialogue and discussions … [that] facilitate the sharing of … knowledge" (Ichijo, von Krogh, & Nonaka, 2000, p.200), and committed relationships (ibid). The centrality of trust is further accentuated by its absence: "mistrust ... makes success harder to attain" (Kanter, 1994, p.105) as it weakens relationships, increases dependence on less information, compromises rational and unprejudiced analysis and exploration, and undermines learning (Luhmann, 1979). Furthermore, it has been recognized that if trust is not prominent, this may lead to dissatisfaction, absenteeism, and even intention to quit (Cunningham & MacGregor, 2000). At the inter-organizational level, trust also plays a vital role since it is found to affect the degree of cooperation among participating parties (Grabowski & Roberts, 1998; Newell & Swan, 2000). This is particularly important for virtual organizations. The business motivation for virtual arrangements is the potential for increased value-added and competitive advantage from the enhanced knowledge stock and core competencies, which are deemed to accrue to such networks (Alavi &Leidner, 2001).

Clearly, there is little dispute over the significance of trust in the organizational literature. However, there seems to be little agreement on how trust is developed and maintained in both the traditional and the virtual organizational literature.

In the traditional literature on trust where face-to-face communication is the norm, trust develops as the degree of familiarity with other people increases; i.e., the more we get to know others, the more likely it is that we trust them (Lewicki & Bunker, 1995,1996). Lewicki and Bunker (1996) take the view that trust varies over time and takes on a different character at the various stages (early, developing, and mature stages) of a relationship, as we not only begin to feel more comfortable with other people as we spend more time with them, but also as our knowledge of their integrity and competence improves. Based on this view, Lewicki and Bunker (1996) suggest three categories of trust, each corresponding to a different stage of the relationship:

- Calculus-Based Trust, the type of trust that is grounded in the rewards to be derived from pursuing and preserving the relationship or in the fear of punishment for violating trust within the relationship;
- Knowledge-Based Trust that assumes that the more information one has about others, the more able one is to predict their actions; and
- Identification-Based Trust, the type of trust that is characterized by mutual understanding among all

parties to the point that each can effectively act for the other.

These types of trust are "linked in a sequential iteration in which the achievements of trust at one level enables the development of trust at the next level" (p. 119).

Familiarity with other people has also been identified as an important antecedent of trust development in virtual teams. According to Handy (1995), for trust to develop in virtual environments there is a need for constant face-to-face communication. As he puts it: "paradoxically, the more virtual an organization becomes, the more its people need to meet in person" (Handy, 1995, p.46). This view has also been reinforced by Lipnack and Stamps (1997, p.226): "if you can drop by someone's office, see first-hand examples of prior work, and talk with other colleagues, you can more easily evaluate their proficiency." Researchers have already argued that the lack of proximity impersonalizes trust (Nandhakumar, 1999), while the virtual context of a geographically dispersed workforce may constrain or even impede rich information exchange[1] since communication becomes highly computer-mediated (Davenport & Pearlson, 1998). It follows, therefore, that trust based on familiarity with other individuals could not be easily developed in virtual settings.

In the following section, the challenges of developing trust in a virtual team setting are discussed by drawing upon the findings of existing empirical research.

Trust and Virtual Teams: Empirical Findings

While trust has been identified as a key feature for the success of virtual interactions, empirical research in this area has remained limited. Jarvenpaa and Leidner (1999) have conducted one of the most detailed research projects into studies on trust and virtual teams thus far. Their eight-week study of 75 teams of university students, each consisting of four to six members, highlighted significant differences in the behaviors and strategies between high- and low-trust teams and supported the existence of swift trust; this type of trust presumes that roles are clear and that each team member has a good understanding of others' roles and responsibilities (Meyerson, Weick, & Kramer, 1996).

However, trust is not always swift. Tucker and Panteli (2003) have illustrated the significance of shared goals and power in influencing trust development; these factors were not identified in the context of university settings as the tasks are often well-articulated in advance while power differentials, which could influence the degree of inter-dependence among members, are not significant in the case of university students. In business environments, however, power differentials prevail. Power, defined as the capability of one party to exert an influence on another to act in a prescribed manner, is often a function of both dependence and the use of that dependence as leverage (Rassingham, 1999). Indeed, power is an important contextual factor that affects trust (Hart & Saunders, 1997) in that it suggests the existence of a unilateral dependency or an imbalanced relationship (Allen, Colligan, Finnie, & Kern, 2000).

Accordingly, within a business environment where conflict and power differentials prevail, building trust is not always a swift process. Instead, it is found that the process of jointly constructing team goals holds significant value as it may provide the "glue" to hold team members together long enough to enable trust development.

Shared goals are and should be a key characteristic of virtual teams. They could provide a means to developing a common sense of identity for team members that can be of particular benefit to those global virtual teams who meet infrequently or perhaps not at all. These benefits include the establishment of a foundation upon which to build trust and minimize the use of coercive power in pursuit of a collaborative and productive relationship. However, the study finds that even though shared goals are important for the success of virtual teams, these should not be taken for granted. Indeed, goals may not be shared either because they do not exist at all, or because team members have not become aware of them, have their own priorities, or share different interpretations of the team's role. Furthermore, this study has also shown that the construction of shared goals is often not a one-off activity, but rather it is a process that requires the ongoing participation of all parties involved. Though this could be a time-consuming, iterative, and difficult process, these findings allow us to argue that it is far better to invest in it and as up front in the project as possible than deal with the vicious, destructive, downward spirals that result from team members with conflicting goals and poor levels of trust.

In considering power within virtual teams, there is an increasing recognition in the literature that knowledge is indeed power and that teams are often formed to create knowledge through combination and exchange. Within these teams, the team member with power at any given time is the one with the most relevant knowledge at that time. Tucker and Panteli (2003) found that in high-trust teams power differentials do not disappear; rather, power shifts from one member to another throughout the life cycle of a project depending on the stage and requirement of each stage.

Further to the issues of shared goals and power, Tucker and Panteli (2003) found support for the need for face-to-face interaction. However, the opportunities to meet face-to-face have been severely limited by economic pressures and, more recently, terrorist attacks. Under these circumstances, those virtual teams that work well tend to undertake regular communications via synchronous, "live" computer-mediated communication (CMC) such as the telephone and videoconferencing systems. Participants confirmed that synchronous media offered more feedback and therefore facilitated understanding more effectively than asynchronous technologies such as voicemail and e-mail. The use of asynchronous technologies was, however, regularly used for documenting and recording agreements and providing brief, simple updates to work progress. The teams that worked well also included a social and fun element in their interactions that appeared to help in creating a stronger shared social context.

Table 1 details the common features and behaviors observed within the global virtual teams studied in Tucker and Panteli (2003, p.91).

FUTURE TRENDS

The increasing pressure to perform in a short period of time with unfamiliar people and within a computer-mediated environment makes it imperative to study not only the type of trust but also how trust is formed and developed in a virtual team context.

It is readily acknowledged that what has been attempted here is only an exploration of contingencies to provide a better understanding of trust within the virtual team environment. There is no doubt that this is only the beginning of our understanding of trust in a virtual context.

Virtual interactions, however, exist at multiple levels—between individuals, individuals and organizations, and between organizations. Nandhakumar, Paneli, Powell, and Vidgen (2004, p.79) have introduced a digital era interaction (DEI) matrix to support exploration of trust relationships at these different levels.

The digital era interaction (DEI) matrix in Figure 1 indicates areas where digital era developments might be expected with consequent implications for trust. It views trust in two dimensions allowing an exploration of its nature in organization-to-organization settings, organization-to-individual and individual-to-organization interactions, and at an individual-to-individual level. In this paper, trust at the individual-to-individual level (and, more specifically, employee-to-employee) was explored. Thus, although the individual-to-organization (I2O) quadrant is currently the least developed of the four, it may prove to be an interesting sector in the longer term. Consumer-to-Business (C2B) is another growing area that allows consumers to organize themselves and use their stronger bargaining power to obtain a better price. As it was put: "The matrix is not exhaustive (for example, it does not include E2C, employee to consumer), but it does cater for the principal electronic relationships that currently exist and highlights ones that will be significant in the future" (p.79).

CONCLUSION

This paper reinforces arguments in the existing literature on the significance and complexity of trust dynamics in building effective virtual teams. It defined trust and outlined its central role in virtual interactions while also

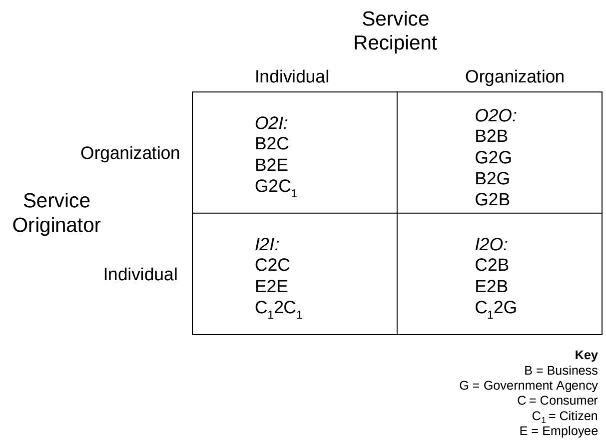
*Regular synchronous CMC	* Time difference matters
*Social interaction	*Little or no social interest

Figure 1. Digital era interactions (DEI)



identifying some of the challenges involved in developing trust in the digital era, arguing that trust is necessary but not sufficient for promoting effective, collaborative virtual interactions using empirical findings. The paper illustrates the significance of shared goals and power in influencing trust development. It has also become apparent that while the agreement of shared goals provides a mobilizing force for the members of global virtual teams, the process of developing these goals holds significant value in terms of the exchange of information, learning, improving understanding, and an opportunity to demonstrate trustworthiness. Repositioning trust in this way increases our chances of making sense of complex virtual, computer-mediated situations, and puts us in closer touch with the challenges of developing trust. In doing so, the paper carries forward an important debate in the digital era.

Diffusion of E-Learning as an Educational Innovation

Petek Askar
Hacettepe University, Turkey

Ugur Halici
Middle East Technical University, Turkey

INTRODUCTION

Most of the discussions related to education are about technological innovations. Indeed as Rogers (1995) stated, we often use the word "innovation" and "technology" as synonyms. Technology is regarded as an agent of change in educational settings, and a quick analysis of the educational projects all over the world shows us that it is not possible to define a future vision of education without technology, especially e-learning, which brings two important concepts together: technology and learning. Therefore as a form of distance learning, e-learning has become a major instructional force in the world.

Besides the technological developments, the last two decades have brought a tremendous increase in knowledge in education, particularly in learning. The emerging views of learning which should be taken into consideration for every learning environment could be stated as follows: personalized, flexible, and coherent (learning is connected to real-life issues); not bounded by physical, geographic, or temporal space; rich in information and learning experiences for all learners; committed to increasing different intelligences and learning styles; interconnected and collaborative; fostering interorganizational linkages; engaged in dialogue with community members; accountable to the learner to provide adaptive instructional environments (Marshall, 1997).

WWW is an environment that fits the new paradigm of learning and facilitates "e-learning" which faces a challenge of diffusion. Diffusion is defined by Rogers (1995) as the process by which an innovation is communicated through certain channels over time among the members of a social system. Therefore the adoption of WWW as a learning environment is influenced by the following set of factors: 1) the individuals' perception of the attributes of e-learning, 2) the nature of the communication channels, 3) the nature of the social system, and 4) the extent of the change agents' efforts in the e-learning. These are the variables that affect the diffusion of e-learning in the schools and countries.

E-LEARNING AND INSTRUCTIONAL DESIGN

E-learning not only opens up new ways of learning and teaching, but also leads to a new way of thinking and organizing learning content. Collaborations among different stakeholders cause new standards for design of knowledge on the Internet. In traditional computer-based instruction, content comes in units called courses. However a new paradigm for designing instruction, grounded in the object-oriented notion of computer science, is called "learning objects."

Learning object is defined by the Learning Technology Standards Committee (2002) of the Institute of Electrical and Electronics (IEEE) as any entity, digital or non-digital, that can be used, re-used, or referenced during technology-supported learning. The features of learning objects are self-contained, interactive, reusable, and tagged with metadata. By the use of learning objects, one can learn just enough, just in time, and just for them. Learning objects can be considered a movement within the field of e-learning, one aimed at the componentization of learning resources, with a view to reusability (Duchastel, 2004).

The idea of educational software as a package is becoming outdated and making way for learning objects as a new way of designing instructional materials. In designing learning objects, the studies on multiple representation of knowledge become important since people have different learning styles and strategies. The associations between these two constructs are the main focus of the new instructional design principles. Therefore, the development of learning objects and the way of creating teaching units are well suited for what we call the Information Age.

A representation of knowledge could be decomposed into its parts, where the parts are far from arbitrary. Then they can be used and reused in a great variety of combinations, like a child's set of building blocks. Every combination is meaningful and serves as an instructional whole. Holland (1995) compares building blocks to the features of the human face. The common building blocks are: hair, forehead, eyebrows, eyes, and so on. Any combination is different and may never appear twice. This analogy could be true of e-learning platforms, where learning objects are put together to make up a meaningful whole, which we call instructional materials.

The five fundamental components of instructional design process are learners, content, objectives, methods, and assessment. Hence, for a systematic instructional design of a subject matter, the basic steps are: learner characteristic identification, task analysis, objectives, content sequencing, instructional strategies, message design, and instructional delivery and evaluation.

The awareness of learner differences with respect to entry competencies, learning styles and strategies, motivation, and interest are critical. However it is difficult to accomplish this task by using ongoing approaches. Indeed, new technologies, if used properly, enable us to make the lessons more individualized. The Learning Objects Metadata Working Group (IEEE, 2002) stated its goal as: to enable computer agents to automatically and dynamically compose personalized lessons for an individual learner. This leads a paradigm shift to approaches to instructional design. As Wiley (2001) stated, a problem arose when people began to actually consider what it meant for a computer to "automatically and dynamically compose personalized lessons." It seems that the idea of learning objects is challenging, but opens to new concepts, strategies, and research areas in the instructional design process.

E-LEARNING AND SCHOOL MANAGEMENT

For most of the last two decades, technology has been implemented in schools, and its potential to change the educational systems has been argued for. There are tremendous efforts to encourage the integration of computers and Internet into schools. However, in one of the diffusion studies conducted by Askar and Usluel (2001), two paths to the adoption of computers are presented. One path is related to the use of technology in the school management system; the other one is related to the use of technology in the teaching and learning process. For many reasons the rate of adoption of computers in management applications is quicker than the learning-teaching applications. Indeed the concerns related to use of computers in the teaching-learning process are still at the awareness stage. On the other hand, the need for using computers and the Internet for management purposes is more relevant and seems more convenient for the current school system.

Educators assert that the central purpose of school management systems should be to improve instructional program quality. In light of this idea, a typical configuration of a Web-based school management system designed—taking this idea into consideration—includes administration, assessment, and communication. The features are: student enrollment, attendance, registration, test scores, grades and other record-keeping tasks, formative and summative evaluation, and feedback to parents and teachers about student learning and performance. In addition, new online management systems include item- banking capability for adaptive testing and online learning modules.

E-LEARNING AND THE COMMUNITY

The modern world requires individuals and communities to be able to continually develop and utilize different skills and knowledge. There is growing consensus among OECD countries that modern economies cannot afford a significant number of uneducated people (OECD, 2000). However, education systems throughout the world are ill equipped to address individual and community learning needs. The existing school system is not flexible for those who for some reason left school early.

Distance education is a recognized solution all over the world for bridging the learning and education divide between the educated and poorly educated. It gives people the opportunity to continue their formal education. Despite the initial concerns that distance education might be lower in quality than traditional method of schooling, many forms of distance education are gaining acceptance (Belanger & Jordan, 2000). Therefore distance education is receiving positive attention from governments as a solution to the educational problem mentioned above.

Also, the trend towards lifelong learning is universal. The transformations taking place in all societies require an increasing participation of individuals, an ability to innovate and solve problems, and a capacity to learn and go on learning (Mayor, 1994). Moreover, the term "open learning" is used to lower barriers that stand in the way of individuals and communities wishing to engage in different learning opportunities.

One of the solutions for the above mentioned problems is learning centers, which are flexible learning organizations and which serve the learning needs of the individuals and communities. A school that is well equipped and organized could be opened during non-traditional school hours. Therefore, schools as learning centers can be critical resources to meet the growing need for distance education students and other community members. However, in highly centralized education systems, it is very difficult to organize schools for those other than the registered students. The rules and regulations for conventional school become real barriers for open learning environments.

FUTURE TRENDS IN TECHNOLOGY

While adopting the current technology for enhancing teaching and learning, advances in micro- and nanotechnology push the limits of miniaturization, and of minimizing the costs and power of microelectronic components and micro-systems. Explorations of alternative materials are expected to allow organic flexible materials for displays, sensors, and actuators so that they can be placed anywhere and can take any shape. Furthermore it is expected that not only PCs, but also all our surroundings, will be interfaced. Instead of only " writing and reading" in human-computer interaction, all senses are to be used intuitively. Information search will be context-based instead of "word " based. Mobile and wireless devices will be used not only for voice transfer, but also for full multimedia (IST WP, 2002)

As information and communication technologies change, open systems and services are to be developed in support of ubiquitous, experiential and contextualized learning, and virtual collaborative learning communities improving the efficiency and cost-effectiveness of learning for individuals and organizations, independent of time, place, and pace. Next-generation learning solutions are expected to combine cognitive and knowledge-based approaches, with new media having intelligence, virtual and augmented reality, virtual presence, and simulation (ISTC, 2001).

CONCLUSION

Our current educational system is highly resistant to change. Making a client-based change rather than a technological based one will be the most important innovation to accomplish for the educational change. While technology is pushing the limits of e-learning environments, special care should be taken in educational and organizational frameworks. The stakeholders of the systems are students, teachers, principals, learners, and community. Their attitudes, needs, and expectations from e-learning are important issues for the change process. The innovation adoption variables of relative advantage, compatibility, visibility, ease of use, results demonstrability, and triability should be considered by school administrators seeking to increase the rate of adoption of e-learning within their organization (Jebeile & Reeve, 2003).

Complexity is another issue to be considered. Fullan (1991) defines complexity as the difficulty and extent of change required of the individuals responsible for implementation. Therefore, there should be an emphasis on simplifying the process of e-learning, while moving from approaches based on knowledge transfer to systems based on the dynamic construction and user-friendly exchange of knowledge between learners, teachers, and learning communities.

The educational community, as the end user of e-learning systems, should be given the opportunity of observing and trying the e-learning systems. Awareness or being informed about the innovation is the key factor for changing the negative attitudes or beliefs. It is known that if people see the implementation and results of innovation, they are more likely to adopt them for their usage. Unfortunately, the benefits of e-learning are not well known and well recognized by all relevant stakeholders. Therefore, a comprehensive and systematic awareness campaign is needed to speed up the rate of adoption.

KEY TERMS

Diffusion: The process by which an innovation is communicated through certain channels over time among the members of a social system.

Distance Education: A type of formal education in which the majority of the instruction, which is transmitted through technology, occurs when student and instructor are not in the same place.

Innovation: An idea, practice, or object that is perceived as new by an individual or other unit of adoption.

Instructional Design: The systematic process of translating general principles of learning and instruction into plans for instruction and learning.

Learning Object: Any entity, digital or non-digital, that can be used, re-used, or referenced during technology-supported learning.

Learning Styles: The ways in which a person takes in and processes information and experiences.

Rate of Adoption: The relative speed with which an innovation is adopted by members of a social system.

Diffusion of Innovations in Organisations

Davood Askarany
University of South Australia, Australia

INTRODUCTION

During the past two decades, the world has witnessed a significant change in the nature of the technological and administrative practices and processes faced by organisations in different areas of their operations, such as manufacturing processes, operation technologies, and information systems (Shields, 1997). To keep pace with other competitors in the global market, organisations are keen to be able to use the best and the latest ideas, techniques, practices, and processes in different aspects of their activities. This has placed a greater emphasis on the diffusion of innovation as a solution to cope with the requirements of such changes. This view is consistent with systems approach theory that suggests that all parts of a system are related to each other, and any change in one part of a system may require the consideration of appropriate change(s) in other parts of the organisation, otherwise, the system may not work properly (Kellett & Sweeting, 1991).

An overview of the diffusion of advanced techniques and the recognition of factors influencing the diffusion of such innovations is expected to facilitate the implementation of recently developed, advanced, and up-to-date techniques and practices in organisations. Given this, the current chapter explains a diffusion model applicable to studies investigating the diffusion of advanced techniques (both technological and administrative innovations). The model incorporates most of the innovation factors addressed in the diffusion and advanced techniques literature. An "advanced technique" is referred to as an innovation in this overview.

BACKGROUND

Rogers (1995) defined an innovation as "an idea, practice, or object that is perceived as new by an individual or other unit of adoption." Further, he suggested that if the individual has no perceived knowledge about an idea and sees it as new, it is an innovation. Likewise, Damanpour and Gopalakrishnan (1998) defined innovation as "the adoption of an idea or behaviour new to the organisation." The common criterion in any definition of innovation is newness. According to Rogers (1995), newness in an innovation might be expressed not only in terms of new knowledge, but also in terms of first persuasion, or a decision to adopt. The second element that needs some clarification is diffusion: Wolfe (1994) explained diffusion of an innovation as a way new ideas are accepted (or not) by those to whom they are relevant. Rogers (1995) extended this definition to consider diffusion as a process by which an innovation is communicated through certain channels over time among the members of a social system.

A clear understanding of the complexities of the innovation process and of alternative diffusion methods is central to any innovation diffusion study. Depending on the source of innovation, the diffusion of the innovation might follow different stages, so that alternative approaches and perspectives might be applicable under different innovation diffusion processes.

According to Damanpour and Gopalakrishnan (1998), diffusion of innovations in organisations takes place in two ways: generation and adoption. In the case of generation, innovations are generated by organisations for their own use or for export to other organisations. In the case of adoption, innovations are imported into the organisation for adoption. The process of adoption of an innovation is a very long and difficult process, especially because many innovations need a long period of time to become widely adopted (Rogers, 1995). Rogers further emphasised that increasing the diffusion rate of an innovation is a common problem for potential adopters of that innovation.

The process of innovation diffusion is different when the innovation is generated by the organisation; in this case, the main stages include the stages of idea generation, project definition, design, development, and marketing and commercialisation (Cooper & Kleinchmidt, 1990). In the case of adoption of an innovation, which has been developed outside the organisation, the stages will be awareness of innovation, attitude formation, evaluation, decision to adopt, trial implementation, and sustained implementation (Zaltman, Duncan, & Holbek, 1973). Furthermore, Wolfe (1994, p. 411) added that when innovation is generated in the organisation, the stages "tend to be mulled and overlapping," while in the case of adoption, the stages "tend to occur in the expected order." Depending on whether the innovation is generated within or adopted by an organisation, two alternative general models can be formulated to describe the diffusion process.

Contributing to the diffusion of innovation literature, Rogers (1995) suggested that there are six phases for the diffusion of an innovation: recognition of a problem or need, basic and applied research, development, commercialisation, diffusion and adoption, and consequences. Given this explanation, Rogers emphasised that these six phases are somehow arbitrary, as they might not always occur in order, and some of them might be skipped in the case of particular innovations. An innovation development consists of all decisions and activities and their impacts that occur during these phases. These suggested stages for innovation development are largely consistent with the generation approach of Damanpour and Gopalakrishnan (1998).

However, Zahra and Covin (1994) adopted a different perspective, suggesting that there are three major sources of innovation: imitative, acquisitive, and incubative. They defined these three major sources of innovation as follows. Imitative sources are those innovations that are first introduced by other firms and then copied by organisations. Acquisitive sources also include those innovations that have been developed by other firms but are acquired through purchase, licensing, acquisition, or merger. Finally, incubative sources are those innovations that have been developed in organisations for their own use. This categorisation is compatible with the generation and adoption approach of Damanpour and Gopalakrishnan (1998) in that "imitative innovations" and "acquisitive innovations" can be classified as "adopted" innovations and "incubative innovations" as "generated" ones.

From a process point of view, Rogers (1995) divided the innovation process in organisations into two subprocesses: an initiation process and an implementation process. The initiation process includes two stages: agenda setting and matching. These two stages involve all activities such as information gathering, conceptualising, and planning for the adoption of an innovation. The implementation process includes three stages: redefining/restructuring, clarifying, and routinizing. These three stages contain all of the actions, events, and decisions involved in implementing an innovation. This classification is again consistent with the adoption method explained by Damanpour and Gopalakrishnan (1998). However, regardless of types, phases, or sources of innovations, there are a variety of factors influencing the diffusion of advanced techniques in organisations. Reviewing the diffusion literature, Askarany (2003) summarised a variety of influencing factors and established a diffusion model applicable to studies investigating the diffusion of advanced techniques.

A DIFFUSION MODEL

Addressing the diffusion of advanced techniques, Askarany (2003) classified all influencing factors into three main categories: factors related to attributes of innovations, to adopters of innovations, and to the social system.

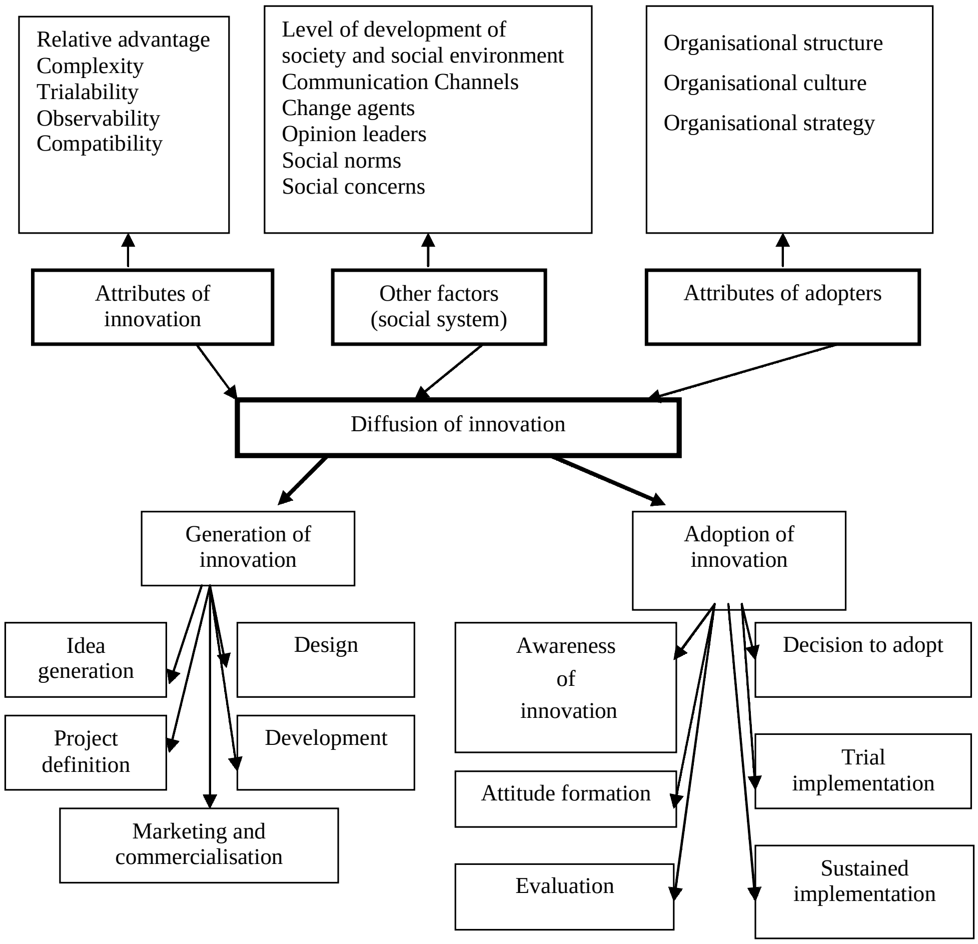
Following Rogers (1995), attributes of innovations include five categories: relative advantage, compatibility, complexity, trialability, and observability. These five categories include a variety of influencing factors, such as the degree of uncertainty associated with the innovation; the amount of investment required to adopt the innovation; the extent of economic advantage of an innovation; continuity of the innovation progress; overall benefit of an innovation (including economic and noneconomic advantage of an innovation); reinventing and dynamics aspects of innovations; profitability, flexibility, and capability of modification of an innovation; availability of an innovation and the information about it for potential adopters; and the type of innovation.

Factors related to the adopters of innovations include three categories: organisational strategy, organisational structure, and organisational culture. In other words, most characteristics of organisations can be explained by these three categories. These categories might include factors such as size of organisations, aggressiveness and innovativeness of their managers, level of information of organisations about the innovation, learning perspectives of organisations, resistance to change, technical skills of the users of an innovation in organisations, competition, and awareness of an innovation as a possible solution or as an available technique for progress.

Factors related to social system include the level of development of a society, communication channels in a society, social concerns, change agents, opinion leaders, and social norms. It might also be possible to include all of the influential factors that could not be related to the innovation category or the adopter's category under a social system category.

Given the above classification, Askarany (2003) suggested that the following general diffusion model (Figure 1) can be developed. This diffusion model is highly likely to be applicable to any diffusion study with minor modifications. Under this model, in general, what makes a diffusion research different from other diffusion research is the type or group of influencing factors and the kind or the number of advanced techniques. So, depending on the type of influencing factors and kind of advanced techniques, a more detailed model can be adopted from the

Figure 1. General diffusion model



suggested general model and modified to tailor a specific diffusion research. Also, depending on the research approaches (generation of innovation or adoption of innovation), the central focus of the research might change.

One of the main advantages of the presented model is that it is not only a comprehensive model that distinguishes between generation and the diffusion of innovations, but it is also a simplified model that classifies most influencing factors addressed in the literature into three main categories.

The above diffusion model does not give priority to any influencing groups. However, according to Rogers (1995), the accumulated body of literature on diffusion indicates that much effort has been devoted to studying the innovativeness and determining the characteristics of adopters, while relatively little effort has been spent on investigating how the "properties" of innovations affect their rates of adoption. He suggested that between 51% and 87% of variance in the adoption rate of innovations can be explained by the *characteristics of innovations*, suggesting that it is these that have the most significant influence on their diffusion. Highlighting this view, recent studies investigating the impact of other influencing factors (e.g., characteristics of innovators and social systems) on the diffusion of administrative innovations have failed to explain the majority of variances in the diffusion of such advanced techniques (e.g., Askarany & Smith, 2003; Beng, Schoch, & Yap, 1994; Bork & Morgan, 1993; Chenhall, 2003; Gurd, Smith, & Swaffer, 2002; Jazayeri & Hopper, 1999; Krumwiede, 1998; Lukka & Shields, 1999; Rogers, 1983, 1995; Williams & Seaman, 2001).

FUTURE TRENDS

The suggested diffusion model in this chapter is highly likely to be applicable to any future diffusion study with minor modifications. By classifying all influencing factors into three main categories, the model proposes that factors related to the characteristics of innovations are among the first influencing factors that determine whether there is a need for change, innovation, or diffusion of innovation. If an advanced technique is expected to replace an applied technique, the first question in considering such a technique for implementation by an organisation would be as follows: what are the advantages or disadvantages of the new technique compared with the existing technique? Before thinking about the other influencing factors, such as organisational culture, strategy, structures, and so on, potential adopters of an advanced technique would ask about the benefits that such an advanced technique is going to offer and that might not be achievable with their current techniques. Even when no replacement is involved, the characteristics of that advanced technique are still among the first factors that potential adopters would consider when adopting such an innovation. Further research is needed to determine the level of the impact of characteristics of innovations on their diffusion.

CONCLUSION

The technological and administrative changes of the last two decades have placed a greater emphasis on the diffusion of advanced techniques as a solution to cope with the requirements of such changes. To facilitate the implementation of advanced and up-to-date techniques and practices in organisations, this chapter explains a diffusion model clarifying different diffusion processes and influencing factors. The developed model suggests that characteristics of innovations are among the most important factors to organisations, managers, consultants, and other decision makers in making decisions regarding implementing such innovations.

KEY TERMS

Compatibility of Innovation: The degree of consistency of an innovation with the needs, expected values, and norms of potential adopters and their social systems.

Complexity of Innovation: The degree to which an innovation seems difficult to understand and use.

Diffusion: A process by which an idea, product, practice, behaviour, or object is communicated and circulated to those to whom it is relevant.

Innovation: Any idea, product, practice, behaviour, or object that is apparent as new.

Observability of Innovation: The degree to which the results of an innovation can be observed or demonstrated.

Relative Advantage of Innovation: The degree to which an innovation seems to be better than the idea, object, practice, or process, which is replacing.

Trialability of Innovation: The degree to which an innovation can be tried on a limited basis before full implementation.

Diffusion Patterns of the Internet Technology Cluster in Irish SMEs

James Griffin
Tipperary Institute, Ireland

INTRODUCTION

Electronic commerce has been recognised as a source of fundamental, pan-sectoral change to the conduct of business; Chan and Swatman (2000) use the term: "A new paradigm for doing business." Other authors have gone further, viewing modern IT developments as the latter part of a period starting in the mid-1970s that represents a transition to nothing less than a new phase of capitalist development (Amin, 1994). Benjamin, Rockhart, Scott Morton, and Wyman (1983) also suggest that the world economy has been fundamentally altered by the globalisation of competition which has largely been caused by the declining cost and consequent increasing spread of IT developments.

The resulting shift in business practices as businesses attempt to exploit these new opportunities will necessitate wide-scale adoption of new processes and technologies. Elliot and Loebbecke (2000) suggest that this requires new thinking on how organisations adopt innovations and the revision of theoretical models of adoption. Bamfield (1994) identifies innovation theory as an appropriate framework for understanding IT adoption processes. La Rovere (1998) concurs, stating that the diffusion of innovations in information technology (IT) is becoming an increasingly important area of study.

Furthermore, any overview of recent Internet-related literature will identify that the issue of mapping diffusion patterns is being increasingly affected by the range and variety of technologies that are drawn into the e-business platform. In terms of understanding the nature of Internet usage and diffusion within SMEs, it is necessary to individually measure the extent to which different elements of what essentially comprise an Internet Technology Cluster are used amongst adopting firms.

This necessitates a definition of the different elements of the Internet Technology Cluster. This can be accomplished through the analysis of past surveys and technical articles written in the field of Internet research. Three basic elements are identifiable. Firstly, several studies have identified e-mail as the most common Internet application used in business (Howe, 2001; Everett, 1998; Feher & Towell, 1997).

Secondly, many of the most common Internet technologies and applications centre around the Internet browser. Graphics, audio, HTML, and HTTP technologies are all involved in the presentation of Web sites to the viewer via the browser, whilst research and communications applications such as search engines, newsgroups and discussion groups, and online journals are viewed via the browser. These elements can be combined together under the banner of Internet browser applications.

Finally, more complex technologies based around back-end activities and remote access to Internet services (through FTP, WAP, and Telnet) can be grouped together to give an indication of the extent of usage of more advanced Internet applications.

BACKGROUND

During the summer of 2001, the author conducted a detailed survey of SMEs in six distinct geographical regions of the Republic of Ireland (three urban and three rural). The survey examined current Internet usage levels, the factors influencing the adoption decision process, and the actual benefits achieved by SMEs that have adopted the Internet.

A stratified sample frame of 700 companies was chosen from the population of 3,500 SMEs. A total usable response rate of 153 responses was achieved. Following readjustments to the sample frame size, the overall response rate for the survey stands at 23.4%.

As highlighted in Table 1 below, the current level of Internet connectivity within Irish SMEs is very high (over 90% of firms). This is no doubt a function of the high level of awareness that has been created over recent years. However, problems arise when the nature of this connectivity is examined in more detail, through the application of the cluster-based definition of the Internet.

The 90.8% of respondents with Internet access were asked to rate the extent to which they used the three separate elements of the Internet Technology Cluster. Rating of each element was on a five-point Likert scale.

In accordance with previous literature, *e-mail* was the most used Internet application, with an average usage

Table 1. Key findings related to the extent of Internet usage in Irish SMEs

	Yes		**No**	
Does your firm currently have Internet access? (n=153)	90.8% (n=139)		9.2% (n=14)	
Does your firm currently have a Web site? (n=139)	52.5% (n=73)		47.5% (n=66)	
	ISDN	**LAN**	**Dial-up**	**Unsure**
Type of connection (n=139)	23% (n=32)	8% (n=11)	62% (n=86)	7% (n=10)

rating of 3.43. *Internet browsers* received an average rating of 2.82, whilst the *Advanced Applications* category received an average usage rating of 1.43.

Only 52.5% of firms with Internet connections have a Web site of their own; this is lower than would have been expected for a 90% rate of connectivity. The type of physical Internet connection is generally a simple dial-up (62%), with few firms engaging in higher speed connections. A worrying 8% of owner managers could not even describe their connection type, suggesting a lack of understanding of, or degree of separation from, Internet applications in their organisation.

Of those respondents without a Web site, 67% did express an intention to set one up within the next 12 months. This fact, coupled with the steadily increasing Web site adoption rate depicted in Figure 1, indicates a pattern that is strongly reminiscent of the types of mimetic and bandwagon diffusion patterns described by Abrahamson and Rosenkopf (1993), DiMaggio and Powell (1983), and O'Neill, Pouder, and Buchholtz (1998). Mimetic and bandwagon diffusion patterns can best be defined as self-reinforcing diffusion patterns that effectively dismiss the technical attributes or properties of an innovation, with its level of adoption instead being a factor of the number of adoptions that have already taken place. Given the coverage and attention that the Internet has received in media, commercial, and academic circles over the past five years in Ireland, it is unsurprising that a mimetic form of diffusion pattern is evident amongst SMEs in Ireland.

CRITICAL FINDINGS

To explore the supposition that Internet technology diffusion in SMEs in Ireland may be following a mimetic pattern, it is helpful to review the main characteristics of mimetic adoption patterns. A review of relevant diffusion theory highlights two key characteristics.

Firstly, many authors, through the examination of the EDI adoption experience in SMEs, have identified a key characteristic of mimetic adoptions to be a reduction in benefit amongst organisations partaking in reactionary and later adoptions vis-à-vis firms engaging in earlier, more strategic adoptions (see Cash, 1985; Friedman, 1998; Raymond, Julien, Carrier & Lachance 1996; Swatman & Swatman, 1992).

Figure 1. Diffusion pattern of Web site development

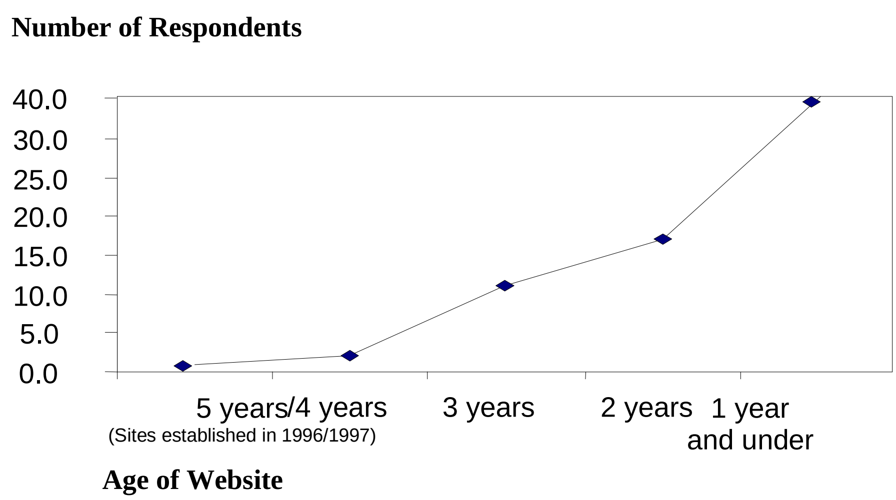

Table 2. Business benefits received compared to Web site age

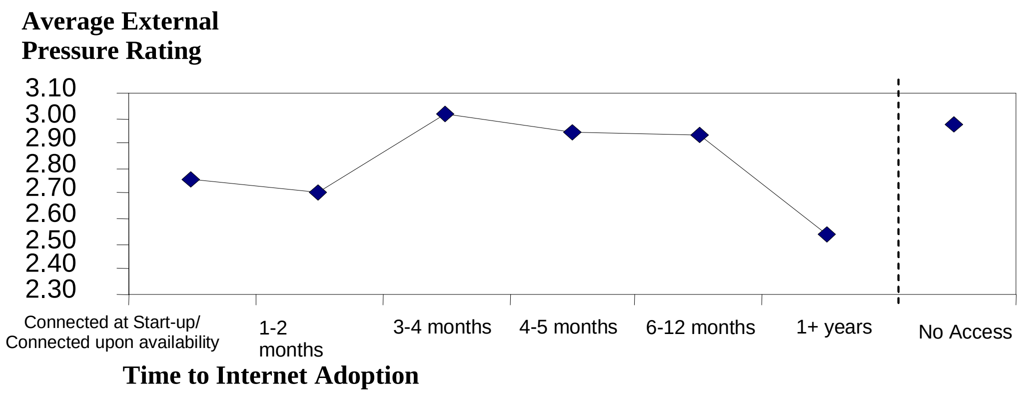
	Website usefulness factor					
	A	**B**	**C**	**D**	**E**	**F**
	Direct selling	Inquiries for offline sales	Advertising the firm	Information to customers	Informing suppliers/ retailers	Providing after-sales service
Ratings for sites over 1.5 years in existence	1.5	2.7	3.1	3.0	2.2	1.7
Ratings for sites 1.5 years and under in existence	1.4	2.1	2.7	3.1	2.2	1.4
Overall Average Ratings	**1.42**	**2.42**	**2.88**	**3.08**	**2.17**	**1.62**

Figure 2. External pressure felt by respondents (grouped by time taken to adopt)



To identify any significant differences between early and late adopters the average age of respondents' Web sites was calculated. The average age of Web sites in the sample was 1.5 years. Table 2 facilitates comparison between respondents with older and newer Web sites, and average Web site usefulness ratings.

Differences between early and late adopters in terms of benefit accrued through Web site adoption are surprisingly minimal, with both sets of ratings tending towards the lower end of the scales.

This finding highlights a major issue for the diffusion of Web technologies, namely that with low benefits accruing to many early adopters in a majority of business categories, the subsequent poor results of adoptions in these firms will represent a significant weakening of the vital '*Reputation Effect*' that sustains mimetic or bandwagon patterns. The result of this reduction in the reputation effect may well be that the sharp increase in uptake that normally gives rise to the early and late majorities in other mimetic adoption patterns may not occur in the case of the Internet and specifically in the case of Web site technologies.

Secondly, a feature of mimetic adoption patterns is that many firms, during the adoption decision process, feel increasing levels of pressure from their external environment. Authors such as DiMaggio and Powell (1983) and Pierce and Delbecq (1977) identified pressure from many elements of the multi-participant environment as creating a considerable impetus amongst later adopters to acquire the IT innovation in question. Amongst the research sample, one would therefore expect to find the level of external pressure increasing the longer a respondent takes to decide to adopt (indicating a reduction in voluntariness over time as the reputation of the innovation grows). It is evident from Figure 2, however, that the level of external pressure felt by respondents does not closely follow such a pattern.

Specifically, two interesting findings arise from Table 2 that merit deeper examination. Firstly, considerably high external pressure to adopt the Internet was reported by respondents with no Internet connectivity at all, suggesting that despite such pressure, others factors are strong enough to overcome the pressure.

Secondly, 'slow adopters' (i.e., respondents who considered their adoption for over a year) exhibited a major drop in perceived external pressure. These results suggest that the influence of peer networks and the pressures they bring to bear in relation to the Internet adoption decision process are decreasing over time, most likely due to low levels of benefits accruing to the adopting firms. This represents a significant shortening of what Thorelli (1986) termed 'innovation poles', described as the influence of peer networks (or 'macro-cultural' pressure) elsewhere in e-business literature. This is indicative of the reduction in the reputation effect of Internet technologies posited earlier, and strongly suggests that this effect has essentially reached its peak and is now beginning to decline, rather than increase over time.

FUTURE TRENDS

Consideration of these issues suggests an Internet diffusion pattern displaying an initially mimetic pattern. Difficulties arise however when we consider how that diffusion pattern is likely to develop in the future.

With the evident reduction in the reputation effect of the Internet, it is unlikely that a high rate of mimicry will continue. With this in mind, different potential diffusion patterns become apparent. These potential patterns centre on the questions: When will the late majority arrive? and Will there be a late majority?'

One conclusion from these findings may be that we may have arrived (or are arriving) at the diffusion 'plateau' described by authors such as Cooper and Zmud (1990) and Kautz and Larsen (2000) in traditional IT/IS innovation diffusions.

Figure 3. The Elongated Diffusion Pattern

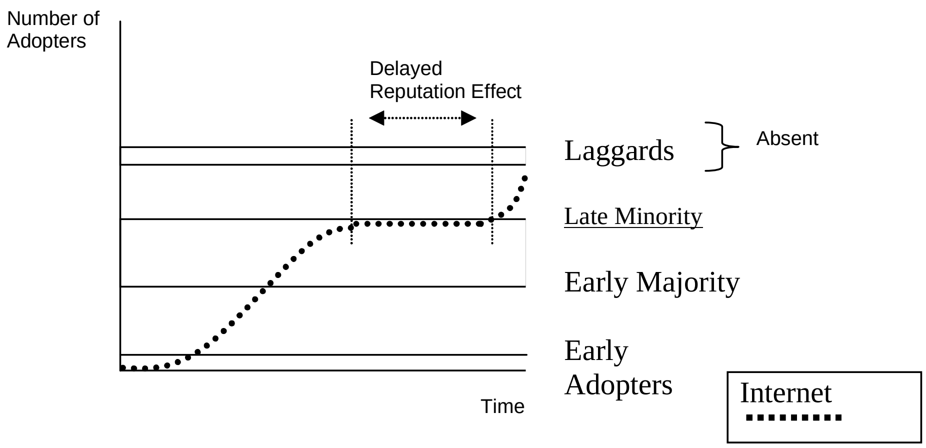


Figure 4. Dipping Diffusion Pattern

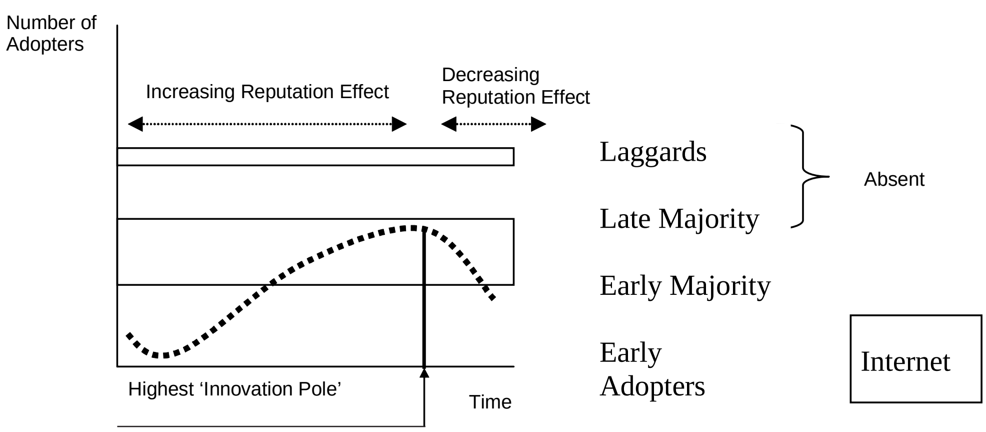

If so, the reduction in the reputation effect of the Internet and the low levels of benefits accruing to firms currently may well create a long hiatus before the 'late majority' of adopters arrive. This long hiatus represents a period where policy makers and development agencies will struggle to improve the strategic nature of current Internet adoptions within SMEs.

This could be termed a *'Delayed Reputation Effect'* and will give rise to an *'Elongated Diffusion Pattern'*. Furthermore, if we take into consideration the extremely high connectivity rates that currently exist at this stage of the diffusion process, this makes the potential numbers for a late majority much smaller than that of the early majority.

This fact, combined with the fact that a declining reputation effect will further reduce the number of later adopters, suggests that it may be more accurate to apply the term *'Late Minority'* to any further adopters of Internet technologies. This possible diffusion pattern is presented in Figure 3 below.

Another conclusion that can be reached from these findings is that we may be about to experience what can best be termed a *'Dipping Diffusion Model'* (shown in Figure 4).

If policy makers and development agencies fail to improve the strategic nature of Internet adoptions amongst SMEs, then the benefits of Web site ownership actually experienced will remain low amongst adopters. If this remains the case, it is likely that firms will become disillusioned with the entire cluster of Internet technologies. This will result in an increase in *'Internet Disconnections'*.

In such a pattern, the late majority of adopters will never arrive and disconnections from the Internet actually begin to result in a reduction in overall numbers of adopters over time.

It is important to note that Figures 3 and 4 are indicative models only and are an attempt, based on the analysis of these research findings, to identify the most likely Internet diffusion pattern that will be experienced amongst SMEs in Ireland in the future. Much will depend on the behaviour of policy makers and development agencies, and their ability to repair the damaged reputation of the Internet as a useful facilitation tool for small businesses.

When considering the advantages that this research gives us in understanding future diffusion patterns, a few points need to be clarified. The reality of which of the two potential Internet diffusion patterns discussed will actually be experienced by SMEs in Ireland can only be tested over time. As such, these findings should be viewed as creating the basis for further extensive longitudinal research in this area. Furthermore, whilst it is a necessarily accepted limitation of this research that only SMEs in Ireland have been studied, the conceptual model for this research is drawn from a wide range of established, international IS/IT literature, and in this way is suitable for application to a wider, international sample. If this approach were to be applied by other researchers in this way, more generalisations and conclusions could be made for the global audience.

CONCLUSION

A significant feature of this article is the presentation of the concept of the Internet as a cluster of technologies. The absence of this approach to date has led to much confusion in the interpretation of empirical findings. The application of the concept of an *'Internet Technology Cluster'* in further research, where technologies such as e-mail, browser, and more advanced uses are examined individually, should ensure greater accuracy in the reporting and analysis of Internet adoption and usage activity in the future.

With this issue in mind, the presentation of the Internet usage findings of this empirical research amongst Irish SMEs provides a strong basis for comparative studies in this field.

Whilst uptake is high in terms of connectivity, the nature of usage is not advanced. It is this *low-end-only* use of Internet technologies in the SME sector that has limited the benefits being derived by these firms. Consequently, firms are becoming disenchanted with their Internet experience, leading to a potentially high and damaging 'disconnection rate', and a tendency for later adopters to postpone their adoption process.

This finding has obvious policy and infrastructural implications for the development of Internet usage in Ireland. SMEs in all sectors of the economy must have access to the *sector-specific* training and support necessary for them to climb the learning curve involved in moving from basic Internet usage to the use of more advanced Internet technologies.

This research highlights the substantial training needs, telecommunications access needs, and financial supports that SMEs have regarding advanced Internet usage. If these supports are not made readily available to SMEs, usage will remain basic and benefits limited, leading to the types of problematic diffusion models predicted above.

KEY TERMS

Advanced Internet Applications: The set of more complex Internet technologies based around design activities, back-end data management activities, and remote access to Internet services.

Dipping Diffusion Pattern: A pattern of IT diffusion in which the late majority/minority of adopters never arrives and disconnections from the Internet result in a reduction in overall numbers of adopters over time.

Elongated Diffusion Pattern: A pattern of IT diffusion in which, due to a reduction in the reputation effect, there is a hiatus prior to the arrival of a late minority of adopters.

Internet Browser Usages: Internet technologies and applications that centre on the Internet browser and that are generally involved in the presentation of Web sites to the viewer, in the undertaking of research and in open-forum communications.

Internet Disconnections: The event of firms becoming disenchanted with Internet applications and removing all Internet-based applications from their organisation.

Internet Technology Cluster: The range of identifiably separate families of technologies involved in the e-business platform comprising: e-mail, browser usages, and advanced Internet applications.

Mimetic Adoption Pattern: A pattern of IT adoption amongst a population of firms in which further adoptions are a function of previous adoptions rather than strategic considerations.

Reputation Effect: The extent of association of a specific information technology with perceived business benefits amongst a population of firms over a period of time, fuelling increased visibility and sustaining a mimetic diffusion pattern.

Digital Asset Management Concepts

Ramesh Subramanian
Quinnipiac University, USA

INTRODUCTION TO DIGITAL ASSET MANAGEMENT

"DAM. Looks like something you might say if you couldn't find a photograph you needed for a front-page story. But DAM—digital asset management—is actually designed to preempt such frustrated outbursts. In an age when oodles of media, including print, images, video and audio, are stored in computers rather than file cabinets, newspapers and other groups need a way to organize, manipulate and share those media quickly and easily." (Grimes, 1998)

Dramatic changes have occurred on the corporate front in the last few years, as more and more businesses have started to conduct commerce on the Internet. New business concepts and products are being developed on a daily basis. The accent is on speed, and changes occur quickly – daily, hourly or even minute-to-minute. Two major facets of these changes are:

1. Large amounts of data are created and stored in digitized forms in organizations, and
2. New "digital products" are created.

As more and more information is created in electronic form, organizations are faced with the following problems:

- The volume of digital data has become cumbersome to manage and reuse (Sharples, 1999).
- Organizations have struggled to reduce cycle time, maintain brand consistency, and coordinate cross-media publishing as well as one-to-one marketing efforts.
- The number of digital assets that an organization may manage has exploded.
- Gistics, a California-based research firm that has studied media asset management for several years, estimates that approximately 30% of all media assets in organizations are misplaced, and then reworked or duplicated.

A 2001 Frost and Sullivan market indicator report by Subha Vivek forecasts tremendous future growth in the U.S. digital media management market (Vivek, 2001). The three market segments that will be affected represent the capture, storage and access, and distribution of digital media, respectively.

The promise of digital asset management has attracted a lot of commercial enterprises and software research laboratories, and several products have been introduced commercially in the last few years. However, due to the "newness" of the field, there is not much academic research literature in the field. A good source of academic thought in this field can be found in the online proceedings of the Annenberg DAM Conference, held at the Annenberg School of Communication, University of Southern California in 1998 (Annenberg DAM Conference, 1998).

BACKGROUND: DIGITAL ASSET MANAGEMENT (DAM) CONCEPTS

This section is adapted from our earlier paper on the subject (Subramanian & Yen, 2002).

A. Definition

A *digital asset* is any asset that exists in a digitized form, and is of intrinsic or commercial value to an organization. *Digital asset management* can be defined as a set of processes that facilitate the search, retrieval, and storage of digital assets from an archive.

B. Basic Features of DAM

The basic features of any DAM system include: storage, search and retrieval, and "thumbnail browsing" (Rosenblatt, 1998). A good DAM system will also include the ability to perform object check-in and check-out.

Other desirable features include:

- Integration of the DAM system with content creation applications on the desktop.
- Enterprise features, that is, features that are necessary for a digital media management system to be useful in a large-scale deployment at a large media company (i.e., an industrial strength, scalable database).
- The ability of a DAM system to have a user interface that can function in a cross-platform environment

(e.g., the Java language from Sun Microsystems, and the development of XML technology).
- The ability to extend the functionality of the DAM system through programming interfaces.

C. What are the basic differences between DAMs and standard data management systems?

One might argue that DAMs are not much different from currently available database management systems that facilitate the search, retrieval, and storage of data. However, DAMs are different in their potential to address four key problems that pertain to the creation, storage, search and dissemination of multi-media data. According to Hilton (Hilton, 2003), those four issues are:

1. Asset mining: New and sophisticated methods for mining multidimensional, multi-media data stores, which can result in the creation of dynamic, "on-demand" digital products
2. Automation: Automated classification and retrieval systems
3. Managing intellectual property (and associated security issues)
4. Engagement: New GUIs and other data manipulation methods as well as collaboration tools

Somani, Choi and Kleewein distinguish traditional data management systems from "content management systems" that handle digital assets, communications and content such as documents, intellectual property, rich media, e-mail and Web data, and discuss the differences between the two types of systems in the following areas (Somani et al., 2002):

1. Data federation to provide in-place access to existing data
2. An expressive data model that accommodates data from very disparate sources
3. Search over metadata and data

Somani et al. then propose an architecture for integrating the two, that is, data and content management systems. A detailed discussion of the architecture is beyond the scope of this article.

DAM SYSTEM ARCHITECTURE

Figure 1 uses a three-tiered architecture of the generic DAM system architecture to show the process followed during an asset creator's session and a client's query session.

In the *asset creation flow*, the Asset Creator creates an asset, which could be in any digital format, and provides the asset and its associated information to the Asset manager. The Asset manager converts the information associated with the asset into an XML metadata format, builds the appropriate data type definitions, and passes the information and the asset to the Metadata manager. The Metadata manager manages the organization of the Metadata Store, which is a database containing meta information on the assets. Appropriate links between the metadata and the actual assets are created and maintained here. The Metadata Store contains information about the digital assets, typically in an XML DTD format. The assets are passed by the Metadata manager to the File manager, which is responsible for the check-in and check-out of the assets into and out of the Digital Asset Store, which is a combination of file systems and databases.

In the *query processing flow*, the Client asks a query. The Query processor parses the query and sends the user information as well as the parsed query to the Metadata manager, which maintains the metadata for the assets. The metadata include not only information about the asset but also information on who is allowed to access the asset. After this information is retrieved from the Metadata store, a message is sent back to the Query processor by the Metadata manager. The message passed may either be a refusal to access the asset, or an affirmation that the requested asset is being retrieved.

The metadata component acts as a store, search, retrieve and security tool, managed by the Metadata manager.

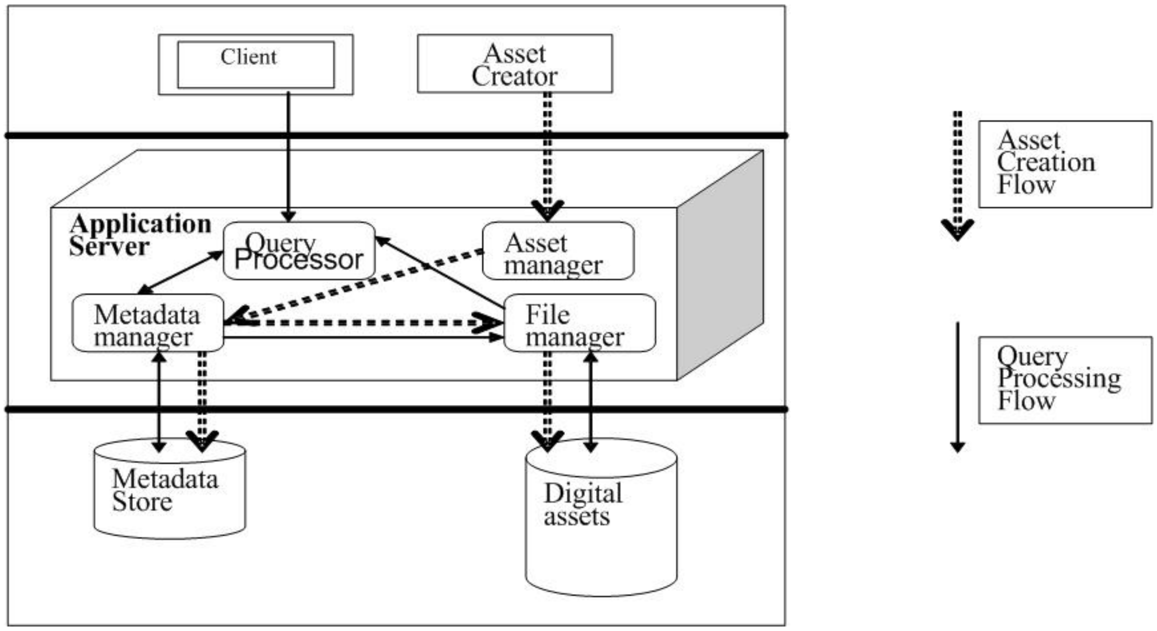
ADDITIONAL ARCHITECTURAL DETAILS

A. An Open and Distributed Architecture

The key to any digital asset management system is to create an open and distributed architecture. A well designed DAM system first should provide the ability for people to take an asset, repository or archive and be able to customize it into their environment and extend it to their existing system and other new systems. The architecture should allow for the following features:

1. Scaling
2. User Interface and Custom Interface

Figure 1. Architecture for DAM system



3. File Management and Asset Association
4. Platform Independence and Transportability

B. Representation and Identification of Digital Assets

1. Representation Issues and Addressable Unit: The three categories of digital asset representation issues are: Production Workflow, Creative Workflow, and the Addressable Unit (Romer, 1998). Production workflow is the ability for metadata to be added throughout the life cycle of digital asset handling (captioning, or cataloging), with appropriate knowledge management capabilities to establish standardization and consistency. Production workflows often deal with known items. Creative workflows are more discovery-oriented, hence more volatile and browse intensive. This workflow is characterized by the need to do many interactive searches and temporarily store candidate assets until a final decision can be made. A good DAM system must allow the designer or user to leverage this valuable production knowledge to help search for what one is looking for, by defining appropriate addressable units within a particular digital asset such as a digital video movie.
2. Identification Issues and Metadata Creation: Organizations are becoming increasingly aware that library science techniques need to be a very integral part of the process of identifying digital assets. DAM systems need to have a very sophisticated metadata model that will store and classify property information, details, names and descriptions, and anything else that the user defines and can be put on top of his/her digital assets. One promising method for classifying digital assets is through the use of "controlled vocabulary". This technique addresses how the hierarchical key words work, so that one can take a system, like the key word structure from the Library of Congress, and apply it to assets inside one's database.

C. Searching Digital Assets

1. "Top Down" Approach: Usually provides specialized searching routines that recognize the properties of the objects being searched. It is also referred to as "Content-based analysis". Image understanding and pattern recognition are all technologies that automatically process images based upon certain inherent properties of the image itself. Some examples are the color, texture and shape recognition systems from Virage (*http://www.virage.com*) or IBM's QBIC application (Faloutsos et al., 1994; Flickner et al., 1995). "Search extenders" facilitate content-based searching of digital files (e.g., content base searching of textural images). Bulldog's Search Extender™ technology allows the search mechanism to recognize the properties of various file types and implement specialized searching routines. They allow users to do context searching,

such as finding the name "Bulldog" very close to information about Sun Microsystems inside the database. Equivalent search extender technology exists for images, video and audio.
2. "Bottom Up" Approach: A method is to design image representation schemes that will match the goals of the search process used for retrieval. The search sub-system was designed with decision support in mind.

TAXONOMY OF DAM SYSTEMS

We have categorized the DAM systems based on two criteria. The first criterion is based on how many people DAM systems need to serve, the price range and their complexity level. In this criterion, DAM can be divided into three categories (Rosenblatt, 1998):

1. The Enterprise category, to give an organization the capabilities to be scalable and with industrial strength. It typically costs in the millions of dollars.
2. The Mid-range category, where the system is purpose-built for a specific asset management purpose. They typically cost in the one hundred to five hundred thousand dollar range.
3. The Low-end category, for basic, low-end solutions that are useful for small installations. These systems cost typically cost around $50K. These are systems that just have basic features, and they run on work group class servers.

The second criterion we use is based on several representative functions of the DAM.

1. The Image Cataloging Feature: With image cataloging feature, systems capture low-resolution thumbnails.
2. The Object Repository Feature: With object repository feature, systems can capture not only thumbnails and metadata, but also high-resolution media files.
3. Content Management Back End for Web Sites Feature: This provides service/editorial environment with content management for the Web. The content can be in different file formats, such as text, graphics, multimedia, XML, and SGML documents.
4. Intelligent Cataloguing and Indexing Feature: This intelligent cataloguing and indexing feature has Web-based interface with intelligent navigation tools, allowing the user to search and organize images, video, audio and text documents easier and more efficiently.

PROTECTION AND DISTRIBUTION ISSUES OF DIGITAL ASSETS

Digital Assets Protection

The rapid growth of multimedia manipulation tools and the wide availability of network access lead to the convenience of digital data processing, delivery and storage. Powerful digital facilities can produce a large amount of perfect digital asset copies in a short period of time. The advanced compression technology also contributes to make the digital content compacted into a small data stream to facilitate transmission. These advantages benefit content users, definitely to raise concerns from content creators and content owners if the intellectual property right cannot be enforced successfully (Su et al., 1999). This is especially true in the present time, which has seen the rapid proliferation of peer-to-peer online file sharing systems such as Napster and Kazaa (Subramanian & Goodman, 2003). Yet, it has been noted by several researchers that senior corporate executives rarely pay a whole lot of attention to computer security and the security of digital assets. Austin and Darby discuss the types of threats that a company is apt to face and propose eight processes, ranging from deciding how much protection each asset receives, to insisting on secure software, to rehearsing a response to a security breach (Austin & Darby, 2003). We discuss the subject of digital assets protection from three different viewpoints, that is, legal, technical and non-technical means to ensure protection of digital assets:

1. Legal Methods: Patents, Copyrights, and Trademarks: A patent is a grant of exclusive right that is given by the government to anybody who files an application for patent protection. It confers upon the applicant the right to exclude everyone else from making, using or selling that patented invention. The term of protection offered by a patent is shorter than that of a copyright by a good deal. The term of protection for a patent is generally 20 years from filing throughout the world. Under the U.S. patent system, that protection is available for any invention. Anything that can be conceived of by humans and put into practice in a useful way that is new and novel can be subject to patent protection. This includes any creation of a human's mind, such as drugs, pharmaceuticals, computer software, inventions, processes, methods of manufacture, chemical compounds, electronic devices, and so forth.
A copyright protects an original work of authorship. The term of protection for a copyright under

the U.S. law is "life of the author and fifty years for the case of a work made in the course of employment by an employee working for an employer". Under certain conditions, the protection period for the latter case could be 75 years from publication or 100 years from creation, whichever expires first. There is a proposal currently in the U.S. Congress to extend the term of copyright protection by an additional 20 years, to bring it up to the level that is guaranteed in the European Union.

A trademark is a right that attaches to a marking used to identify goods and commerce. It helps serve as a guarantee of the source of those goods for consumers, so you know where they come from and you may have expectation as to the quality associated with that mark. Trademarks may be registered with the USPTO; they may also be registered with state authorities. Many states have their own trademark registries. Trademarks can also arise by the operation of common wall.

Copyright laws can be separated into the Anglo-American and the European copyright laws. The Anglo-American laws are followed by America, Great Britain and other British colonies. They adopt a pragmatic, market-oriented approach towards copyrights. On the other hand, under European laws, the copyright is seen as a basic fundamental human right. The economic incentives that it provides are secondary to insuring the protection of someone's personality.

2. Technical Methods for Intellectual Property Protection: Encryption and watermarking are the two most important digital assets content protection techniques. Encryption protects the content from anyone without the proper decryption key. There are two types of encryption existing: symmetric (secret-key) mechanism and asymmetric (public-key) mechanism. Symmetric mechanism uses the same security key to "lock" and scramble a digital file and to recover a bit-exact copy of the original content at the destination. Asymmetric encryption employs dual keys. The sender encrypts the digital with the recipient's public key, and the recipient decrypts it with his or her private key (Cravotta, 1999). Watermarking, on the other hand, further protects the content by embedding an imperceptible signal directly into the content for ownership declaration, play control or authentication (Su et al., 1999).
3. Non-technical methods for intellectual property protection: "This has to do with our providing products at a value above and beyond that provided by those who would pirate our products" (Griffin, 1998).

Digital Assets Distribution

In order to manage the asset owner and the user, the owner of a digital asset must be able to determine the usage scenarios that are appropriate for the asset. The scenarios are summarized by the notion of placement, size, duration, and extent. License management refers to the legal terms and conditions that apply to the specific usage scenario.

CONCLUSION AND FUTURE DIRECTIONS

In the era of e-commerce, digital asset management is emerging as a very hot topic of study for both practitioners as well as researchers. In this article we discuss different concepts and issues of DAM, which include but are not limited to the components and architecture of DAM systems, its basic and desirable features, the taxonomy of DAM systems, and protection and distribution sub-systems of DAM. There are several open issues for research in DAM. A list of these issues includes but is not limited to modeling the storage and organization of digital assets, the digital assets valuation, pricing, rights and licensing models, and methodologies for optimal search and retrieval of digital assets. In a future study, we plan to address some of these open issues.

KEY TERMS

Addressable Unit: A specific unit within a particular digital asset such as a digital video movie.

Asset Creator: Anyone who creates an asset, which could be in any digital format, and provides the asset and its associated information to the asset manager.

Asset Manager: The asset manager converts the information associated with the asset into an XML metadata format, builds the appropriate data type definitions, and passes the information and the asset to the metadata manager.

Creative Workflow: These are more discovery-oriented, hence more volatile and browse intensive. This workflow is characterized by the need to do many interactive searches and temporarily store candidate assets until a final decision can be made.

Digital Asset: A digital asset is any asset that exists in a digitized form, and is of intrinsic or commercial value to an organization.

Digital Asset Management (DAM): Digital asset management can be defined as a set of processes that facilitate the search, retrieval, and storage of digital assets from an archive.

Digital Asset Store: A combination of file systems and databases.

Metadata Manager: The metadata manager manages the organization of the metadata store, which is a database containing meta information on the assets.

Metadata Store: The metadata store contains information about the digital assets, typically in an XML DTD format.

Production Workflow: It is the ability for metadata to be added throughout the life cycle of digital asset handling (captioning, or cataloging), with appropriate knowledge management capabilities to establish standardization and consistency. Production workflows often deal with known items.

Search Extenders: Methods that facilitate content-based searching of digital files.

Digital Government and Individual Privacy

Patrick R. Mullen
U.S. Government Accountability Office, Washington, DC, USA[1]

INTRODUCTION

Individual privacy is freedom from excessive intrusion by those seeking personal information about the individual. This allows the individual to choose the extent and circumstances under which personal information will be shared with others. A related concept, confidentiality, is a status accorded to information based on a decision, agreement, obligation, or duty. This status requires that the recipient of personal information must control disclosure. While privacy and confidentiality are concepts that can be applied to people in all societies, this article discusses them in relation to their treatment by the United States government, in particular with the advent of digital government. The concepts associated with digital government can also apply to non-Americans as well, but the discussion in this article is based on U.S. laws, documents, and relevant literature.

BACKGROUND

The growth of the Internet and digital government—that is, e-government—has dramatically increased the federal government's ability to collect, analyze, and disclose personal information about many private aspects of people's lives. Such information, once available only on paper to a limited number of people, is now instantly retrievable anywhere in the world by anyone with a computer and an Internet connection, including by hackers and firms specializing in selling information on individuals. At the same time as this dramatic increase in digital government, the level of trust in government has declined (Council for Excellence in Government, 2001); currently, many Americans perceive the government as a potential threat to individual privacy. Given these forces at work in American society, one should not be surprised to read the results of surveys that show privacy as a top concern of Americans in the 21st century. If Americans do not believe that the government is adequately protecting individual privacy, they may be less willing to provide the government with information. For example, most surveys by statistical agencies are voluntary, and even others that are mandatory, such as the decennial census and the American Community Survey, can suffer from underreporting by respondents. Such reluctance could compromise the ability of government to collect information necessary to develop, administer, and evaluate the impact of various policies and programs (Mullen, 2004).

FUTURE TRENDS

Generally speaking, e-government refers to the use of technology, particularly Web-based Internet applications, to enhance a specific agency's Web site, for access to and delivery of government information and services to individuals, businesses, and other organizations and government agencies. E-government has been seen as promising a wide range of benefits based largely on harnessing the power of the Internet to facilitate interconnections and information exchange between citizens and their government. A variety of actions have been taken in recent years to enhance the government's ability to realize the potential of e-government, culminating in the enactment of the E-Government Act of 2002 (Public Law 107-347), which includes provisions addressing everything from funding of e-government initiatives to measures for ensuring security and privacy. In addition to the E-Government Act, President George W. Bush designated e-government as one of five priorities in his management agenda for making the federal government more focused on citizens and results. The goals of President Bush's e-government initiative are summarized in Table 1.

Schelin (2003) discusses the rapid growth of e-government and provides an overview of the historical premises, theoretical constructs, and associated typologies of e-government that are a framework for understanding e-government and its potential benefits and related challenges. While the Internet opens new opportunities for streamlining processes and enhancing delivery of services, federal executives and managers must also be cognizant of the responsibilities and challenges that accompany these opportunities (Garson, 2003; Pavlichev & Garson, 2004; U.S. General Accounting Office, 2001a). Some of the responsibilities and challenges associated with managing e-government are summarized in Table 2.

Table 1. Goals of President Bush's e-government initiative

According to the President's management agenda, e-government is expected to:

- provide high-quality customer services regardless of whether the citizen contacts the agency by phone, in person, or on the Web;
- reduce the expense and difficulty of doing business with the government;
- cut government operating costs;
- provide citizens with readier access to government services;
- increase access for persons with disabilities to agency Web sites and e-government applications; and
- make government more transparent and accountable.

Table 2. Summary of e-government responsibilities and challenges

- Sustaining committed executive leadership
- Building effective e-government business cases
- Maintaining a focus on the individual
- Protecting individual privacy and confidentiality
- Implementing appropriate security controls
- Maintaining electronic records
- Maintaining a robust technical infrastructure
- Addressing IT human capital concerns
- Ensuring uniform service to the public
- Empowering citizens in democratic processes

PERSPECTIVES ON PRIVACY

In American society, there is an inherent tension between the desire for the free flow of information versus the concern for maintaining individual privacy. This tension is captured in various congressional statements, included in legislation as well as in executive branch guidance to agencies, which explain how to carry out their seemingly conflicting responsibilities under the law. For example, in passing the Paperwork Reduction Act of 1995, the Senate Governmental Affairs Committee (1995) noted that "information obtained by government is a valuable and useful resource to government and society, if managed in a coordinated and systematic manner." The committee also noted the importance of the free flow of information:

"The advent of the electronic information age presents new opportunities and obligations of the Federal government as it strives to fulfill its continuing responsibility to make government information accessible to the American public. The legislation meets this need by providing for improved dissemination of government information to the public, particularly in electronic formats."

However, these same technological trends also raise concerns about information privacy. As Congress stated in passing the Privacy Act (1974):

"…the increasing use of computers and sophisticated information technology, while essential to the efficient operations of the Government, has greatly magnified the harm to individual privacy that can occur for any collection, maintenance, use, or dissemination of personal information."

While the Privacy Act is the primary law regulating the federal government's collection and maintenance of personal information, the legislative intent has been clarified with subsequent Office of Management and Budget (OMB) guidance to federal agencies. OMB's circular on "The Management of Federal Information Resources" (Circular A-130) also captures the balance between the free flow of information versus individual privacy (U.S. Office of Management and Budget, 2000), addressing (1) the need for agency Web sites to post clear and easily accessed privacy policies and (2) federal agency use of Internet cookies—short strings of text sent from a Web server to a Web browser when the browser accesses a Web page—which poses privacy risks because the data contained in persistent cookies may be linked to individuals after the fact (U.S. General Accounting Office, 2001b). In addition, the Federal Trade Commission (FTC) has issued four Fair Information Principles governing online privacy at commercial Web sites. These principles can be used as criteria to assess federal agency Web sites (U.S. General Accounting Office, 2000; Center for Democracy and Technology, 1999). The principles are included in Table 3.

PROTECTING INDIVIDUAL PRIVACY

Individual privacy is closely related to data confidentiality and security (Boruch & Cecil, 1979; Duncan, Jabine &

Table 3. FTC's fair information principles

1. Notice. Data collectors must disclose their information practices before collecting personal information from consumers.
2. Choice. Consumers must be given options with respect to whether and how personal information collected from them may be used for purposes beyond those for which the information was provided.
3. Access. Consumers should be able to view and contest the accuracy and completeness of data collected about them.
4. Security. Data collectors must take reasonable steps to ensure that information collected from consumers is accurate and secure from unauthorized use.

de Wolf, 1993; Lowrance, 1997; U.S. General Accounting Office, 2001c). If a breach in data confidentiality were to occur, individual privacy might be affected. And a breach in security might affect both confidentiality and individual privacy. By the same token, protecting confidentiality—through various security measures—helps protect individual privacy. The concepts and practices of good data stewardship are important for federal agencies to understand in their role as protectors of individual privacy. A loss of confidence in federal agencies' ability to protect individual privacy would have serious consequences for individuals' trust and participation in government programs. With respect to e-government issues, two key factors are:

1. **Privacy Status:** Whether or not the information about an individual, including his or her personal attitudes or experiences, is known to another.
2. **Privacy Rights:** Whether the individual has control over whether information is shared with anyone else.

Many definitions of individual privacy emphasize privacy rights. Logically, however, an individual's privacy may be preserved, enhanced, or reduced by the choices that he or she makes, as well as by the actions of others, specifically excessive intrusion.

In ensuring individual privacy, the federal government faces challenges while implementing e-government. For example, record linkage is sometimes seen as reducing privacy because of the additional information provided about the individual (the whole may be greater than the sum of its parts). Conversely, record linkage has sometimes been viewed as enhancing individual privacy because the collection of new data may be avoided. Because agency public use data files and Web sites now make the results of research and statistical programs widely available to the public, there is an increased need to make sure that the confidentiality of personal data is strongly protected and that re-identification risks are guarded against.

The Privacy Act can be viewed as striking a balance between government needs for information and individual privacy interests. To strike this balance, the Privacy Act contains requirements that implement the principle of openness, which is similar to the FTC's fair information principle of notice. This principle dictates that an agency of the federal government must be open about its record-keeping policies, practices, and systems that relate to individual privacy. The requirements implementing the openness principle are intended to achieve two general goals:

1. facilitate public scrutiny of federal agency record-keeping policies, practices, and systems by interested and knowledgeable parties; and
2. make the individual aware of systems in which a record on him or her is likely to exist.

Specifically, the Privacy Act applies these goals only to information maintained in a system of records and allows exceptions, under various circumstances, to the disclosure and use of information without the consent of the individual. The advent of e-government has brought new challenges for federal agencies in complying with the principles of the Privacy Act. In addition, various rules and regulations to implement the Privacy Act have been updated in attempts to make these requirements relevant in the era of the Internet and Web-based applications.

The government cannot realize the full potential of the Internet until individuals are confident that the government will protect their privacy when they visit its Web sites. To ensure that individuals understand how their personal information is handled when they visit federal Web sites, OMB issues circulars and memorandums, in accordance with the openness principle. For example, OMB's M-99-18 memorandum requires federal agencies to post privacy policies on their Internet Web sites, providing guidance for doing so. Specifically, the memorandum requires each agency to post privacy policies to: (1) its principal Web sites; (2) any other known, major entry points to the Web sites; and (3) any Web page where substantial personal information is collected from the public. The memorandum also requires agencies to post privacy policies that clearly and concisely inform visitors to the Web sites what information the agency collects about individuals, why the agency collects it, and how the agency will use it. Finally, the memorandum requires that privacy policies are clearly labeled and easily accessed when an individual visits a Web site.

CONCLUSION

New information technologies offer many possibilities for the government to improve the quality and efficiency of its service to individual Americans. Web sites are powerful tools for conveying information on federal activities, objectives, policies, and programs. Web sites also provide a simple and quick way for accessing information about the government and what it is doing on the individual's behalf. Congressional interest in the benefits of e-government and Internet-based operations has resulted in the passage of laws designed to encourage the deployment of e-government functions, while also protecting individuals' privacy. Increasingly, federal agencies are using the World Wide Web and other Internet-based applications to provide online public access to information and services, as well as to improve internal business operations. These developments have naturally resulted in concerns about protecting the privacy of individuals for whom (1) information is electronically available and (2) access to information on federal agency Web sites is intended. Therefore, for digital government to succeed, it is critical that agency officials and staff, such as privacy officers and advocates, disclosure officials, and survey managers, exercise good stewardship of the data for which they are responsible. They can exercise good stewardship by guarding data subjects' personal privacy, as well as data confidentiality and security, through use of cybersecurity practices, such as public key infrastructure (PKI) technology.

KEY TERMS

Confidentiality: A status accorded to information based on a decision, agreement, obligation, or duty. This status requires that the recipient of personal information must control disclosure.

Cookies: A short string of text that is sent from a Web server to a Web browser when the browser accesses a Web page. The information stored in a cookie includes the cookie name, the unique identification number, the expiration date, and the domain.

Individual Privacy: Freedom from excessive intrusion by those seeking personal information about the individual. Allows for the individual to choose the extent and circumstances under which personal information will be shared with others.

Public Key Infrastructure (PKI): A system of computers, software, and data that relies on certain sophisticated cryptographic techniques to secure online messages or transactions.

Public Use Data Files: Electronic computer files containing the results of federal research and statistical programs that are made available for public use, often on agency Web pages.

Record Linkage: A computer-based process that combines sources of existing personal information with additional information that refers to the same person, or to his or her family, friends, schools, employer, area of residence, or geographic environment.

Re-Identification: The risk that publicly released data could allow public identification of a survey respondent's information or could be used in a way harmful to them. Federal agency data releases must comply with statistical disclosure limitation methods to guard against this risk.

Stewardship: Management of another's property, affairs, or, in this case, data. For agencies, stewardship includes functions of officials and staff, such as privacy officers and advocates, disclosure officials, and survey managers. Stewardship carries responsibility for data subjects' personal privacy, as well as data confidentiality and security.

Digital Literacy and the Position of the End-User

Steven Utsi
K.U.Leuven, Belgium

Joost Lowyck
K.U. Leuven, Belgium

INTRODUCTION

As an educational setting, the traditional classroom fails to meet the learner's need for suitable skills to learn with educational software. The development of digital learning skills in school curricula challenges designers of educational software. A useful starting point of research in this domain is the study of literacy, both in its traditional and new forms (Tyner, 1998). It is a powerful background for research on the interaction of learners with educational software platforms. A "platfom" is a particular software package, designed for educational use.

BACKGROUND

Both in school and society, the skill to comprehend and handle printed course materials is essential. Literacy has since long been a vital skill for functioning adequately in an industrial society (see e.g. Marvin, 1984).

An Emerging Plural Notion of Literacy

The International Adult Literacy Survey (IALS) describes literacy as a broad range of information processing skills in relation to written or printed language. Traditional literacy is defined as follows (OECD, 1997, p. 2):

"Using printed and written information to function in society,to achieve one's goal and to develop one's knowledge and potential."

However, traditional literacy is increasingly evolving into a new, plural literacy that refers to making sense of meaningful content in more complex and technological environments (Erstad, 1998). The growing importance of images and of communication technologies has a cultural backlash that even transforms the nature of literacy. Gee (1990) opened up so-called "New Literacy Studies" (NLS). He defends a socio-cultural approach of literacy (p. 153):

"Literacy is the mastery of, or fluent control over, secondary discourse."

While primary discourse pertains to infant face-to-face interaction of children with trusted figures (parents, family, and others), secondary discourse develops through contact with public life and its social and cultural conventions. Secondary literacy is in itself a plural concept: a multitude of social institutions and commitments to public life invade an adult's life and are as many "literacies" to master. As Walter (1999, p. 34) points out:

"The existence of multiple literacies, none more valid than the next, but each specific to a culturally-defined community."

According to this plural notion of literacy, literacy can be neither neutral nor universal, since all literacy includes social and cultural conventions that shape a particular type of "literacy". Visual literacy, for instance, complements traditional literacy and claims a unique position in today's school curriculum. Debes (1969) first mentioned "visual literacy". According to visual literacy, a specific "image" language supports communication. In traditional language, words support verbal communication. Visual literacy may not only be a means of communication, but also a way of thinking (Hortin, 1983). Thinking visually, then, means the ability to think and learn in terms of images. And children's acquisition of skills to work effectively and efficiently with educational software has to underpin this recent position of a new and full interpretation of literacy.

Undoubtedly, it is of prime importance to analyse the nature of skills necessary to take full advantage of today's learning opportunities. In a visual oriented culture the acquisition of new reading and writing skills is indispensable, e.g. the analysis and composition of images. Indeed, literacy supposes an active intervention in a social and cultural context. Avgernou and Ericson (1997) define visual literacy as a group of skills that make it possible for an individual to understand and use visuals for intentional communication with others. This concerns different target groups, for instance primary school pupils or even impaired children.

During the last decade, a wide array of "literacies" relating to information and communication technologies (ICT) surfaced: media literacy (Hobbs, 1998; Potter, 1998), electronic literacy (Maylath, 1993), multimedia literacy (Kellner, 1998), computer literacy (Guthrie & Richardson, 1995; Peha, 1995), and digital literacy (Gilster, 1997). This evolution accompanies the expansion of IT to ICT. Indeed, communication is now a central feature of technological environments, clearly depending on both "traditional" and "new" literacies (Plowman & Stephen, 2003):

"(…) the flexible and sustainable mastery of a repertoire of practices with the texts of traditional and new communication technologies via spoken language, print and multimedia."

The overarching notion "information literacy" denotes the ability to access, retrieve, manage, and use information relevant to an identified need for information (Kuhltau, cit. in Campbell, 1994). Originally, information literacy was limited in scope to computer information. The progress of computer sciences and, more generally, the use of ICT in a wide array of domains broadened its meaning into library skills, computer skills, thinking skills, and critical reading skills.

Media literacy pertains to communication through and critical analysis of a diversity of media; it is the end user's ability to navigate both effectively and efficiently and to keep track of position in electronic media, while "criss-crossing the landscape" (Spiro, R. J., Feltovich, R. L., Jacobson, M. J., & Coulson, R. L., 1991). Gilster (1997, p. 1) defines digital literacy as follows:

"(…) the ability to understand and use information in multiple format from a wide range of sources when it is presented via computers."

Computer literacy is the ability to integrate information and build a personal knowledge base. Both electronic literacy (e-mail reading skills) and multimedia literacy (technical multimedia skills) are building blocks of more general "computer" literacy. Electronic and multimedia literacy explain, for instance, the comprehension of hypertext.

When comparing different "literacies", two observations are important. First, critical analysis, interpretation, and processing of information are attributed to media literacy and digital literacy. The processing and integration of information (computer literacy) and technical skills (electronic and multimedia literacy) have to be critically evaluated by computer users. Secondly, without the notion of traditional and visual literacy, none of the newer forms of literacy can be understood. Indeed, media and digital literacy acquire meaning for users through similar basic mechanisms as traditional and visual literacy. Literacy education elucidates implicit messages, ideological content or even idiosyncratic intentions designers may embed in software packages. On the other hand, the study of ICT related literacies informs software designers of problems encountered by learners with educational software platforms. Traditional issues are accessibility of information and user interface design.

Current Research Questions

The "literacies" debate is a theoretical starting point. Empirically, the detection of specific skills that explain interaction with educational software -digital literacy- is a first research path. These skills have to be integrated in the school curriculum and are treated as abilities underlying new "literacies". Before any application of theoretical insights, a primary research question has to pertain to the relationship between "operational skills" (searching, clicking, and/or dragging screen and user interface objects) and content comprehension in educational software. Is retrieval of information influenced by the mastery of operational skills?

Moreover, information can be represented through text, visualization, or talk. Does the integration of these different symbol systems in educational software alter the typical linear end-user interaction with the computer screen interface? The most common pattern of software use is sequencing interface screen after interface screen in a so-called linear fashion. Clicking hotspots and exploring additional in-depth layers of screens, providing e.g. background information, are seldom spontaneous actions. This type of research question addresses conditions that facilitate "switching content" in -for instance- an educational software package fitted out with hotspots and hyperlinks. The content of an educational platform can for example be organized in an adventure game with hyperlinks, combined with an illustrated encyclopaedia supporting the game with textual and verbal background information. A related question points to the relationship between switching content and retrieving or remembering information afterwards. Is switching detrimental to retrieval of information or does it on the contrary support memory?

Research with 3rd and 4th graders using a multimedia comic strip about World War II (see Utsi & Lowyck, 2002) revealed end-users to anticipate crucial events: they look for objects in the interface screens that most probably will play a crucial role in the next few screens. Mere reactions to audio-visual events in interface screens steadily fade, while searching, clicking, and/or dragging objects become increasingly well-considered throughout the user-interface interaction. Throughout the process, visual literacy gradually changes from superficial use of visual cues to deeper comprehension of educational content. Thus, visual literacy is an essential condition for meeting the educational goals. Multimedia literacy skills are effortlessly acquired on the spot: clicking and dragging objects pose no problem. When first confronted with a new educational software platform, visual literacy seems narrowed to multimedia skills, like clicking and dragging, but gradually visual literacy opens up again to more thoughtful, content driven interaction with all the platform's trimmings.

FUTURE TRENDS

Future studies in this research field can make use of the cognitive load model of Kalyuga, Chandler, and Sweller (2000), who suggest a trade-off effect between text and visual cues. Cognitive load can be defined as the amount of mental resources necessary for information processing. High cognitive load requires the end-user to spend extra memory resources to deal with new incoming information. Accordingly, text and visual cues compete for attention of users since the cognitive span of learners is limited, while effort needed for both task completion -clicking one's way through the platform's interface screens- and content comprehension requires maximum investment of cognitive resources and attention (see also Kirschner, 2002). The trade-off of text and visual cues (Utsi & Lowyck, 2002) yields a clear distinction between low performing pupils clinging to visual cues and the ones who use the full range of novel experiences and skills offered in the educational platform.

Processing and integrating information from different sources is a digital and "computer" (Guthrie & Richardson, 1995; Peha, 1995) literacy skill that may acquire its place in school curricula in due time. Recent and future studies can provide input for implementing research findings with regard to digital literacy in educational software. Like any other type of ICT, educational multimedia runs through a cycle of design, development, and implementation. The shift, in the strip story mentioned above, from the user's shallow reactions to visual stimuli toward anticipation of events is a leading theme. This anticipation can be triggered by visual cues or by story line comprehension. Pupils seem to encounter difficulties to cope with the different layers of multimedia information: text, pictures, motion, music, and sound. They hardly break up the linear nature of the "storyline": background information is scarcely accessed. A core concern while designing, developing, and implementing educational media is the trade-off of textual and visual information in educational multimedia, hampering the break up of linear content material. Textual and visual symbol systems compete for the attention of learners, involved in learning with educational software.

Designers of educational software need to try and ease the integration of text and visuals. Throughout the realization of educational software, care should be taken that the precise role of hyperlinks and hotspots is clear to the user. Indeed, available cognitive span is highly occupied by an educational platform using different symbol systems, such as textual and visual information. The end user's decision to access an additional content layer in the platform needs to be an informed decision. If the learner does not know where a hyperlink or a hotspot will lead to, he may neglect to select the hyperlink, because he is not aware of the relevance of this information for the task at hand. The type and relevance of information hyperlinks and hotspots can be realized through embedded, formal features (for instance glowing or blinking) that signal the information value of a hyperlink or hotspot.

Furthermore, educational software platforms presenting information and exercises in a rousing setting, for instance in an adventure game context, need to ensure that a balanced arch of task tension is built up throughout the platform. Task tension is the "track" of the learner to reach intermediary goals that eventually lead to a successful mastery of an assignment. Regularly, the learner has to be attended to the end goal, for example retrieving a tool for repairing a space ship. This tool has to turn up visually from time to time or nearing it may be signalled by a characteristic sound. Ideally, this arch of task tension implies a series of pauses: moments for the learner to relax and explore course content from another point of view, for instance through the access of background information. Ultimately, tension is discharged in a culminating accomplishment of the assignment or end goal. Pauses can be created through opening up rigid linear progress from one content element or exercise to another and/or and through filling in the "gaps" with interesting, but distracting information or modest tasks. In an educational adventure game, for instance a journey through outer space, a simple, but distracting lottery game can be integrated, without any relevance for the end goal of the adventure game: retrieving a tool for repairing a space ship. Educational material that is presented in a serial, linear fashion without consideration of the limited processing capacities of young learners is doomed to be incompletely and thus inadequately processed.

Information sticks better when the end user's attention is triggered by repeating screen elements that suggest an optimal route across specific content elements offered at a learner's initial level. The design, development, and implementation of educational ICT need to balance the signalling function of visual cues, routing pupils' clicking behaviour, and the effort of learners to look for content, relevant for reaching goals. In educational software, this can for instance be achieved via a "road map", lending learners a hand in orienting themselves on the way to their goal. Small screen elements cue the learner's attention and break up the linear character of traditional course material, if presented in a low task tension context.

CONCLUSION

Digital literacy is a baseline set of skills for successfully coping with a complex, often technological world, holding multiple media messages. In line with traditional reading and writing training, digital literate learners may also cope successfully with new ways of communicating. Digital literacy comprises technical computer skills (searching, clicking, and/or dragging) and visual cue awareness that triggers reading and deepened understanding of information. Support of the user-platform interaction needs to be embedded in the design, development, and implementation of educational software platforms. This interaction is more than merely user-friendly, but it is challenging the in-depth understanding of the information at hand. Cognitive load is an important constraint for unconcerned use of educational software. Apart from hampering processing and transferring information to memory, cognitive load undermines spontaneous exploration across content layers. The linear nature of most actual course material can be broken up by the users' inquisitiveness, but only if they decide to do so and if actions to switch to parallel content layers in an educational software platform do not imply a cognitive burden. The integration of visuals and other media types, text and sound, has to be well-considered. Consistent appearance and use of hyperlinks and hotspots, an arch of tension with some moments to pause, and repeating screen elements are important in designing an appealing and effective educational software platform.

KEY TERMS

Children: Tutees, enrolled in primary school.

Cognitive Load: Amount of mental resources necessary for information processing.

Educational Software: Software packages, supporting specific goals in the education of target groups, e.g. primary school tutees or impaired children.

End-User: Tutee, working with dedicated educational software packages.

Impaired Learners: learners, hampered by physical of psychological deficiencies.

Instructional Design: Lay-out of an optimal integration of educational content and interface lay out of end-user software.

Learning: Cognitive processing and integration of new educational content, if possible induced through exercises or games.

Literacy: Operational and cognitive skills, necessary to work effectively and efficiently with educational software.

Digitization of Library Information and Its Accessibility for People with Disabilities

Axel Schmetzke
University of Wisconsin-Stevens Point, USA

INTRODUCTION

After 20 years of digitization efforts, hardly a single type of library information resource remains that has not shifted, at least to some extent, to an electronic, Web-based format: information about the library itself, catalogs, indexes, dictionaries and encyclopedias, books and journals, tutorials, reserve materials and reference services. The online migration of these resources has opened unprecedented opportunities to people with "print disabilities", who cannot independently access printed works because of lack of sight, dyslexia or insufficient motor control (Coombs, 2000), but who are able to access electronic text with the help of assistive input and output technology, such as modified computer keyboards and screen readers with speech or Braille output (Mates, 2000; Lazzaro, 2001).

The extent to which these new opportunities become realized depends on the design of the Web environment. From the perspective of accessibility, design in the online world matters as much as it does in the physical world. This article seeks to determine the extent to which the library profession addresses the need of people with disabilities for accessibly designed online resources—by reviewing the professional library literature for coverage of this issue, by summarizing empirical accessibility studies, and by analyzing pertinent policies adapted by libraries and their professional organizations.

COVERAGE OF ONLINE ACCESSIBILITY IN THE LIBRARY LITERATURE

In 1996, accessible Web design began to emerge as an issue in the professional library literature. Since 1999, there has been a noticeable increase in library-related journal publications that investigate the accessibility of Web-based library information, seek to raise awareness concerning the need for accessible Web design, and provide practical tips (for a detailed overview, see Schmetzke, 2003, pp.153-156). Since 2001, two library journals, *Computers in Libraries*, "Making Sure", 2001), and *Library Hi Tech* (Schmetzke, 2002a, 2002b) have devoted special-theme issues to online accessibility; *Information Technology and Disability* reports regularly on the subject. In 1999, the American Library Association began publishing monographs that addressed accessible Web design (Lazzaro, 2001; Mates, 2000; McNulty, 1999). Gradually, accessibility is acknowledged as an important aspect even in more general works: While some authors, such as Pace (2003) in his book *The Ultimate Digital Library*, continue to ignore the issue, others deal with it, at least briefly, in connection with topics such as Web page design (Garlock & Piontek, 1999), Web site usability testing (Norlin & Winter, 2002), digital resources selection and digital video (Hanson & Lubotsky Levin, 2003), Web-based instruction (Sharpless Smith, 2001) and virtual reference service (Coffman, 2003).

EMPIRICAL RESEARCH FINDINGS

Of the online resources provided by libraries, Web pages have been studied the most. The vast majority of studies employed Bobby, a software-based accessibility checker, to investigate conformance to the 1999 Web Accessibility Guidelines (WCAG), developed by the World Wide Web Consortium's Web Accessibility Initiative. Recently, researchers also began looking at compliance with the "Access Board" standards, a similar set of accessible design criteria developed under Section 508 of the U.S. Rehabilitation Act Amendments of 1998 (Architectural and Transportation Barriers Compliance Board, 2000).

At the library Web sites evaluated between 1999 and 2002, 19% to 75% of the Web pages were found to be free of major accessibility problems (Blake, 2000; Kester, 1999; Lilly & Van Fleet, 1999, 2000; Schmetzke, 2001a, 2003; Spindler, 2002; Yu, 2002); the average number of errors per page varied between 1.3 and 6.1 (Schmetzke, 2002c). Web accessibility tends to be higher at academic libraries than at public libraries. While Web accessibility has improved in some pockets, such as the libraries within the University of Wisconsin system (Schmetzke, 2004), a comparison of 2000 and 2002 data that were collected from the same nationwide sample consisting of the Web sites of 24 mostly larger academic libraries shows that, on the average, the percentage of barrier-free pages has actually slightly declined—from 59% to 53% (Schmetzke, 2003). A break-down of the Web sites into those that had undergone a major redesign during the period in question, and those that did not, revealed that accessibility at the former had drastically declined (from 47% to 24%), whereas accessibility at the latter had improved considerably (from 68% to 81%). Apparently, Web designers involved in the complete re-design of their Web sites tended not to pay attention to accessibility. That the occasion of a redesign can be an opportunity for improving accessibility was shown by a British study involving Web accessibility audits at 11 higher-education Web sites, at least some of which included "gateways" to information provided by libraries. Of the six sites that underwent a major redesign, all showed significant improvements with regard to the problems revealed during the audit (Sloan, Gregor, Booth, & Gibson, 2002).

Perhaps most remarkable is the fact that the Web pages of accredited schools of library and information science (SLIS)—those institutions that train the next generation of librarians—tended to be particularly inaccessible. In 2002, only 30% of the SLIS pages (at U.S. campuses) were free of barriers. Accessibility was barely higher, at 36%, at Canadian schools (Schmetzke, 2003). It is reasonable to assume that these figures not only reflect wide-spread unawareness about the need for accessible design among the SLIS Web designers but also among the library school faculty and staff, who hire the designers and give them direction. Similar lack of awareness among the leadership was also reported for the area of distance education (Schmetzke, 2001b) and in connection with several high-profile technology-promoting initiatives in higher education (Blair, Goldmann, & Relton, 2004).

Information about the accessibility of Web-based library resources other than library Web pages is comparatively scarce. Prior to 2002, little had been published in this area. Then, in 2002, *Library Hi Tech* (Schmetzke, 2002a, 2002b) published two special-theme issues that included accessibility studies on selected online catalogs, online indexes and databases, e-journals, online reference works and courseware. While few of the online resources reviewed were found to be absolutely inaccessible, most contained at least some accessibility problems (for an overview, see Schmetzke, 2002c). Several authors pointed out that lack of usability, rather than accessibility, was often the problem (Axtell & Dixon, 2002; Byerley & Chambers, 2002). Stewart (2003), who currently provides the most comprehensive and up-to-date information on the accessibility and usability of selected online indexes, databases and electronic journals, provides a similar picture. Comparing his current findings with unpublished data collected in 1999, Stewart observes a "complete reversal in the inaccessibility of the online library databases from approximately 95% inaccessible to 95% accessible". However, he cautions that accessibility, defined in terms of conformance to certain accessible design standards, does not automatically result in usability. As an example, he points to SilverPlatter's database interface which, for the most part, conforms to the Access Board Standards (Section 508), but which is so poorly designed that it is extremely difficult to use with an audio browser.

Until a few years ago, anecdotal evidence suggested that vendors showed little, if any, concern for the accessibility of their products and that their sales representatives were typically ill prepared to discuss the issue. A recent survey by Byerley and Chambers (2003) reveals that the situation has changed significantly: Vendors have become more aware of accessibility and started to remove access barriers from their products. In line with previous findings that usability is often more a problem than accessibility (see previous paragraph), the authors discovered that vendors' efforts are largely focused on conformance to Section 508 standards. Only three of the 11 companies that responded to the survey reported that they conduct usability tests involving people with disabilities. The survey also revealed that most database companies do not provide accessibility information on their corporate Web sites, which makes it difficult for accessibility-conscientious customers to make informed purchasing decisions.

ACCESSIBILITY POLICIES

Under the pressure of the Americans with Disabilities Act of 1990 (ADA Hankbook, 1995) and the widening influence of Section 508, many U.S. colleges and universities have adopted campus-wide accessible Web policies during the past years. Typically, these policies either recommend or require compliance with WCAG, the Access Board Standards issued under Section 508, or some combination or variation thereof (Bohman, 2004).

Some, mostly larger, academic libraries have picked up the campus-wide mandate for accessible Web pages and addressed it in their own policies. Among the first to do so was Yale University Library (2000) which, in its *Library Services for Persons with Disabilities Policy Statement*, requires compliance with WCAG's priority levels one and two.

Very few libraries have adopted policies that address the issue of accessibility in connection with the selection and procurement of online information products. An extensive Web search conducted by this author in November 2003, along with an inquiry posted to axslib-l, an email-based discussion group dedicated to accessibility issues in libraries, yielded all but a handful of such policies: The University of Washington Libraries' (2001) *Selection Guidelines for Internet Resources* direct librarians to consider accessibility when selecting online resources and to weigh the "value of the resource … against the access difficulties presented"; the University of Vermont's (2000) *Electronic Resources Collection Development Policy* simply includes being "accessible to people with a variety of disabilities" as one criterion among the many that collection developers must consider. Neither policy requires that only accessible resources must be selected; they merely emphasize the need to consider accessibility in the selection process. Considerably stronger in tone is the policy adopted by California State University (CSU) (2004). Its *Principles for CSU Acquisition of Electronic Information Resources* stipulates that "[i]nformation providers should offer interfaces that comply with basic standards for accessibility by users with disabilities." In a similar vein, the University of Wisconsin Libraries' *Strategic Directions for 2003-2005* call for accessible "[W]eb-based information resources (such as journal databases), [W]eb-based instructional applications (such as courseware and simulations) and online services". These more stringent policies echo the procurement guidelines of the International Coalition of Library Consortia (1999), an international group comprising over 160 library consortia worldwide, which considers its members responsible for "ensur[ing] that vendor platforms are … ADA compliant" and which urges participating libraries to discuss with vendors the development of accessible products**.**

Recognition of accessibility as an important issue varies among professional library organizations. In 2001, the American Library Association (ALA) (2001) approved a policy drafted by one of its branch organizations, the Association of Specialized and Cooperative Library Agencies (ASCLA), that calls for "equal access to library resources" and urges libraries to use "strategies based upon the principles of universal design to ensure that library policy, resources and services meet the needs of all people". However, the need to create a barrier-free electronic environment is not mentioned at all in the policy's section that addresses, in some detail, the accessibility of library services and collections.

While the call for a barrier-free Web environment is present in the ALA-ASCLA policy at least in the form of a general principle, it is not mentioned at all in the recent *Guidelines for Distance Learning Library Services* issued by one of ALA's major branches, the Association of College and Research Libraries (2000) —guidelines that not only reflect the professional views of the broader library and higher-education community, but that also have been influential in shaping individual libraries' policies and practices.

FUTURE TRENDS

Despite considerable coverage of online accessibility issues in the library literature, much remains to be done. Librarians need to further educate themselves and their leadership, reshape their institutional policies, and develop effective implementation strategies that ensure 100% accessibility of their home-grown Web resources and that challenge vendors to make their Web-based products more accessible. Unless this happens, the online library environment is unlikely to transform into what Berners-Lee (n.d.), WWW inventor and the current director of the World Wide Web Consortium (1999), had envisioned: "The power of the Web is its universality. Access by everyone regardless of disability is an essential aspect."

CONCLUSION

To a large extent, disability is a social construct. Whether individuals with "disabilities" can pursue independent and fulfilling lives is not merely a matter of their particular internal conditions but also a question of enabling or disabling external factors put in place by society and its institutions. Libraries clearly are part of this nexus. By neglecting to remove all barriers from their Web pages and by not adopting policies that seek to realize the opportunities new information technology provides, many libraries currently fail to create the conditions that would enable all people, including those with "disabilities", to participate fully in the evolving information society.

KEY TERMS

Access Board Standards: Technical and functional performance criteria developed by the Architectural and Transformation Barriers Compliance Board (the “Access Board”), a U.S. government agency, under Section 508. Only electronic and information technology conforming to these standards is considered accessible.

Accessibility: As defined within Section 508, accessibility is achieved when individuals with disabilities can access and use information technology in ways comparable to those available to people without disabilities. A narrower, operational definition conceptualizes accessibility in terms of conformance to certain accessibility criteria, such as the *Web Content Accessibility Guidelines* or the *Access Board Standards*.

Accessible Web Design: Also sometimes referred to as “barrier-free Web design”. Web design that strives to accommodate the needs of people with disabilities, including those using assistive technology, to access the Web environment.

Americans with Disabilities Act: U.S. civil rights legislation passed in 1990 that prohibits discrimination against people with disabilities in the areas of employment, transportation, telecommunications, and public accommodation.

Assistive Technology: Specialized software or hardware, such as screen readers, magnification software and a modified keyboard, used by some people with disabilities to interact with the computer.

Audio Browser: Also referred to as “talking browser”. Software that interprets the html code of Web pages and provides speech output for text-based components, along with information provided by the html mark-up tags. Typically, it also enables users to navigate the Web page through alternative keystrokes.

Print Disabilities: Comprises all those disabilities that make it difficult, or impossible, to read printed text. The term includes visual impairment and blindness; cognitive disabilities, such as dyslexia; and certain motor-control impairments.

Screen Reader: Software that interprets the signals sent to the computer screen and reads aloud the displayed text with the help of a speech synthesizer.

Section 508: A provision within the Rehabilitation Act of 1973, as amended by Congress in 1998, that mandates that the electronic and information technology developed, maintained, procured or used by the U.S.

government must be accessible to people with disabilities.

Universal Design: A concept similar to accessible design. Its meaning is broader in that it refers to design that strives to create products that are usable by all people, regardless of age, gender, (dis)ability, handedness, and so forth. Its meaning is narrower in that it seeks one solution to accommodate the needs of all people.

Web Content Accessibility Guidelines (WCAG): Guidelines for accessible Web design developed by the World Wide Web Consortium's Web Accessibility Initiative. WCAG 1.0 were passed in 1999. A working draft of a revised set of guidelines, WCAG 2.0, is currently under review.

Dimensions of Database Quality

John A. Hoxmeier
Colorado State University, USA

INTRODUCTION

The ultimate objective of database analysis, design, and implementation is to establish an electronic repository that faithfully represents the conceptual and logical model of the manageable aspects of a user's information domain. Enterprise and Web-enabled databases must satisfy a wide set of demands and constituents. Software engineering in general and database development in particular can be a complex, complicated process. There is probably no other product development process that faces the same amount of uncertainty, which may account for the high failure rate of software projects. This chapter expands on the growing body of literature in the area of data quality by proposing additions to a hierarchy of database quality dimensions that include model and behavioral factors in addition to the process and data factors.

BACKGROUND

While data quality has been the focus of a substantial amount of research, a standard definition does not exist in the literature (Wang & Madnick, 2000). The International Organization for Standardization (ISO) supplies an acceptable definition of data quality using accepted terminology from the quality field. These standards are documented agreements containing technical specifications or other precise criteria to be used consistently as rules, guidelines, or definitions of characteristics to ensure that materials, products, processes, and services are fit for their purpose. Applying the term *database quality* in this context would build on the ISO definition of quality, that is, "conformance to requirements" and "fitness for use." ISO 8402 as a quality management and quality assurance metric provides a formal definition of quality: the characteristics of an entity that represent its ability to satisfy stated and implied needs. This definition is consistent with the notion of customer satisfaction prevalent in the quality literature (Crosby, 1995; Juran, 1989). Thus, a database can be defined to be of the required quality if it satisfies the requirements stated in a specification, and the specification reflects the implied needs of the user. Therefore, an acceptable level of quality has been achieved if the database conforms to a defined specification, and the specification correctly reflects the intended use. Unfortunately, neither of these definitions is adequate for the purposes of assessing database quality. A database must also be judged by how closely it represents the world of the data consumer (the model), its ability to respond to both routine and unanticipated requests within the domain it is expected to manage (the behavior), and maintain this representation over time. The framework presented herein expands on work previously proposed (Hoxmeier, 1997) and incorporates data quality dimensions put forth by several prominent data quality researchers (Ballou & Pazar, 1995; Krogstie, Lindland, & Sindre, 1995; Lindland, Sindre, & Solvberg, 1994; Orr, 1998; Storey & Wang, 1994; Strong, Lee, & Wang, 1997; Wand & Wang, 1996; Wang, 1998; Wang, Kon, & Madnick, 1993; Wang et al., 1994; Wang, Storey, & Firth, 1995; Wang, Strong, & Guarascio, 1996; Wang, Strong, Kahn, & Lee, 1999). The framework is important because it expands the definition of strict data quality to that of a broader context of database quality and incorporates the importance of process management.

THE CHALLENGE

Many database applications are ultimately unsuitable to the consumer. The process must incorporate three conceptually distinguishable domains: the modeling, the performance, and the enactment domains. Designers attempt to conceptualize the problem domain into a suitable physical model. The proposed physical model is subject to many performance constraints including the physical representation, the network topology, system configuration, and system administration. Finally, and what may be the most difficult to administer, the information is presented to the consumer for interpretation and enactment. The representation of the database after each of these domain layers all contribute to the quality of the solution by the information consumer. The critical elements below are the bases for the discussion on database quality dimensions.

- The cycle process must be managed toward a successful outcome.
- The model itself must represent a usually diverse and fuzzy problem domain.

- The quality of the data in the database must be of sufficient grade.
- The application must behave or have the ability to behave in a way the consumer understands.

To ensure a quality database application, should the emphasis during model development be on the application of quality-assurance metrics (designing it right)? It is hard to argue against this point, but there are a significant number of studies and anecdotal evidence that suggests that a large number of database applications fail, are unusable, or contribute to negative organizational consequences (Abate, Diegert, & Allen, 1998; Redman, 1998; Stackpole, 2001; Standish Group, 1997; Wand & Wang, 1996). The Data Warehousing Institute estimates that businesses lose billions each year attributable to bad data (Eckerson, 2002; Trembley, 2002). A quality process does not necessarily lead to a usable database product (Arthur, 1997; Hoxmeier, 1995; Redman, 1995). There are also many examples of database applications that are in most ways well formed with high data quality but lack semantic or cognitive fidelity (the right design; Motro & Rakov, 1999). Additionally, determining and implementing the proper set of database behaviors can be an elusive task.

While researchers have developed a fairly consistent view of data quality, there is little available in the literature on the evaluation of overall database quality including other considerations such as semantic fidelity (model), behavioral, and value factors.

A Database Quality Framework

It is proposed that through the hierarchical framework presented in Figure 1, one can consider overall database quality by assessing four primary dimensions: process, data, model, and behavior. Portions of the hierarchy draw heavily from previous studies on data and information quality, and documented process quality standards (Arthur, 1997; Department of Commerce, 2004; Wang, 1998). A dimension is a set of database quality attributes or components that most data consumers react to in a fairly consistent way (Wang et al., 1996). Wang et al. define data quality dimension as a set of data quality attributes that represent a single data quality abstract or construct. The use of a set of dimensions to represent a quality typology is consistent with previous quality research (Dvir & Evans, 1996; Strong et al., 1997; Wang et al., 1996). The framework presents the four dimensions in a dimension-attribute-property hierarchy.

Process Quality

Much attention has been given over the years to process quality improvement. *ISO-9000-3, total quality management* (TQM), *quality function deployment* (QFD), and the *capability maturity model* (CMM) are approaches that are concerned primarily with the incorporation of quality management within the process of systems development (Dvir & Evans, 1996; Herbsleb, 1997; Hill, 2003; Schmauch, 1994). *Quality control* is a process of ensuring that the database conforms to predefined standards and guidelines using statistical quality measures. *Quality assurance* attempts to maintain the quality standards in a proactive way. In addition to using quality control measures, quality assurance goals go further by surveying the customers to determine their level of satisfaction with the product. Conceivably, potential problems can be detected early in the process.

Database Data Quality

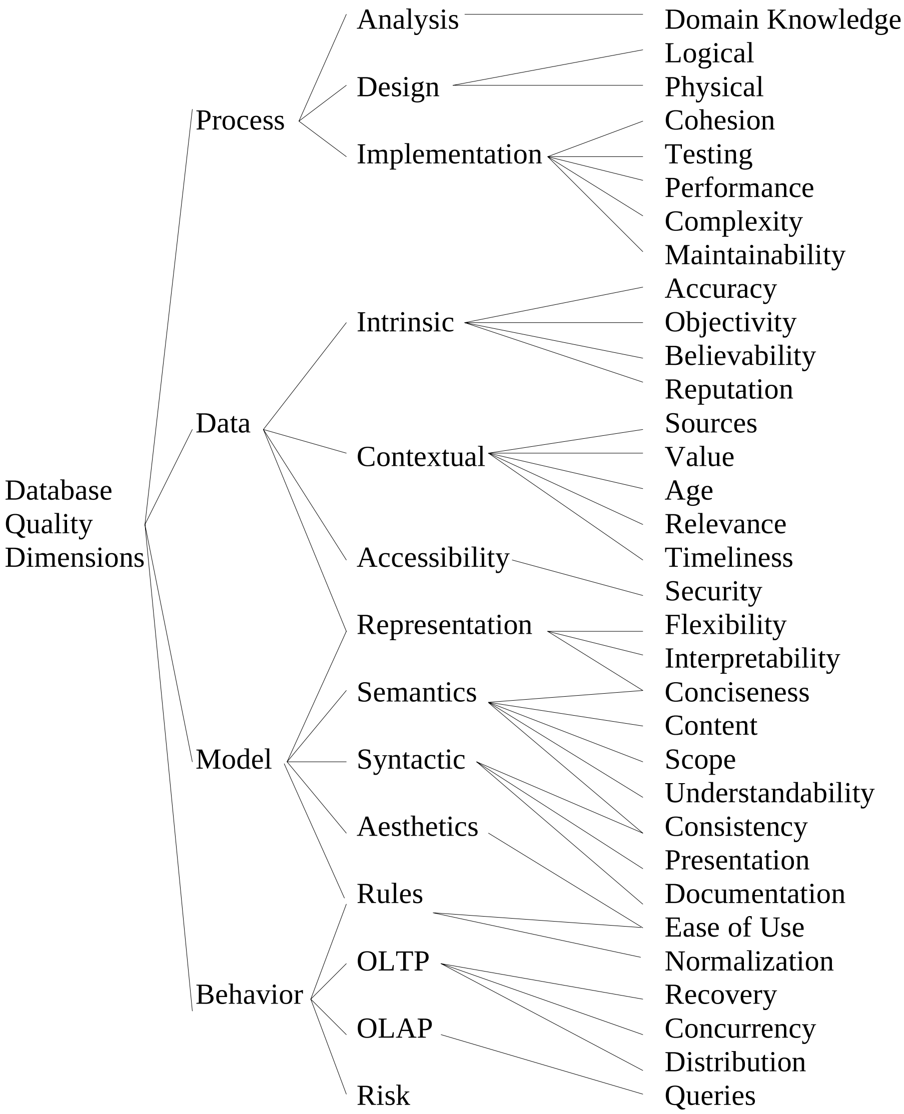
Data integrity is one of the keys to developing a quality database. Without accurate data, users will lose confidence in the database or make uninformed decisions. While data integrity can become a problem over time, there are relatively straightforward ways to enforce constraints and domains and to ascertain when problems exist (Moriarty, 1996). The identification, interpretation, and application of business rules, however, present a more difficult challenge for the developer. Rules and policies must be communicated and translated and much of the meaning and intent can be lost in this process.

Data Model Quality

As has been presented, data quality is usually associated with the quality of the data values. However, even data that meet all other quality criteria is of little use if they are based on a deficient data model (Levitin & Redman, 1995). Data model quality is the third of the four high-level dimensions presented above. Information and an application that represent a high proportionate match between the problem and solution domains should be the goal of a database with high semantic quality. Representation, semantics, syntax, and aesthetics are all attributes of model quality (Levitin & Redman; Lindland et al., 1994).

The database design process is largely driven by the requirements and needs of the data consumer, who establishes the boundaries and properties of the problem domain and the requirements of the task. The first step in the process, information discovery, is one of the most difficult, important, and labor-intensive stages of database development (Sankar & Marshall, 1993). It is in this stage where the semantic requirements are identified, prioritized, and visualized. Requirements can rarely be defined in a serial fashion. Generally, there is significant uncertainty over what these requirements are, and they only

Figure 1. Database quality dimensions



become clearer after considerable analysis, discussions with users, and experimentation with prototypes.

Qualitative and quantitative techniques can be used to assist the developer to extract a strong semantic model. However, it is difficult to design a database with high semantic value without significant domain knowledge and experience (Moody & Shanks, 1998; Navathe, 1997). These may be the two most important considerations in databases of high semantic quality. In addition, conceptual database design remains more of an art than a science. It takes a high amount of experience, creativity, and vision to design a solution that is robust, usable, and that can stand the test of time.

Database Behavior Quality

Many databases are perceived to be of low quality simply because they are difficult to use. Developers tend to focus on aspects of data quality at the expense of behavioral quality. What constitutes a database of high behavioral quality? Are the criteria different than those used for software applications in general? Clearly the behaviors for a database that is used to support transaction processing (OLTP) are different than those of a database used to support analytical processing (OLAP). Software development, in general, is very procedure or function driven. The objective is to build a system that works (and does it quickly). Database development, on the other hand, should be more focused on the content, context, behavior, semantics, and persistence of the data. The process of behavior implementation consists of the design and construction of a solution following the identification of the problem domain and the data model.

FUTURE TRENDS

The framework presented above offers a typology for assessing the various dimensions of database quality. The purpose of this paper was to expand on the existing research on data and process quality in an attempt to provide a more comprehensive view of database quality. The area is of great concern as information is viewed as a critical organizational asset, and knowledge management and the preservation of organizational memory has become a high priority. It has been estimated by the Data Warehousing Institute, the Gartner Group, Tom Redman, and others that organizations are losing billions of dollars due to poor data quality, and the problem is exacerbated by integrated systems. Most organizations realize that their databases may contain inaccurate data, but they underestimate the business risk of the result: poor information quality (Loshin, 2000). Yet most organizations are unwilling to spend the time and resources necessary to improve the situation. Tom Redman (2004) describes such a scenario in his fictitious case study, *Confronting Data Demons*. The case study describes a manufacturing firm's struggle to understand and correct data quality problems. Poor data quality is just one aspect of the case. The problem is magnified by the nature of the integrated database (ERP, CRM) and by poorly structured processes.

Part of the difficulty has been in the justification of such a project. Like many productivity improvement initiatives, a methodology based on ROI is required. Perhaps techniques such as the Data Quality Scorecard hold promise (Campbell & Wilhoit, 2003). Further research is required to continue to understand the risks, quantify the costs, improve the model, validate the frameworks, and identify additional data and database quality dimensions.

CONCLUSION

How does one ensure a final database product that is of high quality? Database quality must be measured in terms of a combination of dimensions including process and behavior quality, data quality, and model fidelity. By organizing attributes into database quality dimensions, many difficulties encountered when dealing with singular attributes can be effectively addressed. So, not only are dimensions more comprehensive, but organizing attributes into dimensions both organizes and minimizes the material that must be comprehended. Moreover, by analyzing dimensions, a data quality researcher may discover systemic root causes of data errors.

KEY TERMS

Data: The raw material that feeds the process of information generation

Database: A self-describing collection of data that represents a model of an information domain

Database Quality: Includes dimensions of data, process, model, information, and behavioral characteristics

Domain Knowledge: Expertise in a given application area

Information: Data with context and utility

Quality: An encompassing term comprising utility, objectivity, integrity, and value

Semantic Model: The conceptual representation of the problem domain

Discovery of Classification Rules from Databases

Graeme Richards
University of East Anglia, UK

Beatriz de la Iglesia
University of East Anglia, UK

INTRODUCTION

In descriptive data mining, the objective is to build an *understandable* model that provides insight into the behaviour or characteristics of some data. The data comprise a set of records, each of which assigns values to a set of features or attributes. One of these features is designated the target feature; the value of this feature is described as the class of the record.

For example, given a set of motor insurance records including features describing car and driver details and claims history, we may wish to build a model that will classify drivers as high or low risk with respect to their claims history. This model could then be used when assessing premiums for new customers. We may also wish to understand what characterises low risk drivers so that new marketing campaigns can aim to attract them.

BACKGROUND

Complete classification, such as that usually produced by decision trees, assigns a class to each record in the data. This is often unsuitable for the descriptive data mining task as the models built are often very large and difficult to understand. Also, overall classification accuracy, often used as the guiding criterion to construct the classifier, does not guarantee accurate classification of minority classes (i.e., classes with few representative records, for example high insurance risk).

Partial classification (also known as *nugget discovery*) seeks to find simple and understandable patterns that represent "strong" descriptions of a particular class. It is often convenient to use *rules* to express such patterns (Ali et al., 1999). Rules are of the general form

antecedent* $\Rightarrow$ *consequent

where the *antecedent* and *consequent* are predicates that are used to define subsets of records from the database and the rule underlines an association between these subsets. In partial classification, the consequent is fixed to be a particular named class. The *strength* of the rule may be expressed by various measures, as described in the following sections.

We are concerned here with the task of partial classification, specifically with the problem of rule discovery. Firstly, we describe the structure of the classification rules used and how rules may be evaluated. We then go on to describe the various techniques that have been developed for the discovery of classification rules. These are:

- Modern Heuristic Methods - The use of optimisation algorithms.
- Multi-Objective Methods – The use of multi-objective evolutionary algorithms.
- All Rules Search – The use of constrained search algorithms.

RULE STRUCTURE

The number of rules that may be constructed is usually very large and often infinite, but imposing constraints on the structure of rules might reduce this. Highly flexible formats allow a rich expression of patterns, which may encapsulate stronger descriptions of a class, but the size of the search space may be very large. Conversely, if the format is too restrictive it will not be possible to express patterns of sufficient interest.

Many rule discovery techniques are restricted to a rule format where the antecedent comprises a conjunction of attribute tests, ATs, and the consequent comprises a single AT representing the class description.

Even with this restriction on rule format, the size of the search space is usually immense for any real-world problem. It is not normally possible to find all rules. Consequently it is necessary to use rule finding techniques that can search effectively within the search space, as described earlier.

D

EVALUATION OF CLASSIFICATION RULES

Two common measures of rule strength are *confidence* and *coverage,* which are described next.

Given a record, t, $antecedent(t)$ is true if t satisfies the predicate, *antecedent*. Similarly, $consequent(t)$ is true if t satisfies the predicate, *consequent*. Then the subsets defined by the *antecedent* or *consequent* are the sets of records for which the relevant predicate is true.

We define three sets of records:

- $A = \{t \in D \mid antecedent(t)\}$, (i.e., the set of records defined by the *antecedent*),
- $B = \{t \in D \mid consequent(t)\}$, (i.e., the set of records defined by the *consequent*),
- $C = \{t \in D \mid antecedent(t) \wedge consequent(t)\}$.

The support for any conjunction of ATs, M, $sup(M)$ is the number of records which satisfy M.

Given a rule, r, we designate the antecedent of the rule r^a and the consequent r^c.

Then, the support for the antecedent, $sup(r^a) = |A| = a$

and the support for the consequent, $sup(r^c) = |B| = b$, (i.e., the cardinality of the target class).

The *support* for r, $sup(r)$, is defined as $sup(r^a \wedge r^c) = |C| = c$

The *confidence* of r, $conf(r)$, is defined as

$$conf(r) = \frac{sup(r)}{sup(r^a)} = \frac{c}{a}$$

The *coverage* of r, $cov(r)$, is defined as

$$cov(r) = \frac{sup(r)}{sup(r^c)} = \frac{c}{b}$$

A strong rule may be defined as one that meets certain confidence and coverage thresholds. Those thresholds are normally set by the user and are based on domain or expert knowledge about the data. Strong rules may be considered interesting if they are found to be novel and useful. That type of criteria, which may be defined subjectively, can only normally be assessed by interpretation of the rule against the domain knowledge, and against the expectations and needs of the data owner, and so forth. In nugget discovery we are therefore interested in presenting a set of strong rules (possibly interesting rules) to the user for further subjective evaluation.

TECHNIQUES FOR THE DISCOVERY OF CLASSIFICATION RULES

Modern Heuristics

Modern heuristic optimisation techniques, namely simulated annealing, genetic algorithms and tabu search, may be used to extract the best classification rules according to a specified measure of interest (de la Iglesia et al., 1996, 2000). In this approach to nugget discovery the problem of finding strong class descriptions becomes an optimisation problem. We represent a conjunctive classification rule as a solution to this problem, and all the classification rules available given a particular rule format constitute the search space. We then evaluate classification rules using some measure of interest so that the search can be guided towards the most interesting rules according to that measure. One such measure is the fitness measure,

$$f(r) = \lambda c - a \text{ where } \lambda \in \Re$$

In this equation a and c are interpreted as described previously. This measure is capable of partially ordering rules according to confidence and coverage under certain constraints. Under the defined partial ordering, if two rules have the same confidence the rule of higher coverage is preferred, and if two rules have the same coverage the rule of higher confidence is preferred. It follows that if a rule has both higher coverage and confidence than another, then the first rule is preferred. The partial ordering defines a high confidence/coverage boundary from which the heuristic techniques would search for solutions. Variations in the λ parameter allow the algorithms to explore different areas of the upper confidence/coverage boundary, by encouraging the search for rules of high confidence or high coverage.

In the implementation given in de la Iglesia et al. (1996, 2000), a solution or rule is represented as a bit string. Each attribute is assigned a number of bits, with numerical attributes defined by a lower and upper limit and categorical attributes defined by a number of labels. The class label does not need to be represented, as it is fixed. Evaluation is conducted by examining the database to count the support for the antecedent and consequent of the rule, and then by calculation of the evaluation function used. Modern heuristic optimisation algorithms are then used to drive the search towards promising areas of the search space.

Multi-Objective

The problem solved by the modern heuristics can be redefined as a multi-objective optimisation problem. In this instance, instead of using an individual evaluation function representing a combination of the individual characteristics of the rule such as the fitness measure, we will treat each measure of interest or strength of the rule as a separate objective to be optimised. We can use the same rule encoding as was used for the modern heuristic approach. However, we will use a multi-objective evolutionary algorithm (MOEA) as the search engine.

A number of Pareto-based MOEAs have been reported in recent years, for example the Niched Pareto Genetic Algorithm (Horn et al., 1994), the PAES algorithm proposed by Knowles and Corne (1999) and, more recently, the Fast Elitist Non-Dominated Sorting Genetic Algorithm (NSGA II) proposed by Deb et al. (2000).

The multi-objective approach has various advantages with respect to the previous approach. First, instead of finding an individual rule at each run of the algorithm, we can find a set of solutions that represent an approximation to the upper confidence/coverage boundary. Second, the utilisation of measures of strength or interest in a multi-objective approach allows for a more flexible search. For example, if simplicity of the pattern obtained is important, having a third optimisation objective based on the number of ATs in the rule could be incorporated.

An implementation of this approach using NSGA-II showed that the approach is efficient on large databases and finds strong nuggets spread over the confidence/coverage boundary (de la Iglesia et al., 2003).

All Rules

All rules search methods attempt to find *all* classification rules that satisfy certain constraints. The problem is an extension of the *association rule* problem, which was introduced by Agrawal et al. (1993). Methods of finding association rules were given by Agrawal and Srikant (1994) and, more recently, by Han and Pei (2000a, 2000b). One of the first effective classification rule search algorithms was the Dense Miner algorithm (Bayardo & Agrawal, 1999, 2000) in which three constraints were used: the confidence constraint, the coverage constraint and the improvement constraint. The values of three parameters, *minConf*, *minCov* and *minImp* are specified by the user. A rule, r, satisfies the confidence constraint if $conf(r) \geq minConf$; it satisfies the coverage constraint if $cov(r) \geq minCov$; and satisfies the improvement constraint if $imp(r) \geq minImp$. The improvement of a rule, r, $imp(r)$ is defined as $conf(r) - conf(r')$ where r' is the subrule of r with the greatest confidence. A subrule of r, r^*, is any rule that has the same consequent as r and where the antecedent of r^* is a subset of the antecedent of r. Thus, the improvement constraint ensures that all ATs in a rule antecedent contribute significantly to its strength.

Dense miner is suitable for finding rules in classification data comprising only categorical data (numeric data must be discretized so that is they are, effectively, categorical). It explores the search space of rules by expanding a set enumeration tree (SE-Tree). Each node in the SE-tree is represented by a structure called a group. A group, g, has a head, $H(g)$, and a tail, $T(g)$, and $g = H(g)|T(g)$. The head is a conjunction of ATs that represents the antecedent of a rule. The tail is a vector of ATs that can be added to the head to form a new antecedent.

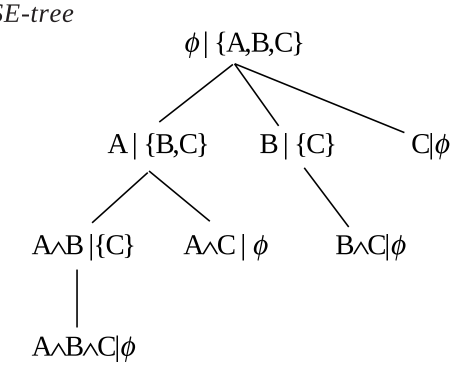
The head and tail of the group at the root of the SE-tree are $H(root)$, which is empty, and $T(root)$, which comprises all ATs in U except those based on the same attribute as the consequent AT, c. A group, g, is expanded to create a set of groups in the next level of the SE-tree by producing one child for each of the ATs in $T(g)$.

Figure 1 shows an SE-tree for the set of ATs {A, B, C}. It can be seen that the antecedent of every possible rule that can be constructed from the ATs is enumerated in the heads of the groups.

During the search, rules that potentially satisfy the constraints are added to a set of rules. A post- processing stage fully enforces the improvement constraint on this set.

To expand the entire SE-tree is usually infeasible. Therefore, at each node, pruning functions are applied. If it can be determined that none of the rules derivable from

Figure 1. SE-tree



a node can satisfy *all* of the constraints then the node can be pruned from the tree without compromising the completeness of the search. The use of these pruning functions is critical to the successful operation of the algorithm. Good pruning functions can ensure that large areas of the SE-tree do not need to be explored.

Algorithm ARA was developed by Richards and Rayward-Smith (2001); this extended the pruning functions used in dense miner (Bayardo & Agrawal, 2000), and a further constraint, the antecedent constraint, was introduced. This constraint restricts the number of ATs that may participate in the antecedent and is incorporated into the pruning functions to allow more efficient search. Subsequently ARA was modified to search effectively for rules that include numerical features, without any preprocessing.

Other rule finding algorithms are described by Megiddo and Srikant et al. (1998) and Brin et al. (1999).

FUTURE TRENDS

Algorithms for finding all rules are being made more efficient, allowing the analysis of larger and more complex databases. In addition, the multi-objective methods are being improved in order to handle ever more complex databases. An emerging technique is the use of these two methods in combination in a complimentary fashion. The multi-objective method may be used to find an approximation to the upper confidence/coverage boundary and then the all-rules method used for a detailed analysis of specific areas of interest.

One of the problems of finding rules is that very many, very similar rules may be found. Therefore, research is being undertaken to develop methods of clustering such rules and representing clusters with single descriptive rules.

CONCLUSION

Nugget discovery is an important descriptive data mining task. Nuggets are simple, understandable, strong, and potentially interesting patterns for a predefined class. A number of algorithms have been devised to find nuggets from databases. All rule algorithms can find all rules that underlie a database subject to certain constraints. The number of rules found might be high, and there may be limitations in their use for large databases. Heuristic methods can sample certain areas of the search space and may be adequate for large databases or for initial searches where an exhaustive search is considered unnecessary.

KEY TERMS

All Rules Search: An algorithm that finds all rules of a defined format that satisfy a defined set of constraints.

Classification Rules: Associations that occur in classification data between an antecedent containing a set of predicates expressing the values of particular attributes or features and a consequent expressing a class label. Classification rules represent concise descriptions of the target class.

Confidence: The proportion of records that belong to the target class from those that satisfy the antecedent of the rule. This is also often called the *accuracy* of the rule. An alternative definition is the proportion of records for which the rule makes the correct prediction of the target class.

Metaheuristic Techniques: Also known as modern heuristics, this refers to methods for the solution of complex optimisation problems that seek good (i.e., near optimal) solutions at a reasonable computational cost. Generally this type of method is based on the imitation of some natural process in the context of optimisation. The best-known modern heuristics are genetic algorithms, simulated annealing and tabu search.

MOEA: Multi-objective evolutionary algorithm. An evolutionary algorithm in which there are multiple objectives to be optimised simultaneously.

Multi-Objective Optimisation: The problem of finding a vector of decision variables that satisfies constraints and optimises a vector function whose elements represent the objective functions. There is often some conflict between the objectives to be optimised; hence the solution to such a problem tends to be a compromise solution that satisfies to some extent the objectives.

Nugget Discovery: The search for strong partial classification rules that are simple, understandable, novel and ultimately useful.

Support: The count of records that satisfy a particular predicate in classification rules.

Distance Education Success Factors

Cathy Cavanaugh
University of North Florida, USA

INTRODUCTION

While effective distance education has been practiced and studied for centuries, it has been in just the last decade that networked digital technology has been employed. Technologies and teaching techniques continue to evolve, and the options continue to expand, emphasizing the need for information that will assist distance education planners and participants in making decisions that will result in optimal learning experiences.

BACKGROUND

The process of developing and implementing effective distance education happens in an iterative cycle. Broadly considered, the three stages in the cycle are (1) procurement and preparation of the resources necessary to meet the distance education goals; (2) delivery of instruction using the best practices from education, business, and research; and (3) analysis of the results of distance education to gauge achievement of the goals. Each stage of the Resources-Practices-Results (RPR) cycle continually revisits lessons learned in the other stages and builds upon the successes realized in the other stages. Each stage requires participation of all stakeholders, including students, instructors, support and design professionals, administrators, and the community. The success factors discussed in each stage are based on decades of research and experience with learners from professions, higher education, and K-12 education (Barker, 1999; Bruce et al., 2000; Cavanaugh, 2001; Educational Development Associates, 1998; Fredericksen et al., 2000; Institute for Higher Education Policy, 2000; Mantyla, 1999).

THE RESOURCES PHASE OF THE RPR CYCLE

The resources required to sustain a quality distance education program exist to support students, faculty, and the program or institution toward achieving the goal of effective and appropriate learning. Responsive and flexible human resources, knowledge, skills, policies, procedures, and technical infrastructure enable quality practices and contribute to quality results. Procurement, development, and adaptation of resources are ongoing processes.

Institutional and Program Resources

To provide a vigorous quality distance education program, an institution begins with a policy that values distance education as an endeavor that integrates seamlessly with the institution's mission and goals. In creating a strategic plan, distance education administrators and instructors engage in continuous dialogue with a broad range of stakeholders in specifying quality benchmarks (Vaughan, 2000). The strategic plan is a financial and philosophical commitment that gives direction to personnel who make specific decisions regarding program implementation. It is a commitment to team support for distance educators and students, technology led by the program's current and future goals, and the development of program standards. Course developers and instructors need target standards to guide course design and delivery. As a partner to the standards, program review procedures must be developed, implemented, and revised frequently to ensure that all components of the program meet standards, and to ensure that the standards contribute to program goals.

Administration of a quality distance education program depends on clear and accurate communication to students. Qualified instructors and support staff must be recruited; they must be provided with development opportunities related to instruction, content knowledge, and technical skill; and they must receive feedback on their teaching. Qualitative input about student performance, satisfaction, and success is at least as important as quantitative data such as enrollment, costs, utilization of technology, and hiring rates. The elements of the comprehensive program evaluation process should be communicated to all stakeholders in advance, and the results should be reported completely and efficiently.

Faculty and Course Support Resources

Qualified and experienced distance education instructors are likely to have the desired attitudes and understanding of the distance education teaching and learning process. For faculty members to succeed in distance education, they need to be supported with accurate and complete information and training in order to develop their skills and understanding. Successful distance educators understand the distance learning environment and the options that exist for instruction.

In support of the design and delivery of quality courses, institutions are responsible for providing training and resources for instructors. Instructors need continual access to the physical resources and human support that will enable development of high quality teaching materials. The best distance learning courses use complete and up-to-date materials to increase the information literacy of students, while allowing opportunities for creative expression and mastery of concepts.

Student Support Resources

The focus of distance education is the students, whose work is made better when they receive well-designed instruction in a well-planned program. For students to maximize the time and effort they spend on their learning, they must minimize the time and effort they spend on solving non-academic problems and on seeking answers. Some students need hands-on technical training using the tools employed in courses and using general learning tools such as libraries and information archives. As students begin the work of learning, they need continual access to instructors, libraries, and other student resources. Students must have adequate access to resources appropriate to support their learning. The institution must assess the student's ability to succeed in online learning (SREB 2000).

Technical Resources

Even given the best plan, program, instructors, materials, and students, distance learning does not occur without the technology for delivery. Technology selection decisions involve all stakeholders. A technology plan guides decision makers in considering student outcomes, program goals, and technical feasibility (Council of Regional Accrediting Commissions, 2000). Support extends to all users of the technology for all facets of the learning process. Users require assistance with hardware and software uses.

Success Factors for the Resources Phase

- Institutional policy that values distance education
- Strategic plan for delivering distance education to students
- Stakeholder analysis to determine needs of graduates
- Financial commitment that gives direction regarding program implementation
- Team support for distance educators and students
- Appropriate technology infrastructure
- Program standards to guide course design and delivery
- Program review to ensure that all components of the program meet standards and to ensure that the standards contribute to program goals
- Effective communication of policies and expectations to students
- Student services: information, advising, orientation, and security
- Information privacy
- Qualified, experienced staff and faculty
- Community involvement in the program's goals, policies, and outcomes
- Information provided to faculty about teaching in the distance learning environment
- Instructor release time for course development
- Instructor training in distance education pedagogy and technology
- Course design and delivery assistance
- Well-designed and appropriate learning materials
- Student orientation and training
- Student access to learning resources and instructors
- Technical support for instructors and students
- Technology plan to communicate goals to all users

THE PRACTICES PHASE OF THE RPR CYCLE

With the right resources in place, the stage is set for dramatic distance learning performance. At this point, the spotlight shifts from the institution to the instructor. Quality distance teaching begins with the careful design of courses, materials, and learning activities. Next, the instructional practices employed during instruction will aim at developing independent learners with the ability to transfer their learning to novel situations. Throughout the course, effective communication and community building are essential foundations for all events.

Course Design Practices

Course design is a series of decisions regarding objectives and the most effective methods to ensure that students accomplish the objectives. Distance course design requires the methods to be effective in a technology-mediated environment. The requirements of the curriculum and the needs of the students lead the technological decisions in a well-designed course. A balance of comfort, control, and challenge can be difficult for distant instructors to achieve, and depends on psychosocial rather than academic strategies. The focus is on the needs of learners and the learning process, rather than on content. The quality service approach emphasizes the course structure and interactions in order to supply flexible scaffolding to learners as needed (Vaughan, 2000).

Communication Practices

Because learning is an interactive activity and constructed socially, a key to success lies in communication between students and others. A quality benchmark is to involve students in communication during 50% of the time they spend on the course. Frequent and active communication with the instructor, fellow students, or experts in the subject is essential in making students feel that they are part of the community of learners. Interaction in a distance learning course is most effective when it occurs through a variety of media, when it occurs with a variety of sources, and when it is integrated into the overall course design. Interactions are most effective when experienced within the context of other course activities. Communication in a course has the greatest value for students when it authentically approaches the kinds of communication students will experience beyond the course.

Instructional Practices

Successful distance educators understand that motivation is among the most important factors in promoting student learning. At the outset, instructors must clearly state the benefits of learning the course content to the student. The course activities should foster both knowledge construction and content understanding through active learning.

Success Factors for the Practices Phase

- Focus on content and students
- Relevant and important skills and knowledge addressed in courses
- Structured information presented in motivating context
- Social strategies to promote student comfort, control, and challenge
- Fast feedback from instructors to students
- Consistent design throughout each course
- Highly interactive activities for student engagement
- Authentic communication among students, instructors, and experts
- Course activities designed to maximize student motivation
- Activities focused on high-level cognitive skills
- Development of information literacy
- Development of applied technical skills

THE RESULTS PHASE OF THE RPR CYCLE

The only way to know whether a distance education program has achieved quality is to compare the program results to established quality benchmarks. Measures of quality are tied to institutional goals and account for the specific context of the program. To maintain success, a distance education program evaluation must account for institutional and instructional factors, as well as student factors. Evaluation of course and program results is a continual process that involves all stakeholders and requires a wide range of tools.

Assessing Learning

When experiencing quality learning, students shift roles from audience to actors as they acquire skills and display their abilities. The display of student abilities is the most important result of distance education. In the course of developing their abilities, successful students manage their learning by engaging in frequent self-assessment (Palloff & Pratt, 1999). Using varied assessment methods is a key to student assessment that gives an accurate picture of student abilities.

Program Review

Evaluation of course effectiveness by students is most useful when it is an ongoing feature of the course. Participation of students, instructors, and the institution is needed to determine the quality of the distance education program. Students should have the opportunity to offer feedback regarding their access to learning activities, course delivery, and technical support (Palloff & Pratt, 1999). The intended program outcomes must undergo review at the institutional level to ensure their clarity and their appropriateness to students who move into work or higher learning roles. Learning outcomes for distance education programs should be clear to instructors and students. Achievement of outcomes in specific courses should be observable and measurable against a known scale or set of criteria.

Accreditation

Accreditation gives an institution a seal of quality because educational standards have been met. A student who expects a distance education course to transfer to another school must be sure that a regionally accredited institution offers the course. Institutions with distance education programs approach accreditation in several ways. The accreditation process varies according to whether a distance education program is offered by a high school, a traditional institute of higher education, or dedicated distance education provider. The public needs information to help them distinguish among the accrediting bodies and the quality control they provide (Council of Regional Accrediting Commissions, 2000; Distance Education and Training Council, 2000; Web Based Education Commission, 2000).

Success Factors for the Results Phase

- Student independence developed through opportunities for self-assessment
- Peer review of student work as a professional experience
- Creation of student portfolios to showcase accomplishments
- Varied assessments for an accurate view of student abilities
- Open-ended assignments to increase thinking skills and reduce cheating
- Secure online testing
- Ongoing course evaluation by students
- Evaluation of program by students and faculty
- Review of program outcomes and components by all stakeholders
- Program accreditation

FUTURE TRENDS

Distance education technology and practice will continue to evolve, necessitating ongoing research into effective practice. The lines between distance and traditional education will blur as the points along the continuum become more finely refined in response to education customized to specific needs and contexts. Developers and learners will need more information to help them make the best choices.

CONCLUSION

A strength of distance education is its potential to focus the learning process on the student. Courses and programs that emphasize their focus on the student's strengths and needs will succeed in attracting students. In order to build their reputations and keep students, courses and programs must reach quality goals. High-quality distance education achievement is the outcome of the dedication of all constituents in the continual quest for the best possible resources, practices, and results. With an increased need for new career skills and improvement in delivery technology, distance education students will demand evidence of quality and authenticity in distance courses. It is imperative that distance education providers implement and review quality benchmarks regarding RPR in response to the needs of students, employers, and the community. Educational institutions must take the lead in developing and maintaining standards, and they must clearly communicate those standards to the public. When students benefit from an education program that meets their needs, the community benefits, as well.

KEY TERMS

Accreditation: Endorsement of quality performance by an outside agency.

Course Design: Decisions regarding objectives and the most effective methods of ensuring that students accomplish the objectives.

Distance Education: A teaching and learning system in which learning occurs in a time and/or place distant from the instructor.

Scaffolding: Cognitive and instructional supports for learning built into course design.

Standards: Benchmarks for quality performance.

Strategic Plan: A process by which quality will be improved and maintained in meeting the goals of the organization.

Technology Plan: Goals and benchmarks for technology systems and support in an organization.

Distributed Construction through Participatory Design

Panayiotis Zaphiris
City University, London, UK

Andrew Laghos
City University, London, UK

Giorgos Zacharia
MIT, USA

INTRODUCTION

This article presents an empirical study of an online learning community that collaborates with the course design team under the Participatory Design methodology. The different phases of this methodology were implemented using a four-stage participatory design process (Zaphiris & Zacharia, 2001):

1) building bridges with the intended users,
2) mapping user needs and suggestions to the system,
3) developing a prototype, and
4) integrating feedback and continuing the iteration.

We took advantage of the online and distributed nature of the student community to asynchronously design, implement, and study the course. We carried out the participatory design methodology by following the Distributed Constructionism pedagogical theory. During the different phases of the design process, we measured the student participation and the changes in their behavior when new design elements were introduced. We conclude that the most important element of this course was our discussion board, which helped us to promote student collaboration and the identification of the key community users who can participate productively in Participation Design activities.

There are three main sections to this article. After defining the key terminology, our Participatory Design approach is presented and its linkage to the Distributed Constructionism pedagogical theory specified. The article ends with ideas for future research and a set of conclusions.

BACKGROUND

Participatory Design

Participatory design (PD) refers to a design approach that focuses on the intended user of the service or product, and advocates the active involvement of users throughout the design process. PD is often termed as the "Scandinavian Challenge" (Bjerknes, Ehn & Kyng, 1987), since it was researchers from Scandinavian countries who pioneered its use in information systems development (Blomberg & Henderson, 1990; Bodker, Gronbaek & Kyng, 1993; Ehn, 1988).

User involvement is seen as critical both because users are the experts in the work practices supported by these technologies and because users ultimately will be the ones creating new practices in response to new technologies (Ellis, Jankowski & Jasper, 1998).

Blomberg and Henderson (1990) characterize the PD approach as advocating three tenets:

- The goal is to improve the quality of life, rather than demonstrate the capability of technology.
- The orientation is collaborative and cooperative rather than patriarchal.
- The process is iterative since PD values interactive evaluation to gather and integrate feedback from intended users.

By involving the users in the design process, the designers also gain knowledge of the work context, so that the new technology explicitly incorporates the values, history, and context of the work system (Ehn, 1988). The users take part in the entire design, implementation, and decision-making processes. Their involvement ensures that their activities are taken into account. Also by participating in the design, the users have a sense of "ownership" (Brown & Duguid, 2000), and the final system will have an increased user acceptance.

Distributed Constructionism

Simply put, Constructionism can be thought of as "learning-by-making" (Papert, 1991). It is both a theory of learning and a strategy for education (Papert, 1993). It focuses on the construction of a system rather than the information that will be used. The theory views computer networks as a new medium for construction, not as an information distribution channel. By embedding construction activities within a community, new ways for students to learn arise (Papert, 1993). Based on Piaget's constructivist theories, people don't get ideas, they make them. Learning is an active process where people construct knowledge from their experiences (Resnick, 1996).

Distributed Constructionism (Resnick, 1996) extends the Constructionism theory (Papert, 1991, 1993) to knowledge-building communities, where the online learning community (instead of one student) collaboratively constructs knowledge artifacts (Resnick, 1996). Distributed Constructionism asserts that "a particularly effective way for knowledge-building communities to form and grow is through collaborative activities that involve not just the exchange of information but the design and construction of meaningful artifacts" (Resnick, 1996). The three major activities of DC, within the context of an online learning community, are (Resnick, 1996):

- *Discussing Constructions:* Students discuss their constructions during the design, implementation, evaluation, and reiteration phases.
- *Sharing Constructions:* Web-based systems allow students to share their constructions and make them part of the shared knowledge.
- *Collaborating on Constructions:* The community can use online communication to collaborate on the design and development of the knowledge artifacts.
- *Distributed Constructionism:* Was enhanced among the users of the system, due to the iterative structure of our Participatory Design approach. Both the learning experience of the users and the content and functionality of the course itself were enhanced by the knowledge artifacts that were contributed to the course.

DESIGN APPROACH AND COURSE EVOLUTION

In this section, a case study applying the theories presented in the previous section is described.

Our focus has been to design an online learning community around a Computer Aided Language Learning (CALL) course. We believe that online interaction and community would increase users' motivation, commitment, and satisfaction with the online course. The Participatory Design methodology blends nicely with our goal. In particular, involving users during system development is thought to lead to greater user commitment, acceptance, usage, and satisfaction with the system (Baroudi, Olson & Ives, 1986).

In the design phase of the online course, we implemented PD as a four-step process (Ellis et al., 1998).

1) Building Bridges with the Intended Users

This step opened lines of communication between intended users and the development team. Specifically, this step involved the initialization of a multidisciplinary development team, identifying key groups of end users, and creating new methods of communication with users.

The development team in this project came out of the Kypros-Net (2002) group. Through their involvement in Cyprus and Greece related projects, they had longstanding relations with the intended user community.

The intended users have been especially people of the Greek Diaspora, travelers to Cyprus and Greece, and other Greek-speaking areas, and people who are generally interested in the Greek culture and language or languages in general. In our case, bridges with the intended users were build through our years of work at providing information about Cyprus through the Web pages of Kypros-Net, which primarily attracts the same user population as our intended Greek language online course.

2) Mapping User Needs and Suggestions to the System

Our conceptual design model has been "to design an effective online Greek language course that can build and sustain an online learning community of students." Based on the questions and inquiries we received from our users, we tried to match their needs (they wanted an easy-to-follow, both elementary and advanced course that they could attend at their own pace) with our conceptual design model.

3) Developing a Prototype

The project consists of 105 audio files, which were originally recorded as Radio lessons in Modern Greek for English speakers in the 1960s. The lessons were retrieved from the archives of the Cyprus Broadcasting Corporation, digitized in Real Audio 5.0 format, and published online through the course. Although, an optional textbook accompanied the original radio lessons, the online lessons were designed as a complete standalone course. We used several tools to assist students with the lessons, including an online English-Greek-English dictionary, a Greek spell checker, and a Web-based discussion board. The discussion boards served as the foundation for creating a community of online students and enhanced the learning experience with Distributed Constructionism.

4) Integrating Feedback and Continuing the Cycle

Feedback from our users and suggestions are continuously incorporated into our design through a series of additions and corrections. For example, we were asked to add an online notes section and to encode some files again because they were corrupted.

An important element in the participatory design methodology is the direct involvement of the users in all stages of the design process. We kept the users involved by participating in the discussion boards, and sharing with them design and development plans for the course.

The students of the audio courses included people with no knowledge of Greek language, bilingual members of the Greek Diaspora, as well as high-school professors of non-Greek language. These students created an open online community whose collaboration has boosted the learning experience of the whole community. The Web-based discussion board has proven to be the most constructive tool for the students' learning experience and the main source of feedback for the maintainers of the project. The experiences shared on the discussion board included tricks and tips on how to record the audio files, installation of Greek fonts, learning methodologies, and questions about the Greek language itself that arise from the lessons. The experienced users (some of them were retired teachers of foreign languages) had taken a lead role in the vast majority of the threads on the discussion board, answering most of the questions and encouraging the beginners to study the lessons further. They have also become the communication interface between the maintainers of the project and the community's requests.

At some point, the users started exchanging, through e-mail, written notes taken by the experienced users. They also used the discussion board to announce the availability of their personal notes. This behavior suggests that we must provide (and we did) the users with the capability to post their notes on the project's site.

The students had initiated Distributed Constructionism themselves. The course designers only provided technical support to facilitate the students' construction activities.

Discussing the Constructions

The course designers offered to provide publishing access to the online course to whomever wanted to contribute their material. Five users asked to be given access. Consequently, the five users, along with the two course designers, constituted the Participatory Design team. The PD team solicited contributions from the user community. The users suggested that they should transcribe the audio lessons, and compile verb lists, vocabulary lists, and grammatical notes for each lesson.

Sharing the Constructions

All the user contributions were shared in the common area of the online course. The user members of the PD team regularly posted notices on the discussion board about new material for the course. Also, other less active users chose to offer contributions for the course, by posting on the discussion board, rather than contacting the PD team. In their study on student involvement in designing an online foreign language course, Zaphiris and Zacharia (2002) state that the discussion board proved to be the most constructive tool for the students' learning experience and the main source of feedback for the maintainers of the project.

Collaborating on the Constructions

The user members of the PD team did not include any native speakers of Greek. They were all learning the language through the online course, and at that stage, they primarily depended on the audio lessons. In order to ensure the quality of the new material before publishing them on the course Web site, the user members of the PD team implemented a peer review process. A group of seven users, which included the five central user PD team members, reviewed and corrected all the material before posting them on the Web site. Each of the seven users offered to transcribe a number of the 105 audio lessons, and two of them also offered to provide verb and vocabulary lists. However, all materials were posted in a private area first, reviewed by the seven user members of the PD team, and posted on the Web site, when the five PD users were satisfied with the quality. Then the two PD course designers, who were both native Greek speakers, would go over the already published material and make sure it was correct. Most of the mistakes we had to correct were spelling mistakes, and we rarely had to correct grammatical mistakes.

Two months after the Distributed Constructionism effort started, students of the audio lessons managed to transcribe 81 out of the 105 lessons, correct them through the peer review process among themselves, and post them on the project's Web site. Six months later, the students had transcribed and peer reviewed all 105 lessons.

The knowledge constructed attracted significant user attention. The access to the audio lessons, the language tools, and the total access of the message board and the notes pages all kept increasing exponentially (Zaphiris & Zacharia, 2001). However, once we allowed our users to publish their own notes, there was a dramatic shift of traffic from the message board to the notes pages. In our view this is due to the fact that the users did not need to visit the discussion board any more to find out where other users had posted their notes. All the content was already aggregated and organized in a central location.

The course's popularity is apparent from the fact that the course currently has more than 25,000 registered students who actively participate in an online community that evolved around the course.

FUTURE TRENDS

Future work on this specific project will focus on a non-virtual, face-to-face participatory design team. Like the previous PD team, key stakeholders (teachers of Greek in the Diaspora, students, administrators, and designers) will work together, participating and interacting throughout the whole iterative design process. They will once again collaborate on the content and functionality development, peer review, and publish content contributions.

We believe that by encouraging the active involvement of the users, the product developed will be more enjoyable, more usable, and most importantly, more catered to their specific needs and requirements.

Also we anticipate that the expected benefit of this face-to-face PD team versus the virtual PD team will be that everyone involved will feel more like a team and have a stronger relationship with each other. Since the PD team will be a face-to-face one, communication will be better and there will be fewer misunderstandings or misinterpretations, and finally the collaboration results should be more immediate, and the final product more usable and acceptable by all the stakeholders.

From our analysis of existing literature, we observed that there is a need for additional research in areas like ethnography in participatory design and the application of our proposed methodology to new domains. As new delivery e-learning technologies are constantly emerging, research into Distributed Constructionism with the latest technology also remains important. Finally, evaluations of case studies of PD and DC will be very useful to case-specific applications of the theories.

CONCLUSION

By facilitating Distributed Constructionism in the iteration phase of a Participatory Design methodology, we enhanced the learning experience in our Web-based training. A questionnaire evaluation (Zaphiris & Zacharia, 2001) shows that the end system received high usability ratings from the users. Therefore, Distributed Constructionism enhanced the learning experience of both the PD team and the more passive users.

The students who participated actively in the design of the course also played a central role in the discussion board, answering other students' language questions, helping students to overcome technical problems, and helping them to find other resources to enhance their learning of the Greek language. These observations are with agreement the underlying goals of Participatory Design, which was an integral part of the development of this specific course.

Furthermore, the results of the analysis of the user questionnaire and the server logs shows that the final product (the course) meets—to a very large extent—the expectations and needs of the whole user population of this specific course. We believe that the direct involvement of the users in the development of the course helped in designing a more usable course that enhanced the learning of our users, and provided them with an enjoyable and rewarding experience.

KEY TERMS

Computer Aided Language Learning (CALL): The use of computers in learning a language.

Distributed Constructionism (DC): An extension of the Constructionism theory to knowledge-building communities, where the online learning community (instead of one student) collaboratively constructs knowledge artifacts.

Ethnography: The branch of anthropology that provides scientific description of individual human societies.

Human-Computer Interaction: The study, planning, and design of what happens when humans and computers work together.

Participatory Design (PD): A design approach that focuses on the intended user of a service or product, and advocates the active involvement of users throughout the design process.

Pedagogy: The activities of education or instructing or teaching.

User-Centered Design: Puts the user into the center of the software design process.

Web-Based Training (WBT): Anywhere, anytime instruction delivered over the Internet, or a corporate intranet to learners.

Distributed Recommender Systems for Internet Commerce

Badrul M. Sarwar
University of Minnesota, USA

Joseph A. Konstan
University of Minnesota, USA

John T. Riedl
University of Minnesota, USA

INTRODUCTION

Recommender systems (RSs) present an alternative information-evaluation approach based on the judgements of human beings (Resnick & Varian, 1997). It attempts to automate the word-of-mouth recommendations that we regularly receive from family, friends, and colleagues. In essence, it allows everyone to serve as a critic. This inclusiveness circumvents the scalability problems of individual critics—with millions of readers it becomes possible to review millions of books. At the same time it raises the question of how to reconcile the many and varied opinions of a large community of ordinary people. Recommender systems address this question through the use of different algorithms: *nearest-neighbor algorithms* (Resnick, Iacovou, Suchak, Bergstrom, & Riedl, 1994; Shardanand et al., 1994), *item-based algorithms* (Sarwar, Karypis, Konstan, & Riedl, 2001), *clustering algorithms* (Ungar & Foster, 1998), and *probabilistic* and *rule-based learning algorithms* (Breese, Heckerman, & Kadie, 1998), to name but a few. The nearest-neighbor-algorithm-based recommender systems, which are often referred to as *collaborative filtering* (CF) *systems* in research literature (Maltz & Ehrlich, 1995), are the most widely used recommender systems in practice. A typical CF-based recommender system maintains a database containing the *ratings* that each customer has given to each product that customer has evaluated. For each customer in the system, the recommendation engine computes a *neighborhood* of other customers with similar opinions. To evaluate other products for this customer, the system forms a normalized and weighted average of the opinions of the customer's neighbors.

The emergence of the Internet and its far-reaching deployment is changing the way commerce is done. Economists and commerce experts are now suggesting companies to shift from the old world of mass production characterized by "...standardized products, homogenous markets, and long product life and development cycles..." to the new world where "...variety and customization supplant standardized products" (Pine, 1993). In his famous book *Mass Customization*, Joe Pine also suggests that building one product is simply not adequate anymore. Companies need to be able to develop multiple products that meet the multiple needs of multiple customers. The movement toward Internet commerce has allowed companies to provide customers with more options. However, in expanding to this new level of customization, businesses increase the amount of information that customers must process before they are able to select which items meet their needs. Traditional data-analysis techniques are often not sufficient to process this huge amount of data in real time as needed by the Internet sites. Recommender systems, by providing a "personalized" interface to each customer, can potentially automate personalization on the Internet. Personalization to this extent is one way to realize Pine's ideas of the "new world order" of Internet commerce.

As discussed by Schafer, Konstan, and Riedl (1999), recommender systems can help Internet commerce sites boost their business in several ways. First, by providing personalized recommendations on various products, they help convert browsers into buyers. Visitors to a Web site often look over the site without ever purchasing anything. Recommender systems can help customers find products they wish to purchase and can potentially increase sales. Second, recommender systems improve cross-sell by suggesting additional products for the customer to purchase. If the recommendations are good, the average order size should increase. For instance, a site might recommend additional products in the checkout process based on those products already in the shopping cart. Third, recommender systems help capture customer loyalty. Internet commerce is getting competitive day by day. Freed from large capital investment and recurring costs for physical storefronts, an unprecedented number of businesses are using the Internet to market and sell goods, potentially creating a vicious price war. As a consequence, gaining customer loyalty becomes an essential strategy for businesses to survive on the Internet nowadays (Reichheld, 1993; Reichheld & Sesser, 1990). Recommender systems improve loyalty by creating a value-added relationship between the site and the customer. Sites invest in learning about their users, use recommender systems to operationalize that learning, and present custom interfaces that match customer needs. Customers repay these sites by returning to the ones that best match their needs.

RECOMMENDATION INTERFACES

There is more than one way to display recommendations to a customer. The method selected may well depend on how the Internet commerce site wants the customer to use the recommendation. In the following we will examine several recommendation interfaces and how each assists the site in making money. While some of these methods have their roots in traditional commerce, each of them draws upon the strengths of ubiquitous Internet to provide more powerful recommendations. We present these interfaces in Table 1 (Sarwar, Konstan, & Riedl, 2001; Schafer et al., 1999).

DISTRIBUTED RECOMMENDER SYSTEMS

In the past, participating in commerce meant that the consumer had to travel to the location of the store from which he or she wanted to purchase a product. Today, participating in commerce may be as easy as moving a mouse and typing a few keystrokes. In the future, participating in commerce will become even easier. With the introduction of new wireless devices that enable commerce on the palmtop, consumers will be able to shop from wherever they happen to be. The result of technical improvements like wireless Web browsers is that consumers will come to expect the same shopping experience when travelling as they currently receive when directly connected to the Internet. For instance, a customer who uses a restaurant recommendation service in his or her hometown will expect to be able to use the same restaurant recommendation service while traveling. In fact, the recommendations will be even more valuable on the road since the customer will know less about what is available.

Creating good recommendations for a traveling consumer is challenging, though, especially for the leading recommendation technology, collaborative filtering. Many Internet commerce sites, including several of the largest ones, are now using CF recommender systems as part of their personalization effort. As the largest Internet commerce sites attempt to use these systems, however, they are discovering the drawbacks of today's centralized systems. While a centralized architecture may be useful for smaller applications, there are several key drawbacks to centralization as shown in Table 2. Together, these issues point toward distributed architectures for collaborative filtering (Sarwar, Konstan et al., 2001).

There are four fundamemtal components that are to be considered for designing a framework for distributed recommender system:

1) *Products*: Are the products of local or global interest?

Table 1. Recommendation interfaces for Internet commerce

Browsing: Recommended browsing helps the users narrow down their choices and makes them feel more confident about their decision buying decision by providing organized access to the recommendations.
Similar Item: Recommender systems display items based on the item in which a customer has shown interest. In so doing, sites increase customers' exposure to their product line and are ideally able to sell more items per order.
E-mail: Recommendations can also be delivered directly to customers through e-mail. This extension of the traditional direct-mail campaign is also expected to generate more sales.
Text Comments: Sites can provide customers with recommendations based directly on the text comments of other customers.
Average Rating: Recommender systems show the average ratings for particular items.
Top *N*: Once each site has learned details about a customer's likes and dislikes, each is able to provide the customer with a personalized list of the top-*N* unrated items for that customer. It helps sites convert browsers into buyers as well as helps customers in making a decision about a product that they originally held in doubt.

Table 2. Drawbacks of centralized recommender systems

Scalability: The largest Internet commerce sites have millions of customers and up to millions of products. Recommendation generation is becoming an increasingly computation-hungry process.

Fault Tolerance: This provides a central point of failure that is unacceptable.

Performance: Global businesses cannot deliver reliable, low-latency performance around the world from a single, potentially overloaded recomender system.

Security and Privacy: Consumers are becoming increasingly wary of businesses that attempt to "own" data about them.

2) *Ratings*: Are the ratings being used from local customers or all customers?
3) *Neighborhoods*: Are the neighborhoods formed by using local customers or all customers?
4) *Predictions*: Are the products for which predictions are formed local or are they all avialable products?

However, from an algorithmic perspective, the two most important of these components are the neighborhood-formation and prediction processes since these decide what data are used by the recommender system, where the data are stored, and how that data are used. Based on these two dimensions that can be either local or global, we find four potential models that present a taxonomy of distributed recommender-system applications. These are shown in Table 3 (Sarwar, Konstan, et al., 2001).

Using this taxonomy, we present three implementation frameworks for different types of distributed collaborative filtering. At the heart of all three of the frameworks are protocols for storage, exchange, and maintenance of customer preference profiles. These are listed below.

- **Local Profile Model:** The profile database is stored locally. A customer requests recommendations from recommender systems that retrieve the profile from the customer's client and computes prediction. The main advantage of this model is its simplicity. It also ensures security and privacy as the profile database is maintained solely at the customer site. It also provides the fastest recommendations compared to other models. However, the communication of profile data to a remote recommendation server is cumbersome.
- **Central Profile Model:** The profile data is stored in a central database. This solves the profile exchange problem, but the central profile storage can be a performance bottleneck and a security and privacy hazard. Also, the latency is higher due to increased communication with the profile storage.
- **Geographically-Distributed Profile Model:** The profile database is distributed on a number of interconnected but geographically distributed profile servers. Due to the fully distributed design, this model circumvents the bottleneck problem of the central profile model and provides a smoother way of sharing profile data. However, partitioning of the profile data according to the geographical distribution as well as consistency management can be a challenging task.

Table 3. Taxonomy of distributed recommender system

Global Neighborhood and Global Prediction: This is the most common application of RS on the Internet. All customers have opinions about all products and interest in all products. This model is likely to continue to be very successful in the Internet commerce domain.

Global Neighborhood and Local Prediction: This is most useful when the customer is traveling. Recommendations for local items will be produced based on a global opinion. Large cities with active Web populations are likely to have many entertainment venues that fit these criteria.

Local Neighborhood and Global Prediction: This is potentially useful for travelers. It automates the typical word-of-mouth recommendation. Since the neighborhoods are formed based on local ratings, the relationships between the neighbors are likely to be stronger, and hence these systems are expected to generate better recommendations

Local Neighborhood and Local Prediction: This is similar to the global-global case, but the items used for neighborhood formation and prediction generation are of local interest only.

CONCLUSION

Recent marketing trends suggest that personalized service is highly valued by the respective customers (Peppers & Rogers, 1997). One important component of personalized service is capturing and using customer preferences to treat each customer according to his or her taste. Recommender systems are capable of providing such value-added services for customers. These systems provide an Internet commerce site with most of the fundamental methods for achieving goals of mass customization listed in Joe Pine's book (Pine, 1993). Recommender systems achieve these goals by providing a customized service that enables Internet commerce sites to sell their largely commodity products more efficiently by creating "customizable products and services" and by directly "customizing the point of delivery" for the Internet commerce site. Recommender systems will become increasingly important in the future as modern businesses are increasingly focused on the long-term value of customers to the business (Peppers & Rogers). These systems are expected to be used in the future to "predict demand for products," enabling earlier communication to back the supply chain. Currently, most recommender systems are centralized and are run and controlled by a single Internet commerce merchant. Recommender systems will become more and more distributed over time, driven by user needs for less effort and better service. In this article, we have introduced the concepts of recommender systems and how they are being used to make money by capturing customer loyalty. We then presented a taxonomy of the application space for distributed recommender systems. We studied several frameworks for implementing distributed recommender systems and presented three different implementation models.

KEY TERMS

Collaborative Filtering: A recommendation technique that uses k-nearest neighbor learning algorithm. Variations include user-based and item-based algorithms

Neighborhood: A list of like-minded customers that are discovered by looking into the ratings database and by using a similarity measure such as correlation

Prediction: An output interface of a recommender system. Given a customer and a product, the system generates a score expressing the predicted liking in a scale the same as the ratings.

Profile Database: Collection of customer preference data, possibly along with the customer's demographic information

Rating: An opinion of a customer about a product used by recommendation algorithms. This is usually expressed in a Likert scale (e.g., from 1 to 5).

Recommendation: An output interface of a recommender system. Given a customer, the system recommends a list of products the customer will be interested in (e.g., top-10 products).

Recommender System: An information-filtering technique based on machine learning and/or statistical methods. Widely used in Internet commerce nowadays

Dot-Coming SMEs in Singapore for the New Economy

Leo Tan Wee Hin
Singapore National Academy of Science, Singapore and Nanyang Technological University, Singapore

Ramesh Subramaniam
Singapore National Academy of Science, Singapore and Nanyang Technological University, Singapore

INTRODUCTION

Small- and medium-sized enterprises (SMEs) play a very significant role in the economies of all countries. They outnumber big corporations, and are conspicuous by their ubiquity in all sectors of society. The contribution of SMEs to a country's Gross Domestic Product is high by virtue of the large number of people they employ and the diversity of services that they offer (Unctad Secretariat, 2002). SMEs also offer a starting platform for entrepreneurs to realize their aspirations.

Globalization and the Internet have started to transform the global economic landscape. Capital mobility and the connectivity provided by the Internet for business processes are reengineering the contours of international trade significantly and giving rise to an international common market. Traditional structures of businesses are starting to atrophy to varying extents and new business models are emerging. These are affecting the competitiveness of nations. Since these affect the employment of workers (Tan and Subramaniam, 2001), they therefore impact on all business sectors. Those business outfits not able to compete in the emerging economic order face the possibility of being sidelined by the forces of globalization and Internet-based business practices. In particular, SMEs are vulnerable as they generally operate in a local environment. To compete in the new economy, these businesses need to reformat their work processes as well as adopt e-commerce.

BACKGROUND

There is no unambiguous definition in the literature of what e-commerce means, as the concept is still evolving and not many countries have embraced it in totality. Many countries are in different stages of economic development, and those that have warmed towards e-commerce have adopted it to varying extents. Broadly speaking, e-commerce refers to the use of the Internet to do business with suppliers, clients, and others in the business value chain (Zwass, 2003).

The definition of SMEs also varies among countries. In Singapore, which is the focus of this article, the following criteria is used to define an SME (http://www.singapore-sme.com):

- there must be local equity stake of at least 30 % in the company
- the net book value of the company's fixed assets, that is, factory building, machinery, and equipment, must not exceed S$15 million
- the workforce must not exceed 200 for non-manufacturing enterprises

The Internet offers a leveling field for SMEs to compete globally and overcome geographical barriers and other limitations. Whilst SMEs in the USA and Western Europe have adopted e-commerce significantly (Euro News, 2002; Fife and Pereira, 2001; Quayle, 2001), the same cannot be said of other countries. Among countries in Asia, only Singapore, Taiwan, Hong Kong, Australia, Japan and South Korea have good e-commerce infrastructures (Wong, 2001; OECD, 2000). In South-East Asia, Singapore is the only country with an advanced e-commerce infrastructure (Tan and Subramaniam, 2004a; 2004b).

This article examines the use of e-commerce as a business enabler for SMEs in Singapore. The rationale for selecting Singapore as a case study is as follows:

(a) Singapore was among the earliest adopters of e-commerce in the world, and thus its experiences can offer useful lessons for other countries.
(b) The use of state intervention strategies in getting SMEs to adopt e-commerce is a key feature of Singapore's approach as compared to other countries, where it is generally private sector-driven.
(c) Recognizing the differing levels of economic development in countries in the South-east Asian region, of which Singapore is a part, and the fact that they are on different learning curves and achievement bands as regards e-business initiatives, exploring the state of e-commerce in SMEs in a particular country is more meaningful and revealing.

HOW SMES ARE ENABLED IN SINGAPORE BY E-COMMERCE

Over 100,000 businesses in Singapore are SMEs – this represents 90% of all business establishments. They employ over 50 % of the workforce and generate about 30 % of the total value-added to the economy.

A good measure of the willingness of SMEs to try out e-commerce initiatives can be gauged from the extent to which the necessary infrastructure and frameworks for these are in place. The infrastructure relates to the presence of an advanced telecommunications network. A good infrastructure creates economic value for SMEs to ride on, as well as decreases their operating costs. The frameworks refer to the set of policies, e-payment protocols, and other enabling services that help companies use e-commerce in their businesses. These are elaborated upon in this section for Singapore.

Digital Telecommunications Network

An advanced telecommunications network leveraging three broadband platforms—Asymmetric Digital Subscriber Line, Hybrid Fibre Coaxial Cable Modem, and Asynchronous Transfer Mode—has been in operation since 2000. The technical aspects of these services have been addressed in detail by Tan and Subramaniam (2000, 2001). The maturation of the broadband market has led to Singapore being among the top 10 broadband economies in the world (Asia Pacific Telecommunication Indicators, 2002).

The cost of Internet access has been brought down drastically over the years through generous government subsidies for bandwidth. This has allowed telcos to pass on the savings to consumers and businesses, and has been an important factor in Singapore: having an Internet penetration rate of over 90 % (Tan and Subramaniam, 2003).

That Singapore is effectively networked for the new economy is shown by the fact that it has been ranked third, ahead of Finland and the USA, for networked readiness in the new economy (Dutta and Jain, 2003).

Frameworks for Electronic Commerce

Singapore was among the early adopters of e-commerce in the world. A comprehensive range of initiatives and frameworks (http://www.ec.gov.sg) has been put in place to allow businesses to capitalize on the potential that e-commerce presents. Fine-tuning of the frameworks on the basis of accumulated experiences in the local market and cognizance of best practices in overseas countries have been done on an ongoing basis. Some of the more important initiatives that have been put in place are:

(a) Alternative Payment Modes

For e-commerce to be entrenched in the business landscape, multiple payment systems of a secure nature are indispensable. Four payment channels are in common use in Singapore:

- A Secure Electronic Transaction (SET) system has been in place since 1997 to service credit card transactions over the Internet, this being a world-first
- NETSCash, the digital equivalent of the cash card, is available to service low-value purchases (S$0.01—S$500.00)
- Debiting via Internet banking has been available since 1997
- Electronic inter-bank payments via NETS Financial Data Interchange

(b) Use of digital certificates

Security of financial transactions on the Internet is important if businesses are to be encouraged to go online. In this context, two government-linked Certification Authorities (CA) have been established, and they have been empowered to issue digital certificates to businesses that require cross-checking of user credentials as well as assurance of high network security. On the certificates are digitally embedded details of the CA, the expiry date, encoded information about the user's public key, and details of the account.

(c) Application Service Providers

Application Service Providers (ASP) in the e-commerce industry provide services such as human resource management, sales and marketing, customer service, and even collaborative working with businesses. Their emergence have allowed SMEs to concentrate on their domain expertise whilst ancillary functions are outsourced to these ASPs.

(d) Business-to-Business Security Service Providers

For e-businesses that are hesitant to set up their own e-commerce infrastructure because of cost constraints and uncertainty of the business model, B2B service providers have emerged in the market. They provide a secure e-commerce network between companies, thus saving them considerable manpower and infrastructure costs as well as recurrent expenses.

(e) Legal and Policy Frameworks

In Singapore, there is recognition that for the support of businesses in the digital economy, the government must take the lead in laying down the administrative frameworks relating to regulatory and legal issues. These frameworks must not only be transparent and pro-business, they must also be seen to not stymie the growth of business enterprises or hamper innovation.

Currently, the following frameworks are in place – Intellectual Property Rights Act, Electronic Transactions Act, use of e-applications and e-licenses for businesses, commerce code for e-commerce transactions, Public Key Infrastructure, Computer Misuse Act, Electronic Evidence Act, and guidelines on tax issues in relation to e-commerce.

(f) E-Government

An e-government is in place to service the needs of the public and businesses. As of December 2001, all government services that need to be accessed by the public and businesses have been placed online. Some of these include: registering a business, tendering for government contracts, and e-filing of income taxes. Through these initiatives, the government aims to provide the public and businesses more convenience and prompt services 24/7. A key feature of the e-government is the Government-to-Business (G2B) portal, which streamlines various processes for businesses. (Table 1).

Of interest to note is the government's TradeNet initiative, which is an Internet-based system for processing 99% of all trade declarations made by businesses since 2002. This paperless processing system provides savings of about S$2.8 billion annually. Fisher (2000) has noted that enhancing business productivity through similar practices can boost GDPs of many Asian countries by 5-12% in the long run.

DISCUSSION

With an advanced infrastructure providing effective network connectivity and affordable access, and the frameworks promoting trust and user confidence, novel ways of doing business are emerging. It is not surprising that the take-up rate of e-commerce among SMEs has been very significant (Tan and Subramaniam, 2004b). For the period from January 2000 to March 2001, the growth rate was about 1800%, constituting nearly 20% of the total number of SMEs (Table 2) (Kwong & Lim, 2001).

Significant emphasis is also being placed on state intervention strategies to get more SMEs to embrace e-commerce. A key national agency, Spring Singapore, has been entrusted with this important responsibility. Some of the initiatives that it has introduced are addressed now.

Recognizing the high cost of setting up the necessary e-commerce infrastructure for a company (Koh, 2000), generic jump-start packages that enhance the online capabilities of businesses have been introduced. In contrast to customized solutions, this strategy has been found to be effective in getting more SMEs to embrace e-commerce since the package is less expensive and offers a quicker approach to joining the mainstream of e-commerce (Kwong and Lim, 2001). Further support for the efficacy of such jump start packages for implementing e-business solutions has been reiterated in another independent survey (Kwong and Lim, 2001) that further revealed the following findings:

- 21% of SMEs have e-commerce capabilities.
- About 50% of SMEs with e-commerce capabilities have performed some online transactions.

Table 1. Comparison of some services on civil service and e-government platforms

Item	**Civil Service Procedure**	**e-Government Procedure**
Submitting business plans	Entails separate submission of documents to 12 departments.	One-stop submission at G2B portal. Savings of S$450.
Incorporating new company	S$1,200 to S$35,000, depending on size of company. Approval time of 2 days.	Online incorporation at a cost of S$300. Approval time of 2 hours.
Opening new entertainment outlet	2 months for approval.	2 weeks for approval.

Source: http://www.egov.gov.sg

Table 2. E-commerce adoption rate among SMEs in Singapore

Year	Number of SMEs
Jan 2000	800
Mar 2000	4,000
June 2000	10,000
Sep 2000	16,000
Dec 2000	17,500
Mar 2001	19,000

Source: Interpolated from data presented in Kwong and Lim (2001)

- About 60% of SMEs believe that the Internet is an important tool for business.

Another important initiative is the establishment of industry-specific portals on the Internet. These portals are customized for the special needs of a particular industry. Besides catalyzing the evolution of online trading communities among the SMEs, they also facilitate a myriad of transactions. Examples of these portals include

http://www.Asiafurniturehub.com and http://www.kafe123.com. The portal operators also offer online links to overseas trading partners, thus opening up more opportunities for SMEs.

The government recognizes that a targeted and focused approach on SMEs would encourage more of them to embrace e-commerce. As it is, the sectoral mix of SMEs in Singapore indicates that many are in the brick-and-mortar business and only a small percentage are technology-based or are big enough to embark on e-commerce initiatives. Moreover, with Singapore's city/state structure, high population density, and presence of retail outlets and convenience stores within short traveling distances, the penchant for online purchases by consumers, and thus this aspect of promoting e-commerce, is not pronounced.

In the context of the foregoing, a national plan to boost the capabilities of SMEs in the new economy was instituted in 2000. Called SME 21, the ten-year strategic plan aims to raise the status of SMEs in a focused and selective way so that more of them can ride on the advanced telecommunications infrastructure and other frameworks set in place (http://www.singapore-sme.com). More specifically, the following initiatives have been put in place:

(i) Develop productive sectors in the SMEs

This plan aims to pivot SMEs up the value chain in the local economy through a process of restructuring, revitalizing, and upgrading. The aim is to double the productivity of the retail sector from S$28,000 per worker to S$56,000 per worker.

(ii) Groom innovative high growth SMEs

This plan aims to triple the number of local SMEs with annual sales turnover of S$10 million and above from 2,000 to 6,000 companies. That is, it aims to ensure that 1 in 15 companies will go on to become large corporations.

(iii) Institute a knowledge-based and pro-enterprise environment

This plan aims to create conditions where appropriate mindsets for business are inculcated, technopreneurship and innovation are encouraged, and obstacles to growth removed. In this way, it is expected to quadruple the numbers of SMEs transacting online from 8,000 to 32,000 companies. That is, one third of local SMEs will be plugged into the global economy.

To accelerate the realization of the above targets, schemes to provide grants and subsidies to SMEs whose corporate focuses are aligned with national objectives have been put in place.

Recognizing that the logistics and transportation sectors contribute significantly (8%) to the GDP, a three-year plan costing S$12 million was rolled out by the government in 2000 to enable SMEs in these industries to use e-commerce.

Promising SMEs are also being incentivised through the provision of grants and other assistance packages to morph from brick-and-mortar enterprises to click-and-mortar enterprises. As of 2001, a total of 165 SMEs have reinvented themselves in this way (Kwong and Lim, 2001).

To increase e-commerce practices among SMEs, focus has also been on large enterprises outside the SME fold. As they adopt e-commerce, SMEs, by virtue of their linkages with these enterprises, will be forced to adopt these practices in order to service them. For example, B2B turnover in Singapore has shown rapid growth (Tables 3 and 4), indicating that many big businesses have entered the e-commerce ecosystem (Ho, 2002). This is having implications for SMEs to embrace new economy paradigms.

FUTURE TRENDS

E-commerce is poised to be a key enabler for many SMEs to be competitive in the emerging new economy. The increase in penetration rates of the Internet, as well as the extent to which business practices are being reengineered to suit the contours of the competitive global economic landscape, means that those companies not in the economic value chain face the prospect of being side-lined if they are not responsive to the new ways of doing busi-

Table 3. Business-to-Business sales value in Singapore

Year	Value (S$ million)

2000	92,701
2002	109,460

Source: Ho, 2002

ness. For those which are in the brick-and-mortar business as well as those which do not have the necessary sales turnover, it would be a challenge to dot-com them. Further research is needed to evolve cost-effective e-business models for some of these SMEs to be brought into the e-commerce ecosystem.

CONCLUSION

The telecommunications infrastructure as well as the regulatory and policy frameworks for the support of e-commerce in Singapore are of a high standard. Whilst there is still quite some way to go for SMEs to embrace e-commerce, the Singapore experience shows that state intermediation strategies, especially with regards to business-friendly legislation, generous tax incentives, and technology grants are effective. More importantly, a targeted and focused approach in identifying promising SMEs to adopt e-commerce is more effective than targeting all, since many are brick-and-mortar companies whose lean operations do not justify adoption of e-commerce. In many cases, market developments will also generate competitive pressures for many SMEs to adopt e-commerce practices.

KEY TERMS

Asymmetric Digital Subscriber Line: A technology which enables transmission of information at high rates over an ordinary phone line by capitalizing on the unused bandwidth outside the voice portion of the line.

Asynchronous Transfer Mode: A high-speed, low delay, multiplexing and switching technology that allows voice, image, data, and video to be transmitted simultaneously rather than through traffic-specific networks.

Bandwidth: Transmission capacity (in kilobytes per second) of a telecommunications line.

Broadband Network: A telecommunications network that can transmit information well above the normal rate (56K) on ordinary phone lines.

B2B: Business-to-Business

E-Commerce: The use of the Internet to conduct business and financial transactions.

E-Government: Public administration infrastructure of a government on the Internet; a range of services needed by citizens and businesses can be accessed here.

Hybrid Fiber Coaxial Cable Modem: A technology which enables transmission of information at high rates over the cable television network's infrastructure comprising optical fibers and coaxial cables.

Small- and Medium-Sized Enterprises: Companies which employ a limited number of people and which have a certain turnover, with the numbers varying among countries.

Supply Chain: The network of producers, wholesalers, retailers, distributors, transport operators, and storage hubs that are involved in the production and delivery of a product to the consumer.

DRM Technology for Mobile Multimedia

Sai Ho Kwok
California State University, Long Beach, USA

INTRODUCTION

Mobile multimedia has been promoted as a promising service and application in mobile e-commerce (m-commerce) by many mobile operators and mobile service providers, when high-speed mobile networks are expected to take off in the near future. However, at present, mobile multimedia is still in its infancy, accessed by relatively low-end mobile devices with limited bandwidth and resources. A typical example is Orange in Hong Kong which launched a low-grade multimedia service in 2000 to test the market with current mobile technologies. Due to the physical constraints of a 2.5G mobile network, audio broadcast is the best service that the network can offer up to date. However, in the near future, when advanced mobile networks and technologies become available, higher demands will be placed on the quality of mobile multimedia services. Such services support both audio and video data, for example, video conferencing, music video, video-on-demand and so on. Rights management deserves more serious concern because intellectual property of distributed multimedia content is as valuable as a company's physical assets (Doherty, 2002). This will become even more important when mobile multimedia services become marketable and an essential part of the business. The purpose of a digital rights management (DRM) system is to allow owners of digital assets (movies, songs) to distribute their products/services/contents electronically in a controlled way (Peinado, 2002). DRM technology makes various online payment schemes possible, such as pay-per-view, pay-per-download, pay-per-game and so on. Hence, mobile service providers are able to control end users' use of, and accessibility to, their products, and stand to gain huge profits from this capability with the DRM technology (Foroughi, Albin, & Gillard, 2002). A successful DRM system should address both business and technical issues (Grab, 2002), but this chapter only addresses and presents issues in the technical side due to the nature of this book. We present some critical issues of mobile DRM for mobile multimedia. A proposal of mobile DRM framework is presented to meet the urgent DRM needs with the existing 2.5G mobile technology. This chapter is concluded by presenting future directions of mobile DRM for mobile multimedia.

BACKGROUND

Internet Commerce

In the Internet domain, Vidius Incorporated estimates 450,000 to 580,000 downloads of unprotected full-length films are transferred over the Internet daily (Grab, 2002). Protection of distributed multimedia has been a growing concern to creators, distributors, copyright owners, publishers, and governments. DRM is considered to be one of the desirable solutions to this problem, and it can protect distributed media contents delivered over the Internet.

Several international standard organizations have been developing DRM solutions for various distributed multimedia, for example, digital music and video. The Secure Digital Music Initiative (SDMI) (SDMI, 2003), backed by the Recording Industry Association of America (RIAA) and 200 music and technology companies (as of October 2003), has been proposed to provide a secure environment for music distribution over the Internet. Another standard being developed by the Moving Picture Experts Group (MPEG) is known as MPEG-21 (Bormans & Hill, 2002) dedicated to distributing digital multimedia content. MPEG-21 defines an interoperable framework for Intellectual Property Management and Protection (IPMP). The IPMP can be interoperable with other MPEG standards, for example, MPEG-4. Therefore, the property protection will be also applicable to most of the MPEG video standards in the future. In addition, there are commercial DRM systems especially for the wired Internet business. They include Windows Media Rights Manager by Microsoft, and MetaTrust by InterTrust Technologies (InterTrust, 2000).

The above DRM standards and systems can be classified into two groups, namely, cryptographic-based and watermark-based DRM solutions (Kwok, 2003). Cryptographic systems permit only valid key-holders to access the encrypted data after receiving it from the authenticated senders. However, once such data is decrypted, it is impossible to track its reproduction or retransmission. Therefore, cryptography only provides protection during data transmission. Digital watermarking technology seems to complement the cryptographic process and to protect

Table 1. Summary of features of DRM solutions

- Media right protection and management
- Secure delivery and distribution of digital contents
- Processing authorization, data authentication and verification for content service
- Data security, integrity check, access control, and management for distributed systems and peer-to-peer (P2P) networks
- Multimedia watermarking for copyright protection, media authentication and integrity checking, finger-printing, and data annotation

Table 2. Problems and issues for mobile DRM

Mobile DRM standard: There is not yet a winner of mobile DRM standard. Open Mobile Alliance (OMA) DRM standard is one of the outstanding mobile DRM standards for mobile phones (Poropudas, 2003). However, other DRM standards, such as Windows Media DRM for Pocket PC (Microsoft, 2003), are highly competitive.

Trustful DRM protocol: Since DRM involves many parties, for example, technology service providers, mobile operators, service providers, creators, distributors and so forth, trust may not exist in all of these parties, for example, in a second-hand market. Hence, a trustful DRM protocol that can deal with DRM but without assuming mutual trust between involved parties is needed. A similar protocol was proposed by Cheung and Curreem (2002).

Robust and secure watermarking: A secure and robust watermarking algorithm is required to protect the distributed multimedia content. Such watermarking algorithm should resist attacks of any kinds. However, it cannot guarantee that a watermarking algorithm can resist all upcoming attacks (Tsang & Au, 2001).

Payment scheme: When trust does not exist, for example, in the second-hand market, a reliable payment scheme becomes an important issue.

Rights expression language: This is a need for a cross-platform rights expression language for all involved parties to specify and utilize their rights.

copyright ownership (Kwok, 2002). Digital watermarks can be visible but they are preferably invisible identification codes that are permanently embedded in the data and present within the data after any decryption process (Doherty, 2002).

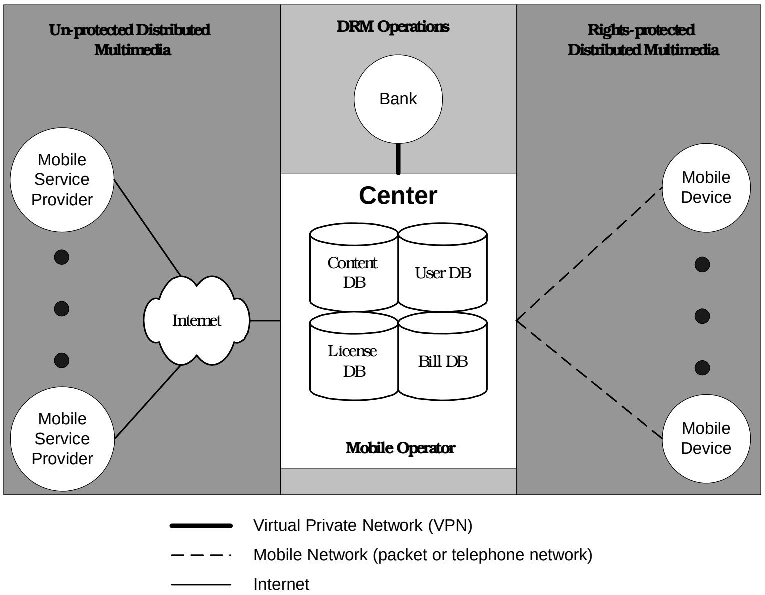
In order to manage digital rights effectively and efficiently, many commercial DRM solutions employ license management models (Kwok & Lui, 2002). A license management model consists of a digital license that keeps access and control rights. Corresponding rights enforcement DRM applications determine usage rights based on these digital licenses.

Mobile Commerce

The current 2.5G mobile technologies for mobile multimedia service are fundamentally different from those used for Internet commerce service, and they impose many limitations and constrains upon the sophistication of mobile multimedia service. This explains why existing DRM systems for Internet commerce cannot be applicable to DRM over the mobile environment in a straightforward way. Some of the most important technical and physical obstacles are summarized as follows:

1. *License management:* A mobile device usually has limited resources of both memory and processing power to handle and process license documents and rights-protected contents.
2. *Limited storage and processing power:* Due to the limited resources of the mobile device, it is not possible to download rights-protected contents to the mobile device and play it there.

Figure 1. DRM solution for mobile multimedia



3. *Rights insertion:* A sophisticated consumer's ID cannot be kept on the consumer's device due to the storage limitation, and it must be provided by another party or uploaded for rights insertion.
4. *Rights enforcement:* An active rights enforcement cannot take place at the mobile device because the device is not capable of intensive computation.
5. *Payment:* Mobile devices cannot support the elaborate computations required for the encryption and de-encryption process of electronic payment, and mobile networks may not be adequately secure to prevent the exposure of personal and credit card information.

CRITICAL ISSUES OF DRM FOR MOBILE MULTIMEDIA

For mobile multimedia, DRM involves specifying and associating rights with the distributed multimedia contents, placing controls on the content to enforce rights, enabling access checks, and tracking permissions usage and payment. For a general mobile service, the required capabilities include:

1. rights specification and rights label management;
2. rights authorization;
3. content protection, rights enforcement, and trusted rendering;
4. rights tracking; and
5. a security and commerce infrastructure.

Business transactions, such as payment, ordering, customer enquiry, and so forth, may occur between the concerned parties during content packaging, distribution, and usage. Managing rights in all these transactions is necessary. To support DRM operations in mobile multimedia, a DRM system needs to perform rights insertion and rights enforcement operations. In addition, a license management mechanism is also needed in managing license documents. A DRM solution for mobile multimedia should possess features stated in Table 1.

There are still many un-resolved technical problems and issues to be addressed before a successful DRM system for mobile multimedia can emerge. Some existing problems and issues are listed in Table 2.

A MOBILE DRM FRAMEWORK FOR MOBILE MULTIMEDIA

This chapter proposes a mobile DRM framework for mobile multimedia, derived from Kwok (2002). The framework is a closed system that hosts all DRM operations within its center and provides a platform for mobile service providers to conduct business with their customers. Apart from rights insertion and enforcement operations, the center can handle transactions with a highly secure payment scheme. It is assumed that the central party is mutually trusted by both the businesses and consumers. A trustful center can be a mobile operator. The distributed multimedia contents between the center and the mobile users are rights-protected with a digital license and watermarking, while the multimedia contents transferring to the center do not require rights protection.

Figure 1 presents the mobile DRM framework for multimedia distribution in a mobile environment. The center of the framework is a mobile operator that manages information to and from mobile devices, mobile service providers and other concerned parties. The principal components include: (1) a mobile network infrastructure; (2) a DRM system; (3) a payment system; and (4) databases. There are three types of parties involved in this framework: the mobile service providers (both official and unofficial sites), the bank, and the mobile users. The communication channels between different parties and the mobile operator are different from and independent of each other depending on the required security level. For example, a virtual private network (VPN) is used between the bank and the mobile operator, since highly confidential information is transferred through this channel, while the mobile operator relies on the packet network for multimedia content distribution, and the mobile service providers transfer multimedia contents to the mobile operator using the ordinary Internet.

The distinct features of the proposed framework include the following.

1. *DRM operation:* All DRM operations are performed by the center. It shifts all the processing and storage requirements to the center and relieves the burdens of the mobile devices and service providers.
2. *Independence of mobile devices:* The center can tailor the format of the distributed media for a specific mobile device. Besides, streaming technology is used in order to overcome the problems of processing power and storage requirement in the 2.5G mobile devices.
3. *Independence of mobile technology:* The framework can be applicable to 2.5G, 2.75G, 3G, 4G, and even higher because it does not depend on any specific mobile standard.
4. *Standardized rights expression language:* Since all DRM operations are managed by a single party—the mobile operator—the rights expression language can be standardized.
5. *Sharing and trading:* It facilitates media sharing and trading between users. Detail may be referred to Kwok (2002).
6. *Payment:* Transactions and payments are handled centrally through a secured channel.
7. *Ease of use and user satisfaction:* All DRM operations are completely transparent to mobile users and the mobile service providers.

FUTURE TRENDS

Mobile DRM for mobile multimedia is still at its infancy. The direction of mobile DRM is driven by the following factors.

1. *DRM standard:* One key player in mobile DRM standard, OMA mobile DRM has been proven successful in applying to music distribution. The standard is currently supported by some major labels, including Warner Music and BMG. However, the spectrum of mobile multimedia covers more than digital music, but also includes visual-audio data, such as movie, video conferencing, and so forth. It is still uncertain whether the market will accept OMA mobile DRM as the common standard for mobile multimedia.
2. *Mobile network:* Mobile multimedia demands a highly capable mobile network to support its services. An independent and constantly high transmission rate mobile network is the basic requirement for satisfactory mobile multimedia services. Unfortunately, the current mobile network, 2.5G or 2.75G, cannot provide a stable multimedia transmission. This problem will be overcome when 3G or 4G is launched.
3. *Mobile device:* The capabilities of mobile devices will be a major factor affecting the quality of mobile service. Pocket PCs usually perform better than smart phones when viewing mobile movie as their viewing screen and processing power are higher.

CONCLUSION

This chapter presents a mobile DRM framework for mobile multimedia. It is a practical and useful DRM framework when common mobile DRM standard and high bandwidth mobile channel are not available. This temporary but timely DRM solution could meet the urgent needs of DRM in mobile services. The primary objective of the framework is to impose DRM on mobile multimedia services without affecting the service providers and users. This is rather different from the emerging mobile DRM standards that require mobile users and service providers to adopt and apply their DRM technologies to mobile devices and distributed multimedia contents. However, privacy is the major problem of the proposed framework because the mobile operator possesses all of our transactions records. To respond to this problem, a possible solution may be encryption (Torrubia, Mora, & Marti, 2001) and an adapting system (Kenny & Korba, 2002).

KEY TERMS

Digital License: A digital license can be a separate file or message embedded in a media file. The license document states all of the terms and conditions concerning the use of the licensed media file. These terms and conditions can be static or dynamic depending on the payment scheme (Kwok, 2002).

Digital Rights Management (DRM): A set of technologies for content owners to protect their copyrights and stay in closer contact with their customers. In most instances, DRM is a system that encrypts digital media content and limits access to only those users who have acquired a proper license to play the content. That is, DRM is a technology that enables the secure distribution, promotion, and sale of digital media content on the Internet.

Identifiers and Metadata: Identifiers (unique labels for entities) and metadata (structured relationships between identified entities) are prerequisites for DRM. The essence of DRM is the control (licensing, etc.) of copies of entities; the identifiers and metadata are then essential to the management of this process, and to distinguishing and expressing relationships such as replicas and derivations (Paskin, 2003).

License Management: A mechanism to execute the terms and conditions stated in the license. This requires coordination among the media player, the media file, and other supporting modules; for example, the payment module. From the technical perspective, license management refers to issuing, hosting, and verifying the license (Kwok, 2002).

Rights Enforcement (or Verification): There are two types of rights enforcement: namely active enforcement and passive enforcement. The active enforcement takes place within the media player as a built-in function. The passive enforcement is an off-line ownership verification operation to check for the hidden owner identities (Kwok, 2002; Kwok, Cheung, Wong, Tsang, Lui & Tam, 2003; Kwok, Lui, Cheung, & Tam, 2003).

Rights Insertion: An operation to embed the identities of the concerned parties and assign business rules and conditions to the distributed multimedia content (Kwok, 2002; Kwok, Cheung, Wong, Tsang, Lui, & Tam, 2003; Kwok, Lui, Cheung, & Tam, 2003).

Watermarking: A technique for media authentication and forgery prevention. It is also viewed as an enabling technology to protect media from reuse without adequate credit or in an unauthorized way (Trowbridge, 2003). A watermarked media, M', can be mathematically represented as $M'=M + W$ where M is the original media content and W is the embedded watermark. It is common that the extracted watermark, W', could be different from the original watermark W because of the intentional or unintentional attacks or post processing. To detect the watermark, a watermark detector is used to evaluate the similarity between W and W'.

Dynamic Multidimensional Data Cubes for Interactive Analysis of Massive Datasets[1]

INTRODUCTION: DATA WAREHOUSING, OLAP, AND DATA CUBES

Rapidly improving computing and networking technology enables enterprises to collect data from virtually all its business units. The main challenge today is to extract useful information from an overwhelmingly large amount of raw data. To support complex analysis queries, data warehouses were introduced. They manage data, which is extracted from the different operational databases and from external data sources, and they are optimized for fast query processing. For modern data warehouses, it is common to manage Terabytes of data. According to a recent survey by the Winter Corporation (2003), for instance, the decision support database of SBC reached a size of almost 25 Terabytes, up from 10.5 Terabytes in 2001 (Winter Corporation, 2001).

Human analysts cannot "digest" such large amounts of information at a detailed level. Instead they rely on the system to provide a summarized and task-specific view of selected data. Consequently, *efficient summarization and aggregation of large amounts of data* play a crucial role in the analysis process. The goal of Online Analytical Processing (OLAP) is to support this style of analysis at interactive response times for massive data collections. OLAP applications often maintain aggregate information in data cubes. Pre-computed aggregate values that speed up query execution for group-bys, cross-tabs, and subtotals can be easily included in the model (e.g., CUBE operator, which is discussed later).

WHY MAKE DATA CUBES DYNAMIC

The primary goal of data warehouses is to support data analysis. Update costs were often not considered to be important, and hence systems are typically oriented towards batch updates, which are applied to the warehouse during times of low system load. The corresponding data cubes would be batch-updated as well, or even be recomputed from scratch. There are several arguments why incrementally maintainable *dynamic* data cubes are preferable.

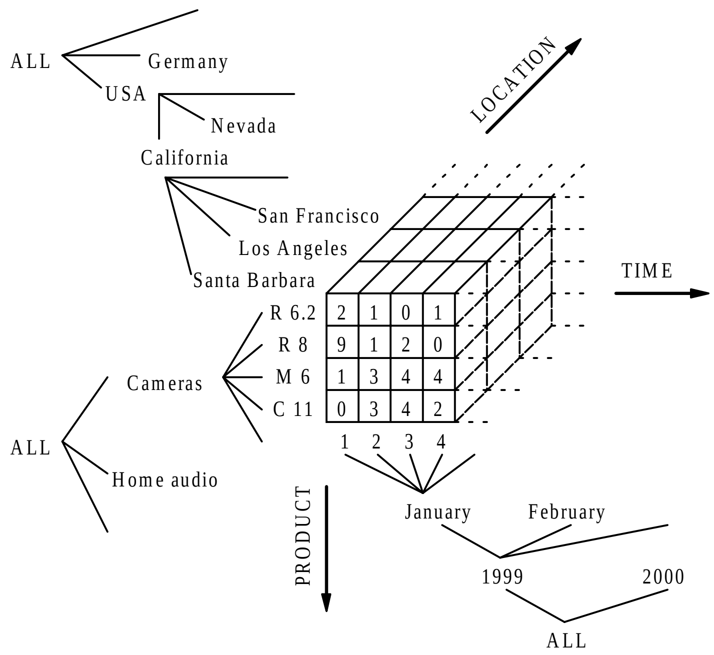
First, for very large data collections, re-computing a data cube from scratch is very costly, even if updates are batched. Second, some data structures that are heavily optimized towards query processing (e.g., the PS technique as discussed below) support only very limited update rates even if the updates are applied in batches. Third, OLAP is inherently an *interactive* information exploration process that includes what-if scenarios. What-if analysis requires real-time and hypothetical data to be integrated with historical data for the purpose of instantaneous analysis and subsequent action.

This article surveys dynamic solutions that offer different tradeoffs between query, update, and storage costs, allowing an administrator to find the matching approach for each application. It will be shown that efficient queries and updates can both be supported for multidimensional data cubes.

BACKGROUND

The terms "cube" and "data cube" are not used consistently in the data warehousing research literature. In this article they refer to a conceptual model similar to a multidimensional array. A simple example is a sales data cube SalesCube with dimensions product, time, and location, and the measure attribute amount (value of sales transaction). Figure 1 shows a possible instance with dimension hierarchies indicated (ALL represents the whole domain of an attribute). Note that we do not advocate any

Figure 1. Cube example



particular cube implementation (Roussopoulos, Kotidis & Roussopoulos, 1997; Sarawagi & Stonebraker, 1994) or system architecture like MOLAP or ROLAP.

Dominant aggregate query types on data cubes are roll-up/drill-down and slice-and-dice (Chaudhuri & Dayal, 1997). These queries are typically *range queries* or sequences of related range queries like hierarchical range queries (Koudas, Muthukrishnan & Srivastava, 2000). Hence we are mainly concerned with support for *aggregate range queries*. For the cube in Figure 1, an example is: "Compute the total sales of cameras in California for the first half of January 1999." The corresponding SQL query is

```
SELECT SUM(amount)
FROM SalesCube
WHERE time>='1-Jan-1999' AND time<='15-Jan-1999' AND
location.state='California' AND
product.category='Cameras'.
```

Note that location is a *categorical dimension* for which arbitrary range selections like "San Francisco < town < San Diego" are not meaningful. On the other hand it is very common to aggregate according to the dimension hierarchy. In the example, California corresponds to a range of selected cities (by making sure the dimension values are ordered according to the hierarchy). The same holds for other categorical dimension attributes like product.

For the following discussion we assume that the data cube has N cells in each dimension, that is, it has a total of N^d cells. Note that all techniques also work for cubes with different dimension sizes, but since our goal is to present the main tradeoffs of the techniques, we try to avoid notational clutter as much as possible. For the same reason we also omit ceiling and floor brackets from the formulas.

DATA CUBES FOR INVERTIBLE AGGREGATE OPERATORS

For invertible aggregate operators like SUM, COUNT, and AVG (when expressing it with SUM and COUNT), elegant techniques have been developed that do not require additional storage compared to materializing the original (dense) MOLAP cube. In the following we will survey techniques for the operator SUM. Other invertible operators are handled in a similar way.

Let A denote the original data cube. The cost of an operation is measured in terms of accessed cube cells, for example, updating a single cell in A results in a cost of 1. Answering an aggregate range query using A can be very costly. Even for a small cube with only three dimensions which contains data about 1,000 products, 100 store locations, and six years (about 2,000 days), a query in the worst case has to access and aggregate the values of 200 million cells. Hence using the original data cube *A* for OLAP represents a perfectly dynamic solution, but achieves only unsatisfactory query efficiency.

Trading off Query and Update Performance

Ho et al. (1997) addressed the problem of high query costs with the Prefix Sum (PS) technique. The main idea is to answer queries using a prefix sum cube *PS* whose cells *c* store the pre-computed sum of all cells in *A* which have smaller or equal dimension coordinates than *c*. Based on the principle of inclusion-exclusion, each range sum query on *A* can be computed from up to 2^d appropriately selected prefix sums in *PS*. Note that this cost is independent of the size of the data cube and the size of the selected query range. Unfortunately, the query efficiency comes at a price: in the worst case a single update could require the re-computation of the entire *PS* cube (at a cost of N^d).

To avoid PS's expensive cascading updates, Geffner and his colleagues (1999a, 1999b) introduced the Relative Prefix Sum (RPS). A later version of RPS removed the initial storage overhead (Riedewald, Agrawal, El Abbadi & Pajarola, 2000b). The main idea is to partition *A* into smaller hyper-rectangular chunks, called *boxes*. The *inner* cells of a box store prefix sums local to the box, while the *border* cells in selected surfaces also aggregate outside values. When the side-length of a box is set to $\sqrt{N}$ in each dimension, then the worst-case costs are 4^d for queries and $(2\sqrt{N})^d$ for updates.

The Dynamic Data Cube (DDC) proposed by Geffner, Agrawal, and El Abbadi (2000) balances query and update costs such that they are both polylogarithmic in the data size. Riedewald et al. (2000b) removed the considerable storage overhead of the original technique. Like RPS, DDC conceptually partitions the original cube into boxes. However, in contrast to RPS the partitioning is applied recursively to both inner and border cells. If the recursive box partitioning always divides boxes in half, the technique guarantees worst-case costs of $(2\log_2 N)^d$ and $(\log^2 N)^d$ for queries and updates, respectively.

Schmidt and Shahabi (2002) proposed ProPolyne, a wavelet-based pre-aggregation technique, which also guarantees polylogarithmic query and update costs. Depending on the selected wavelet encoding, all aggregates that are polynomials up to a fixed maximum degree over the measure values can be supported by a single data cube. The authors also show that high-quality approximate results can be obtained at a fraction of the cost of the exact result. Interestingly ProPolyne and DDC not only have the same asymptotic query and update cost; they also have the same storage requirements. Choosing wavelets that support higher-degree polynomials for ProPolyne has the same effect on storage as storing additional measure values of higher degrees in a DDC cube.

Chan and Ioannidis (1999) are the first to explicitly explore the possibility of letting the user choose a query-update tradeoff by parameterizing the construction of the pre-aggregated cube. They apply ideas from bitmap index design and define a class of so-called Hierarchical Cubes (HCs). The data cube is hierarchically partitioned into smaller boxes of equal size. According to the partitioning, the cells are assigned to classes, which determine the aggregate stored in a cell. Explicit, but complex, cost formulas enable an analyst to choose the best parameter setting for an application by experimental evaluation.

Combining Efficiency, Flexibility, and Simplicity

RPS, DDC, and HC are sophisticated multidimensional pre-aggregation techniques. Hence the corresponding algorithms are typically complex (Chan & Ioannidis, 1999; Geffner et al., 2000), and it is difficult to prove their correctness and to analyze their performance. The different dimensions of a data cube are treated uniformly in the sense that even though box sizes might vary, the same general scheme is used for each dimension. However, in practice, attributes have very diverse characteristics, for example, gender and income in a census data set. Also, for some attributes a priori information about the query workload could make one aggregation technique preferable over another.

This is the motivation behind the Iterative Data Cubes (IDC) approach proposed by Riedewald, Agrawal, and El Abbadi (2001). The approach provides a modular framework for combining *one-dimensional* pre-aggregation techniques to create space-optimal multidimensional pre-aggregated data cubes. An analyst can select the most appropriate technique for each dimension attribute independently, then the corresponding *multidimensional* IDC cube is automatically generated. Query and update algorithms for a *d*-dimensional IDC cube are a straightforward combination of the one-dimensional algorithms. Similarly, query and update *costs* for a *d*-dimensional IDC cube can be computed as the product of the corresponding costs for each single dimension. Table 1 shows selected techniques with their respective worst-case costs for vectors with *N* elements. The possibility of combining arbitrary one-dimensional pre-aggregation techniques allows generating a great variety of IDC instances.

Table 1. Query-update tradeoff for selected one-dimensional techniques

	Query cost (worst case)	**Update cost (worst case)**
Original array (A)	N	1
Prefix Sum (PS)	2	N
Relative Prefix Sum (RPS)	4	$2\sqrt{N}$
Dynamic Data Cube (DDC)	$2\log_2 N$	$\log_2 N$

DATA CUBES FOR OTHER AGGREGATE OPERATORS

Popular aggregate operators like MIN and MAX cannot be handled by the techniques discussed in the previous section due to the lack of an inverse operation. This section summarizes approaches that work for these two operators, and other commutative semigroup operators as well.

In Ho et al. (1997), a technique for the computation of range max queries is proposed. The data cube is recursively partitioned into smaller chunks. For each chunk, the position of its maximum value is stored. The corresponding tree is traversed top-down, using pruning techniques to reduce the number of accesses. Lee, Ling, and Li (2000) use a similar data structure, but a different pruning strategy. They obtain constant average query cost and logarithmic update cost in the size of the data cube (for fixed dimensionality). Poon (2003) develops an optimal range max data cube for the static case (no updates) that guarantees constant query cost and a storage cost that is linear in the size of the original cube.

Poon (2001) also proposes a general approach for commutative semigroups. Similar to Iterative Data Cubes, it combines one-dimensional schemes. Query, update, and storage costs for range max queries are $O((4L)^d)$, $O((12L^2 N^{\frac{1}{L}}\gamma(\mathrm{N}))^d)$, and $O((6N\gamma(N))^d)$, respectively. Here $L\in\{1,...,\log N\}$ denotes a user-controlled parameter and $\gamma(N)$ a slow-growing function. Applied to invertible operators, the query, update, and storage costs are $O((2L)^d)$, $O((2LN^{\frac{1}{L}})^d)$, and $O((2N)^d)$, respectively. Note that the greater generality of the technique comes at a cost: techniques like IDC, which are optimized to take advantage of the inverse operator, achieve better cost tradeoffs for invertible operators. For instance, for $L = 1$, an IDC that uses PS in each dimension achieves the same query, but lower update and storage costs (please see Table 1). Similarly IDC using RPS (DDC) in each dimension offers a better solution than the above technique for L=2 (L=log$N$).

THE DATA CUBE OPERATOR CUBE

CUBE, as proposed by Gray et al. (1997), generalizes SQL's GROUP BY operator. It computes the results of grouping a data set by all subsets of the specified d dimensions. Hence 2^d related groups, called *cuboids*, are generated. The overall result of CUBE will be referred to as *Cube*. In relational database terminology the cuboids are *views* generated by the corresponding GROUP BY queries.

Cube's main purpose is to support aggregate queries. A query that only selects a few attributes can be efficiently answered by processing the appropriate compact cuboid. Specialized index structures for Cube (Johnson & Shasha, 1999; Roussopoulos et al., 1997; Sismanis, Deligiannakis, Roussopoulos & Kotidis, 2002) further reduce query time. A large body of research focused on efficient computation, maintenance, and space reduction for Cube (Beyer & Ramakrishnan, 1999; Gupta, Harinarayan, Rajaraman & Ullman, 1996, 1997; Shukla, Deshpande & Naughton, 2000; Sismanis et al., 2002; Wang, Lu, Feng & Yu, 2002; Baralis, Paraboschi & Teniente, 1997).

CONCLUSION AND FUTURE TRENDS

We have discussed several approaches for supporting dynamic data cubes, focusing on MOLAP techniques. The commonality between all approaches is that they try to find a certain balance between query, update, and storage cost. While earlier work mostly focused on query and storage aspects, large data sets with frequent updates created a need for more dynamic solutions.

In the future, support for *sparse* and *high-dimensional* data will become increasingly important for supporting analysis of complex business processes, which depend on many attributes. Existing approaches from the computational geometry (de Berg, van Kreveld, Overmars & Schwarzkopf, 2000; Chazelle, 1988; Willard & Lueker, 1985) and database communities (Riedewald, Agrawal & El Abbadi, 2000a) have infeasible storage overhead or do not provide non-trivial performance guarantees. Independent of the data being dense or sparse, the current trend of rapidly growing data collections creates a strong incentive for developing new powerful *dynamic* approaches for maintaining data cubes *incrementally*.

KEY TERMS

Aggregate Range Query: Selects a range of values in each dimension (dimensions not specified in the query are by default completely selected) and computes an aggregate, e.g., SUM, MAX, or COUNT, over the measure values of all data cube cells whose coordinates fall into the selected range. A typical aggregate range query is: "Compute the total sales of cameras in California for the first half of January 1999."

Cell: A point in the multi-dimensional data space. For a *d*-dimensional data cube, it is defined by a *d*-tuple of dimension values. A cell contains the values of the measure attributes of the data item that falls into that cell. If there is no such data item, then the cell is empty.

Data Cube: A data set is conceptually modeled as being embedded in a multidimensional hyper-rectangle, or data cube for short. The data cube is defined by its dimensions and stores the values of measure attributes in its cells.

Dense Data Cube: A data cube is dense if a significant number of its cells (typically at least 1 to 10%) are not empty.

Dimension: A dimension attribute of an entity is a functional attribute that describes an aspect of the entity, e.g., location or product. Dimension attributes can be hierarchical, e.g., year-quarter-month-day for the time dimension.

Measure: A measure attribute of an entity is an attribute of interest whose value depends on the dimensions of the entity. Measure values are aggregated and analyzed in OLAP. Examples are revenue and cost.

MOLAP: OLAP architecture that is based on a multidimensional database server. It typically maintains data cubes in compressed array-like data structures.

OLAP(Online Analytical Processing): A category of applications and technologies for collecting, managing, processing, and presenting multidimensional data for analysis and management purposes (Pendse & Creeth, 2003).

ROLAP: OLAP architecture that is based on a relational database engine. Data cubes are maintained in relational tables.

Sparse Data Cube: The vast majority (e.g., 99%) of the data cube cells are empty.

E-Business Systems Security for Intelligent Enterprise

Denis Trcek
University of Primorska, Koper, Slovenia

INTRODUCTION AND BACKGROUND

Security became a topic of research with the introduction of *networked information systems*, or networked IS, in the early eighties. In the mid-nineties the proliferation of the Internet in the business area exposed security as one of the key factors for successful online business, and the majority of effort to provide it was focused on technology. However, due to lessons learned during this period, the paradigms have since changed, with increasing emphasis on human factors. It is a fact that security of information systems is becoming part of the core processes in all e-business environments. While data is clearly one of the key assets and has to be protected accordingly, IS have to be highly integrated and open. Appropriate treatment of these issues is not a trivial task for managers of intelligent enterprises and requires new approaches, especially in light of new technologies.

Proper management of security in *e-business systems* requires a holistic methodology with a two-plane approach, technological and organizational. In every case IS security management starts with the identification of threats and threats analysis - a typical example is based on risk probability and damage estimates (Raepple, 2001). Following this, the approach differs according to the plane:

- The technological plane takes into account machine-related interactions. This plane is about deployment of appropriate *security services* that are based on *security mechanisms*. To become operational, key management issues (i.e., handling of cryptographic algorithms' keys) have to be resolved. Finally, human-to-machine interactions have to be addressed carefully.
- In parallel, it is necessary to properly address the organizational plane where human resources management plays a central role. This plane emphasizes the organizational issues and socio-technical nature of contemporary IS, where modern methodologies play a central role.

FUTURE TRENDS: TECHNOLOGICAL PLANE OF IS SECURITY MANAGEMENT

From the technological point of view, the prevention of threats is achieved by use of security mechanisms and security services (ISO, 1995). Mechanisms include symmetric and asymmetric cryptographic algorithms, for example, AES (Foti, 2001) and RSA (RSA Labs, 2002); one-way hash functions such as SHA-1 (Eastlake, 2001); and physical mechanisms. For devices with weak processing capabilities like smart-card, elliptic curve-based systems such as ECDSA (ANSI, 1998) can be used. Regarding physical security, using cryptographic algorithms one can only reduce the amount of data that has to be physically protected, but the physical protection cannot be avoided.

To ensure that a particular public key indeed belongs to the claimed person, a trusted third party called *certification authority*, or CA, has to be introduced. The CA issues *public key certificates* that are digitally signed electronic documents, which bind entities to the corresponding public keys (certificates can be verified by CA's public key). CA also maintains certificate revocation lists, or CRL that should be checked every time a certificate is processed in order to ensure that a private/public key is still valid. The de iure and de facto standard for certificate format is X.509 standard (ITU-T, 2000).

By use of security mechanisms, the following security services are implemented:

- Authentication: Ensures that the peer communicating entity is the one claimed.
- Confidentiality: Prevents unauthorized disclosure of data.
- Integrity: Ensures that any modification, insertion, or deletion of data is detected.
- Access Control: Enables authorized use of resources.
- Non-Repudiation: Provides proof of origin and proof of delivery, where false denying of the message content is prevented.

- Auditing: Enables detection of suspicious activities and analysis of successful breaches, and serves as evidence when resolving legal disputes.

To enable these services, a certain infrastructure has to be set up. It includes a Registration Authority (RA) that serves as an interface between a user and CA, identifies users, and submits certificate requests to CA. In addition, a synchronized time base system is needed for proper operation, along with a global directory for distribution of certificates and CRLs. All these elements, together with appropriate procedures, form a so-called *public key infrastructure* or PKI (Arsenault, 2002).

To provide security, mostly commercial off-the-shelf solutions are used. Such solutions typically include firewalls, which are specialized computer systems that operate on the border between the corporate network and the Internet, where all traffic must pass through these systems (Cheswick & Bellovin, 1994). Further, real-time intrusion detection systems (Kemmerer, 2002) are deployed for detecting acts that differ from normal, known patterns of operation, or for detecting wrong behavior. Further, IPSec (Thayer, 1998), which is a security enhancement for IP protocol, can be used to prevent masquerade, monitoring of a communication, modification of data, and session overtaking. IPSec is suitable for Virtual Private Networks or VPNs, where one can establish secure private networks using public networks such as the Internet. Further, Secure Sockets Layer protocol or SSL (Freier, 1996) provides a common security layer for Web and other applications, and is available by default in Web browsers. It provides authentication, confidentiality, and integrity with the possibility of negotiating crypto primitives and encryption keys. Further, Secure/Multipurpose Internet Mail Extensions standard or S/MIME (Ramsdell, 1999) is often deployed as security enhancement for ordinary e-mail, and provides authentication, confidentiality, integrity, and non-repudiation.

Finally, the security of new paradigms has to be covered. These paradigms include objects, components, mobile code (computing), and *intelligent agents*. Every code (and object) can be treated as an electronic document. The creator defines its initial data and behavior (methods) and, optionally, signs it. The signature on the code gives a user the possibility to be assured of proper functioning of this object, where the problem is analogous to that of ensuring authentication and integrity for ordinary electronic documents. When considering intelligent mobile agents that are objects that satisfy certain conditions (Griss, 2001), the security paradigm is reversed. Agents operate in unpredictable environments and have to be protected from malicious hosts. These important issues have yet to be resolved (FIPA, 2001).

FUTURE TRENDS: ORGANIZATIONAL PLANE OF IS SECURITY MANAGEMENT

Even superior technological solutions will be in vain, if the complementary organizational issues are not treated properly. Therefore the second plane must be concentrated on organizational issues through human resources management, which has to be properly embodied in *security policy*. The basic standard in this area is BS 7799 (BSI, 1999), which recently became an international standard (ISO, 2000). It presents the main methodology, which is followed by the growing number of organizations for establishing security policy. It consists of two parts. The first part describes a code of practice for information security management, while the second specifies information security management systems.

This standard plays a central role as far as security policy is concerned. However, to implement successfully a concrete security policy, it is essential to support managers of intelligent enterprises with appropriate techniques. The organizational plane is characterized by a complex interplay between human factor and technology. The two constituent parts are coupled in many ways, such as by interactions - a large number of these interactions form various feedback loops. There are also soft factors that have to be taken into account, for example, human perception of various phenomena like trust. Therefore, to support decision making properly with regard to security, one has to deal with physical and information flows. Additionally, decisions are often to be made in circumstances where there is not enough time or resources to test decisions in a real environment; often such checks are not possible at all. Therefore support from computer simulations is highly desirable.

The methodology that can be used to support the resolution of the above-mentioned problems is *business dynamics* (Sterman, 2000). It enables qualitative and quan-

Table 1. Summary of basic security-related elements—technological plane

titative modeling of contemporary IS. Using this methodology, one starts with the identification of variables that are relevant to system behavior and defines the boundary distinguishing between endogenous and exogenous variables. Variables are connected by causal links which have positive polarity if increase/decrease of input variable results in increase/decrease of output variable. In a case when increase/decrease of input variable results in decrease/increase of output variable, the polarity is negative. Some variables are of a stock nature (also called levels), and these introduce persistency (inertia) to the system. They decouple inflows and outflows, and thus present a kind of buffer or absorber. When building a model of a system by this approach, so-called causal loop diagrams are obtained which provide a very useful means for management of e-business systems security. Finally, causal loop diagrams are upgraded with appropriate equations and tuned using real data to enable quantitative analysis, that is, computer simulation.

Business dynamics can be further enhanced by linking it to *business intelligence* (Ortiz, 2002) in order to achieve an appropriate architecture for qualitative and quantitative management of security in intelligent enterprises. The basis is operational security-related data that comes from various sources: general host logs, router logs, application logs, phone and fax logs, physical security system logs, and so forth. These operational, legacy data have to be transformed in the next step, which means preparation of data for a security data warehouse. The exact data that have to be captured in a security warehouse are defined in line with the causal loop diagram model of an organization. This also implies that such a solution will have to be tailored to the needs of each particular organization.

Summing up, security policy is the main document about risk management in every organization, and its introduction and maintenance has to be adequately supported by use of modern business intelligence techniques. Using causal loop diagramming, decision makers can get a holistic perspective on their systems, but to verify and properly adjust these models, they have to link them to appropriate sources to obtain real-time data for simulations. The resulting architecture provides an important tool for information security management of intelligent enterprises with emphasis on the human factors that are critical in the context of security policy.

CONCLUSION

Even in the era of intelligent enterprises, security management cannot avoid technical foundations. It is a fact that classical, cryptography-based approaches form the core of all security management, so that each IS security has to start with addressing these issues. However, this basis serves as a starting point for further development of methodologies for risk management that are concentrated on human resources. Experience shows that human factors play an increasingly important role. Taking this into account and due to the emergence of business intelligence, it is possible to further support the management of IS security. Using business dynamics and business intelligence techniques, decision makers can obtain data in real time and simulate the effects of their decisions in advance. This way they are armed with additional tools for successful protection of their IS.

KEY TERMS

Business Intelligence: Deployment of (usually artificial intelligence-based) techniques such as On-Line Analytical Processing and data mining to analyze information in the operational data sources.

Certification Authority: An authority trusted by one or more users to create and assign public key certificates.

E-Business System: An organized, structured whole that implements business activities that are based on electronic technologies, methodologies, and processes.

Networked Information Systems: An IS that is strongly integrated in a global network. From the technological point of view, the difference between the IS and the global network is blurred; however, it exists from the administrative point of view.

Public Key Certificate: The public key of a user, together with some other information, rendered unforgeable by encipherment with the private key of the certification authority that issued it.

Public Key Infrastructure: The infrastructure capable of supporting the management of public keys able to support authentication, encryption, integrity, or non-repudiation services.

Security: A set of processes aimed at minimizing the vulnerability of assets and resources.

Security Mechanism: A basis for a security service—using particular security mechanism (e.g., cryptographic algorithm), the security service is implemented.

Security Policy: These are documented procedures that focus on the organization's management of security; it is about information confidentiality, integrity, and availability of resources.

Security Service: A service provided by an entity to ensure adequate security of data or systems.

System Dynamics: An interdisciplinary method to enhance learning of complex systems that is based on nonlinear dynamics and feedback control.

E-Business Transaction in Web Integrated Network Environment

V.K. Murthy
University of New South Wales, Australia

E.V. Krishnamurthy
Australian National University, Australia

INTRODUCTION

The World Wide Web (or the "Web") is revolutionizing the concept of service -oriented computing. It permits the integration of the local area networks (LAN) and wide-area networks (WAN), thereby providing servers that are interconnected at a worldwide or an intergalactic level. Such an integration serves as a backbone for the Web-based business or e-business to access information, as well as perform e-business transactions across the globe with adequate security and reliability. In this article, we describe the issues involved in the design of an e-business transaction processing system and the solutions that have been proposed for these problems using the techniques of AI, conventional database transaction processing methodology and protocol engineering principles. These techniques will be useful for improved transaction throughput and scalability in e-commerce (Brancheau & Shi, 2001; Menasce & Almeida, 2000; Murthy, 2002).

BACKGROUND

Transaction management is a well-established research area with many successful results having been achieved so far. Transactions that have ACID (atomicity, consistency, isolation and durability) properties have traditionally been used to ensure consistent database management through atomicity (all or none) of actions as well as isolation of user actions (Elmagarmid, 1995; Krishnamurthy & Murthy, 1992). Recent advancements in transaction management have relaxed some of these traditional properties of transactions. The appropriate properties for transactions in a *Web-integrated network environment* (we use the acronym WINE, for brevity) have been studied recently by Chen and Dayal (2000), Ghezzi and Vigna (1997), and Murthy (2002). These papers also discus issues and problems that mobility brings into transaction management, and describe new methods using workflow and mobile agents and various types of new software tools currently available such as Java, Java database connectivity and CORBA (Common Object Request Broker Architecture-Dignum & Sierra, 2001). A distributed multi-database system with many autonomous and heterogeneous component databases will provide support for the management of global e-business (also known as "intergalactic") transactions and data resources in a WINE with mobile and stationary hosts.

The WINE consists of a collection of dissimilar (heterogeneous) computers (fixed host computers (FH) and mobile client computers (MC)) connected through the fixed-wired networks (such as the Ethernet), as well as wireless (mobile) networks connected together via a fixed high-speed network (Mbps to Gbps). The mobile clients (MC) are capable of connecting to the fixed network via a wireless link. Fixed host (FH) provides mobile application services and coordinates tasks to mobile hosts. MC supports query invoking and information filtering from FH to provide personal information service. Since the computers may have different computational powers and may use different representations for data we need to take care of not only the incompatibility among their representations, but also about their interoperability in using different pieces of software. Also, to achieve high performance and reliability (that provides maximal concurrency and recovery under failure), we need suitable computational models to help understand and analyze their behavior.

MAIN THRUST OF THE ARTICLE

The following subsections bring out the main thrust of the chapter, and deal with the following aspects: requirements for e-business transactions, operational models for e-business systems, intergalactic computing for e-business, new logical modes for e-business environment, communication bandwidth management, agent technology, and e-business protocols.

REQUIREMENTS FOR E-BUSINESS TRANSACTIONS

E-business transactions need to have the following properties: attribute-sensitivity, attribute tolerance, time-criticality, and time-tolerance and eventual consistency. Attribute and time tolerant, and time critical transactions arise in planning or "what-if" programming mode (subjunctive) where we execute hypothetical or pseudo-transactions to test the intention of actions for trial-error design. For example, such transactions arise in real-time transactions in e-shopping carts.

The e-shopping cart holds a record of the selection the buyer intends to buy. At any point the buyer can review the items, remove items, or change their quantity, type and brand. It is useful to have the shopping cart in place even if the buyer leaves the Web site to do something else and come back later. Such a persistent e-shopping cart is very useful for grocery shopping. This of course requires a deadline on the availability, as well as pricing, since some items can go up or down in pricing. Thus the buyer does not only control the items selected, but the shop automatically changes its current availability and pricing at the time when intention commit becomes an action commit. The time-tolerant and eventual consistency property is used in e-tailing. To handle time-criticality, for example, inconsistency on deadlines, we need to ensure that the fixed host can meet the required deadline by determining a priori whether an incoming transaction or a part of a transaction from a mobile host is schedulable within that deadline. A bounded amount of inconsistency may be introduced to finish a task within a deadline or accept inconsistency only when the transaction is about to miss the deadline. This can be specified by condition-event-action or rule based systems. Thus in e-business, the traditional transaction model needs to be replaced by a more realistic model called "workflow" between the customer and the trader (Geppert, 2000; Murthy, 1998, 2001).

OPERATIONAL MODELS FOR E-BUSINESS SYSTEMS

Many applications in e-business require several different services: file service, transaction processing, database access, and applications including graphics. Since no one system can be versatile enough to provide all these services, we need to bring in a client-server relationship among the consumer and the service provider so that the required server processes run in separate machines and the client requests any one of these or a combination of these services through a network of interconnected servers. Typically, these services are built using middleware packages that tie the client to the servers by coordinating client-server interactions. A beautiful property of the client-server relationship is that it is flexible and malleable.

In fact, the distributed applications can be split between client, as well as server by appropriately adding extra functions to either one of them, making them "fat clients" or "fat servers" or even peers so that they are equals. Hence the name peer-to peer or P2P computing is currently widely used.

As examples of fat client and fat server, we can recall the functions such as Code on Demand (COD) and Remote Evaluation (REV) used in earlier days. The COD represents a simple fat client; here, to obtain a single value from a table of data, the searching routine is transmitted from the client to the remote server. In REV we have the simplest "fat server"; here, to obtain a single value from a table of data, the searching routine is implemented in the server and this routine is activated by remote invocation or by a trigger. In fat clients the bulk of the applications run in clients, while in fat servers the bulk of the applications run in several servers. To make the task easier, the two-tier client server is replaced with three or more tiers, where the middle tier or tiers handle the application services.

For example, in the N-tier system (NTS), the middle tier is not implemented as a monolithic program, but as a collection of components that are used in a variety of client-initiated business transactions. Each such component realizes a small business function.

The three-tier and N-tier models provide for excellent security, better performance, ease of development, hardware flexibility, rich communication choices and heterogeneous functionality support (Orfali, Harkey & Edwards, 1996, 1999).

INTERGALACTIC COMPUTING FOR E-BUSINESS

To develop a suitable inter-galactic computing model for e-business the client-server needs to provide a very high bandwidth for WINE so that it provides an information highway for an electronic bazaar. This requires handling architectural heterogeneity between communicating machines. Also appropriate choice of programming paradigms and related software tools are to be made available to the mobile host so that clients can install special purpose interfaces with appropriate properties they require at the remote fixed-host.

Some key technologies necessary for these developments are:

a. ***New logical modes of computation:*** These modes support a variety of trial and error transactions, long duration diagnostic transactions, and speculative business-to-business transactions (B2B).

b. ***Bandwidth requirements:*** Very high bandwidth is needed to connect to the access point on the WAN, high bandwidth for connecting wireless link to the LAN or WAN.

c. ***Agent technology:*** An agent is a code-containing object along with the data and the execution context. It can travel through the network, collect information, gather statistics, and perform a variety of tasks across different hardware platforms.

NEW LOGICAL MODES FOR E-BUSINESS ENVIRONMENT

An e-business environment needs to be rich in its problem solving capability, since it needs to serve as a virtual logical tool for the user. Such a tool is meant for effective decision making using different logical modes to cooperatively solve a business problem. Most conventional programming uses two types of logical constructs: declarative (declaration or assertion oriented) and imperative (command oriented). In a e-business environment, in addition to these constructs we need two other logical modes - subjunctive (what if I do this? or speculative) and abductive (how did this happen? or diagnostic) programming features that add additional power to the user and provide for various forms of reasoning to aid planning, analyzing, acquiring and arguing.

The subjunctive logical mode arises in practical situations such as: planning, reservation, purchases and forecasting. Abduction is useful in e-business as a diagnostic tool, especially in a failure diagnostic situation. For the subjunctive and abductive modes, the conventional transactional model is unsuitable due to ACID properties and serializability requirements. Atomicity is very restrictive, since all or no operations should take place indivisibly as one entity. Also, consistency may not be achievable in subjunctive and abductive reasoning situations. In addition, we may have to relax the isolation property, since it prevents each transaction from looking into what other transactions are doing at intermediate stages; here we need data exchanges to achieve consistency. Durability and recovery are to be supported under failures and voluntary disconnection and reconnection of the mobile hand fixed hosts and have to take place through data exchange that is not atomic. Thus disconnection and reconnection are essential functions and protocols are to be designed using suitable logs and recovery mechanisms.

COMMUNICATION BANDWIDTH MANAGEMENT

Bandwidth determines the information capacity of a network per unit of time. Text requires the lowest bandwidth, while audio and video data and signals require significant increase in bandwidth. Specification of bandwidth to be used and compression techniques used are to be laid down so that the data and images that are transmitted for e-business should be of high quality for advertising and marketing so as to serve their purpose appropriately.

Wireless networks deliver lower bandwidth than a wired network. Hence software techniques based on compression should be used for effective communication. Also scheduling communication intelligently can save bandwidth. For use in e-market, such techniques should be extremely reliable.

AGENT TECHNOLOGY

An agent is a code-containing object that along with data and execution context can migrate autonomously and purposefully within a computer network. Thus an agent knows what to do with the information obtained from its environment. They behave like actors and have intentions and actions. In addition, agents are flexible, proactive and have multithreaded control. These properties enable the consumers to place agents to look after their interests and business organizations to deploy agents to sell their products. Agent technologies are also useful for cross-platform operation and in efficient management of communication and the consequent reduction in bandwidth requirements, security enforcement, error-correction, transaction and notification services, and numerous other services (Nagi, 2001; Woolridge, 2002).

E-BUSINESS PROTOCOLS

We mentioned that the traditional transactional model is not well suited in WINE, since data consistency, deadlines and scheduling are to be taken care of. In such systems it is preferable to have a negotiation protocol between the client and host to carry out tasks reliably. This can go through two phases, called intention phase and action phase. These phases enable us to carry out subjunctive or “what-if” programming in which we execute hypothetical or pseudo-transactions to test the intention of each party and then perform actions. The subjunctive programming paradigm is widely applicable in mobile computing, as it allows the mobile client and fixed host to interact and negotiate and carry out transactions, workflows, as well as connection - disconnection protocols and propose-revise protocol for the abductive mode of tele-reasoning.

FUTURE TRENDS

New Software Tools

There are several available languages (Knabe, 1996; Yourdon, 1996) for programming the different operational models. Java seems to be ideally suited to our requirements. Java is a complete programming language, which offers all the basic mechanisms for communication and synchronization between processes and guarantees portability of the code across multiple architectures and operating systems in a high performance secure way. The distributed networking nature of Java permits the development of all the six models of distributed systems. Also the Java Database Connectivity Application Program interface (JDBC API) provides for simultaneous connection to several databases, transaction management, simple queries, and manipulation of precompiled statements.

Agent-based technology will provide new approaches to e-business transactions. Mobile agents in Java can also be very useful in mobile computing. Java is very suitable for CORBA (Common Object Request Broker Architecture) application development since Java and CORBA are similar in architecture; this similarity in architecture results in the near seamlessness between Java and CORBA (Lucena et al., 2004; Orfali, Harkey & Edwards, 1996; Rosenfeld & Morville, 1998; Siegel, 1996). Java provides to CORBA the capability to develop a client-side application once and run it on many platforms. Also, CORBA provides the benefit of cross-language interoperability to Java. CORBA provides an object-oriented abstraction that permits Java-based systems to communicate with applications written in almost any language.

CONCLUSION

We described the key issues involved in the design of online e-business transaction processing systems in a Web integrated network environment (WINE) and the solutions available for these problems using the techniques of AI, conventional database transaction processing methodology and protocol engineering. Agent technology will play a key role in e-business transaction management.

KEY TERMS

ACID Properties: Conventional online transaction processing (OLTP) requires the following properties called "ACID properties":

- **Atomicity (A):** All changes are totally done (committed) or totally undone (rolled back).
- **Consistency (C):** The effect of a transaction preserves the invariant properties of the system.
- **Isolation (I):** Intermediate results are not visible to other transactions. Transactions have the effect of executing serially, although they act concurrently.
- **Durability (D):** The effects of a transaction are persistent; changes are not lost except under catastrophic failure.

Agent: A system that is capable of perceiving events in its environment, or representing information about the current state of affairs and of acting in its environment guided by perceptions and stored information (current definition by AOIS, agent oriented information system community).

CORBA - Common Object-Request Broker Architecture: This is an object oriented architecture that provides a standard mechanism for defining the interfaces between components, as well as tools to facilitate the implementation of interfaces using the developer's choice of languages, thus providing for language and platform independence.

Programming Modes

- **Abductive Mode:** This mode permits programs to explore "how did this happen?" or provides for diagnostic programming features.
- **Declarative Mode:** Declaration oriented languages-such as Prolog, using declarative statements such as: x is greater than y.
- **Imperative Mode:** Command oriented languages-such as Fortran, Cobol, using commands, DO, GO TO, and so forth.
- **Subjunctive Mode:** This mode permits programs to do speculation, namely, "what if I do this?" mode.

Protocols: A set of rules that dictate the behavior of objects for communication and interaction.

Transactions

- **Attribute-Sensitive:** The transactions are to be committed or aborted locally or globally depending upon their exact attribute values.
- **Attribute Tolerant:** The transactions can be permitted to be locally relaxed in terms of certain constraints on attributes, but globally consistent eventually.
- **Time-Tolerant and Eventually Consistent:** Some transactions can wait until reconnection takes place, and are not time- critical, in the sense they will not create global inconsistency, but are only necessary to provide an eventual consistency with respect to the user and the relevant database.

Workflow: A collection of tasks organized to accomplish some business activity between the customer and the trader supported by suitable protocols.

E

E-Collaboration Support Systems: Issues to be Addressed

Nikos Karacapilidis
University of Patras, Greece

INTRODUCTION

Removal of communication impediments and provision for techniques that systematically direct the pattern, timing, and content of cooperative processes are two key prerequisites in the contemporary organization. Their establishment has been proven to facilitate the solution of ill-structured problems by a set of individuals working together as a team, through the interactive sharing of information between them. E-collaboration involves a variety of both communication and cooperation issues, in that it leverages the connective powers of a computer network to coordinate the efforts of a group of people. By using e-collaborative capabilities in an organization, people can operate as a single business entity, thus making joint decisions of added value.

Issues to be addressed in the establishment of an e-collaboration environment should have a strong organizational focus. These include work structuring in order to improve coordination, use of communication technology to make collaboration more efficient and effective, enforcing of rules and procedures for achieving consistency, and automating data processing in data intensive situations. One should further consider the conceptual, methodological, and application-oriented aspects of the problem. Conceptual focus is associated with the consideration of the nature of individual and organizational processes, methodological focus with the integration of existing computer-based tools, techniques and systems into the human decision making context, and application-oriented focus with the consideration of the real organizational needs by extending decision support to business teams (Angehrn & Jelassi, 1994).

BACKGROUND

The environment in which a collaborative process takes place sets different communication requirements. Issues to be taken into account in the design and implementation of an e-collaboration system include the following:

- The *spatial distance* between team members. This refers to whether full face-to-face communication among team members is possible. Depending on the group size and the proximity of members during a decision-making procedure, the following settings have been identified (DeSanctis & Gallupe, 1987): (i) the *decision room*, where an electronic version of a traditional meeting situation is established; (ii) the *legislative session*; (iii) the *local area decision network*, where group participants can communicate with each other and with a central processor through a local-area network; and (iv) the *computer-mediated conference*, where communication is provided between two or more remote groups by linking decision rooms together through audio and video facilities.
- The *temporal distance* among the activities performed by the individual group members. This refers to whether collaboration is taking place through meetings at a particular time, such as in conventional meeting or teleconferencing environments, or whether participants submit their input at different points in time, based on electronic mail, bulletin boards, newsgroups, and computerized conferencing concepts.
- The *type of participants' goals* distinguishes between an environment in which a group wants to solve its common problem cooperatively, and another in which bargaining takes place. Issues arising in the first case concern knowledge sharing, preference aggregation, and negotiation support. Depending on the degree of cooperativeness among the decision makers, three modes of reaching a decision have been reported (Jelassi & Foroughi, 1989): (i) the *pooled mode*, where there is so much cooperation that the individuals act almost as a single decision maker; (ii) the *cooperative mode*, where decision makers may have difficulties in understanding and accepting each other's positions; and (iii) the *noncooperative mode*, where a series of negotiations must integrate the diverse, often conflicting and incompatible individual problem representations into a common solution.
- The type of *control* over the collaborative process. There may be cases where the participants follow a democratic process in order to reach a solution, and

cases where the system is supported by a human group leader or mediator. In the former, communication and coordination are achieved by the users or directly by the system. The latter can be further distinguished in those where the human mediator cannot impose decisions on the participants, and those where there is compulsory arbitration from a group leader. Referring to a Group Decision Support System, for instance, three levels of control have been identified, namely, democratic participative decision making, semi-hierarchical decision making, and third-party arbitration (Jelassi & Foroughi, 1989).

- *Separating people from the problem*. The system designer has to evaluate the individual and group characteristics of the participants, as well as their motivations, disagreements, and conflicts, in order to reduce (if not avoid) the negative impact that misunderstandings, emotions, and bad communication may have. Different approaches to conflict resolution include (i) *contending or positional bargaining*, where a party is trying to convince the opponent(s) to accept its favorite position; (ii) *accommodating*, involving a party's effort to help another party meet its objectives; (iii) *compromising*, meaning a splitting of the differences between interested parties, that is satisfying but not optimizing; (iv) *collaborating*, involving parties working together to optimize their joint outcome, such as in group problem solving settings; and (v) *avoiding* the negotiation process for various reasons such as fear of conflict, not worth bargaining issues, or intention of negotiations' postponement (Lewicki & Litterer, 1985).
- The *type of communication* between the participants. Collaborative environments can be based either on *point-to-point communications* or on *broadcasting* of messages.

Furthermore, approaches for the development of a framework for e-collaboration have to address both behavioral and technical aspects (Zigurs et al., 1988). Behavioral issues concern the diffusion of responsibility, pressures toward group consensus, and problems of coordination. A framework that integrates behavioral and technical perspectives may reduce the negative impact and enhance the positive effects of the former ones. Issues involved in the design of such a framework are (i) support (or not) of anonymity, depending on the type of discussion; (ii) enforcement of participants' self-awareness; (iii) display of group inputs at any stage of the discussion; (iv) structure of the decision process (the actions the participants should follow may improve the efficiency of the system in terms of accuracy and response time); (v) ability to support communication, information sharing, and democratic control (provision of communication and information sharing helps participants to create a shared workspace on which the discussion will be based.

COMPUTER-SUPPORTED COOPERATIVE WORK

Computer-supported cooperative work (CSCW) has been defined as computer-assisted coordinated activity, such as communication and problem solving, carried out by a group of collaborating individuals (Greenberg, 1991). The multi-user software supporting CSCW is known as *groupware* (Ellis et al., 1991). Sometimes this term is broadened to incorporate the styles and practices that are essential for any collaborative activity to succeed, whether or not it is supported by a computer. CSCW may also be viewed as the emerging scientific discipline that guides the thoughtful and appropriate design and development of groupware (Greenberg, 1991). Key issues of CSCW are group awareness, multi-user interfaces, concurrency control, communication and coordination within the group, shared information space, and the support of a heterogeneous open environment that integrates existing single-user applications.

The most successful CSCW technology to date is undoubtedly electronic mail. Other well-developed technologies so far comprise computer conferencing, teleconferencing or desktop videoconferencing (the act of conferencing at a distance with the aid of audio and video links), group authoring (enabling cooperative writing with additions, revisions, comments, and annotations), and group decision support systems (problem solving is directed at the organization of the issues involved). The last category comprises mediating systems that support discussion, argumentation, negotiation, and decision-making in groups.

As illustrated in Table 1, most taxonomies of CSCW technologies distinguish them in terms of their abilities to bridge time and space (the table is a more elaborate version of the one appearing in Baecker (1993). As cited in Baecker (1993), groupware technologies of the future need to span all quadrants of this table. This is usually described as anytime/anyplace groupware. During the last few years, CSCW has been strongly supported and explored by both industry and academic research. Everybody speaks for the shifting role of computers in that they do not merely handle information processing issues, but they appear as tools for managing commitments and their fulfillment and as tools for producing and "listening to" the assertions and assessments that structure the organization (Winograd, 1992). Computers can make explicit the structure of human interaction in an organization,

Table 1. A taxonomy of CSCW technologies

	Synchronous Communications	**Asynchronous Communications**
One group site	Electronic Meeting Facilitation Decision Rooms	Media spaces Desktop Conferencing
Multiple individual or group sites	Teleconferencing Desktop Videoconferencing Broadcast Seminars	Electronic-Mail Voicemail Collaborative Writing Workflow Management Group Decision Support Cooperative Hypertext

providing new operational means for generating and monitoring workflows, being a more effective observer in what is going on, and determining what is needed when, for whom, and for what is to be done.

A principal aim for the designer of an e-collaboration framework is to apply state-of-the-art telematics and groupware technology to provide advanced support for the users over wide area networks—in particular, the Internet. Generally speaking, CSCW tools can harness the complexity of the social and knowledge processes involved, thus providing benefits in terms of speed and accuracy, and facilitating the development of business policies. Such tools can be used to support the group reasoning processes (i.e., to facilitate the evaluation of proposed solutions and their support; to structure the decision-making process through the implementation of specific methodologies; and to help group members to reach a shared understanding of the issue by supporting knowledge elicitation, knowledge sharing, and knowledge construction). Moreover, by exploiting intranet or Internet technologies, they can connect participants with similar interests, encouraging dialogue and stimulating the exchange of knowledge.

A plethora of systems that support capturing of decision rationale and argumentation for different types of user groups and application areas has been already developed. For instance, QuestMap, which is based on gIBIS hypertext groupware tool (Conklin & Begeman, 1987), can capture the key issues and ideas during meetings and attempt to create a shared understanding by placing all messages, documents, and reference material for a project on a "whiteboard." Euclid (Smolensky et al., 1987) is another system in this category, which provides a graphical representation language for generic argumentation. On the other hand, Janus (Fischer et al., 1989) is based on acts of critiquing existing knowledge in order to foster the understanding of design knowledge. Sepia (Streitz et al., 1989) is a knowledge-based authoring and idea-processing tool for creating and revising hyperdocuments that view authoring as a design process. QOC (Questions, Options and Criteria), based on a representation model of the rationale of reasoning in a decision-making process, allows users to represent and integrate rationale of varying degrees of stability at different stages in a design process (Shum et al., 1993). Finally, Sibyl (Lee, 1990) is a system that provides services for the management of dependency, uncertainty, viewpoints, and precedents. Generally speaking, the above systems meet the collaboration requirements concerning the type of control, conflict resolution, and behavioral issues, as discussed in the previous section, by providing a cognitive argumentation environment that stimulates reflection and discussion among participants. However, issues related to temporal and spatial distances are not fully addressed. These systems do not exploit any network infrastructure; thus, users can work in an asynchronous way only through a human mediator who receives their contributions and appropriately deploys them to the system (similar criticism holds for the display of each collaboration instance to all parties involved). Most important, this category of systems does not integrate any reasoning mechanisms to (semi)automate the underlying decision making and negotiation processes.

Increasing interest also has been developed in implementing Web-based conferencing systems, such as AltaVista Forum Center, Open Meeting and NetForum. Such systems exploit the platform-independent communication framework of the Web, as well as its associated facilities for data representation, transmission, and access. They usually provide means for discussion structuring and user administration tools, while the more sophisticated ones allow for sharing of documents, online calendars, embedded e-mail, and chat tools. Discussion is structured via a variety of links, such as simple responses or different comment types (e.g., qualify, agree, example in Open Meeting) to a previous message. This category of systems fully meets the requirements that are related to the spatial and temporal distances between members of a team. However, the above systems merely provide threaded discussion forums where messages are linked passively; this usually leads to an unsorted collection of vaguely associated comments. As pointed out by the developers of Open Meeting, there is a lack of consensus-seeking abilities and decision-making methods (Hurwitz & Mallery, 1995). Moreover, as in the previous category of systems, issues related to the appropriate storage of knowledge in order to be exploited in future collaboration settings are not addressed.

FUTURE TRENDS

We argue that services to be provided in a contemporary e-collaboration framework can be classified in three levels (see Table 2):

- The *information services* should deal with the interoperability of proprietary systems, providing efficient and cost-effective access to multimedia data in heterogeneous, distributed databases over wide-area networks. In particular, services should be included for finding relevant data and converting proprietary data to standard formats for data interchange. Additionally, these services should include ways of controlling remote servers from within compound documents and general-purpose electronic mail, conferencing systems, and hypermedia systems, such as the World Wide Web. Another major issue here concerns the provision for customized solutions that adapt to a team member's profile according to his or her preferences, abilities, experience, and collaboration mode, as well as aspects related to technical specifications of his or her platform, software available, and network connection. In order to be effective, such solutions have to remove barriers imposed by noninteroperable collaboration tools, inadequate infrastructure, undefined data sharing policies and standards, and differing priorities for presentation formats. What is often required is the generation of customized content through approaches such as document transformation, dynamic documents generation, adaptive hypermedia, and provision for personalized collaboration tools based on adaptive learning techniques that track a team member's activity and interactions with the system, analyze the feedback, and accordingly identify his or her needs or interests.
- The *documentation services* should provide a "shared workspace" for storing and retrieving the documents and messages of the participants, using appropriate document formats such as XML. As argued in Prahalad and Hamel (1990), an organization's only advantage in today's business environment is its ability to leverage and utilize its knowledge. While a firm comprises individuals and a set of objectified resources, its most strategically important feature is its body of collective knowledge (Spender, 1996). Such knowledge resides in an evolving set of assets, including the employees, structure, culture, and processes of the organization. Of these, employee knowledge (particularly tacit knowledge) is identified as the dominant one, which is decisive at all mental levels and has to be fully exploited (Nonaka, 1994). Such an exploitation refers to the transformation of tacit knowledge to codified information, which is considered a core process for economic activity and development. Security and privacy issues should be also addressed here. Moreover, controlled experimentation by simulation may augment the quality of a collaborative process by providing insight into the dynamic interactions and feedback loops formed by the problem elements (Sterman, 2000). A simulation

Table 2. E-collaboration services

Category of Services	**Purpose**
Information Services	Information search and retrieval, interoperability, adaptability
Documentation Services	Information transformation, knowledge management, meta-data, ontologies, experimentation, security, and privacy
Mediation Services	Conducting of debates, argumentation, negotiations, handling of conflicts, decision making

model can map organizational knowledge onto appropriate graphs, quantifying the problem under consideration and thus providing a clearer understanding of which alternative solution seems to be more prominent at the moment. Moreover, it can provide the means for an individual to conceptually define his or her position and perform experiments before asserting it to the "shared workspace." Taking into account the current state of the overall process, individuals may thoroughly contemplate on their next move to assure that it will have the best impact on the ongoing discussion. Finally, databases containing project documents may also become part of the collective memory of a community, facilitating the design and reuse of plans.

- The *mediation services* should regulate the group's activities and facilitate the underlying decision-making processes. Commercial workflow systems can be used to support well-defined, formal administrative procedures within organizations. Decisions should be considered as pieces of descriptive or procedural knowledge referring to an action commitment. In such a way, the decision-making process is able to produce new knowledge, such as evidence justifying or challenging an alternative or practices to be followed or avoided after the evaluation of a decision, thus providing a refined understanding of the problem. On the other hand, in a decision-making context, the knowledge base of facts and routines alters, since it has to reflect the ever-changing external environment and internal structures of the organization (Bhatt & Zaveri, 2002). Knowledge management activities such as knowledge elicitation, representation, and distribution (discussed in the previous category) influence the creation of the decision models to be adopted, thus enhancing the decision-making process (Bolloju et al., 2002).

The mediation services of the system are based on the specification of the underlying logic, the argumentation structure, and actions (i.e., duties and rights) of the team members. More specifically, mediation services should consist of the following four levels:

- the *Logic Level*, where the notions of consequence and contradiction are defined. This level formally specifies the notions of theory that will be used and provides the appropriate inference relations.
- the *Argumentation Framework Level*, where the concepts of positions, supporting arguments, counterarguments, and issues, as well as linguistic constructs for arguing about priority relationships among competing arguments are defined. The argumentation concepts at this level result in a kind of nonmonotonic formalism, founded on argumentation principles.
- the *Speech Act Level*, where the space of possible kinds of actions a participant may perform during a discussion is defined. Participants may alter the structure of the Argumentation Framework at the second level by, for example, adding and deleting claims or arguments.
- the *Protocol Level*, where norms and rules about duties and rights of the participants to perform actions defined at the previous level are specified. Such norms or protocols provide a means for structuring in advance demands for possible communication actions and should promote fairness, rationality and efficiency by taking into account the roles of participants, the types of their goals, and the type of control needed.

CONCLUSION

We have summarized a series of communication and cooperation issues to be considered in the development of systems supporting e-collaboration in the contemporary organization. Services to be provided by such systems have been classified in three levels: information, documentation, and mediation services. We argue that much more research and applied work need to be carried out on issues concerning the synergy of knowledge management and decision-making, while this should be further enhanced by providing advanced argumentation and experimentation features. Much attention should be also paid to adaptability issues by thoroughly taking into account an individual's profile during a collaborative process. Finally, we argue that more tools based on the concept of intelligent agents (Wooldridge, 2002) should be developed. Exploiting the basic characteristics of intelligent agents, such tools may perceive conditions holding in a dynamic e-collaboration environment, act with respect to these conditions, and reason to draw inferences and solve problems, thus facilitating the tasks of the individuals involved.

KEY TERMS

Computer-Supported Cooperative Work (CSCW): A computer-assisted coordinated activity, such as communication and problem solving, carried out by a group of collaborating individuals. Key issues of CSCW are group awareness, multi-user interfaces, concurrency control, communication and coordination within the group, shared information space, and the support of a heterogeneous open environment which integrates existing single-user applications.

E-Collaboration: The process in which a set of individuals communicate through an intranet or Internet to coordinate their efforts towards the solution of a problem.

Group Decision Support System: An interactive, computer-based system that aids a set of decision-makers working together as a group in solving ill-structured problems. It enables decision-makers to analyze problem situations and perform group decision-making tasks.

Groupware: The multi-user software supporting CSCW. Sometimes this term is broadened to incorporate the styles and practices that are essential for any collaborative activity to succeed, whether or not it is supported by computer.

Intelligent Agent: A software entity that performs a set of operations on behalf of a user or another program. Such entities are embedded in computer-based information systems to make them smarter. This is usually achieved with the employment of artificial intelligence techniques.

Knowledge Management: The active management of the expertise in an organization involving collection, categorization, and dissemination of knowledge; the activity of representing and processing knowledge.

Ecological Models and Information Systems Curriculum

Arthur Tatnall
Victoria University, Australia

Bill Davey
RMIT University, Australia

INTRODUCTION

To those of us involved in research and teaching in information systems (IS) it is clear that curriculum innovation and change is complex, and anything but straightforward. The amount of control that individual IS academics have over the curriculum varies between universities. In some cases there is complete control over curriculum content, whereas in others just control over delivery with content determined externally. This chapter concentrates on the former situation but still has some relevance to the latter. All curriculum innovation is complex (Fullan, 1993) due to the involvement of a large number of human actors, but in information systems curriculum change this is particularly so due to the need to consider the part played by such non-human actors (Latour, 1996) as the technology itself.

We will argue that if you want to understand *how* IS curriculum is built, you need to use models and metaphors that relate to how people interact with each other, with the environment, and with non-human artefacts. One such approach is provided by the ecological metaphor described in this article in which we argue that systems of education may be seen as ecosystems containing interacting individuals and groups. The interactions between these will sometimes involve co-operation and sometimes competition, and may be interpreted in terms of these forces along with mechanisms for minimising energy expenditure. In this article we will examine the application of this metaphor to curriculum change in information systems.

BACKGROUND

Models of Curriculum Development

Nordvall (1982), building on the work of Havelock (1969, 1971), identifies several models for curriculum change that he suggests all have relevance, in the higher education context, at the subject, course, and institutional levels. These are:

- research, development and dissemination models;
- problem solving models;
- social interaction models;
- political and conflict models; and
- diffusion, linkage or adaptive development models (Tatnall, 2000).

Models of change based upon a process of research, development and dissemination (RDD) are probably the most common way of attempting an explanation of the process of curriculum development (Nordvall, 1982). In models like this, relying on logical and rational decisions, curriculum change depends on the use of convincing arguments based on programs of research. A rational and orderly transition is then posited from research to development to dissemination to adoption (Kaplan, 1991). These could then be considered as "manufacturing models", as they follow a fairly logical and straightforward mechanical approach with one thing leading directly to another and do not allow for or consider other influences such as those due to human interactions. If we were to accept a manufacturing model like this then we might expect some curriculum outcomes to be apparent across the world:

- As research would have shown that several specific programming languages were much more widely used and better to teach than others, all courses requiring programming would use just these few languages, and there would be no arguments regarding the best language to teach.
- As research would show the advantages of object-oriented methodologies all computing courses would teach only these and ignore other approaches.
- The content of courses around the world would be designed to achieve similar goals and outcomes, and contain similar content.
- Research would show the ideal method of teaching computing concepts and issues and classroom delivery of content would be moving towards this researched ideal. Everyone would then use these ideal delivery methods.

Figure 1. Research, development, diffusion and dissemination models

Research → Development → Production → Dissemination → Adoption

It is easy to illustrate that these predications are not borne out, in fact, as programs of study show wide variance within any given country and around the world. Many different programming languages and development methodologies are used, and a wide variety of techniques are adopted for classroom delivery. Some innovations seem to be accepted worldwide, but many are accepted only locally. Here, We will provide an alternative model that we believe better explains how IS curriculum is actually developed.

Metaphors and Models

Before proceeding however, we need to caution the reader on the limitations of models and metaphors. The dictionary describes a metaphor as a term "applied to something to which it is not literally applicable, in order to suggest a resemblance" (Macquarie Library, 1981, p. 1096). Metaphor are useful, not in giving a literal interpretation, but in providing viewpoints that allow us to relate to certain aspects of complex systems.

We contend that most curriculum models and metaphors are too simplistic to allow a useful view of a curriculum development as a complex system involving human and non-human interactions. In this regard, the ecological model offers two main advantages:

- A way of allowing for the inclusion of complexity.
- A new language and set of analytical and descriptive tools from the ecological sciences.

AN ECOLOGICAL MODEL OF CURRICULUM CHANGE

In ecology organisms are seen to operate within a competitive environment that ensures that only the most efficient of them will survive. In order to survive, they behave in ways that optimise the balance between their energy expenditure and the satisfaction they obtain from this effort. These two key principles underlie the discipline of ecology, which is concerned with the relationship of one organism to another and to their common physical environment (Case, 2000; Townsend, Harper & Begon, 2000). Habitat, ecological niches, and the exploitation of resources in predator-prey interactions, competition, and multi-species communities (Case, 2000) are all important considerations in ecology.

We have argued (Tatnall & Davey, 2002, 2003) that these ideas correspond to the process of curriculum development in that an educational system may be seen as an ecosystem, and that the interactions within this can then be analysed in terms of ecological concepts such as competition, co-operative behaviour and niche-development. Curriculum change can be interpreted in terms of mechanisms for minimising energy expenditure and decisions that individuals make about whether to co-operate or to compete.

In information systems curriculum development we should thus look at all the factors, both human and artefact, to see which could be expected to compete, and which to co-operate to become part of the surviving outcome. A non-human stakeholder such as a development tool or methodology must co-operate with the environment, compete successfully, or die out. This may mean a new curriculum element becomes incompatible with an old element and so replaces it. Alternatively it may mean that two new design tools can be used together, or that a particular curriculum element is compatible, or perhaps incompatible, with the desires and interests of a particular faculty member.

Ecological metaphors have been used in areas other than biology and IS curriculum change. An ecological framework has been used quite successfully in other areas including mathematics curriculum (Truran, 1997) and a study of the effects of violence on children (Mohr & Tulman, 2000). Ecology as a framework tells us to expect progress of a task through co-operative or competitive behaviours of the animate and inanimate factors in the environment. A factor that cannot compete or co-operate is inevitably discarded.

Ecosystems and Complexity

An ecosystem contains a high degree of complexity due to the large number of creatures and species living in it, and to the variety of interactions possible between each of these. The "ecosystem" represented by the curriculum in a university information systems department contains (at least) the following "species": lecturers, researchers, students, professional bodies, university administrators and representatives of the computer industry. The "environment" also contains many inanimate objects relevant to the formation of the curriculum, including: computers, programming languages, textbooks, lecture rooms, analysis and design methodologies, networks, laboratories, programming manuals, and so on.

Curriculum development can be seen as attempting to introduce change within an ecosystem. The problem, of course, is the large number of interested parties that must be contended with before change can be implemented. Curriculum development is more complex than resolving the conflicting needs of students, employers, academics and the academy. There is ongoing conflict between many things such as educational philosophies, pedagogical preferences, perceived resource constraints and personal issues. To investigate the interrelationships between these entities we will look now at competition, co-operation, niche formation and energy expenditure.

Competition

Competition in nature can occur both within and between species. In many species the males compete with each other for mates, while different species of fish compete for the best feeding areas. In IS curriculum we see many examples of competition, some of which are useful in determining the "fittest" topics and techniques best suited for survival (Darwin, 1958) in the curriculum, while others involve time-wasting clashes of personality between academics.

One example of competition seen in recent years in many IS departments is in programming between .Net and Java. The advocates of Java will contend that its use in producing Web-based applications and its non-proprietary nature mean that it is the best language to teach. .Net advocates, on the other hand, argue that while this may be so, .Net is easier to use and being backed by Microsoft has a considerable advantage in its use by industry. This, they contend, makes is the best vehicle to introduce students to programming. The result of this competition is, most likely, that one language will survive in the curriculum and the others die out. Similar examples can often be seen in competition between different methodologies and between software products. Most university courses now make use of Microsoft Office rather than Lotus, Word Perfect and the like, as Microsoft has clearly won the competition and become dominant in this area.

Co-operation

There are many examples of unexpected co-operation between organisms in nature: the oxpecker bird that lives with a rhinoceros, sharks and suckerfish, barnacles that attach themselves to whales, and dogs and cats living in close proximity with people. It is also possible to think of an organism living in co-operation with its environment, something the native peoples of many countries speak about.

In an educational program such as an IS degree some courses rely on earlier courses: that is, they have prerequisites. This can be seen as a form of co-operation in which each course benefits from the existence of the other. Another similar example is in software and programming languages where, for instance, the use of VB in a computer laboratory requires the presence (and co-operation) of Microsoft Windows. Likewise, subject material that relies on the use of a specific textbook could also be seen as an example of co-operation.

Ecological Niches

An ecological niche is a place where a particular species that is well suited to this environment is able to thrive, where other species may not. A curriculum example of this is in the teaching of the PICK operating system by a university in Australia. Some years ago PICK was a serious challenger to UNIX for the "universal operating system" in business, but PICK has now decreased in importance. Despite the fact that no other university in the region now teaches it, and its place being challenged by more recent operating systems, PICK has remained in the curriculum of this university. It has remained largely because an academic involved in its teaching was able to argue convincingly (Tatnall, 2000) that learning PICK allowed students to take up jobs in the small number of prominent local industries using this system: in other words, that it filled an important ecological niche.

Energy Expenditure

It is easy to find examples of minimisation of energy expenditure in curriculum development in the use of curriculum templates and the copying of curriculum from other institutions. Perhaps the greatest reduction in energy expenditure can be gained by using, without change, a model curriculum or the curriculum from another university. A related example is seen in choosing curriculum elements so that they fit in with existing university resources.

FUTURE TRENDS

Application of the Ecological Model

Please refer to the Application of the Ecological Model illustrated in Table 1.

CONCLUSION

Researchers investigating curriculum development, or any other field, must use language in framing their re-

Table 1. Application of the ecological model

Step	Ecological model	Example
1.	Examine the environment in which the IT curriculum change occurs.	This might be a university Department of information systems or computer science, a departmental sub-unit, or perhaps an entire university Faculty.
2.	Look for all relevant entities that might constitute this ecosystem.	Academics, students, university administrators, course advisory committees, local industry representatives, computer networks, programming languages, development methodologies, text books, courses of study, university handbooks and so on.
3.	Look at all interactions between entities and classify these as: cooperative, competitive or niche forming.	Some interactions may not easily fit a single category.
4.	Look for examples of potential cooperation and for cooperative entities.	One academic course can be seen to cooperate with another by acting as a pre-requisite. Visual Basic requires the cooperation of Microsoft Windows in laboratory computers in order to operate.
5.	Look for examples of potential competition and for competitive entities.	The Java and .Net programming systems can be seen to be in competition with each other. Another example is OO development methodologies and conventional structured methodologies.
6.	Look for potential niche applications	In one particular university the teaching of the Pick operating system and Pick basic constitutes a niche application as it prepared this institution's students for work in specific local companies.
7.	Look at the level of energy expenditure (both in keeping the current curriculum in place and in introducing change).	How much energy does a reactive Head of Department have to expend to prevent change? Alternatively, how much energy does an enthusiastic faculty member have to expend to bring about drastic change? (There are, of course, many other possibilities regarding energy expenditure between these extremes.)

search questions. The language used often reflects a general viewpoint of the field being investigated and will always embody some metaphor for the principle components of the field. The metaphor is not useful in *proving* relationships but can be used to convey meaning once relationships are discovered, and an appropriate metaphor can lead the researcher towards or away from useful possible conclusions. Many of the metaphors for curriculum development are simple ones from areas such as the manufacturing-type research, development and dissemination models described earlier. Any investigation of development processes in rapidly changing areas such as information systems shows that a common factor is complexity. This leads the search for a suitable metaphor to those disciplines that have accommodated complexity. One such area is ecology and we have shown how ecological principles appear to provide good descriptions of common curriculum development activities. The ease with which the metaphor can be used to describe actions within IS curriculum development shows that it can be useful as a set of language elements that might lead the researcher to framing useful questions that do not trivialise the complexity of the field.

IS curriculum development involves a complex process of negotiation between actors, and one that cannot be simply explained by reference to a set process of referring new ideas to a series of university committees. The choices of individual academics, or groups of academics, to adopt or ignore a new concept or technology, and to compete or co-operate, must also be considered. This inevitably involves a negotiation process between many different actors. We have argued that this negotiation process can be analysed in terms of ecological behaviour, and have utilised an ecological metaphor to assist in visualising the curriculum development process.

KEY TERMS

Competition: When two individuals or species are in competition with each other, they are each striving for the same thing. In biological systems is typically food, space or some other physical need, but in the model described in this article can be any matter relating to IS curriculum. When the thing they are striving for is not in adequate supply for both of them, the result is that both are hampered, or adversely affected, in some manner.

Co-operation: Occurs when one species works with another in order to achieve an outcome beneficial to one of both. Proto-cooperation is the situation in which both benefit by the co-operation, but can survive without it. Mutualism occurs when each benefits and cannot otherwise survive. Commensalism occurs when two species habitually live together, one species being benefited by this arrangement and the other unharmed by it.

Ecological Metaphor: A way of describing a complex situation, such as IS curriculum development, by providing a way of allowing for the inclusion of complexity, and a language and set of analytical and descriptive tools from the ecological sciences.

Ecological Niche: A place where a particular species that is well suited to this environment is able to thrive, where other species may not.

Ecosystem: In the context of this article, the ecosystem represented by the curriculum in a university information systems department contains (at least) the following "species": lecturers, researchers, students, professional bodies, university administrators and representatives of the computer industry.

Metaphor: A term applied to something to which it is not literally applicable, in order to suggest a resemblance.

Minimisation of Energy Expenditure: A principle of ecology in which a species uses the least possible amount of energy to achieve its purpose.

E–Commerce Curriculum

Linda V. Knight
DePaul University, USA

Susy S. Chan
DePaul University, USA

INTRODUCTION

This article begins by tracing the rapid development of e-commerce curricula in response to demand from employers and students, and the subsequent impact of the dot-com implosion on e-commerce degree programs. The main portion of the article then identifies the major approaches currently taken by universities with respect to e-commerce curricula and explores the three critical e-commerce curriculum issues facing universities. These issues concern (1) whether e-commerce is indeed a separate and distinct discipline, (2) appropriate e-commerce curriculum content, and (3) strategies that can facilitate implementation of an e-commerce program. In the next section of the article, five trends are identified that are critical to the immediate future of e-commerce curricula. Finally, conclusions are drawn concerning the long-term prospects for e-commerce degree programs.

BACKGROUND

In 1995, Vanderbilt University was the first in the world to establish a curriculum area with an emphasis in digital commerce (Vanderbilt University, 2003). By 1997, such schools as the University of Texas at Austin, Duke, Harvard, MIT, Stanford, the University of Michigan, and the University of Rochester were also active in the field (Lewis, 1997). By 1998, George Washington University was offering an electronic commerce class where students from a variety of disciplines bought and sold goods and services over the Internet while they designed and developed the supporting marketing and record-keeping infrastructure (Dhamija, Heller, & Hoffman, 1999). This type of integration of business principles with technology is a hallmark of many e-commerce curricula. In May 1999, Carnegie Mellon University began what is widely credited with being the first e-commerce master's degree in the United States, and over the next few years, e-commerce programs burst onto the academic scene. This rush was uncharacteristically rapid and inconsistent with the historical development of many schools' curricula. Joseph Alutto, business dean at Ohio State, indicated that "It took 20 years to get business schools to focus on international business, and some schools still aren't dealing with entrepreneurship….Yet, within a two- or three-year period, the rate of acceptance and integration of e-commerce into curriculum is much greater than anything we have seen before" (Fitzpatrick, 2000a). Several schools that were early adopters of e-commerce curricula, like Bentley College (Fedorowicz & Gogan, 2001) and DePaul University (Knight & Chan, 2002b), noted the importance of rapid curriculum development practices in responding to the swift emergence of the field.

Universities began offering e-commerce courses because of "the demands of technologically savvy students—and the businesses who want to hire them," according to Andrew B. Whinston of the University of Texas at Austin (Lewis, 1997). A secondary incentive for the development of e-commerce programs was the millions of dollars in funding offered by major corporations like IBM, Ford Motor Co., General Electric, Microsoft Corp, and iXL Enterprises (Dobbs, 1999). The appropriateness of simply responding to business and student demands has been questioned. Bailey and Dangerfield (2000) have maintained that business school curricula should not be driven by immediate customer demands, but rather should take a longer-range view, anticipating customers' expressed and latent needs. Bailey and Dangerfield attribute this approach to Slater and Narver's recommendation that organizations in general should be market-oriented, but not customer-led (Slater & Narver, 1998). Others, including Lightfoot (1999), have maintained that curricula should be driven primarily by educators with long-range perspectives, rather than by shorter-term demands of businesses or students.

With the widespread dot-com bankruptcies and drying up of venture capital funding that began in 2000, many universities began reexamining their e-commerce offerings. Georgia State University terminated its innovative global e-commerce master's program and incorporated e-business courses into other MBA programs (Georgia State University, 2003). DePaul University introduced more advanced technical courses on e-business enterprise architecture design (DePaul University, 2003). Bentley College added more user-centered Web development methods and mobile commerce courses (Bentley College, 2003). As institutions kept pace with industry, curricula moved from an emphasis on entrepreneurial, dot-com implementations to the use of Internet technology in traditional organizations.

ALTERNATIVE CURRICULUM APPROACHES NOW IN USE

The broad range of e-commerce programs has been categorized into a manageable number of models by profiling the programs along three dimensions—career target (a generalist or specialist focus), curricular thrust (a business or technology emphasis), and integration (the extent to which business and technology topics are integrated at the course level) (Chan, 2001). Examples of this classification scheme are depicted in Table 1.

CRITICAL ISSUES OF E-COMMERCE CURRICULUM

Is E-Commerce a Separate Academic Discipline?

As early as 1997, an issue arose that still plagues academics, "Is e-commerce actually a new discipline with a new set of rules and a unique knowledge base?" (Lewis, 1997). Many have argued that e-commerce is a distinct academic field. Donna L. Hoffman of Vanderbilt noted, "The Internet is radically different from traditional markets, and we're discovering that you need radically different approaches for teaching business." (Mangan, 1999). On the other hand, James Ho of the University of Illinois at Chicago stated, "Business is business. Everyone is talking about e-this and e-that, but we didn't say 't-business' when the telephone came along or 'f-business' when the fax came along." (Fitzpatrick, 2000b). The view that

Table 1. Sample classification of e-commerce curricula (Derived from Chan, 2001)

Institution	Career Target	Curricular Thrust	Integration
Bentley College (2003) MBA concentration in e-business	Specialists in accounting, IS, marketing, or finance	Business emphasis	Separate business and technology courses
Carnegie Mellon MS in e-commerce	Both generalists and specialists. Managers, planners, analysts, programmers	Equal emphasis upon business and technology	Separate business and technology courses. Integration of both in the practicum course
City University of Hong Kong (2004) MS in e-commerce	Both e-commerce managers and developers	Equal emphasis upon business and technology	Separate business and technology courses
DePaul University (2003) MS in e-commerce technology	Specialists in e-commerce development, project managers, and consultants	Somewhat greater emphasis upon technology	All e-commerce courses integrate business and technology
University of Westminster (UK) (2004) MS in e-commerce	Specialists in e-commerce development and technology managers	Stronger emphasis on technology	Primarily technology courses
Victoria University (2004) (Australia) Various bachelor of business degrees in e-commerce	E-commerce application developers in various industries	Technical skills, coupled with domain knowledge in a variety of fields	Separate business and technology courses

eventually e-commerce would be assimilated throughout traditional curricula has become increasingly popular as e-commerce curricula have matured. However, integration of new material within an already over-burdened curriculum is difficult. For many, the issue is what to remove in order to bring in more e-commerce concepts. Further, there is at least some evidence that traditional business faculty may not be effectively integrating e-commerce principles into traditional classes. A survey by Morrison and Oladunjoye (2002) of middle schools, secondary schools, community colleges, and colleges indicated, "business educators are not infusing e-commerce topics sufficiently into existing curricula to prepare their students for roles in companies where e-commerce is an integral part of operations." The study concluded that educators at all four teaching levels "reported a similar lack of involvement in e-commerce-related activities such as having read an e-commerce book within the last 6 months or having taken an e-commerce seminar within the past year."

What is the Appropriate Content for an E-Commerce Curriculum?

There is no widely recognized model curriculum for e-commerce, and considerable variation exists across universities. King, Frank, and Platt (2001) studied 65 syllabi from 47 institutions, and noted that most programs were graduate level, and electronic payment, security, and business models were the only topics covered by most institutions. Etheridge (2001) studied 77 e-business programs at AACSB-affiliated institutions, and concluded that the most commonly offered courses were e-business marketing at the graduate level and an introductory survey course at the undergraduate level. Durlabhji and Fusilier (2002) examined 67 North American programs and found that most offered more non-technical than technical content. In a follow-up study a year later, they found that, while the U.S. was "the treasure trove of e-business education," there were multiple programs in Australia, the UK, and Asia (Fusilier & Durlabhji, 2003). Further, technical programs predominated outside North America and were growing faster than more business-oriented programs. The most prevalent strategy among North American master's degrees remained a concentration or track within an existing Master of Business Administration (MBA) program.

Mechitov, Moshkovich, and Olson (2002) examined 26 U.S. MBA programs with emphasis in e-commerce and 10 U.S. M.S. programs in electronic commerce, and compared these programs with 16 non-U.S. programs. They concluded that the non-U.S. programs were similar to United States M.S. programs, although they found that the American M.S. programs were more likely to include courses on high technology management and e-commerce law. White, Steinbach, and Knight (2003) examined only more technically oriented programs, and concluded that graduate level courses commonly include courses in networking, client side Web development, supply chain management, security, and marketing, along with a project course or practicum. At the undergraduate level, they found that a survey of e-commerce, networking, business math and statistics, Web application models, database, marketing, and a senior project course were the most common.

The Mechitov (Mechitov et al., 2002) study proposed an e-commerce program model that included an introductory course, followed by six technology topics (Web site design and development, Web programming, networking and telecommunications, database management, e-commerce security, and systems analysis and design) and six business topics (e-commerce management, hi-tech management, e-commerce strategy, e-commerce marketing, supply chain management, and e-commerce law). The model is capped off with an internship or project course.

Two sets of authors have proposed specific sets of learning objectives for an e-commerce program. The categories of learning objectives identified here built upon those proposed earlier by Knight and Chan (2002a, 2002b) and Brookshire, Williamson, and Wright (2002). At the fundamental level, students should be able to exhibit knowledge and competency in the following areas: practical applications and evolving e-commerce business models within the context of organizational strategies; user-centered Web site design principles, techniques, and engineering processes; hands-on use of e-commerce technologies and tools; rapid Web engineering processes to integrate business models, strategies, design methodologies, and technologies; and individual and team-based solution development; privacy and ethical issues that surround e-commerce. At the advanced level, students should be able to exhibit knowledge and competency in the following areas: e-business architecture design; e-business security; e-business solutions for common business applications, including customer relationship management, supply chain management, B2B exchanges, and portal strategies; design, implementation and evaluation of Web-based marketing campaigns; mobile commerce; Web data mining for business intelligence; Web services; and peer-to-peer technologies.

What Strategies Can Facilitate the Implementation of an E-Commerce Program?

The multi-disciplinary nature of e-commerce requires integration of business strategies and technology issues. This is possible at two levels (Chan, 2001). Integration at the curriculum level expects students to integrate knowledge gained from separate business and technical courses. Course-level integration achieves a higher degree of integrated learning, but is more difficult to accomplish because it requires greater faculty efforts in curriculum design and course development, and greater faculty cooperation across traditional boundaries. Each institution must evaluate whether it possesses sufficient resources to integrate business and technology at the course level. If not, practicums may be used to facilitate student integration of discrete learning. Typically, practicums are introduced at the end of a program. However, some researchers have noted that introducing practicums early in an e-commerce curriculum can facilitate students' ability to integrate knowledge from multiple courses throughout the rest of their programs (Chan & Wolfe, 2000).

As Rob (2003) noted, "Without a core faculty taking full responsibility for its upkeep, an e-commerce program cannot survive." Knight and Chan (2002a, 2002b) recommend leveraging limited existing faculty resources by facilitating cross-disciplinary collaboration between business and technical programs, and providing opportunities for faculty development and retooling. Further, they note that creating a culture that encourages sharing instructional materials can lessen the burden on faculty straining to keep up with rapid technology change. Finally, involving industry partners in guest presentations, teaching, curriculum development, sponsorship of student internships or in-class projects, and lecture series and roundtable discussions is essential for augmenting faculty resources and keeping the curriculum current.

FUTURE TRENDS

Five trends are critical to the future of e-commerce curricula.

(1) **E-business will continue to expand worldwide.** Organizations throughout the world will continue to adopt Internet-based solutions for lowering operating costs, increasing productivity, and strengthening relationship with customers and trading partners.

(2) **Internet-enabled B2B collaboration will dominate e-business development.** Business is moving toward an e-business Web model where members of a participating network of suppliers, distributors, service providers, and customers collaborate. Such Internet-enabled industry value chains redefine e-business as collaborative commerce. Incentives for participants include cost and time reduction, real-time communication, lead-time reduction, and improved collaborative planning and forecasting (Lee & Whang, 2001).

(3) **Architecture for inter-enterprise collaboration is becoming a critical success factor.** Companies are seeking flexible, agile, and economical approaches to collaboration with trading partners. Enterprise architecture must consider external linkages and inter- and intra-enterprise communication through existing systems as well as public and private B2B exchanges (Genovese, Bond, Zrimsek, & Frey, 2001). Web service technologies are emerging as the foundation for a new generation of B2B applications and as the architecture of choice for integrating enterprise applications.

(4) **Inter- and intra-enterprise process will be redesigned.** The emerging framework for collaborative commerce may lead to more loosely coupled processes for component-based architecture and information exchange. Internal business processes in turn will become public through value chain integration. New approaches for process design and application development may emerge in the near future.

(5) **Academic programs need to bridge the gap in the e-commerce IT workforce.** Offshore outsourcing has decreased demand for lower level e-commerce IT jobs in programming, Web development, and design (ITAA, 2003), and companies are seeking more advanced IT skills in architecture, systems integration, collaborative systems development, and complex business process redesign. Yet, few academic programs emphasize advanced technology and business issues. Continuous curricular innovation and faculty development is critical to the future viability of e-commerce education.

The five future trends described above will produce major challenges for universities offering e-commerce curricula. As the technological environment continues to morph, universities will be pressed to keep up with the latest technologies and tools. At the same time, the increasingly complex nature of Web-based business applications will mandate more extensive projects to accurately simulate the intricate nature of real world e-business.

CONCLUSION

From an historical perspective, organizations are just beginning to realize the potential of the Internet. E-commerce solutions are increasingly technically sophisticated and involve increasingly more sophisticated business processes and strategies. In such an environment, e-commerce curriculum must continue to develop rapidly as well.

E-commerce has brought new dimensions to both business and information technology education. Business programs reflect new methods and strategies for organizations interacting with their customers, suppliers, and competitors. In IT programs, beyond the obvious addition of Internet technologies like markup languages, there is a new level of interest in cryptography, human-computer interaction, and networking, along with recognition of the need to combine business and technical knowledge (Ge & Sun, 2000). The latter, the coupling of technology with business, has long been a goal of information systems programs. Its realization may well be the primary lasting legacy of e-commerce curricula.

KEY TERMS

E-Commerce Security Course: Technologies, architectures, and infrastructure for securing electronic transactions over nonproprietary networks. Implementation and maintenance of mechanisms that secure electronic documents with confidentiality, authentication, integrity, and non-repudiation. Public key certificate. Digital signature.

E-Marketplace Technology Course: System development for online trading applications supporting complex interactions among a variety of users. Theoretical models of online information exchanges supporting negotiations, including auctions, brokerages, and exchanges.

Internet Supply Chain Management Course: System architectures, technologies, and infrastructure requirements in the context of supply chain systems. Design, development and implementation of systems that facilitate collaboration with customers and suppliers. Development of messaging-based collaborative frameworks using Web services.

Intranet and Portal Course: Intranet development methodology, data warehousing, and online analytical processing (OLAP). Enterprise information portals. Transforming information into knowledge. Decision support. Customer applications. Content personalization.

Mobile Commerce Course: Bandwidth, platforms, form factors, mobile data services, and security and transaction models. Web synchronization. Server-side content management. Wireless Application Protocol (WAP). Wireless Markup Language (WML). Handheld Device Markup Language (HDML). Wireless user interface design. Wireless Web development tools.

User-Centered Website Engineering Course: Web site engineering lifecycle and user-centered design. Site goals, business models, value propositions, user analysis, information architecture, interface and navigation design, usability guidelines, database, testing, hosting strategies, usage metrics, and collaborative development.

Web Data Mining Course: Data collection, data extraction, and knowledge discovery for e-business intelligence. Web usage mining, Web content mining, and Web structure mining. Site management. Personalization. User profiles. Privacy issues. Collaborative and content-based filtering.

E-Commerce Taxation Issues

Mahesh S. Raisinghani
University of Dallas, USA

Dan S. Petty
North Texas Commission, USA

INTRODUCTION

This article is designed to give the reader a balanced perspective on some of the issues surrounding the current discussions related to state and local taxation of Internet access fees and sales transactions. It attempts to express the issues being discussed and presents several viewpoints. The proponents of Internet taxation are searching for technological and administrative system to meet their goal. After much deliberation, the Advisory Commission on Electronic Commerce released its final recommendations to Congress in April 2000. Major emphasis is being placed on simplification, neutrality, avoiding double taxation and accepting the existing tax rules with no new taxes.

The United States economy has benefited tremendously by e-commerce. This escalation has created numerous highly skilled jobs, providing the consumer with goods and services at competitive prices. The Internet Tax Fairness Coalition and many other groups feel that implementing taxes on the Internet transaction can have an adverse affect on the businesses. According to the Supreme Court of United States, a vendor has a sales tax obligation only when the buyer and seller are in the same state or has a physical presence (nexus) in the buyer's state. These coalitions feel that entry barriers for new and old companies, who have yet to exploit the e-commerce, will slow the growth in this sector. With over 30,000 taxing jurisdictions, tax collection and payment can be a complex process. Many street retailers collect at a single rate, and prepare and file a single tax return at one place. Taxation of online transactions would require the vendor to identify and send forms to all taxing jurisdictions. Under the present circumstances, the ever-changing maze of state and local tax policies makes application of a single Internet transaction tax policy virtually impossible.

The complicated, complex and ever changing maze of state and local tax policies and laws make application of a sensible, fair and easily understood Internet transaction tax policy virtually impossible under the present circumstances. James Plummer, a policy analyst at Consumer Alert wrote, "Nefarious new taxes and regulations will kill many new start-up e-businesses before they even start up; denying consumers their chance to find the specialized products and services for their needs" (Plummer, 2000).

The anti-tax community and coalitions have a strong adversary in the National Governor's Association. The State is worried that the brick and mortar stores are jeopardized by the popularization of Internet commerce, which is tax-free. The Governors suggest that government tax policy offers a competitive advantage to Internet stores. Major brick and mortar retailers such as Sears and Wal-Mart are concerned that if unresolved, this issue may gain much public resistance, thus making the taxing of e-commerce politically impossible.

BACKGROUND

The United States Congress enacted The Internet Tax Freedom Act in 1998, imposing a three-year moratorium on new Internet taxation. It also established the Advisory Commission on Electronic Commerce to address the issues related to Internet taxation (Advisory Commission on Electronic Commerce, 2000).

The Advisory Commission has representatives from state and local governments and e-commerce industry. It is to conduct a study of federal, state, local and international taxation and tariff treatment of transactions using the Internet and Internet access, and other comparable sales activities. The Commission's recommendations are to be submitted to Congress no later than April of 2000. Based on testimonies, the Commission is reviewing barriers imposed in foreign markets on U.S. property, goods or services engaged in Internet and its impact on U.S. consumers, and ways to simplify federal, state and local taxes imposed on telecommunications services.

The National Governor's Association's Perspective

Today, 46 states have a sales tax of some sort. All of the 46 states that have a sales tax also have what is called a complementary use tax. Consumers pay the sales tax when they buy goods and services in their own state and use tax when they buy from other states. This strategy avoids double taxation. When the consumer buys from an out of state merchant, such as mail order or the Internet, tax is collected and sent to the consumer's state only if the merchant has a nexus in the consumer's state. According to U.S. Supreme Court 1967, National Bellas Hess and 1992 Quill decisions, the merchant is not required to collect the use tax and remit it to the state of residence of the consumer. Consumers then are responsible for paying taxes on goods they purchase through mail-order catalogues and over the Internet. This subsidizes one category of businesses at the expense of their competitors.

The Governors have suggested a streamlined sales tax system for the 21st century. Some of the features of the governor's proposed streamlined system include:

- Maintain the current definitions of nexus and eliminate collection of state and government taxes
- Simplify the current system and without any federal government intervention
- Eliminate the cost of compliance, tax returns and payments and tax audits
- Eliminate tax-rate monitoring and implementation.
- Eliminate risks for sellers exercising reasonable care

The states would implement uniform laws, practices, technology applications, and collections systems to achieve the goals and results. These goals, when implemented, would achieve the first step of the streamlined system. The second step would be for all state and local governments to adopt the same classification systems, definitions and audits

The overall concept of the streamlined system is to reduce the costs and burden of sales tax compliance by shifting sales tax administration to a technology oriented business model operated by trusted third parties (TTPs).

THE E-COMMERCE COALITION PERSPECTIVE

The e-Commerce Coalition is a broadly based national coalition dedicated to providing sound policy information on electronic commerce taxation, and includes AOL, Bank One, Cisco Systems, and the like. Can e-commerce step up the process of making each state responsible for administration of its own tax system and simplification? Time is of the essence because of the speed at which this industry is growing and changing.

GOVERNOR JAMES GILMORE'S PERSPECTIVE

Governor James Gilmore of Virginia is Chairman of the Advisory Commission on Electronic Commerce. Governor Gilmore submitted a proposal to the Commission on November 8, 1999 entitled "No Internet Tax" (Gilmore, 1999).

The Governor believes that American public policy should embrace the Internet and the borderless economy it creates.

- Prohibit all sales and use taxes on business-to-consumer interactions and protect companies from unfair taxes imposed due to their virtual presence
- Amend the Tax Freedom Act to prohibit all taxes on Internet access
- Abolish the federal 3% excise tax on telephone service
- No international tariffs or taxes on e-commerce

E-COMMERCE TAXATION FROM AN INTERNATIONAL PERSPECTIVE

The problem with international taxation is essentially that it is likely not possible to govern well when there is no international government to create an appropriate incentive structure to induce and compel good behavior (Bird, 2003). Molina and Michilli (2003) discuss how e-commerce is emerging in European regions. For instance, the region of Veneto has implemented "Bollo Auto" — the payment of car taxes through a digital network making use of lottery terminals located in the popular tobacco shops (*tabacchinos*). Since July 1, under the aegis of "leveling the playing field," the European Union (EU) has been imposing a value-added tax (VAT) on digital goods — namely games, music, and software — downloaded from non-EU companies via the Internet by EU citizens (Pappas, 2003). McLure (2003) concludes that any failure to apply value-added tax (VAT) to electronic commerce crossing borders between EU member states and other countries should not affect the value added-tax liability of registered traders, even if the reverse charge rule (taxation in the hands of recipients) is not applied. The study notes that the sales of digital content to consumers and unregistered traders that constitutes a minuscule fraction of purchases by households and unregistered traders (given the extremely low level of small-business exemptions) is problematic.

Li (2003) provides a technical and policy analysis of the Canadian Goods and Services Tax (GST) in the context of e-commerce and suggests some options for reform. Even though the GST has had a bad reputation in Canada and its integrity is now threatened by growing online cross-border shopping, based on the revenue potential of the GST, a replacement is highly unlikely, and a cleaned-up or reformed GST is more practical. Thus the government should take advantage of the opportunity presented by e-commerce to reform the GST.

In an application of the substance over form doctrine to the international e-commerce taxation issue, Ngoy (2003) proposes an approach consisting of applying what is called here the permanent establishment (PE) function test to e-commerce infrastructures in order to see whether they qualify for being fiscally treated as PE, if they pass the concerned test. The study concludes that some of them substantially have the same function as the category of office PE, and they should be fiscally treated as this category of PE no matter the form they have.

SUMMARY OF OPTIONS FOR RESOLUTION OF INTERNET TAXATION ISSUES

The European Union has worked out a system where all 15 members impose hefty value-added taxes and all retailers must collect the tax for all sales within the union. United States negotiators are working with groups internationally to come to some understanding regarding these complex issues (Landers, 2000). Senator Ron Wyden and Representative Christopher Cox state that they would work to extend the e-tax moratorium for 5 more years and permanently bar all access taxes (Business Week, 2001).

On the other hand, the taxing entities feel that the online retailers should have to collect the same taxes as brick and mortar businesses. They have signed on to the Streamlined Sales Tax Project, whereby they have agreed to pattern their tax system from a model code (The Wall Street Journal, 2001). Four states, California, Massachusetts, Virginia and Colorado, who are leading technology states, put forth the argument that taxing Internet access and commerce would harm the growth sector of their economies.

Congress has taken the first steps to make sure states cannot impose sales taxes on Internet access, use or content and cannot impose multiple or discriminatory new taxes. Congress has also encouraged and supported the work of the Streamlined Sales Tax Project so states can continue to receive sales tax revenues from Internet transactions, just as they would if the transactions took place in a brick and mortar location. Retail businesses that enter into Internet commerce will be required to collect sales taxes on Internet sales in accordance with the rules that state develops. Sales taxes will remain solely under the jurisdiction of state and local governments for the foreseeable future (Goold, 2003).

The Streamlined Sales Tax Agreement (SSTA) sets uniform definitions and other standards that will make it easier for retailers to collect tax from out-of-state purchasers. The SSTA would make it easier for states to collect taxes on Internet purchases — an extra-territorial money grab strikingly similar to the EU's plan. Although 31 states have already approved the new SSTA, the agreement is voluntary since remote Internet and mail-order sellers are still not legally obligated to collect any tax from out-of-state consumers. However the new Simplified Sales and Use Tax Act of 2003 introduced in Congress by Representative Ernest Istook (R-OK) and a companion bill sponsored by Senator Mike Enzi (R-WY) would effectively make the SSTA mandatory (Pappas, 2003; Rankin, 2003).

Most of the 45 states in the United States that impose sales and use taxes consider the advent and expansion of e-commerce the greatest threat to their financial stability since catalog merchandising. The Constitution's Commerce Clause grants Congress the power to regulate commerce among the several States. In Quill Corp. v. North Dakota, the Supreme Court revisited its long-standing rule that a state could not establish nexus with a remote seller unless the remote seller was physically present in the state. The U.S. Supreme Court reaffirmed that nexus cannot be established in the absence of a remote seller's physical presence in a state (Trealease & Storum, 2003).

FUTURE TRENDS

After reviewing some of the information available, it appears that an interim solution might evolve from the final report and recommendations of the Advisory Commission on Electronic Commerce, including an extension of the moratorium on taxes on Internet access. The infant industry argument is that a tax hurts an emerging industry that still needs a small boost to continue expanding and developing new products and new technology. Critics of Internet taxation charge that it is also unconstitutional and unfair. However, "unfair" is also what land-based retailers might cry, as they claim that Internet retailers have an undue advantage. For both catalog and Internet sales, states want to be able to tax those purchasers who live in their state (Jossi, 2003). Although there are serious and complex issues, it appears that a resolution can be constructed that will be favorable to consumers and businesses alike, including technology being applied to the collection process, standardization of tax systems, and state and local governments being responsible to pay the costs of newly developed and technologically sophisticated collection systems. In February 2003, high-profile retailers such as –INCLUDEPICTURE "http://proquest.umi.com/images/common/circlei3.gif" * MERGEFORMATINET—Wal-Mart, –INCLUDEPICTURE "http://proquest.umi.com/images/common/circlei3.gif" * MERGEFORMATINET —Target, Toys R Us, Marshall

Field's, and –INCLUDEPICTURE "http://proquest.umi.com/images/common/circlei3.gif" * MERGEFORMATINET —Mervyn's began voluntarily collecting sales taxes from their online customers. However, substantial nexus is the keystone of a state's taxing jurisdiction over remote sellers. If substantial nexus does not exist between the state and a remote seller (whether an Internet seller or not), the state may not validly impose tax liability on the remote seller or require it to collect and remit such tax. Perhaps, just as the Internet added new confusion to the area of sales and use taxation, emerging technology-based alternatives may eventually help Internet sellers efficiently carry some of the burdens of multistate tax compliance (Trealease & Storum, 2003). A system currently being used in Europe contains most of the features that states would find necessary for the proper and efficient collection of their taxes. The European Union has worked out a system where all 15 members impose hefty value-added taxes and all retailers must collect the tax for all sales within the union. That is, an Internet purchase made in Germany by a customer in Portugal gets taxed at the VAT rate for Portugal; the German seller collects it. United States negotiators are working with groups internationally to come to some understanding regarding these complex issues (Landers, 2000). State and local governments have acknowledged that their system of sales and use taxes must change in a substantial manner if they are to remain viable in the 21st century.

CONCLUSION

Seven criteria have been laid out for use in designing an acceptable cyber tax system. The system should be equitable and simple, ensure user confidence, prevent tax evasion and economic distortion, maintain a fair balance among countries, and not introduce a new form of taxation (Lee & Hwangbo, 2000). Without the assurance of a uniform nationwide approach, even the most sophisticated technological solution will collapse. It is critical to resolve the e-commerce taxation issue by finding a feasible way to implement a multi-state system for collecting taxes from literally hundreds of tax jurisdictions across the country. The Streamlined Sales Tax Project has been launched by some 30 state governments "to develop a radically simplified sales and use tax system that eases the burden of state use and tax compliance for all types of retailers, particularly those operating on a multi-state basis" (Rankin, 2000). The outcome will have long-term consequences for U.S. retailing, and, according to some, for the American system of government itself.

KEY TERMS

Double Taxation: When the same taxable item is taxed more than once by either the same or by different government agencies, there is said to be double taxation. The juridical type of double taxation happens when comparable taxes are imposed by two or more taxing jurisdictions on the same taxpayer in respect of the same taxable income or capital.

E-Commerce: Conducting commercial transactions on the Internet, where goods, information or services are bought and then paid for.

Moratorium: Temporary suspension of payments due under a financial or tax agreement. For example, a governmental body may offer a tax moratorium as an incentive to entice a business to locate and/or start up operations in its jurisdiction.

Nexus: The general concept of some connection or link to the taxing jurisdiction. In the U.S., jurisdiction for levying taxes has a Constitutional basis.

Sales Tax: An excise tax imposed on the transfer of goods, typically at retail. States vary as to whether the tax is imposed on the seller of goods or on the buyer; however, sales taxes are almost universally collected from the purchaser at the time of sale.

Use Tax: A complementary or compensating tax imposed by all states that impose a sales tax. Use taxes are typically charged on the "storage, use, or consumption" of goods in the taxing state. Liability to remit use taxes usually falls on the buyer of taxable property or services. Since it is administratively difficult to compel individual self-assessment of use taxes, most of those taxes will go uncollected unless the states can compel sellers to collect them. Significantly, a state may impose use tax collection responsibilities on Internet sellers if they have nexus with the state. The use tax is intended to stem the erosion of the sales tax base when a state's residents purchase taxable goods or services from sellers located outside of the state.

E-Commerce Training for SMEs

Yanqing Duan
University of Luton, UK

INTRODUCTION

E-commerce offers companies tremendous opportunities to improve their business performance in new and innovative ways. However, its potential benefit would only be realised by capable managers who can deal with these emerging technologies and implement them wisely. A skills shortage has been categorised as one of the challenges facing global e-commerce by Bingi and Khamalah (2000). The demand for highly knowledgeable and skilled managers and workloads places enormous pressure upon companies to improve or update their current knowledge and skills. This is particularly important in small and medium enterprises (SMEs),[1] as compared with their larger counterparts, they are often described as "lacking the expertise needed to set up the technologies necessary, despite having a great deal to gain from doing so" (Anonymous, 1998, p. 52). Training is often seen as the most effective way to help SMEs to cope with the increasing demand on improving their skills, while not increasing staffing.

BACKGROUND

E-Commerce Challenges for SMEs

E-commerce and e-business affect the whole business process and cover a wide range of business activities. As a result, its success poses a significant challenge to SMEs. The issues related to the e-commerce challenges within these areas can be examined from different perspectives. From the strategic perspective, Laudon and Laudon (1999) summarised them as:

- The strategic business challenge
- The globalisation challenge
- The information architecture challenge
- The information systems investment challenge
- The responsibility and control challenge

From the operational perspective, Bingi and Khamalah (2000) categorised e-commerce challenges along four major dimensions:

1. Economic: cost justification, Internet access, telecom infrastructure, skill shortage.
2. Technical: security, reliability and protocols, bandwidth, integration.
3. Social: privacy/security, cultural diversity, trust, absence of "touch/feel".
4. Legal: intellectual property right, legal validity of transactions, taxation issues, policing/regulation.

Despite the widespread use of numerous electronic tools, SMEs are described as the slowest sector to embrace e-commerce (Poon & Swatman, 1999). For many small businesses, e-commerce seems like a confusing nightmare. They are not able to react to the rapid changes brought about by this emerging technology, but on the other hand they are scared to be left behind and therefore eager to embrace the technology (Hobson, 2000). The fear of being left behind was also recognised by focus group discussions conducted by Mullins et al. (2000).

Cragg and King (1993) discover that the strongest inhibiting factors for small firms' implementation of information technologies are lack of IS knowledge, lack of managerial time, poor support and limited financial resources. Corbitt (2000) argues that if management is not made aware of new and enabling technology, then it is not surprising that they are unwilling to adopt e-commerce. Timmers (2000) also concludes that a lack of awareness and understanding is one of the reasons for hesitation among many companies about committing any major effort to e-commerce. Lack of skills is perceived to be the most significant barrier to uptake of information and communication technologies (ICTs) (Auger & Gallaugher, 1997; Duan & Kinman, 2000).

Skills Shortage and Importance of Training

Research by Corbitt (2000) found that there was an obvious concern that electronic commerce was not fully understood and the "I do not know" response was the prevailing view on e-commerce understanding in companies studied. Considering the barriers for e-commerce adoption in SMEs, a number of studies (e.g., Drew, 2003; Jones et al., 2003; Lawson et al., 2003; Matlay & Addis, 2003; Quayle, 2003; Ramsey et al., 2003) have been conducted to address this issue and identified that lack of skills and knowledge is one of the barriers for the uptake and use of Internet and e-commerce. There is sufficient evidence from literature on skills and knowledge deficiency in SMEs, which is and will continue to be a significant impediment to the uptake of new technology, and will increasingly disadvantage the competitiveness of SMEs. Thus, it is essential to address the issues of improving skills by effective training and support.

"Skills shortage and training: a forgotten dimension in new technology" is a concern raised by Foley and Watts (1994) nearly a decade ago, but the relationship between skills shortage and training in ICTs deserves even more attention presently. Skills and training issues were often forgotten or misjudged during the new technology appraisal process (Foley & Watts, 1994). Poon and Swatman (1998) found out that research on the topic of the Internet and small business points to the importance of training and demonstrated benefits. Education and training can bridge the gap between development and successful implementation of new technology (Singh, 2000). The rate of change in ICTs means that the training of IT staff is a continual challenge (Dench, 1998). It is particularly essential to keep managers educated on what is going on in order to make informed decisions in today's competitive environment. Although training has been highly regarded as an effective tool for addressing skills shortage, small businesses are particularly reluctant to train (Elbadri, 2001; Johnson & Loader, 2003).

A critical task that all SME managers are facing is how to respond to e-commerce challenges. The initial challenge is to address the current lack of appropriate skills. These can be broadly defined in two areas: technology understanding and ability to facilitate successful technology implementation through appropriate strategic thinking and business planning. Therefore, there is a need for better education and support for SME managers to ensure successful adoption and running of their e-business activities. Although lack of proper training and support is not a specific problem associated with e-commerce adoption in SMEs, it is becoming more prominent for e-commerce success, as managers not only need to become equipped with technical awareness and understanding, but more importantly, with its profound business implications. Evidence from the literature (Drew, 2003; Jones et al., 2003; Lawson et al., 2003; Matlay & Addis, 2003; Quayle, 2003) appears to suggest that there is a gulf between the level of skills and knowledge required for e-commerce success and the current level of skills that managers possess. To reduce the gap, effective training and education is paramount. However, to provide training in the most effective way and at most appropriate level, better understanding of what SME managers really need is deemed critical.

SMEs E-COMMERCE TRAINING AND SUPPORT NEEDS

To investigate the current training provisions and identify managers' perceived training needs for adoption and implementation of e-commerce, a study (Duan et al., 2002) was conducted with SMEs across five European counties, including Germany, Poland, Portugal, Slovak Republic and the United Kingdom (UK). In their studies, it shows that SME managers in general would like to receive training in e-commerce. The majority of SMEs indicate their training needs in e-commerce, Internet, EDI, and related business issues. In more detail, on average, 82% would like to have training on e-commerce/business, 83% on Internet, 77% on the strategic and managerial issues on the use of ICTs, 75% on general knowledge of ICTs and their use in SMEs, 72% on business Web page writing and 72% on EDI. As expected, e-commerce is ranked as a top priority for training, which may reflect the SME's strong willingness to embrace the technology. The least needed areas highlighted are teleworking (55%), video conferencing (60%), mobile communications (57%) and CD-ROM and electronic storage (58%). It seems that some SMEs show lower interest in applying these advanced technologies at the present time. SMEs are not yet convinced that the cost can be justified by the benefits (Spectrum, 1999).

As the implementation of e-commerce will have a profound impact on the overall business process in a company, business issues should always come before the technical issues. Most importantly, "a clear strategy for an e-commerce solution is the key to the door of success" (Cunningham, 1998), as e-commerce takes more than the technology and needs to be treated as a strategic business decision, not just a technology decision (Golderg & Sifonis, 1998; Turban et al., 2004). This issue is clearly reflected in the managers' needs for training and support by the survey conducted by Duan et al. (2002). On average the most demanded area for e-commerce training and support is "business strategies for successful e-commerce", followed by "managing e-commerce operations" and "security". Compared with traditional IT training, which is mainly concerned with technical aspects of information systems, training in e-commerce needs to address not only technical skills, but more importantly business issues related to performance analysis, strategy development and implementation. It is evident that managers are aware that the appropriate e-commerce strategy and management is vital for any business and should be considered as the most important area for training and support. These findings are also confirmed by focus groups conducted by Mullins et al. (2000) which show that strategic issues are very important for SMEs, but managers are not sure what strategy they should follow due to a lack of knowledge. It is not surprising to find that even if the right strategy has been implemented, managing e-commerce operations is also considered a vital area which needs further support. E-commerce is not a one-off event. Effective measures should be implemented to ensure its continuing effective operation.

In terms of training levels for those who have indicated the need for training, survey results by Duan et al. (2002) show that most SMEs would like to be trained at the beginner and intermediate level, although the levels vary according to the training areas and countries. The areas that require more advanced levels of training are e-mail and mobile communications.

Training can be delivered in different ways. How would the managers like to be trained? Some results from the survey (Duan et al., 2002) suggest that the most preferred way of receiving training is on site by external resources (48%), followed by off site training by training organisations (37%). Computer-based self-training delivered by CD-ROM comes as the most preferred self-training method (24%). This may reflect the research finding by Riemenschneider and Mykytyn (2000) which indicates that smaller firms could investigate newer forms of IT training, such as computer-based training or even an intelligent CBT system that contains expert-like capabilities to guide the trainee. It appears that Web-based self-training through the Internet is least popular, especially in Poland. Considering the hurdles, such as limited bandwidth and slow speed of Internet access, it is no surprise that managers would like to have off-line training with CD-ROM. However, it is anticipated that online training, particularly at the advanced level, will become more popular with improvements on Internet access speed. It is also possible that the lower enthusiasm for the Web-based training method is closely linked with the lower level of computer literacy among SME managers.

CONCLUSION

Rapid changes in information and communication technologies have brought enormous opportunities as well as challenges. To handle the challenges effectively and turn the opportunities into real benefits, managers in SMEs need to be equipped with new skills and better knowledge. Companies that are successful in traditional business transactions will be affected if they are left behind. SMEs need to address skills challenges faced by modern business managers, to understand the importance of training for e-commerce success, and more importantly, to identify training needs adequately. Though managers believe that effective training is very important or essential for the success of e-commerce, most SMEs only provide occasional training for their employees. Research suggests that the most needed training areas for e-commerce are e-commerce strategy development, managing e-commerce operations and Internet security. SMEs would like to be trained at beginner or intermediate levels. The most popular human training method is on-site training using external resources and the most preferred computer-based training method is self-training delivered by CD-ROM.

KEY TERMS

CD-ROM: A computer storage device offering a relatively high capacity. The acronym name CD-ROM stands for Compact Disc –Read Only Memory, denoting the fact that CD-ROM discs are read-only devices; data cannot be written to a CD-ROM by a conventional player.

Computer-Based Training (CBT): It can be defined as training and education delivered or enhanced using a computer-based system.

E-Commerce: Refers to the process of buying and selling goods and services electronically involving transactions using Internet, network, and other digital technology.

E-Learning: It can be broadly defined as the use of information and communication technology (ICT) for online delivery of educational courses as part of traditional on-campus learning, distance learning or corporate training. E-learning offers a new opportunity to widen student access to education and vocational training, enabling students to take control over their learning environment and providing enhanced student learning experience through greater interaction between teachers and students, and students with students.

Electronic Data Interchange (EDI): A standard used by businesses to transmit documents such as invoices and purchase orders to each other electronically. The parties who exchange EDI messages (which can be encrypted and decrypted) are refereed to as trading partners.

Small and Medium Sized Enterprises (SMEs): The definition of SMEs varies in different countries. It is normally defined as having between 10 and 249 employees in the UK and Europe.

ENDNOTE

[1] The definition of small and medium-sized enterprises (SMEs) adopted for the purpose of this research is that of the EU's recommendation (see Barry & Milner, 2002), where SMEs are defined as having between 10 and 249 employees.

eCRM in a Manufacturing Environment

Aberdeen Leila Borders
University of New Orleans, USA

Wesley J. Johnston
Georgia State University, USA

INTRODUCTION

This article examines the issue of electronic customer relationship management (eCRM) in a manufacturing context. eCRM has been described as the fusion of a process, a strategy, and technology to blend sales, marketing, and service information to identify, attract, and build partnerships with customers (Bettis-Outland & Johnston, 2003; Jaworski & Jocz, 2002). Although some customers still pay a premium for face-to-face or voice-to-voice interaction in today's high-tech world, through external (e.g., advertising) and internal (e.g., word-of-mouth) influence, the diffusion of the use of eCRM to build and sustain customer loyalty as a firm's strategy is on the rise.

BACKGROUND

Before the 1930s, the production era in which firms pushed to be the "provider" of products, whether customers needed, wanted, or could afford them, was prevalent. From the 1930s to the 1960s, the selling era dictated the commerce arena in which salespersons were encouraged to make sells, regardless of costs. The onset of the 1960s to the 1990s portrayed the infancy of the marketing era in which the marketing concept (or satisfaction of the customer) laid the historical foundation of eCRM. From the 1990s, the partnering era has predominated, and some functions previously performed by marketing have become absorbed into other functional areas, such as manufacturing. Today, value lies within customer relationships that are satisfying to both the customer and the company.

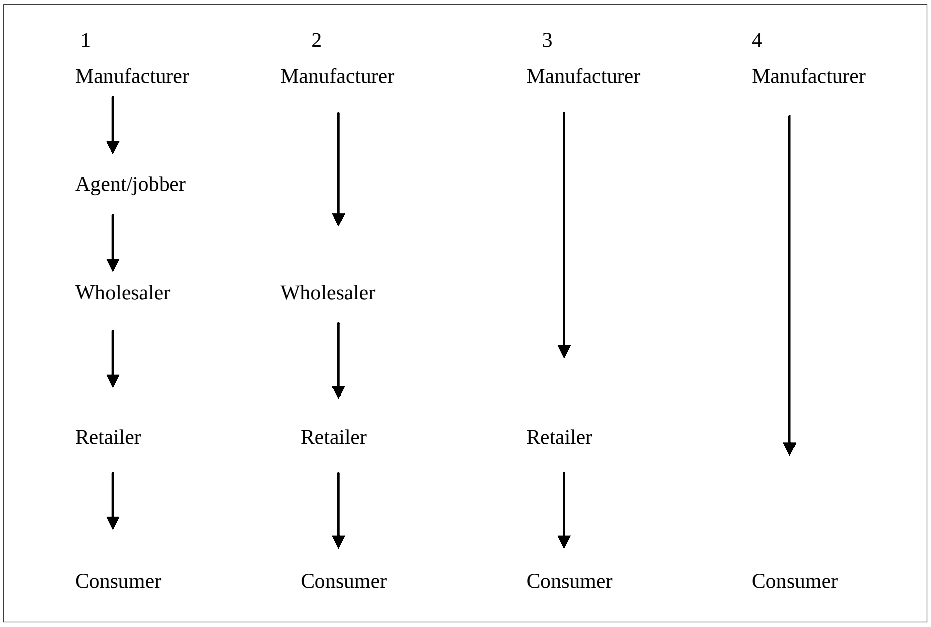
VALUE OF ONLINE SPACE

In reaching the maximization of value, businesses must define value, deliver it, and communicate it to customers. Value to the customer is his or her perception of the use of a product or service in relation to expectations. Drivers of value differ in physical (offline) and online places. Krishnamurthy (2003) viewed online operations as either profit centers (sources of income) or loss centers (offered as service to consumers). The 4 Ps (product, price, place, and promotion) primarily drive physical places. Online, the 6 Cs are the drivers—commerce, content, communication, connectivity, community, and computing (Krishnamurthy, 2003). *Commerce* describes the selling of products from the manufacturing, distribution, and retail firms to customers. Included in this category are the large businesses buying from other businesses in electronic marketplaces. *Content* is applicable to the news publishers (e.g., CNN, *New York Times*, etc.), e-books, or companies using the Internet to educate their customers (e.g., Procter and Gamble at Crest.com). *Communication* involves Web-based seminars, Internet company meetings, and e-mail-based customer service. *Connectivity* refers to the interconnections that employees and users have through the use of the Internet or other knowledge management tools. *Community* is portrayed through special user groups. *Computing* is manifested through tools, such as mapping software, tracking software, and other portfolio management tools that empower customers. Manufacturers build online trust and commitment and potentially increase their value to customers by designing interactive Web sites (Merrilees, 2002). Integrating online operations with physical operations and leveraging company assets provides synergy between physical and online stores that is key to effective eCRM.

DIGITALITY

Digitality refers to the proportion of a company's business that is online (Krishnamurthy, 2003). The digitality of a business lies between zero and one. A business that is completely online with no physical components has a digitality of one. An example is one in which all employees telecommute, digital products such as software are sold, and customers communicate directly with the company's Web site. Alternatively, businesses with no representation in the online space have a digitality of zero. Most manufacturing firms would have digitality close to zero, except those that have incorporated online activities, like Dell or Boeing.

Figure 1. Channel types



MANUFACTURING PROCESSES

Manufacturing processes are the most likely places for sources of innovation and are probably 10 years ahead of service or customer-facing processes (Dixon & Duffy, 1990). Although speed of production still reigns as important in manufacturing processes, the quality of the manufactured product, the flexibility to manufacture different types of products, reliable and predictable adherence to manufacturing timetables, and lowering of the cost and price of products must be matched against the marketing, engineering, and manufacturing capabilities for firms to become world-class competitors in the eCRM world (National Center for Manufacturing Services, 1990).

Typically, sales, manufacturing, and logistics are tightly woven. In coordinating manufacturing with sales, companies attempt to manufacture products and quantities to customer specifications and to minimize delays in delivery. This process has been described as the "lean production system" in automobile manufacturing (c.f. Davenport, 1993). In consumer foods, sales and manufacturing are driven to retail, wholesale, and distribution outlets by consumer demand. A common eCRM tool used is the salesperson's handheld computer that assists with the aggregation of store-level data, enabling linkages to materials and inventory systems, logistics, and sales departments.

Equipment maintenance is another key area in which knowledge and information must be shared in a manufacturing environment to avoid downtime or scheduling and resource requirements conflicts. Radical changes, even lofty customer-initiated improvements, have to be phased in incrementally due to interfaces with legacy systems and logistical concerns in manufacturing arenas, regardless of the company's eagerness to be customer responsive. Many companies innovating with eCRM to coordinate the procurement and delivery of goods, on the outbound logistics side, find it advantageous to use just-in-time delivery or electronic data interchange to shorten the order-to-delivery cycle (Borders, Johnston, & Rigdon, 2001). Finished goods customization, in some instances, is created only to fill customer orders and to ship goods to the customer, eliminating the need for warehousing. Customers with great bargaining power relative to their suppliers often initiate influence tactics that force suppliers to deliver on rapid, short terms (Borders, 2002).

DISINTERMEDIATION

In many cases, the Internet has become another sales channel with complementary features for bricks-and-mortar stores. The role of intermediaries is to facilitate buyer–seller transactions. Understanding disintermediation (the process of eliminating intermediates) requires familiarity with traditional business-to-business channels. Figure 1 illustrates business-to-business channels 1, 2, and 3.

In Figure 1, channel 1 is common in food markets, channel 2 in beer markets, and channel 3 in drugstore lines. Channel 4 is pervasive in the catalog line. Because the Internet makes it easy and relatively inexpensive to interact with customers directly, disintermediaries must prove their value. Channel 4 represents a business-to-consumer (B2C) disintermediated channel in which brokers or infomediaries prevail, as follows:

B2C intermediaries:
- Brokers (facilitate transactions, charge a fee on transactions)
- Infomediaries (serve fulfillment roles, act as filters between companies and consumers, sell market research reports and help advertisers target their ads, e.g., ETrade, virtual malls that help consumers buy from a variety of stores, etc.)

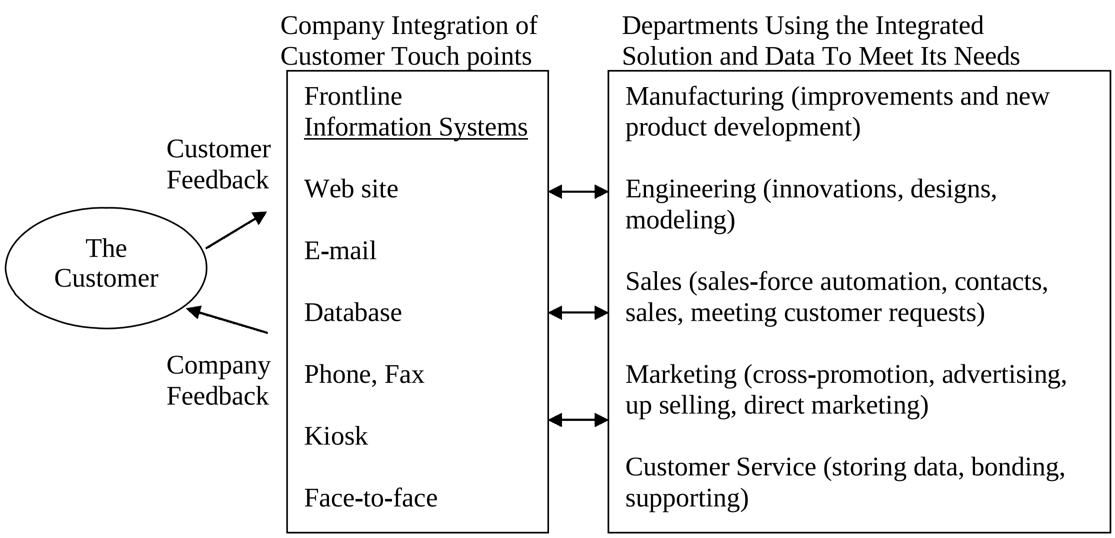
Other disintermediated channels are consumed by metamediary figures to encourage procurement activity. These channel members offer consumers access to a variety of stores or provide transaction services and include search agents (e.g., My Simon, that helps consumers compare different stores); bounty brokers that charge a fee to locate a person, place, or idea (e.g., Bounty Quest); or advertisement-based businesses (pop-ups, banners, other Internet linkages). In disintermediated channels, the major challenges that manufacturing firms face include building online traffic and sustaining customer loyalty and derived demand.

DERIVED DEMAND

Once a manufacturer builds customer traffic, switching costs for the customer increase. The provision of detailed personal and payment information, and "mental transaction costs" relating to trust and privacy by using too many vendors, can be costs that customers will choose to avoid. In employing eCRM, firms should use the appropriate mix of low-tech, middle-tech, and high-tech tools to acquire customers and satisfy them, and the appropriate metrics should be in place for low-profit or high-profit customers.

Krishnamurthy (2003) recommended that firms steer clear of too much eCRM customization and characterized online customers as simplifiers, surfers, bargainers, connectors, routiners, and sportsters. *Simplifiers* respond positively to easier and faster on- rather than off-line experiences. *Surfers* like to spend a lot of time online, and thus, companies must have a huge variety of products and constant updates. *Bargainers* are looking for the best price. *Connectors* like to relate to others. *Routiners* want content. *Sportsters* like sports and entertainment sites. Manufacturers target and build positive brand associations through opinion leaders that identify and attract customers most economically (Krishnamurthy, 2003). This subset of market segmentation is described as "customer profiling." Once these customers begin using the products, they serve as role models and influencers of others in their communities and subcultures in the persuasion of purchasing products.

Figure 2. How eCRM works



Source: Adapted from Timm and Jones (2005) and Sheth and Sisodia (2002).

HOW ECRM WORKS

Successful e-commerce operations involve three elements (Figure 2)—Internet technology, a business model, and marketing (Krishnamurthy, 2003). eCRM describes an Internet-enabled system that leverages the power of the Web to deliver the best possible customer experience. The cost per customer runs from a low of $5 for individual customers to a high of $6,244 for business customers (Chatham, 2001).

Effective eCRM solutions create synergy among sales, marketing, and customer-service activities. With multiple customer contact points, time frames, and systems, customer conversations can be disruptive and content can be lost, if they are not managed properly. eCRM consolidates customer information, such as personal data, preferences, inquiries, and order information and eliminates customers being given the run-around from department to department. eCRM is a supportive technology, whereby timely, targeted, personalized information and solutions are possible for customers.

ONLINE KNOWLEDGE

The quality of the online customer relationship is influenced by the *interactivity* between the customer and the firm, as mediated by the computer (Merrilees, 2002). Interactivity is described in terms of communication as follows:

1. The ability to address someone
2. The ability to gather information and responses from someone
3. The ability to re-address the individual with a unique response (Deighton, 1996)

It is prudent to use a database to target different consumers for different direct mail campaigns. However, junk mail (online or offline) should not be directed at customers merely because the firm has customer contact information. On the other hand, some customers such as “surfers” welcome any contact with the firm. What might be right for a financial institution may be entirely wrong for a small appliances manufacturer. eCRM allows for the creation of the type of relationship that best suits and satisfies the customer’s needs. When the information is “siloed” or stored in different places and is not easily accessible or compatible, there is a call for eCRM.

eCRM is embraced through automated quote generations, where customers can provide specifications for products, e.g., computers, sales referral tracking, travel expense reporting, account management, and sales activity. By studying Web site traffic, companies are in better shape for advertisement placement, budget preparation, and demographic campaign management.

ECRM AS A SOLUTION

“The true business of every company is to make and keep customers” (Drucker, 1954). The Web has become an outstanding channel for delivery of customer assistance and effective customer support activities. In an eCRM environment, the Web allows customers to troubleshoot their own problems with a computerized assistant guide. In a manufacturing environment, when moving customer support to the Web, a firm might start with a static Web page, similar to an electronic version of a marketing brochure, or an information base of common questions and answers. From the company’s perspective, these “low-assistance delayed communication” forms are the least expensive to implement. Self-serve personalized answers, such as tracking status, personalized pages, and real-time data are also eCRM features tailored to meet customers’ needs. Self-service can be provided through quick, simple, and accurate global 24/7 representations. Moving past the self-serve common-answer category is a self-learning knowledge base. Manufacturers that encourage customers to use online knowledge to answer their own questions share in the wealth of information gained from service resolution, abandonment rates, average site connect time, and they are able to better serve their customers by improving content site and contact information (Timm & Jones, 2005).

When customers cannot find the answers they need from self-serve sites, they can then turn to e-mail, in which customer service representatives respond. In comparing transaction costs per channel, Timm and Jones (2005) contended that firms have come to realize that the average transaction cost for Web self-service and interactive voice response (IVR) self-service ($0.24 and $0.45, respectively) compares more favorably than e-mail and phone customer care ($5.00 and $5.50, respectively).

THE BRICKS-AND-CLICKS BUSINESS MODEL IN THE ECRM MANUFACTURING ENVIRONMENT

In several manufacturing areas, it makes sense to combine online capabilities (clicks) with the advantages of traditional stores (bricks). The Internet allows an additional channel for customers to reach businesses and, in turn, through which businesses can reach their customers. For several product categories, such as furniture and apparel, individuals like to touch, feel, order, or try on the product before buying. Manufacturers set up "virtual dressing rooms" that provide customers the opportunity to try on a dress or shirt or other product before ordering it. Therefore, the bricks-and-click models can assimilate the experience of the product. The Internet could be used to locate the store or the variety of merchandise and to keep track of the status of the order.

Partnerships with brick-and-mortar stores can help alleviate delivery problems by providing another outlet for a customer to pick up a delivery that may have been placed online. Likewise, brick-and-mortar outlets that assort several items for shipping, and reduce the cost of shipment per item can aid in returning items to manufacturers. Functionality that makes it convenient for the customer is the motivation behind several eCRM efforts. Deshpandé and Farley (2002) agreed that the appropriate level of customer attention [market orientation] should be what the customer thinks it should be.

WHEN A MANUFACTURER MUST CHOOSE

When manufacturers diversify to create new revenue streams (by creating online tangential sales), they expose themselves to new levels of competition and vulnerability. Firms enhance the shopping experience by remembering relevant information about customers that can establish switching costs. They then use the positive brand-associated name to introduce other products through e-mail alerts, and they provide recommendations.

When implementing eCRM, economics of scale can be garnered when spreading costs across greater categories and leveraging the same brand name and customer base. In the electronics business, manufacturers have stringent requirements for retailers on how they will display and sell their products. Thus, after becoming an authorized dealer, one can get lower prices, money for cooperative advertising, and the right to sell warranties. Improved cross-marketing, copromotion programs, and customer acquisition are provided when manufacturers such as metal companies, thermoplastics companies, and automobile and airplane manufacturers participate in *buy-centric markets*, whereby large, influential buyers find a place where small and fragmented sellers can sell their goods.

EFFECTIVENESS OF ECRM

The hallmark of eCRM is perceived personalization. It promotes cross selling of additional products, and up selling of more profitable products. Determining the needs and wants of customers and satisfying these needs better than the competition while keeping and strengthening the customer relationship bond is the business of eCRM (Kalwani & Narayandas, 1995). eCRM allows firms to solve the problem (competence), apologize for inconvenience (care), and offer a peace token such as waiving fees (comfort).

FUTURE TRENDS

An interesting aspect of some manufacturers' eCRM strategy is to implement programs similar to Amazon's associates or affiliates program. The thrust behind these programs is to have small sites generate traffic by having content with a link to Amazon or other manufacturers. The originating site receives a commission for referred purchases and a smaller commission for other purchases made by the customer. Amazon's brand enhances the smaller site's presence. Partnering with other businesses that sell products the manufacturer does not is a profitable revenue stream (Timm & Jones, 2005).

Manufacturing operations and other backroom processes are now absorbing previous frontline customer-facing functions. Large numbers of food products previously sold in bulk to retailers are now being shipped and sold by manufacturers in smaller packages or multiple size packages, as customers demand (Sheth & Sisodia, 2002). Although many agree that eCRM is a business strategy to select and manage the most valuable customer relationships, business processes are aligning with customer strategies to build customer loyalty and increase profits over time (Rigby, Reichheld, & Schefter, 2002).

CONCLUSION

Three areas of importance that cannot be neglected in eCRM manufacturing processes are the leveraging of database technology, the value of frontline information systems, and the importance of having the right employees (Sheth & Sisodia, 2002). Leveraging database technology leads to better targeting of and maintenance of customers. The frontline information systems (FISs) approach allows customers and frontline employees to be at the cutting edge of information technology that supports relationships and directly impacts customer satisfaction. Having employees that are responsive, courteous, professional, and competent improves a firm's productivity, profitability, and employee and customer satisfaction. Considering the operating costs of serving customers over time and the costs of customer turnover, manufacturers may find the value from customer loyalty, behavior, and satisfaction far exceeds the costs of implementing and maintaining appropriate eCRM systems (Jones & Sasser, 1995; Kundisch, Wolfersberger, & Kloepfer, 2001).

KEY TERMS

Commerce: The selling of products from the manufacturing, distribution, and retail firms to customers.

Connectivity: The interconnections that employees and users have through the use of the Internet or other knowledge management tools.

Customer Profiling: Selecting customers you want to find, going after them, and keeping them.

Digitality: The proportion of a company's business that is online.

Disintermediation: The process of eliminating intermediaries in the channels of distribution.

eCRM: The fusion of a process, a strategy, and technology to blend sales, marketing, and service information to identify, attract, and build partnerships with customers.

Interaction Management: An entire system that monitors customer communications at every possible contact point, regardless of source, i.e., Web, telephone, fax, e-mail, kiosks, or in person.

Knowledge Base: An online repository of information that represents the collective wisdom regarding a product or service.

Educating the Business Information Technologist

John Mendonca
Purdue University, USA

INTRODUCTION

The ways in which computers have been applied to business have evolved over the past 40 years. In the commonly accepted three-era model of applied computing, the first era focused on automating processes, and the second on providing management information. The current era embraces information technology (IT) as a strategic resource and critical asset of the organization (Jessup & Velacich, 1999; Ward & Griffiths, 1996; and others). IT is a transformation enabler or driver that allows organizations to meet both their short-term and long-term objectives. Under this latter model, organizations expect IT to create new ways to compete, new products, new processes, new marketing channels, and even new organizational forms that promote "better-faster-cheaper." Strategic IT thus provides an anchor for competitive advantage—enabling the efficiencies, innovation, market expansion, speed, and alliances that differentiate one company from another.

The pressures of IT globalization have also posited new challenges for the education and employment of traditional non-management IT workers. The growth of offshore outsourcing and insourcing (foreign workers employed overseas by American companies) seems inevitable. Perhaps upwards of 100,000 new jobs that serve American markets have been created in India in the past 4 years at a time when employment in some sectors of the American software industry has seen notable decline (Howell, 2004). The Gartner, Inc., consulting group has projected that, while 5% or fewer of IT jobs have been globally sourced as of the first quarter of 2004, by 2010 nearly 25% of those jobs will be so situated (Gaudin, 2004). While the extent to which global sourcing will be, or should be, embraced is somewhat debatable, IT managers will certainly consider, and at least partially adapt to, this cost-reducing opportunity.

The strategic use of IT, combined with the movement for global outsourcing, forces non-management IT workers to be more knowledgeable about how IT contributes to the organization and to have higher-level IT skills. The framework suggested in this article will help to advance the skill level of such workers by a building a strategic perspective for IT work.

BACKGROUND

Courses in management of information systems and technology, particularly leadership courses at the graduate level, have adapted to the paradigm of IT as strategic transformation agent. On the one hand, these courses, designed for managers, regularly include the use of information as a strategic resource and are amply supported by texts and other academic and professional literature. On the other hand, general undergraduate education in IT—that which produces the basic business information technology worker—continues to focus on producing programmers, systems developers, and systems analysts with first and second-era approaches to their work.

As both the expectations for IT increase and offshore sourcing becomes a reality, information technology education in the U.S. will need to adapt by moving beyond developing basic skills such as programming to developing higher-level skills, such as those required for communication, integration, project evaluation, and value assessment. In addition, the demands on IT to deliver better-faster-cheaper and the need for domestic IT workers to function as leaders and facilitators will require that *all* information technology workers adopt an entrepreneurial perspective consistent with third-era expectations. Organizations need more than traditionally educated programmers and analysts. They need business information technologists who understand such concepts as the organizational impact of IT, enterprise information architecture, enterprise application integration, rapid application development, and process re-engineering, and have good knowledge of analytical and value assessment tools. A basic characteristic of business information technologists should be that they are business information strategists who have, and apply, a strategic perspective toward their work.

The context for discussing and pursuing strategic IT has been developed primarily within the conceptual framework of strategic information systems (SIS). Basically, an SIS is one that supports an organization's competitive strategy—that is, its strategy for gaining advantage over its competitors (Ward, 1996). This concept, therefore, is primarily externally focused. The extension of that concept internally, where strategy is implemented through systems design, redesign, and implementation, is a necessary requirement for fulfillment of better-faster-cheaper in today's IT environment.

Set within the framework of IT as a strategic resource, these realities dominate the contemporary environment, and are serious challenges to the pace and manner in which all IT workers work:

- The rapid pace at which new technologies (software and hardware) are introduced
- The demand for expedited development and implementation of new systems and technologies, leading to new processes and techniques
- Emphasis on value returned on investment
- Telecommunications integrated into, and inseparable from, the computing environment
- Process re-engineering
- Need for integration of seemingly incompatible diverse systems and technologies

The significant driving force behind these realities is the strategic use of IT, and the result is a heightened focus on value contributed by IT. In response, an effective information technologist adopts a strategic perspective that manifests itself in these work attributes:

- An appreciation of IT within the context of business value
- A view of information as a critical resource to be managed and developed as an asset
- A continuing search for opportunities to exploit information technology for competitive advantage
- Uncovering opportunities for process redesign
- Concern for aligning IT with organizational goals
- A continuing re-evaluation of work assignments for added-value
- Skill in adapting quickly to appropriate new technologies
- An object/modular orientation for technical flexibility and speed in deployment

A FRAMEWORK FOR IT EDUCATION

Traditional tools for IT valuation, such as return on investment (ROI) and net present value (NPV), continue to be primarily the domain of financial analysts. IT managers have supplemented these tools with others that add qualitative assessment in addition to financial ones, for example Kaplan and Norton's (1996) balanced scorecard approach, which has gained wide attention. It attempts to apply metrics to an organization's value contribution components, such as customer service (Berkman, 2002).

The tools noted previously are management tools and many require complex analysis. The challenge of developing a strategic perspective for the non-manager business information technologist is to find simple but effective frameworks that can be used to develop the necessary work attributes within the context of SIS. The key question is, therefore: How can organizations get their non-management information technologists to think and act strategically?

The phrase "better-faster-cheaper" used earlier is a good characterization and summation of the concept "strategic". Because of its brevity and clarity, it is easily remembered and readily used internally, at the application implementation level. Information technologists with a strategic perspective can not only use better-faster-cheaper as a standard for examining the value added by information technology activities, but also to uncover IT strategic opportunities. This paradigm suggests important questions technologists should ask about their work assignments. These questions include: How does this IT activity create better products or processes for the customer? How does this IT activity support faster processes? How does this IT activity increase efficiency?

A framework for developing a strategic perspective should include these three elements in its foundation: 1) understanding of the business value of IT; 2) knowledge of key processes within the organization; and 3) understanding the precepts of business process reengineering (BPR) and its application.

The base for the framework, the first element, begins with understanding the potential strategic value of IT. IT is arguably the most disruptive force in organizations within many decades (Mendonca, 2003). IT can be either a driver, such as when it is *the* critical component of an organization's business function (Amazon.com and Ebay are examples); or it can be an enabler, in the case where it serves a significant support function (Federal Express Corp. is an example). In either case it can act as a change agent by being an enabler/driver of success or a significant inhibitor. In the extreme case, "IT can have a transformational effect on a business; IT can change a business in the areas of process, service, management, and even environment" (Luftman, 2004, p. 14).

In their classic work, which focused on the external (environmental) value of IT, Porter and Millar (1985) argued that IT could be used as an enabler of competitive advantage through the creation of new products and processes and the transformation of market forces. Charles Wiseman's strategic thrusts model (Wiseman, 1988) brings an internal perspective to the examination of the business value of IT. It recognizes that individuals and groups within an organization often have opportunities to contribute significant (competitive) value. Business value can be gained through process or product changes, for example in efforts that reduce costs significantly or improve product quality to the extent that it changes the behavior of customers or suppliers and has an impact on the competitive environment. Wiseman's "thrusts" include the following: differentiation, cost, innovation, growth, and alliance. Business information technologists can use both perspectives to assess the value of their own work, to improve that value, and, especially, to look for other opportunities for value enhancement. The significance of this element in the framework is that it answers the question: *What* is business value?

The second element of the framework is knowledge of key processes within the organization. Michael Porter's value chain model (1980) provides a good basis for identifying the fundamental interdependent activities that add value to a product or service as the organization brings the product or service to the customer. IT can profoundly impact the effectiveness and efficiency of these value-adding processes by altering the activities themselves or the relationships between activities. The model, presented in the context of a manufacturing organization, identifies five major functions: inbound logistics; operations; outbound logistics; marketing and sales; and customer service. While some adjustment might be made for other types of organizations, the basic concept holds. The significance of this element in the framework is that it answers the question: *Where* can value be added to the organization through enabling IT?

The third element of the framework is understanding the precepts of business process reengineering (BPR) and how to use it. BPR, developed and popularized by Hammer and Champy (1993), was a shining star of the business environment in the early '90s, but had faded somewhat by the end of that decade, probably because of its over-hyped expectations and poor application. Davenport, Prusak and Wilson (2003) see its resurgence, particularly for the redesign of business-to-business processes necessary for e-commerce. And Garland (2001) makes a case for the survival of the basic concepts as they apply to IT, especially as a critical element in development of enterprise-wide strategic systems such as enterprise resource planning, supply chain management and customer relationship management systems. In this IT education context, BPR is a good mechanism for "triggering" process improvement thinking because it provides guidelines for action. The basic objectives of BPR include:

- Elimination of non-value added processes
- Minimization of value-added processes (reduce the number of activities)
- Simplification of processes, forms, communications
- Integration of jobs, customers, suppliers
- Automation of difficult or hazardous processes

The significance of this element in the framework is that it answers the question: *How* can value be achieved?

The elements of the framework interact to achieve strategic value by considering what value is, where in the organization it can/should be applied effectively, and how it can be achieved. For example, strategic IT may be engaged through significant cost reduction (what) applied to operations (where) through the elimination of a non-value-added process. Another example of strategic IT engagement might be innovation (what) applied to customer service (where) that increases integration with customers (how). The three elements of the framework can be integrated into a structure for activating IT value thinking (Mendonca, 2003). The framework supports IT workers not only in thinking about their current work from a better-faster-cheaper perspective, but also in uncovering opportunities for value contribution.

FUTURE TRENDS

Change in formal IT education, like change in other areas of academia, will probably be slow. In the early 2000s, the impact of the weak U.S. economy, combined with offshore sourcing trends, enforced a perception and predictions that future IT jobs will not be as plentiful as once anticipated. Whether or not extensive global outsourcing will be a significant factor in IT employment is less important, ultimately, than the dominance of IT as possibly the best means by which organizations can achieve "better-faster-cheaper" to survive and thrive in a competitive and fast-changing environment. If educational institutions do not formally adopt new ways to develop entrepreneurial skills and strategic attitudes among their graduates, surely corporations will expand their training in this area to support non-managerial IT staff in their incessant drive for increased value through IT.

CONCLUSION

Because it is a strategic resource that is complex, costly and permeates all functions of the modern organization, information technology is closely scrutinized for its contributed value in relation to resources expended. Consequently, developing a strategic perspective among IT workers is a crucial enabling factor for successfully exploiting IT's transformation capabilities. Information technology within a fast-paced, fast-changing competitive environment places the burden of strategic thinking, and of achieving better-faster-cheaper, on all IT workers, not just managers and leaders.

KEY TERMS

Balanced Scorecard: A valuation methodology, here applied to IT, that assigns metrics to non-financial value contributions for the organization, including customer service, innovation, and others.

Better-Faster-Cheaper: A shorthand label for processes that contribute value through better quality, less costly products and services, at a faster production pace.

Business Process Reengineering (BPR): The analysis and redesign of processes within and between organizations. Usually differentiated from process improvement, which is less transformational.

Global Outsourcing/Insourcing: In this context, the sourcing of IT jobs to foreign countries and corporations (outsourcing) or employment of foreign nationals in foreign countries by U.S. corporations (insourcing).

Strategic Information Systems: As opposed to operational systems, those information systems that support and promote the long-term goals of an organization, generally in terms of its competitive advantage in the business environment.

Strategic Information Technology: Computer-based technologies that specifically support and promote the long-term objectives of an organization, both financial and otherwise.

Value Chain: The fundamental organizational processes that add value to the product or service that is produced by a company.

Effective Learning Through Optimum Distance Among Team Members

Bishwajit Choudhary
Information Resources Management Association, USA

INTRODUCTION

For several years, researchers have argued that too much closeness or distance among the team members inhibits intellectual debate and lowers the quality of decision-making. In fact it is often said that if two people always agree, then one is useless and if they always disagree, then both are useless. While too much "closeness" leads to copycat attitude, too much "distance" among the team members results in incompatibility. Creating teams in which the members experience "optimum distance" is not easy.

In this backdrop, we have identified certain gaps in the contemporary organizational learning theories and developed conceptual constructs and conditions that are likely to cause optimum distance in teams.

BACKGROUND

Organizational learning (OL) gained currency when interpreting market information ahead of competitors was seen as a source of competitive advantage (DeGeus, 1988). Organizations increasingly realize the need to maintain a right degree of balance between exploiting the existing and exploring new knowledge base (Cox, 1993; Jackson et al., 1995). Concepts such as double loop learning (Argyris, 1977) and generative learning (Senge, 1990) have underlined the need for innovation and creativity in learning processes.

Research in organizational networks has primarily focused on knowledge creation at organizational levels (Nonaka et al., 1994). Almost all the analyses of networks have focused on inter-organizational groupings (Van De Ven & Walker, 1984). Andersen et al. (1994) define a business network as a set of two or more inter-connected business relationships and claim that the parties in networks have traditionally been shown to come from the same industry.

MAIN THRUST OF THE ARTICLE

In spite of pioneering attempts to conceptualize OL, lately, the researchers have expressed concerns. Ritcher (1998) remarks that the current literature does not adequately explore the dynamics of learning process. Nonaka et al. (1995) claim that "There is very little research on how knowledge is actually created *and hence there is a need to understand the dynamics of knowledge creation*" (italics added).

Alter and Hage (1993) have argued that new theories should be developed to encompass knowledge creation as a result of inter-firm collaboration. Macdonald (1995) claims that the current theories have neglected external-to-firm factors. The aim of OL should be to enhance innovation and not learning merely for the sake of it (Nonaka et al., 1994). D'Aveni (1995) argues that businesses need breakthrough innovations through industry-oriented learning processes and adequately respond to the dynamic external environment.

We now summarize the critical overview of the OL literature presented previously:

- Absence of external-to-firm factors in OL processes.
- Unclear conceptualization of optimum distance in teams.

WHAT IS OPTIMUM DISTANCE?

We delve deeper into OL processes by understanding the factors that constitute perceived distance among the team members by defining the relevant concepts.

Member Distance (MD)

Inkpen (1988) argues that in inter-organizational teams, distrust among members from the participating firms (who perceive each other as competitors) inhibits learning. We believe that this distrust among the team members is the result of the so-called "member distance". Member distance (or MD) reflects overall differences among the members due to objective factors (e.g., members' experience and education) and subjective factors (e.g., members' behavior, values and personality).

Extending Inkpen's (1988) classification of inter-organizational teams, we propose three team compositions comprising managers from:

- Different departments within the same firm (cross-functional teams).
- Same industry-sector but different firms (forums comprising partners).
- Different industries, but similar department (e.g., coordination forums for inter-sector policies or standards body, etc.).

Knowledge Distance (KD)

Managers in different industries need to know some basic industry-specific issues. For example, in the banking sector, managers need the knowledge of payment systems, customer support, and so forth, while in the telecommunication sector, managers need the knowledge of communication networks, mobile devices and so on. Knowledge distance (KD) conceptualizes industry-specific knowledge differences among managers from different sectors.

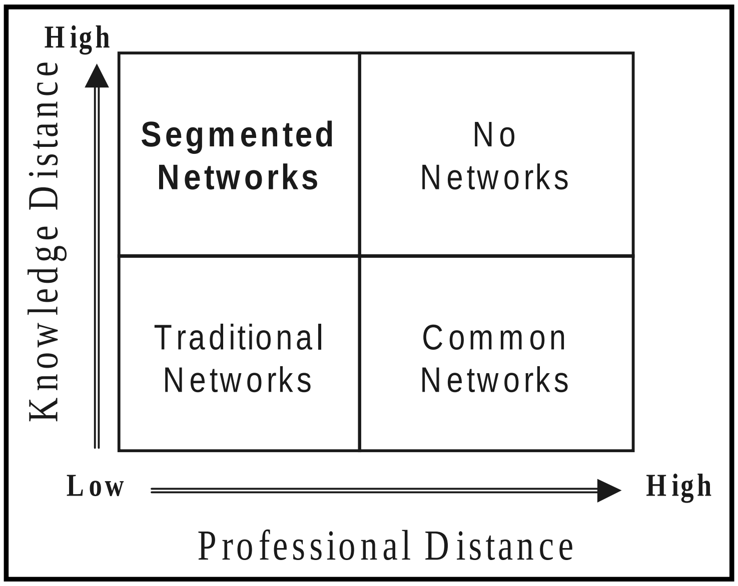
Professional Distance (PD)

Prolonged working and dedicated experiences within a specific department can influence managers' behavior at the workplace. Zuboff (1988) cites several examples (showing the impact of automation on employees' behavior). We refer to job-specific behavioral differences among managers as professional distance. Stated formally, professional distance (PD) comprises intuitive and often subjective personality differences among managers from different departments.

We now summarize some important observations on KD and PD:

- KD captures dissimilarities among managers due to external-to-firm and knowledge specific factors. PD conceptualizes department-specific, behavioral differences among managers.
- KD represents the member-distance at a macro (inter-sector or firm) level. PD represents subjective and more complex personality-based differences at a micro (or department) level.
- Since PD depends on the department dynamics (which impact managers' behavior at the workplace), PD will be low between managers of similar departments even if they come from different industries. KD in a team will be low only when the managers come from firms within the same industry.
- The unit of analyses of learning processes in an individual (manager).

Figure 1. Balancing member distance for effective learning in various teams



Since the large firms usually have a number of specialized departments, we may conceptualize such departments as micro-level "professional personality domains" and firms as "macro-level knowledge domains". KD and PD can then be used to conceptualize different team compositions as shown in Figure 1.

It is evident that the traditional networks occur when both KD and PD are low. These are the internal-department teams and found in all organizations. We refer to them as the "traditional networks".

When integrating knowledge from different departments is needed (in projects, for example), cross-functional teams are often created. In such teams, members have different behavioral approaches to problem solving (hence, high PD). However, their behavioral approaches are often complementary as well given their respective dedicated experience in different functional areas (as technology, business, finance and so on). However, as the managers in cross-functional teams come from the same firm, they share similar broad-based knowledge on industry-level issues (hence, low KD). In addition to low KD, the managers also share common objectives as they work for the same firm. Since such teams are very common, we refer to them as the "common networks".

When KD and PD are both high, no teams can (and should) be formed. Such teams would be difficult to manage and lack common interest areas. We do not discuss this scenario further.

SEGMENTED NETWORK

Varying knowledge-based competencies and similar professional personalities mark the conditions in this team. The presence of high KD creates knowledge-based differences, while low PD implies that members essentially share similar behavior at workplace. This so-called optimum balance between members' distance and closeness is achieved through knowledge-based differences but behavior-based similarities. High KD (through task-oriented conflicts) will lead to higher quality decisions as well (Schweiger et al., 1986) as well.

Segmented network (SN) is hence a team with conditions for optimum distance. It can typically be a forum to create best practices and inter-sector policies (e.g., standards, benchmarks, quality requirements). Use of macro (firm and industry) level and micro (department and individual) level factors facilitate our conceptual understanding of the relation between manageability of knowledge flow and team compositions. Such cross-sector forums are emerging fast (e.g., standards bodies, benchmarking forums, professional services (as consulting, law) firms). Although the participants in SNs come from different sectors, they usually serve the same (or same type of) user base, putting customers at the center-stage.

FUTURE RESEARCH

We now summarize the limitations of this work and identify areas of future research.

Measuring KD and (especially) PD may not be easy, but must be done one way or another. Conceptualizing learning processes with the assumptions of discrete activity is not realistic in a network sector where the value-creating activities are highly information-intensive and overlapping. We also ignored the impact of hierarchy and power on team dynamics for the sake of simplicity. Finally, the challenge in managing segmented networks would be high-level political issues and in turn, that would test the leadership skills of the team's coordinator.

CONCLUSION

By using the conceptual constructs as KD and PD we tried to plug the gaps in the contemporary organizational learning research. As the impact of external forces on firms' performance becomes increasingly pronounced, organizations will need learning processes that are inter-sector and not merely internal to the firm. Segmented networks fulfill this very important premise. Past research also supports our view that high degree of task-oriented conflicts (or high KD, as is the case in segmented networks) increases the quality of decision (Schweiger et al., 1986, 1989). Teams with a high degree of task-oriented conflicts are easier to manage than and may indeed be preferred to teams with a high degree of personality-oriented conflicts. Manageability of teams is a key issue.

Note that the common networks (or the cross-functional teams) also carry the important element of balance within them and their usefulness is well known. SNs offer a similar possibility at an inter-sector level, thereby complementing the internal-to-firm focus of the common networks. SNs are novel and manageable. Inter-sectors forums are growing especially fast in the network industries and so is the need for OL theories to conceptualize and understand SNs. In the network industries (such as banking, telecom sectors), interoperability of systems and procedures is a key success factor.

KEY TERMS

Knowledge Distance (KD): Conceptualizes industry-specific knowledge differences among managers from different sectors.

Member Distance (MD): Reflects overall differences in approach among the members due to objective factors (e.g., members' experience etc.) and subjective factors (e.g., members' values etc.).

Optimum Distance (OD): Appropriate degree of closeness (or distance) among the team members achieved through the combination of KD and PD, leading to the so-called creative tension.

Professional Distance (PD): Comprises behavioral differences among managers from different departments.

Segmented Network (SN): Inter-sector teams with high KD and low PD, leading to conditions for the so-called optimum distance.

Efficient Multirate Filtering

Ljiljana D. Milić
University of Belgrade and Mihilo Pupin Institute, Serbia and Montenegro

INTRODUCTION

Efficient multirate filters have been developed during the past three decades for implementation of digital filters with stringent spectral constraints (Crochiere & Rabiner, 1981, 1983; Ansari & Liu, 1993; Bellanger, 1984, 1989; DeFata, Lucas & Hodgkiss, 1988; Vaidyanathan, 1990, 1993; Fliege, 1994; Zelniker & Taylor, 1994; Proakis & Manolakis, 1996; Mitra, 2001; Milić & Lutovac, 2002; Hentschel, 2002).

A multirate filter can be defined as a digital filter in which the input data rate is changed in one or more intermediate points. With the efficient multirate approach, computations are evaluated at the lowest possible sampling rate, thus improving the computational efficiency, increasing the computation speed, and lowering the power consumption. Multirate filters are of essential importance for communications, digital audio, and multimedia.

MULTIRATE FILTERING TECHNIQUES

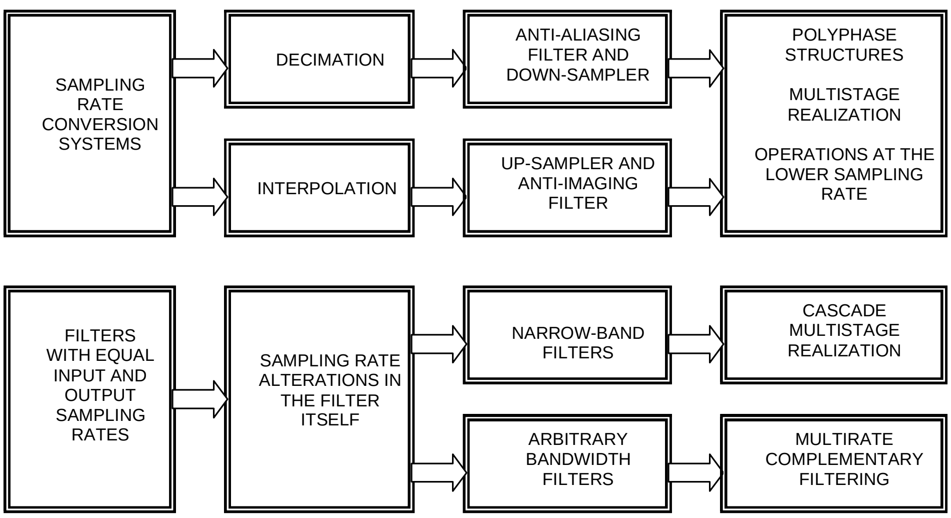
Multirate filtering is one of the best approaches for solving complex filtering problems when a single filter operating at a fixed sampling rate is of a very high order. With a multirate filter, the number of arithmetic operations per second is considerably reduced. The multirate technique is used in filters for sampling rate conversion where the input and output rates are different, and also in constructing filters with equal input and output rates. For multirate filters, FIR (finite impulse response) or IIR (infinite impulse response) transfer functions can be used. An FIR filter easily achieves a strictly linear phase response, but requires a larger number of operations per output sample when compared with an equal magnitude response IIR filter. Multirate techniques significantly improve the efficiency of FIR filters that makes them very desirable in practice.

Figure 1 depicts an overview of different multirate filtering techniques.

Polyphase Implementation

Polyphase realization is used to provide an efficient implementation of multirate filters. A polyphase structure is obtained when an Nth order filter transfer function is decomposed into M polyphase components, $M<N$. For FIR filters, polyphase decomposition is obtained simply by inspection of the transfer function (Crochiere & Rabiner, 1983; Vaidyanathan, 1993; Fliege, 1994; Proakis & Manolakis, 1996; Mitra, 2001). For multirate IIR filters, several approaches to polyphase decomposition have been developed (Bellanger, Bonnerot & Coudreuse, 1976;

Figure 1. An overview of multirate filtering techniques



Crochiere & Rabiner, 1983; Drews & Gaszi, 1986; Renfors & Saramäki, 1987; Russel, 2000; Krukowski & Kale, 2003).

Filters for Sampling Rate Conversion

Filters are used in decimation to suppress aliasing and in interpolation to remove imaging. The performance of the system for sampling rate conversion is mainly determined by filter characteristics. Since an ideal frequency response cannot be achieved, the choice of an appropriate specification is the first step in filter design.

Reducing the sampling rate by a factor of M is achieved by omitting every M-1 sample, or equivalently keeping every Mth sample. This operation is called down-sampling. In order to avoid aliasing, a low-pass anti-aliasing filter before down-sampling is needed. Therefore, a decimator is a cascade of an anti-aliasing filter and a down-sampler. To increase the sampling rate (interpolation by factor L), L-1 zeros are inserted between every two samples (up-sampling). An interpolation filter has to be used to prevent imaging in the frequency band above the low-pass cutoff frequency. An interpolator is a cascade of an up-sampler and an anti-imaging filter.

The efficiency of FIR filters for sampling rate conversion is significantly improved using the polyphase realization. Filtering is embedded in the decimation/interpolation process, and a polyphase structure is used to simultaneously achieve the interpolation/decimation by a given factor, but running at a low data rate.

Due to the polyphase multirate implementation, the number of arithmetic operations in linear phase FIR filters is decreased by a factor M (or L). An effective method, which leads to high efficiency for a high-order FIR filter, is proposed in Muramatsu and Kiya (1997). Efficient decimation and interpolation for the factor M=2 (L=2) is achieved with FIR half-band filters, since the number of constants is a half of the filter length.

Polyphase IIR filters require lower computation rates among the known decimators and interpolators (Renfors & Saramäki, 1987). If a strictly linear phase characteristic is not requested, an IIR filter is an adequate choice. Moreover, an IIR transfer function can be designed to approximate a linear phase in the pass-band (Jaworski & Saramäki, 1994; Lawson, 1994; Surma-Aho & Saramäki, 1999). An IIR decimator or interpolator is particularly useful in applications that cannot tolerate a considerably large delay of an adequate FIR decimator or interpolator. For a restricted class of filter specifications, an attractive solution based on all-pass sub-filters can be used, leading to very efficient implementation (Renfors & Saramäki, 1987; Krukowski & Kale, 2003). The most attractive solution is an IIR half-band filter implemented with two all-pass sub-filters (Renfors & Saramäki, 1987; Johansson & Wanhammar, 1999; Milić & Lutovac, 2002; Krukowski & Kale, 2003). For a rational conversion factor L/M, a very efficient decomposition of IIR filter is proposed in Russel (2000).

Filters with Equal Input and Output Rates

Digital filters with sharp transition bands are difficult, sometimes impossible, to be implemented using conventional structures. A serious problem with a sharp FIR filter is its complexity. The FIR filter length is inversely proportional to transition—width and complexity becomes prohibitively high for sharp filters (Crochiere & Rabiner, 1983; Vaidyanathan, 1993; Saramaki, 1993; Fliege, 1994; Proakis & Manolakis, 1996; Mitra, 2001). In a very long FIR filter, the finite word-length effects produce a significant derogation of the filtering characteristics in fixed-point implementation (Mitra, 2001). IIR filters with sharp transition bands suffer from extremely high sensitivities of transfer function poles that make them inconvenient for fixed-point implementation (Lutovac, Tošić & Evans, 2000). In many practical cases, the multirate approach is the only solution that could be applied for the implementation of a sharp FIR or IIR filter. Thus to design a multirate narrowband low-pass FIR or IIR filter, a classic time-invariant filter is replaced with three stages consisting of: (1) a low-pass anti-aliasing filter and down-sampler, (2) a low-pass kernel filter, and (3) an up-sampler and low-pass anti-imaging filter (Crochiere & Rabiner, 1983; Fliege, 1994; Mitra, 2001; Milić & Lutovac, 2002). The total number of coefficients in a multirate solution is considerably lower than the number of coefficients of a single-rate time invariant filter.

Multistage Filtering

For decimation and interpolation filters, and for multirate narrowband filters, additional efficiency may be achieved by cascading several stages, each of them consisting of a sub-filter and down-sampler for decimation and an up-sampler and sub-filter for interpolation (Fliege, 1994; Mitra, 2001; Milić & Lutovac, 2002). Design constraints for sub-filters are relaxed if compared to an overall filter. Hence, by using the multistage approach, the total number of coefficients is significantly reduced when compared with the single stage-design. The effects of finite word-length in sub-filters are low in comparison with the single-stage overall filter. When a decimation/interpolation factor is expressible as a power-of-two, the application of half-band filters improves the efficiency of the system.

Multirate Complementary Filters

This method can be used in designing filters with any pass-band bandwidth. The multirate techniques are included to reduce the computational complexity. Using the complementary property, the multirate, narrow pass-band filter designs can be used to develop high-pass and low-pass filters with wide pass-bands (Ramstad & Saramäki, 1990; Fliege, 1994; Mitra, 2001). When the output of a low-pass multirate filter is subtracted from the delayed replica of the input signal, the result is a wideband high-pass filter. The delay has to be selected to exactly equal the group delay of the multirate filter. For a low-pass wideband filter, the multirate narrowband high-pass filter has to be used.

Efficient FIR filters with an arbitrary bandwidth can be designed using multirate and complementary filtering (Ramstad & Saramäki, 1990; Fliege, 1994; Johansson & Wanhammar, 2002). The overall design is evaluated by cascading complementary multirate filtering two-ports composed of two series branches and one parallel branch. The cascade is terminated with a simple kernel filter. One series branch of the cascade is a decimator (filter and down-sampler), while the other is an interpolator (up-sampler and filter). The parallel branch is a delay. The most efficient solution is obtained when half-band filters are used in the cascade.

Recently, the complementary filtering approach is extended to IIR filters (Johansson, 2003). The overall filter makes use of an IIR filter as a kernel filter, the periodic all-pass filters for constructing complementary pair, and linear phase FIR filters for the sampling rate alterations.

Half-Band Filters

Half-band filters are basic building blocks in multirate systems. A half-band filter divides the basis band of a discrete-time system in two equal bands with symmetry properties. The FIR filters are most often used as half-band filters. For a linear phase FIR half-band filter, half of the constants are zero valued when the filter order is an even number (Saramäki, 1993; Mitra, 2001). A half-band IIR filter can have fewer multipliers than the FIR filter for the same sharp cutoff specification. An IIR elliptic half-band filter, when implemented as a parallel connection of two all-pass branches, is an efficient solution (Milić & Lutovac, 2002). The main disadvantage of elliptic IIR filters is their very nonlinear phase response. To overcome the phase distortion, one can use optimization to design an IIR filter with an approximately linear phase response (Surma-Aho & Saramäki, 1999), or one can apply the double filtering with the block processing technique for real-time processing (Powel & Chau, 1991; Lutovac et al., 2000).

For the appropriate usage of digital filter design software in half-band filter design, it is necessary to calculate the exact relations between the filter design parameters in advance (Milić & Lutovac, 2002). The accurate FIR half-band filter design methods can be found in Vaidyanathan and Nguen (1987), Saramäki (1993), and Wilsson (1999). For the IIR half-band filter design, see Schüssler (1998) and Milić and Lutovac (2002, 2003).

Multiplierless Solutions

The efficiency of multirate filters is significantly improved by simplifying arithmetic operations. This is achieved by replacing a multiplier with a small number of shifters-and-adders. Generally, implementing multiplierless design techniques in sub-filters, at the cost of a slight derogation of filtering performances, increases the efficiency of the overall multirate filter. For instance, one can use the optimization technique (Kaakinen & Saramäki, 1999), the multiplier block approach (Dempster & Macleod, 1995), or design based on EMQF (Elliptic Minimal Q-Factors) transfer functions (Milić & Lutovac, 1999, 2003; Lutovac & Milić , 2000). A well-known solution for large conversion factors in decimation is a cascaded integrated comb (CIC) filter, which performs multiplierless filtering (Hogenauer, 1981; Mitra, 2000; Hentschel, 2002).

CONCLUSION

The multirate filtering techniques are widely used in sampling rate conversion systems, and for constructing filters with equal input and output sampling rates. Various multirate design techniques provide that the overall filtering characteristic is shared between several simplified sub-filters that operate at the lowest possible sampling rates. Design constraints for sub-filters are relaxed if compared to a single rate overall filter. Hence, by using the multistage approach, the total number of coefficients is significantly reduced. As a consequence of the reduced design constraints, the effects of quantization (finite word-length effects) in sub-filters are decreased. Multirate filters provide a practical solution for digital filters with narrow spectral constraints that are very difficult to solve otherwise.

KEY TERMS

Decimation: Decreasing the sampling rate. Decimation process consists of filtering and down-sampling.

Down-Sampling: Discarding every M-1 samples (retaining every Mth sample).

FIR Filter: A finite impulse response digital filter.

Half-Band Filters: A low-pass or high-pass filter that divides the basis band in two equal bands, and satisfies prescribed symmetry conditions.

IIR Filter: An infinite impulse response digital filter.

Interpolation: Increasing the sampling rate. Interpolation consists of up-sampling and filtering.

Multirate Filter: A digital filter, which changes the input data rate in one or more intermediate points in the filter itself.

Multistage Filtering: Cascade of filters and decimators (interpolators and filters).

Polyphase Decomposition: Decomposition of a transfer function in M (L) polyphase components that provide sequential processing of the input signal at the lower sampling rate.

Up-Sampling: Inserting L-1 zeros between every two samples.

E-Government Interoperability

Dirk Werth
German Research Center for Artificial Intelligence, Germany

INTRODUCTION

The rise of the Internet has structurally changed not only the business area, but also governments and administrative authorities. The usage of information and communication technologies (ICT) influenced the organizational behavior and the daily work of public administrations. In parallel, a new management paradigm has grown in governments and administrations: The New Public Management (NPM) aims to a new orientation on the impact of public activities and on the benefit of public services for its customers, namely citizens and businesses (Barzelay, 2001). It puts the administration and its activities in the triangular relationship between politics, administration and citizens (Osborne & Gaebler, 1992). Within this "ecosphere", decentralized steering models (Reichard, 2002) as well as market mechanisms are introduced and emphasized (Pollitt & Bouckaert, 2000).

Both factors, ICT and NPM, have resulted in the electronic (E-) Government. E-Government is the support of public service processes through ICT. It affects all areas of governmental work and acting. For this article, we focus on the production and distribution of public services (Reinermann, 2002). However, even in this limited area, the implementations vary from case to case. In order to rate the effects and benefits of E-Government, that strongly depend on the interaction abilities already usable, a measurement is needed. Currently, the realization degree indicator is commonly used for this purpose. Table 1 summarizes the commonly used categories of realization steps for E-Government:

BACKGROUND

Integration requires a seamless and customer-oriented integration of public services across organizational borders and through different application systems (Wimmer & Traunmueller, 2002). This results in the need for public administrations to open themselves towards other authorities as well as to their customers, namely citizens and businesses and to actively collaborate with them. The area E-Government Interoperability covers strategies, organizational concepts and information technology to link administrative business processes and to interconnect application systems.

Conceptual and technical E-Government Interoperability infrastructures are considered as prerequisite for the creation of advanced public services and the distributed processing of multi-agency business processes (Werth & Zangl, 2004). Conceptual solutions mainly cover Enterprise Architectures and reference models for specific use in public authorities. In this context, Enterprise Architectures are representing the public authority in terms of organisation and operations (e.g. processes, behaviour, activities, information, decision and object flows, resources and organisation units, system infrastructure and architectures), in order to reach some finalities. Finalities here indicate the creation of explicit facts and knowledge that add value to the enterprise or can be shared by business applications and users for the sake of improving the performance of the organization (Interop, 2003). Especially, operations require the management of the public services as the external view (Glassee, Van Engers, & Jacobs, 2003) and of the business processes as the internal implementation (Seel, Guengoez & Thomas, 2004). Furthermore, reference process models represent the unifying abstraction of a variety of process models in different authorities. They can be used in multiple administrative scenarios to support the realization of services described by these reference models (Martin, Seel, Kaffai & Thomas, 2004).

However, these concepts also demand on capable and effective interoperational infrastructures for public administrations to operate (Fernandez, 2002). Furthermore, they foster "the transition from the current paradigm of highly fragmented, isolated applications and islands of functionality to a situation promoting consolidation to an integrated, collaborative and secure architecture" (Werth, 2003). Most approaches specify components for different tasks within the infrastructures, usually "definition/configuration", "discovery", "connection", "processing" and "monitoring/administration". First approaches base on workflow management architectures (Reinermann, 1997). The resulting technical infrastructures cover most or all of those components and organize them either in a centralistic or distributed way. In centralistic architectures, there is only one instance of a component that controls the activities. Distributed environments miss this single control instance in favour of self-organizing and –controlling techniques. Both approaches may be adequate for integration scenarios depending on the structure of the orga-

Table 1. Stage-wise realization model of e-government

I. *Information (enhanced)* – This first stage is the easiest to implement. It comprises electronic availability and provision of thematically structured information. This represents an unidirectional communication relationship between public administrations and their customers. A website is a typical example for this stage.
II. *Communication (interactive)* – extends the information stage by a feedback channel. Hence a bidirectional communication is established. Common technologies are e-mail, chats and forums.
III. *Transaction (transactional)* – The transaction stage describes the online availability of public services, i.e. it becomes possible for a citizen to trigger online a legally binding public service. It can also include electronic payment and all relevant phases of a transaction.
IV. *Integration (networked)* – This highest stage of realization, only rarely used, describes the integration of the customer himself into public administration processes as well as the collaboration of public services. The customer can influence the execution of public services without having the knowledge about the way of working and processing of the respective services. At this stage, full electronic support is required, covering all public services and the according processes.
The attributes in brackets state the presence measurement expressions of the United Nations (cf. United Nations, 2003).

nizational system to be integrated. In centralistic environments, (e.g. hierarchical ordered authorities) centralistic technical architectures are mainly suitable, whereas in decentralized organizational networks (e.g. in federative states), distributed architectures will fit the best.

A suitable approach to decompose E-Government Interoperability is given by three layers, as shown in Table 2.

APPROACHES AND TECHNOLOGIES

Currently, two major research streams address this topic from different directions and with diverging intentions:

The *Front-end interoperability* approach is user-centric and tries to realize an easy and direct access to exposed public services. It focuses on a consistent presentation and thematic structuring, based on the interests of the citizen. Mainly the attempt is to group those public services that are assumed relevant for a specific situation of a citizen's life (schooling, full age, building a house, retirement, etc.) or a business event (founding, location, economic simulation, etc) (Reinermann, 2002). This concept is called "live event oriented" for citizens resp. and "business episode oriented" for companies (Vintar & Lebel, 2002). To realize this concept, Internet-based portal technologies access services located at different authorities, without regarding institutional boundaries (Klischewski, 2001). Such integrated portals result in one-stop-shop E-Government solutions. They enable the triggering of single services or groups of them via one interaction step using the normal web browser (Tambouris, 2001).

The scope of the *Back-end interoperability* approach is the cross-organizational business process. The intension is to link business processes and their executing application systems. Therefore, it corresponds to the area of Enterprise Application Integration (Linthicum, 1999). On the backend side of service processing, adequate public services have to be identified, discovered and accessed. Implementing infrastructures mostly rely on middleware (Pasic, Diez & Espinosa, 2002) or agent tecnnologies (Carvalho, Moreira & Sa-Soares, 2003). Middleware is mostly used for data replication, transformation and transportation. Thus, single messages representing data items are passing through the applications following a specific rule set. This technology realizes simple data integration. Using agent technologies, the integration can be augmented to the functional level. Here, autonomous software components (agents) try to form a predefined behavior by calling functions (methods) of other agents. Emerging developments on Service-Oriented Architectures (SOA) and Web Services foster a new dimension of back-end interoperability, due to open standards and interfaces. By exposing encapsulated functionalities by self-describing Web Services, a public authority is enabled to use business functionalities that are processed by other authorities. Hence, it becomes

Table 2. Layer decomposition of e-government interoperability

- *Business Interoperability* – covers the exchangeable specification of public services, business processes and organizational structures, their transformation into compatible ones and the mechanisms to interconnect them.
- *System Interoperability* – means the enabling of communications and data exchange of application systems in order to realize a common, distributed application behavior.
- *Semantic Interoperability* – the need for this layer came from the fact, that "discrete resources use different terms to describe similar concepts or use identical terms to mean different things" (Miller, 2000). This layer includes data interpretation as well as knowledge representation and exploitation in order to create common semantic meanings.

possible to compose different services available within the network in order to realize its own business process. This approach is called business process orchestration (Gortmaker & Janssen, 2004).

FUTURE TRENDS

The domain of E-Government Interoperability is currently emerging. It is expected that several national solutions will arise that propose solutions to this problem domain. Actually, several national-driven E-Govern-

Table 3. International e-government interoperability initiatives

- *Federal Enterprise Architecture Framework (FEAF, USA)* – aims to create an enterprise architecture description, specifying the overall organization and relationships of public administrations. It comprises a business architecture (process and organization), a data architecture (data types), a application architecture (applications and capabilities) and a technology architecture (hard- and software, physical factors). (CIO Council, 1999)
- *E-Government Interoperability Framework (e-GIF, UK)* – is a collection of policies and standards for governmental IT systems. It was created and is updates by the British Cabinet Office. The framework is decomposed in two parts: Part One containing high level policy statements as well as management, implementation and compliance requirements and Part Two including technical policies and specifications in the five major categories "Interconnection", "Data integration", "Content management metadata", "Access" and "Business areas". (Office of the e-Envoy, 2003a & 2003b)
- *European Interoperability Framework (EIF, EU)* – defines "a set of recommendations and guidelines for Government services so that public administrations, enterprises and citizens can interact across borders, in a pan-European context. The target audience of the EIF is the managers of eGovernment projects in Member States Administrations and EU bodies. Member States Administrations should use the guidance provided by the EIF to supplement their national eGovernment Interoperability Frameworks with a pan-European dimension and thus enable pan-European interoperability." (IDA, 2004, p.3)

ment initiatives exist worldwide, addressing the field of interoperability. The most advanced are being developed in the United States, the United Kingdom and the European Union. Table 3 provides an overview on these activities:

CONCLUSION

E-Government Interoperability will be the enabler for the future development of E-Government. However, it should be considered not as the aim but as the instrument. The improvement of public services towards integrated and collaborative provision and processing techniques requires sustainable interoperability infrastructures. They comprehend Enterprise Architectures, addressing networked governmental structures on a conceptual level as well as application integration systems, realizing Internet-connected, decentralized, service processing grids. The key success factor for interoperability is the holistic development of business-, system- and semantic-layers and consequently, the creation of solutions integrating the three layers. Intensive further research on this topic may – in some years – discover the extension of the E-Government stage model, the fifth stage.

KEY TERMS:

Back-End Interoperability: Business-process-centric integration approach that interconnects different application systems in order to enable the execution of cross-organizational business processes.

E-Government Integration Stage: Also partially referred as Participation stage; means the formation of networked governments and the integration of public services both internally (i.e. electronically interconnected, multi-tier-transaction-enabled business processes) and towards the customers, citizens and businesses (i.e. offering of unified user access interfaces directly linked to integrated services).

E-Government Interoperability: The ability of a public service to collaborate (i.e. to work together) with other public services without special effort on the part of the processing unit. This comprehends the collaboration of the service-executing business processes as well as the interaction of the process supporting application systems.

Front-End Interoperability: User-centric integration approach, that presents consolidated information retrieved from different sources and that enables the access to multiple application systems in order to perform a set of coherent transactions at once.

Interoperability Enterprise Architecture: A set of consistent methods to specify the interaction behavior of a network of public organizations. It includes organizational structures, public services, business processes as well as interaction interactions, protocols and patterns.

Life-Event / Business-Episode Concept: The approach to classify and cluster public services by repeating, specific situations that often occur during the life of a citizen resp. the different periods of an enterprise. Typical examples are marriage for a citizen and VAT declaration for a company.

One-Stop-Shop E-Government Solutions: Are Internet portals of public authorities, offering to citizens and enterprises the life-event- resp. business-episode-structured access to a group of coherent public services via a single user interface. All services within this group can be triggered by one interaction ("one click").

E-Government, E-Democracy and the Politicians

Birgit Jaeger
Roskilde University, Denmark

INTRODUCTION

The development of Electronic or Digital Government (E-Government) has varied throughout the world. Although we give it the same name, we know from different studies that, for example, the concept of information society can be interpreted in different ways in different cultural settings (Sancho, 2002; Williams & Slack, 1999). This article provides a general outline of the development of E-Government in the West and is primarily based on European and Scandinavian experiences.

It is only possible to give an introduction to E-Government if we can define what we are talking about. E-Government is still a rather new concept, thus its definition is not yet completely accepted, but for the time being, most people agree that E-Government includes the following features:

- E-Government is based on Information and Communication Technologies (ICTs)
- E-Government is taking place in public administration
- E-Government concerns electronic ways to perform all kinds of internal administrative tasks
- E-Government also concerns the communication between the public administration and the citizens and other actors in the surrounding society (Jæger, 2003)

BACKGROUND

Based on the first part of this definition the history of E-Government starts in the beginning of the 1960's when the magnetic tape replaced the punched card. During the 1960's and 1970's big central databases were built and were run on big mainframe computers. The databases mostly contained administrative data from fields where the law and regulations were clear and there was a large amount of data to process. In this period, large registers concerning, for example, public institutions were formed; and software systems for the government of the economy including salaries, taxes and pensions were developed. These activities were often run centrally and the results were delivered to the relevant authority.

When we turn to the second characteristic, we have to include the development of the public administration as well. During the 1980's and 1990's most Western countries have experienced a profound modernization of their public administration. At first, this modernisation was marked by reforms that have since been collectively labelled New Public Management. According to Rhodes (1997), New Public Management can be said to involve two different types of initiatives, the first of which relates to the management itself. These initiatives include a focus on management by objectives, clear standards, and an evaluation of the quality of service, while at the same time granting greater attentiveness towards the users of the public service in question. The other type of initiative deals with the introduction of economic incentive structures. This involves the dissection of the public administration in demarcated services, contracting out some services, and other services that are sought and arranged in competitive-like situations by establishing quasi-markets in which the consumers of the services are provided with an opportunity to choose between different services.

These alterations have had a more or less unintended consequence – the emergence of new policy networks around the provision of public services (Rhodes, 1997; Stoker, 1998; Heffen, Kickert, & Thomassen, 2000). These policy networks draw new agents into the management of the tasks in question, including agents from the business community as well as from civil society. Now we see private companies carrying out publicly-commissioned services. We also see civic groups in the local community, NGO's, sports clubs or interest organisations take over more social and caring-type tasks, which were earlier defined as public. (Again, we have to be aware of different traditions in different countries, but especially in the Scandinavian countries many of these tasks have been defined as public, whereas in other Western countries the family and local community have played a much bigger part in taking care of these things.) These agents are now engaged in relations with the public administration in collective, binding policy networks. This general development is often described in terms of the transformation of public sector regulation from government to governance.

These reforms differ from country to country (Rhodes, 1999), but the general picture is that these reforms have had great impacts on the way the public administrative tasks are preformed. Here the development of E-Government plays a significant role. Many of these reforms would have been very difficult to realize without ICTs. An example of this is the decentralization of administrative tasks from town halls to public institutions in Denmark. This reform was based on the use of PCs and the development of an internal electronic network between the town hall and all the public institutions. Today we describe it as the start of the development of the intranet in the authority in question (Jæger, 2003).

This development has continued and today we have a wide range of different software systems for all kinds of administrative tasks. These include electronic archives, systems for handling electronic documents, systems for consideration of different cases and so forth. Garson (2000) provides an overview of this field as well as a review of the literature.

Rather early on, it became clear that the development of E-Government was not just the design of an information system and its implementation in an organization. Thus, over the years, a lot of effort has been put into developing methods for the process of design and implementation (Bødker, Kensing & Simonsen, 2000). Based on different analyses of failures, it was acknowledged that it is very important to draw on the experience of the potential users in the design process. Otherwise, it is easy to produce systems that do not fit their needs. The experience also showed that the implementation of the system is very important if the organization is going to harvest the benefits of the system. A lot of parameters have to be taken into consideration in this process. The staff has to be informed and drawn into the process. It also is likely that some training is needed. In addition, the way to organize the consideration of cases has to be carefully examined, and it is perhaps necessary to draw in other competences than those that already exist in the organization. The inclusion of all these factors is important if one wishes to ensure that the design and implementation of a new information system is to be a success for the public administration.

During the last couple of decades, public authorities on different levels have developed their own information systems for performing their tasks. This has lead to a situation where many public agencies are unable to communicate electronically because they use different technological standards. Thus, there is a need today for developing common standards for electronic communication between public agencies at different levels. In recent years, this has become a barrier to the development of E-Government and therefore a large amount of resources is now spent on solving this problem.

E-DEMOCRACY

Nevertheless, public authorities do not only communicate internally or with other public agencies, they also communicate with citizens, private companies and other users of public services, which is the last of the features of E-Government listed above. With the introduction of the World Wide Web in the 1990’s, the public authorities were given a tool for this external communication. During the late 1990’s, and since, most public agencies have developed their own website where they place a lot of information, and electronic forms citizens have to fill out to apply for a public service and so forth.

Also in this area of the E-Government, we find different kinds of development. In a study of the development of Digital Cities in Europe (Bastelaer, Henin, & Lobet-Maris, 2000), (Williams, Stewart, & Slack, Forthcoming) it became clear that in some cities (e.g. Copenhagen (Jæger, 2002)) the website was developed as a part of the E-Government and interpreted as a tool for communication between the public authorities and the citizens, while in other cities (e.g. Amsterdam (Van Lieshout, 1999)) the website was developed as a tool for communication between citizens and did not involve the public authorities very much.

In terms of definitions, this is the most debated aspect of E-Government. Some people interpret a public website only as being a tool for administrative tasks for use between the public agency and the citizens, while others see the website as a place for debate and a tool for democracy as well. The first group defines the objectives of E-Government as a way to rationalize public administration and increase its efficiency, thus democratic debate should, in their understanding, not be a part of a public authority’s website but should be developed as something else – as E-Democracy. The last group defines the objectives of E-Government as a tool for all the tasks a public authority has and, consequently, also a tool for the democratic process. In this understanding, the democratic use of ICTs should be developed side by side with the administrative use.

Whether E-Democracy is developed as an integrated part of E-Government or as a special service, it is the least developed use of ICTs. To further this development, it is necessary to define what kind of democracy the technology should support. Without going into a theoretical discussion on the concept of democracy, it is possible to state that we have at least two different kinds of democracy: representative democracy and participatory democracy. Representative democracy is what the Western world mostly defines as democracy, and functions through a parliament where all the citizens in a country have the possibility to elect some people to represent them. Participatory democracy is defined as the wide range of activities in which citizens participate in the political process. It is important to remember that these two kinds of democracy are not mutually exclusive. In most Western countries, the two kinds of democracy exist side by side.

Technology will be developed differently in accordance with the type of democracy it should support (Hoff, Horrocks, & Tops, 2000). If E-Democracy is going to be a tool for the representative democracy, it can be used for electronic voting or online referendums (Hauge & Loader, 1999). Or it can be used to support the political parties in their dialog with the voters (Löfgren, 2001; Nixon & Johansson, 1999). If E-Democracy is going to be a tool for participatory democracy, it should be used to support political debate, for example, in a local community or in other political processes. Then it is a question of making websites containing information about the political process and chat rooms or newsgroups where people can discuss different political subjects and where politicians have an opportunity to argue for their opinions.

In recent years, there have been a lot of small-scale experiments where ICTs have been tried out as a tool for E-democracy. Some of these have been promising (especially the experiments with electronic voting), but many have more or less failed (especially the experiments with political debates on the Internet). Even if some of these experiments have been promising, we still lack a convincing example of large-scale use of ICTs in E-democracy.

THE POLITICIANS AND E-GOVERNMENT

The development of E-Government has a great impact on the people who are affiliated to the public administration. During a recent Danish study of the role of politicians in the development of E-Government (Jæger, 2003, in press), it became clear that they play a very limited part in this development. It is mostly the civil servants who decide how to apply ICTs in E-Government. Hesitancy among politicians towards becoming involved in the development of E-Government and determining the means by which ICT is utilised in administration, is largely due to their role conception, for example, whether or not they perceive involvement in such concrete, technical tasks, as being a part of their role.

The role of the politician builds on a sharp distinction between politics and administration. The politician is to represent the people and put forward grand political visions for societal development. Conversely, the administrator's role is to serve the politicians by carrying out their visions and generally administrating society on the basis of the politically defined framework. The means by which administrators implement and administer political decisions is regarded as a technical matter. The administrators themselves can therefore choose the methods and instruments they consider to be most suitable and efficient in the given situation. According to this perception of the division of roles, it is clearly up to the administrators to determine how E-Government should be shaped.

This distribution of roles between politicians and administrators has long historical roots and has been working well for generations. But due to the shift in the public administration from government to governance, the politicians have to change their role if they want to maintain their positions as governors of the public sector. Sørensen (2002; see also Kooiman, 2000) describes the new requirements of politicians under governance regulation as different means of exercising meta-governance. The requirements of politicians exercising meta-governance concern the creation of frames to allow other actors to participate in the process. The role of the politicians as meta-governors is then to specify the competence that various actors have to perform, and to make decisions. In order to get this range of independent actors to work in the same direction, the politicians are also responsible for standing forth to offer political leadership capable of creating meaning via a common understanding of the general goals.

The development of E-Government can serve as a possibility for the politicians to fulfil the requirements for exercising meta-governance. The manner in which public authorities are presently co-ordinating their utilisation of ICTs will determine the electronic infrastructure these authorities must use internally and with external actors for many years to come. Accordingly, E-Government can be configured in a way that supports the politicians as meta-governors. The use of ICTs can make it easier for the politicians to communicate with the external actors, and by doing so make the framework for co-operation visible, just as they can use the technology for debates that are important in their efforts to create common understanding and meaning. But this development will not happen by itself. The politicians must perceive E-Government as a dimension of the institutional framework for network regulation, just as they must conceive of technology as part of their work to create meaning and identity, as well as in their work with the construction and support of various policy networks. At the same time, the involvement of politicians in the E-Government design process could probably lead to a further development of E-Democracy where the democratic use of ICTs would receive greater emphasis.

FUTURE TRENDS

The potential of E-Government is not yet fully discovered. In the coming years, we will see new ways of utilising ICTs, which will enhance the performance of E-Government. The field of communication between different public agencies especially can prove to increase the effectiveness of E-Government if the developers succeed in agreeing to common standards for communication and the exchange of information.

Furthermore, the field of a safe and accountable identification of the user has great potential for increased effectiveness. With the successful development of one it will be possible to design a long row of forms, which require a safe identification of the user, and as a result shift a lot of work from the civil servants in the public administration to the individual user of public services. At the same time, an accountable identification of the user will make it possible for the public authority to give the citizens access to the information about them and to follow the consideration of their own cases. By doing this, it will be possible to have a much more open administration than the one we know today.

CONCLUSION

E-Government is here to stay. Even though we still lack the results from a general study, which proves that E-Government is a more efficient way to perform public administration and establishes how much money E-Government has saved, some case studies have shown that a public administration using ICTs at least in these cases can perform more tasks, with the same amount of staff, serving a bigger population than the public administration without using ICTs (Jæger, 2003, pp. 107-110).

The further success of the development of E-Government is of course also dependent on the attitude of the citizens. If they do not have access to the technology, do not know how to utilize a computer, do not accept public services in an electronic way, or if they do not trust the electronic services but are afraid of misuse, then it will not be possible to realize the potentials in E-Government. In this way, it becomes a task for the public authorities to prevent a digital divide among the citizens.

It is still rather unclear what will happen to the development of E-Democracy. As it looks today, it is unlikely that E-Democracy will be developed as an integrated part of E-Government. On the other hand, the many small experiments with different forms for E-Democracy point to an independent development where the democratic potentials of ICTs are tested and new applications are developed. This situation is even more likely to take place if the politicians revise their role and start to interpret the development of E-Government as a part of their role.

KEY TERMS

Accountable Identification: A way to identify a person in an electronic interaction and to give legal status to electronic documents. Different technologies have been tried out like e.g. chip cards and digital signatures.

Digital City: Usually a website, which is centered on a city, where public authorities, business and citizens can communicate and exchange information.

E-Democracy: Depending on what type of democracy it should support, ICT can be used for electronic voting, online referendums, or to support the political parties in their dialog with the voters. It can also be used to support political debate in a local community or in other political processes.

E-Government: Based on ICT, taking place in public administration, concerns electronic ways to perform administrative tasks, and the communication between the public administration and the citizens.

Meta-Governance: A new way to govern independent policy networks. The politicians have to create the frames that make it possible for other actors to participate in the policy process. They have to specify the competence of the various actors and to create meaning via a common understanding of the goals for the performance of the network.

New Public Management: Includes initiatives which relate to management of the public administration like e.g. management by objectives, clear standards, and evaluation of the quality of service. It also includes initiatives that deal with the introduction of economic incentive structures like e.g. outsourcing of public tasks and establishing of quasi-markets for public services.

Policy Network: Are centered on the provision of public services and include, beside the public administration, agents from the business community as well as from civil society, like e.g. NGO's, sports clubs or interest organisations. These agents are engaged in interdependent relations with the public administration.

E

Eight Key Elements of Successful Self-Funding E-Learning Programs

Yair Levy
Nova Southeastern University, USA

Michelle M. Ramim
Nova Southeastern University, USA

INTRODUCTION

The Greek philosopher Aristotle indicated that learning is the outcome of both teaching and practice. Clearly, learning is not confined exclusively to classroom lectures. In the past several decades, educators explored the possibilities of providing learning experiences to remote students. With improvement in technology and the growing popularity of Internet usage, e-learning caught the attention of both corporations and educational institutions. However, traditional learning methodology began transforming when elite universities embraced the Internet as a vehicle for their degree programs (Forelle, 2003). Progress in e-learning has increased its popularity in the past decade (Levy & Murphy, 2002). Consequently, it is carving a new brand of universities causing traditional schools to rethink their business model. Furthermore, some elite schools have developed specialized online degree and certificate programs. In doing so, these schools strive to compete on this new learning medium and create a new source of revenue, especially due to the declining enrollment and lower government funding resulting from the events on September 11, 2001 (Roueche, Roueche, & Johnson, 2002, p. 10). This paper provides definitions of the eight key elements any institutions should have in order to successfully implement self-funding e-learning systems.

BACKGROUND

In the past few decades, universities and colleges have been faced with a growing demand to graduate qualified students. At the same time, however, universities and colleges were faced with increased demand by local communities and governments to provide more scholarships and financial aid for local students, in spite of the reduction in financial support allocated to academic institutions (Cusick, 2003). As a result, higher education administrators have been seeking to increase their overall revenues from corporate sponsors and investors by crafting specialized degree and certificate programs. Not surprisingly, universities and colleges have been relying on international students to compensate by admitting a large number of full-fee paying foreign students (Surek, 2000). Since this has become such an important revenue stream, many business schools have gone beyond designing attractive specialized programs for international students and have even collaborated with international universities around the world to create joint programs.

In the post-September 11, 2001 era, because some of the hijackers came to the U.S. on student visas, new tougher Immigration and Naturalization Service (INS) regulations were installed to control and evaluate the issuing of student visas. These new regulations are dramatically affecting the number of international students seeking U.S. education. That impact is a result of a decrease in overall student visas issued by the INS and the sluggish process of new student visa seekers. At the same time, current international students who were already in the U.S. were forced to return to their home countries and reapply for student visas under the new regulations, and then wait months for permission to come back. As a result, online learning programs have become an alternative solution for international students seeking U.S. academic degrees.

In the past few years, Information and Communication Technologies (ICT), such as online learning, has grabbed the attention of many higher education administrators. In the late 1980s, Canadian schools invested enormous amounts of time and resources to develop learning programs for a distance delivery. U.S. schools quickly followed with some top business schools like Duke and Michigan implementing online learning programs in the 1990s. As the use of the Internet increased during the second half of the 1990s, many other U.S. universities, headed by their business and engineering schools, implemented online learning programs where almost all included one version or another of MBA programs (Davids-Landau, 2000; Forelle, 2003).

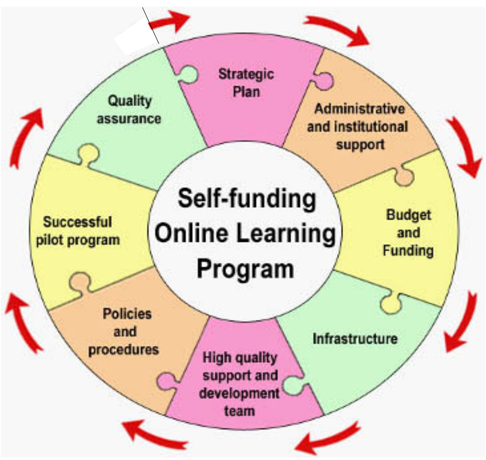
Today, more than ever, higher education administrators are very much interested, in online learning programs, as they face declining student enrollments, an aging student population, and a reduced level of federal, state, and local funding. This has resulted in a growing number of institutions that are looking for new innovative ways, mainly through the use of ICT, to attract both U.S. and international students in remote or distance locations. However, literature suggests that faculty members without prior online teaching experience have very little understanding of the skills needed to make their online teaching effective (Conrad, 2004). Moreover, literature suggests that tremendous efforts are needed also from institutions in order to prepare their faculties to effectively teach online (Chacon, 2001). Thus, the next section of this paper concentrates on the key elements needed in order to deploy a successful online learning program.

THE KEY ELEMENTS

Overview

Implementation of e-learning systems can be challenging, as only a limited number are successful in sustaining programs to the point of self-funding. In order to achieve a successful self-funding e-learning program, investment of both time and capital is essential in the period prior to implementation. Nevertheless, successful implementation of an e-learning system is a success ticket for a self-funding program. This paper will present the eight key elements of successful implementation (See Figure 1). Additionally, it will provide a roadmap that can help institutions to develop self-funding e-learning programs, along with the justifications for the importance of each key piece that comprises the overall success of the project. In the following sections, definitions of the eight key elements of successful self-funding e-learning programs are provided.

Figure 1. Eight key elements for self-funding e-learning program.



Strategic Plan

A vital step in the project is to devote adequate time for proper planning. A good strategic plan should include an analysis of all key elements presented in this paper, along with the development of a detailed blueprint—or strategic plan—of the implementation process. Such a plan should also include foreseeable problems and some suggested solutions or avenues of findings solutions to such challenges. A viable plan should be based on a gradual development process, rather than implementing a full-fledged program without proper adjustment by faculty, students, and administrators. This suggested methodology will allow institutions to progress with their projects one step at a time, while building and improving based on feedback and constructive comments from users, faculty, and administrators. At the same time, a detailed strategic plan would provide a solid plan for scalability and ability to reach a self-funding stage.

Administrative and Institutional Support

Administrative and institutional support is another key piece of successful implementation in the pursuit of a self-funding e-learning program. It is important to emphasize to the administrators the potential benefits associated with such programs and, at the same time, candidly present the challenges foreseen in such projects. The lack of knowledge related to the benefits and limitations of such technologies may cause some misconceptions and reservations about such projects resulting in roadblocks for the successful implementation.

Numerous institutions that seek to provide e-learning programs invest tremendous efforts in the development of e-learning courses, faculty training, and equipment, but lack the overall united institutional support for e-learning students. Institutional support for e-learning students goes beyond the access to the e-learning system and interactions with the professor. Students enjoy all of the benefits as if they are on-campus, but in a format that is available via the Internet or the web (Levy & Ramim, 2003). Such a support activities and benefits should include online access to: registration, financial aid, library, bookstore, advisors, student organizations, and virtual communities. In most institutions, these support functions are already available and just need integration or a single point of link to provide students' with a centralized point of entry. Such a centralized point of entry, or portal, can be created via the e-learning platform where links to the institutional support functions are provided along with links to the online courses. Furthermore, a centralized point of entry would enable a seamless integration of online and on-campus services.

Budget and Funding

Funding and budgetary issues are major key challenges for many e-learning programs. On one hand, the development of a professional e-learning program is dependent on adequate funding for leading-edge hardware and software, highly trained staff, and incidental expenses. On the other hand, many e-learning programs initially encounter either minimal funding or even insufficient funding. Such a state can trigger a "domino" effect, where the limited or decreased funding reduces the quality of support, development, and other needed resources (Alavi. Yoo, & Vogel, 1997). Consequently, funding sources must be incorporated as a key component of the implementation plan to avoid such derailing. One solution for the funding source includes an application for an institution, state, or federal grant that provides the seed funding for the project.

E-learning courses require a tremendous amount of development, student and faculty support, infrastructure, and other resources, which in most cases is not provided by the university or academic institution. Therefore, an additional fee is needed to cover such operations. This fee for e-learning courses should be collected and utilized for the maintenance of the program. For private universities, such additional fees can be added onto the general term fees in the same fashion that parking, health, or lab fees are added onto students' tuition each term. For state or public universities, the common and recommended way of collecting such funds is by adding an added-value charge for all e-learning courses as an "over tuition fee" similar to a computer lab fee. *Over tuition fee* is commonly defined as an assessed fee charged for certain classes in addition to the current state fees in order to cover the special expenses that such a course or program accrued. In some universities, both private and public, a small portion of such fee must be shared with their overhead charges, while the rest of the funding can be channeled into the program.

Infrastructure

Software

When evaluating in-house development of a customized platform, the school must be aware of both the costs and benefits associated with such avenues. If special features or customized features are needed, a customized solution of some form is probably necessary, although not always. Schools should determine to what degree their desired features are unique or non-standardized and how much effort will be needed to develop such features. If the unique features desired by the school are not addressed by any available commercial packages, a thorough investigation is needed. One aspect of the investigation should look into the costs associated with such development, including: time to develop, salaries for developers, upgrades and scalability, proprietary versus open code, training material, etc. The other aspect of the investigation should look at the benefits that will result from the development of customized platforms in comparison to commercially available solutions. If the desired features are standardized, the school would likely be better off with a commercially available platform than going through a system development life cycle.

Higher educational institutions are in the business of providing education and not in the business of software development (Levy, 2001). Therefore, a wiser way to pursue such implementation is to evaluate current commercially available packages and determine which platform best addresses the needs of the school, provides better support, allows easy upgrades, integrates best with current platforms on-campus, and is scalable. Choosing a good and credible solution can be a very critical decision. Taking the time to effectively examine and evaluate commercially available platforms may make the difference between a successful program and a costly failure.

Hardware

Evaluation of existing hardware or a proposal for needed hardware must be included early in the strategic planning stages of the project. Outsourcing and in-house are two main avenues to consider for the hardware infrastructure solution. In the event that competent employees with experience in hardware infrastructure are not available or difficult to obtain, outsourcing may be the appropriate solution. It is recommended to investigate the cost associated with large-scale operations at the initial stage. Some hosting services will provide a reduced rate for initial implementation, but dramatically increase rates once the program is growing and expanding, both in the magnitude of the hardware and bandwidth needed.

In the event that competent employees can be hired or utilized in-house, the avenue of in-house existing infrastructure and in house development should be pursued (Levy, 2001). Looking at in-house implementation of such a solution requires attention to the subcomponents needed to link the hardware piece. Such subcomponents include: networking and telecommunications, server architecture, along with backup devices and backup policies and procedures. The increased use of network traffic is a commonly overlooked component by many institutions and may cause a bottleneck effect, thereby reducing the confidence of faculty and students. Network testing and feasibility analyses prior to implementation are recommended to adequately support such a project in-house. The emerging use of minicomputers (or small to medium servers) for e-commence solutions has accelerated the development of server scalability and modular component-based methodology to hardware support. This allows institutions to start with a small installation and scale up by integrating more servers to the cluster as needed.

High Quality Support and Development Team

Institutions should not spend time and money on training professors to develop their own courses, as we don't train vehicle drivers to assemble cars. Rather, they should train professors to effectively use the tools and to deliver their course content via the Internet in the same way we train vehicle drivers to drive and obey road signs (Levy, 2001). It is best to assemble a professional support and development team to provide student support and to coordinate online course development with professors.

Support and development team can be created using in-house expertise. Often, retaining IT and instructional media developers in educational institutions is a challenge. However, institutions can provide some incentives, such as partial- or full-tuition reimbursement or other benefits in order to retain competent employees. In some cases, using an inside group can provide great first-mover advantages, as these employees know the environment and the settings of the institution, with a limited learning curve for these issues as compared with an outside group. Using an outside consulting company or an Internet course development company can be quite expensive and may require considerable coordination efforts. Furthermore, most publishers today provide canned content (electronic package or "e-pack" in short) that is based on the textbooks they published, thereby extensively reducing the development time of the course content.

Policies and Procedures

The first step to establish a high quality program should be the establishment of guidelines for official policies and procedures similar to the ones used for on-campus courses. Teaching requirements should be defined in terms of academic and professional experience essential for course instruction. Both professors and students should maintain a minimum technical proficiency to prevent the technology from becoming a hurdle in the education process (Levy, 2001). Some institutions have established a mentoring program where new faculty members are mentored by experienced online faculty members during their first online term. Such mentoring has proven vital in the event that other initial training or a web-assisted period is not feasible.

Policies and procedure manuals usually include documentation on issues such as:

- Teaching Requirements, including academic experience, professional experience, technical proficiency, and other competencies.
- New Faculty Hire Mentorship, including contacts, FAQs, technology setup, best practices.
- New Course Development, including learning objectives, online assessments types, student motivation techniques, information sources, syllabus development, and textbook selection.
- Facilitating an Online Course, including course orientations, instructor accessibility, grading, motivational techniques, continuous improvement, and evaluations.
- Student Issues, including e-registration, e-advising, e-bookstore, e-library, grievance, and online student code of conduct

SUCCESSFUL PILOT PROGRAM

The temptation to launch a full-fledged e-learning program quickly is tremendous. Nevertheless, a proper gradual process is recommended. It is recommended to start with web-assisted or web-enhanced capabilities for current on-campus courses, rather than with full-fledged online courses (Hiltz, Coppola, Rotter & Turoff, 2000). This will allow the faculty to learn the system and get comfortable with the technologies without the pressure of swiftly adjusting to a new medium of teaching. It is also recommended to start with faculty who are recognized "first adopters" of technology, as such programs rely heavily on technology and provide close monitoring and support to all students participating in online courses.

Incorporating feedback and making adjustments to policies and business processes is a valuable outcome of the pilot program. As part of the quality improvement process, feedback and adjustments for learning objectives and teaching methodologies (what works and what doesn't) is needed. Doing so right after the pilot program not only helps the institution in developing an effective and successful program with potential for increased funds, but is also useful for the accreditation purposes.

Quality Assurance

Pedagogy

A high quality course includes clearly defined course objectives and assessment tools such as the ones used in a traditional on-campus course. However, creation of an incremental assessment is recommended as a means of encouraging students' learning pace, constant interaction with the professor, and discouragement of cheating. Useful assessment measures include weekly quizzes, and multiple small and large assignments during the course of the semester. Quality assurance improves over time as the e-learning course infrastructure expands and best practices emerge. For increased effectiveness, continuous improvement and evaluations must be part of the program culture. As the program progresses, a yearly faculty retreat can facilitate discussion within the institution on best practices and improving the quality of teaching provided by the whole program.

Technology

Technology should not become an obstacle for delivering the educational experience. By the same token that schools are required to maintain their physical classrooms and to make students comfortable when learning on-campus, technology should be transparent and free of errors or down-time periods. The institution should spend time to evaluate current commercially available e-learning systems to find one that best matches their expertise and budget.

Once an e-learning system is selected, the institution should create a standardized interface thereby defining the page appearance, the institution's logo, the professor's image and biography, and common links to the institution's key sites, such as library, registration, and technical support sites. Color palettes and banners should also be uniform, as should the selection of communication tools available to the learners. This will assure consistency and reliability of the learning medium as users move from one course to another, providing a high quality experience from a technology prospective, while simplifying the job of the programming team. This is similar to the "brick and mortar" classroom features that are uniform in nature.

FUTURE TRENDS

The future trends in this area should include the exploration of successful e-learning programs and validation of this model through various case studies beyond the one documented by Levy and Ramim (2003). Moreover, as additional traditional higher educational institutions are implementing e-learning programs, it will be fascinating to explore the difficulties and challenges they face as a result of the lack of one or more of the eight key elements proposed in this article. Additional research should also focus on augmenting the model proposed here with newer formats of e-learning, such as the ones that include a mixture of synchronous and asynchronous learning tools for the same e-learning courses.

CONCLUSION

In this paper, the eight key elements for successful implementation of self-funding e-learning programs were defined and articulated. The tremendous growth and potential of e-learning in the business world and corporate training centers in the past few years is making its way to the academic world. As more and more individuals are stressed for time and the demand to expand their education and knowledge increases, greater pressure is put on administrators of higher education institutions and universities to come up with new, innovative ways and new technologies to satisfy those needs. Consequently, higher educational institutions have to spend more time investigating and planning the appropriate methods to implement their self-funding e-learning programs in the era of decreased funding.

Successful implementation of self-funding e-learning programs requires careful research, strategic planning, and forecasting. This paper reviewed and defined the eight key elements needed to achieve a self-funding level of e-learning programs. The key elements include: strategic planning, administrative and institutional support, budget and funding, infrastructure, high quality support and development team, policies and procedures, successful pilot program, and quality assurance.

KEY TERMS

Administrative and Institutional Support: All the benefits students enjoy when they are on-campus, but in a format that is available via the Internet or the Web, beyond the access to e-learning courses and interactions with the professor. These include e-registration, e-financial aid, e-library, e-bookstore, e-advisors, e-student organizations, and virtual communities.

E-Learning Program: The entire organizational, technological, and administrative structure that enables student learning via the Internet.

E-Learning Program Strategic Plan: The blueprint of the e-learning program implementation process that also includes foreseeable problems and solutions to such challenges.

E-Learning Support and Development Team: The team includes: program director, a program coordinator or assistant, instructional designer, system administrator(s), multiple developers/programmers, multiple support staff (for faculty and students), graphics and video production artist, and marketing coordinators.

E-Learning System: The technological and management system that facilitates and enables student learning via the Internet.

Over Tuition Fee: An assessed fee charged for certain classes in addition to the current state fees to cover the special expenses such course or program accrued.

Policies and Procedures of E-Learning Program: A set of guidelines and requirements for faculty to be able to teach online and for students to learn online. For faculty these may include: teaching requirements, new faculty hire mentorship, new course development, facilitating an online course, and student issues; for students: a minimum technical proficiency, new students' orientation, grievance process, and an online student code of conduct.

Quality Assurance of E-Learning Program: The inspection and maintenance of a high quality program that is based on two major components: 1) the pedagogy aspect and the effectiveness of the learning experience; and 2) the technology aspect and the quality of the online course.

E-Learning Environment

Mizue Kayama
Senshu University, Japan

Toshio Okamoto
University of Electro-Communications, Japan

OVERVIEW OF E-LEARNING

Nowadays, the concept/system of *e-learning* (or *eLearning*) is widespread with the advent and prevalence of the Internet. Via the Internet, people can communicate with each other at anytime and from anywhere. People can also share, rebuild, stock, and reuse various kinds of information. Here, it is clear that e-learning gets citizenship in the educational society instead of CAI (computer-assisted instruction) and CMI (computer-managed instruction). As a response to society's advance, it is necessary to construct a new learning ecology, such as a learning organization or a learning community. To date, the need for an understanding of e-learning issues has not been met by a coherent set of principles for examining past work and plotting fruitful directions. Obviously, it would be difficult to document the many seeds sown now.

The e-learning environment is cataloged as follows (Okamoto, 2000):

- Individual learning environment with learning materials
- Group learning/collaborative learning environment with some shared tools/applications
- Classroom learning (lecturing)

This learning ecology has the mixed mode of either synchronous or asynchronous by using any teaching/learning contents and audio/visual devices, such as videoconference and other communications tools.

e-Learning is a learning/education/training style that uses information technologies. In the past, this type of learning/education/training was called various names, like "distance learning," "distance education," "cyber learning," "virtual learning," "Web-based training (WBT)," "Web-based learning (WBL)," "online learning," and so on. Nowadays, e-learning is innovated by using the latest information technologies, including WWW technology for e-learning course delivery, movie/speech compression technology for e-learning content production, and the learning technology standards (SC36, 2004), like LOM (learning object metadata), SCORM (sharable content object reference model), and collaborative technology, for keeping the interoperability of e-learning systems/contents/courses.

The main advantages of e-learning are, as is well known, from "to any place, at any time" attributes. Often, the free education aspect also appears, although much of the educational software offered today is not free, and many educational institutions offer e-learning programs at a price. Plain, text-based course materials are not enough anymore. The recent increases in bandwidth made more avenues of expression possible, images on the Internet are commonplace, soundtracks and videos are used with growing frequency, and other (multi- and mixed) media types evolved (animation, simulation, collaboration, etc.).

Before now, based on learner modeling, adaptation of teaching strategies and intelligent user adaptation in intelligent tutoring system (ITS) were developed. More recently, the field of adaptive hypermedia (De Bra et al., 1999) emerged, at the crossroads of hypertext/hypermedia and user modeling. Adaptive presentation of the educational material can mean one or more of the following: providing prerequisite, additional, or comparative explanations; conditionally including fragments and stretchtext; providing explanation variants; reordering information; etc. Adaptive navigation support can mean one or more of the following: direct guidance, sorting of links, links annotation (Brusilovsky, 1999), link hiding, link disabling, link removal, and map adaptation. Another main advantage of the Internet is that it favors collaborative work, which, in turn, favors learning (Dillenboug, 1999).

Moreover, we regard e-learning as meaningful self-development of an environment for lifelong learning. The recent technological changes are influencing our society, and people are asked to acquire new knowledge all the time. The opportunities to take education with high quality have to be provided for all sorts of people who have different backgrounds, different abilities and knowledge, and various needs. E-Learning is one answer to the rigidity of the present Web-based courses and courseware.

THE DESIGN OF AN E-LEARNING ENVIRONMENT

When we think modality of computerization on education, it is generally categorized as follows:

1. Self-study entity through electronic information media-based materials and courseware
2. Learning entity, with electronic information media (e.g., computer) as learning/problem-solving/representing/knowledge-transmitting tools
3. Learning entity about information and communication technology, social problems, etc.
4. Computerizing entity of education

The relationships among those entities should be compensated for mutually, and an e-learning cycle can be developed. The idea here is in line with building the environment for "anybody" to learn something from "anywhere" and at "anytime" in the e-society. There are two purposes for this expansion: on one hand to enlarge the study opportunity, and on the other, to develop people's new competencies.

When we build an e-learning environment, at least three issues should be considered (Okamoto, 2000). The first is the pedagogical goal representing ability and knowledge as learning objectives. The second is the subject contents. The third is the learning forms, defined by seven learning environments:

1. Distance individual learning environment for mastery learning. This environment provides courseware for knowledge and skills acquisition, i.e., the typical e-learning course, such as WBT/VOD (video on demand) systems (Hui, 2000).
2. Distance individual learning environment for discovery learning using various search engines (VOD search and navigation mechanism).
3. Distance individual learning environment for problem-solving learning using simulations, such as ILE (interactive learning environment), and so on.
4. Videoconference system in the classroom environment for discussion, instructional presentation, questions and answers sessions, and telecommunications (Chen, 2001; Nieminen, 2001).
5. Collaborative learning environment for a small group or pairs using videoconferencing, some kind of communication tool, or various applications accompanied by a screen-shared viewer and learning log tracking mechanism.
6. Collaborative simulation learning environment for different learners performing different functions in a teamwork learning pattern, and as such, forming a special skill in the learner's own domain, e.g., a collaborative activity within the jet plane's cockpit.
7. Linkage and coordination among different organizations and areas, e.g., access the online school library, online museum, and so on.

In the establishment of e-learning environments, the most important idea is to start by defining the instructional goal and then classifying learning contents that are best equipped to build the learning environment. Moreover, the research on the method is required in order to build the asynchronous collaborative learning contents (Dryden, 2001). Further research directions should be placed on the study of the learning environment, with emphasis on the virtues of individualized learning and collaborative learning. In this case, transmission of real images and voice data is required. The fundamental environment components for e-learning systems include the whole information system related to e-learning environments. It consists of several management functions, such as curriculum and learning-materials management, learners' profile and log-data management, LMS (learning management system) and LCMS (learning contents management system). In order to construct those educational management systems, we need, technologically, several data/file-processing modules, such as a distributed file system, synchronous data communications, and so on. If any applications and tools related to e-learning can be plugged in the core framework, we would build an integrated e-learning environment where learners can share and operate these software/data in real time. In addition, the total management system of e-learning is required in order to execute a real educational project or practice, which means research project management, learning schedule management, courseware development, and so on.

COLLABORATIVE LEARNING UNDER E-LEARNING ENVIRONMENT

Collaborative learning is a participants' initiative learning form that has been stressed with the paradigm shift from the teaching side to the learning side in the current learning ecology. The objectives of collaborative learning are the effective and efficient group activity and the collaborative mutual interdependence relations within the group. In collaborative learning, each learner is submitted a subtask, and he or she is expected to accomplish it. As the result, the group goal and each learner's learning goal would be achieved.

Distributed collaborative learning is a type of collaborative learning that can take place in the Internet environment (e.g., e-learning environment) with multiple learners geographically far from one another (O'Malley, 1994). Geographically, a distanced situation can mean remote or far physically, but this also covers cases where direct interaction and dialogue are not possible among participants due to other reasons. The urgent research topic is how to support distributed collaborative learning, including how to support the collaboration among plural learners according to a teacher's educational objectives. This type of learning is called CSCL (computer-supported collaborative learning). CSCL focuses not on the efficiency of group work, but on a deep and comprehensive understanding with self-reflecting and self-monitoring (Dillenboug, 1999). In general, the CSCL management software provides two types of activity space: a private working space and a collaborative working space, where the learners can exchange information in a synchronous or an asynchronous manner. Many researches are discussing these two types of activity space: the information exchange types that exist, and those that are necessary (Synnes, 1999).

The resources required in a collaborative learning (CL) environment are taken up as follows (Okamoto, 2001):

- Technologically mediated dialogue channel
- Shared workplace for a group
- Personal workplace
- Learning materials and learning tools
- Analyzing tools of data/information
- Repository/memory for data/information revealed in CL
- Reference channel for the collaborative repository
- Modeling tools for monitoring the process of CL

In order to support collaborative learning in an e-learning environment, many platforms are proposed. For instance, Timbuku (Netopia), NetMeeting (Microsoft), Media-Fusion (Apple Computer), Habanero (University of Illinois/NCSA), MatchMaker (University of Duisburg), SimPLE (University of Maryland), CSILE/Knowledge Forum (University of Toronto/Learning in Motion) and REX (University of Electro-Communications). We can also mention the performance support system (PSS). In such a system, learning activity is directly connected to problem solutions in the real world. The PSS in a virtual environment is used in many fields, such as flight (flight simulator), shipping (navigation simulator), and fire (fire simulator).

FUTURE WORK

The traditional classroom teaching method is limited in time, and it is difficult to supervise all students. In order to realize individual learning, educators must prepare and provide a tailored curriculum teaching method for each student's needs. However, it is difficult for a teacher to manage such a teaching activity when considering students' individual differences. On the other hand, the e-learning paradigm provides a solution to these problems. Adaptive/personalized/individualized learning environments seem to be more useful than the traditional classroom teaching environment. In addition, we can enhance the quality of the course contents by effectively using learning media.

However, when we build a desirable learning environment to promote learning effectiveness, we have to tackle the following questions:

- **Should it be an e-learning system?** Who are the target learners, and how far are they from the site? Are these features appropriate for the e-learning paradigm? Can we expect to include the number of learners from a time and location point of view? We should also consider the needed type of e-learning system and the technical tasks of the e-learning system based on those aspects mentioned above.
- **Should it be an intelligent, adaptive system?** Are the students very different? Do their backgrounds vary? Do the students belong to different age groups? Are they full-time and part-time students? Are there company workers among them? Does the subject of the course include features that might be relevant to different people? Do all students have to study the whole material, or should there be alternatives according to their needs? How granular is the course presented? In this case, we have to consider both the predicted student attention span and the smallest educational unit containing useful information. These kinds of questions, again, do not only point to whether an adaptive system is needed or not, but they also show what kind of adaptation is necessary.
- **Are various media needed?** Does text suffice for the presentation? Can we expect a better student reaction from different media? May the media motivate the learners? May the media make progress in their understanding of the contents? What kind of media is appropriate? What part of the e-learning system (contents presentation module, testing module, education tactics planning module, and so on) will be best suited for the media?

CONCLUSION

The retrospective of education in the 20th century is portrayed by classroom teaching and learning, group learning, and individual learning in traditional teaching and learning forms and e-learning forms. Education is changing as technology advances. Internet technologies are highly influential in developing and presenting teaching and learning activities. The Internet is used as a place to look for information, communicate, and realize self-development. Moreover, the innovation of technology will prospectively increase the speed and capacity of processing and the availability of access.

Learning needs are dynamic and vary in the computerization age. As a response to this society advance, e-learning is here to stay, as it involves the methodology of instruction, cooperative and collaborative learning, self-study, and all kinds of media, and furthermore, it engages various evaluation ideas. Nevertheless, it is important for people to form new competencies and abilities and to create and obtain sound attitudes toward the new era. In keeping with these purposes, we need to design the learning environment to foster deep and wide competency. Moreover, teachers need to put their expertise to this learning environment through their educational practices. The method of group formation and organization, the preparation of the learning contents and media, and teamwork among teachers are the most eloquent and meaningful matters.

Finally, we would like to portray some essential matters in order to achieve real success in the e-learning world:

1. Quality of contents based on well-examined curriculum (or competency library) reflecting the specified learning goals
2. Quality of services from educational and technological perspectives
3. Involvement and commitment of human mentors
4. Copying technology changes
5. Seamless information flow and easy access
6. Knowledge repository for reusing resources
7. Integration of authoring and delivering
8. Sharing functions such as “plug-ins” for applications and tools

These essential matters set the stage for the 21st century to host collaborative development of infrastructure for large-scale use by the profession, and conduct essential research into the advancement of education.

KEY TERMS

Collaborative Learning: This is a form of learning that involves collaborative learning processes. It is designed for coaches, helpers and faculty, and groups of learners to fulfill the learning objectives of groups and of each learner through sharing resources and interacting.

E-Learning: A learning/education/training form/shape using information technologies. E-learning can provide learning/education/training services for anyone, from/to anywhere, and anytime. By network technology and learning technology, the following matters work at the e-learning environment: blending of learning and teaching methods (virtual classroom, simulation, collaboration, community, and classroom); supporting learning and teaching services (from assessment through testing and certification); online administration (handling user and course registration and monitoring learner progress); and so on.

Learning Contents Management System (LCMS): This is a system that is used to create, store, assemble, and deliver personalized content in the form of learning objects in an e-learning environment. LCMS includes and combines the functions of a content repository/database or CMS (content management system) and a LMS. Although the LMS has functions to manage the learning courses, the LCMS has functions to manage the content and permit locating stored content, authoring new content, attaching metadata to content, and managing versions of content.

Learning Management System (LMS): An e-learning infrastructure with real-time databases that deal with user (learner, coach, faculty, and so on) information, including the user's learning competencies, learning objects for each type of learning style and form, and learning activity and performance log tracking. An extended LMS may also support authoring, performance assessment, classroom management, competency management, knowledge management, certification and compliance training, personalization, mentoring and coaching, and communication.

Learning Object: This is any entity (digital or nondigital) that may be used for learning/education/training. A learning object is usually the smallest unit of instruction managed by a LMS. However, a learning object may grow increasingly complex, have any internal structure, and may get more size or granularity. In order to reuse, learning objects are described by metadata (LOM : learning object metadata).

Learning Technology Standard: This is a *de jure* standard for learning/education/training with information technology. This type of standard includes a formal accredited normative specification or set of guidelines, typically including conformance criteria. A standard is created by a formal standards development organization (SDO), like the European Committee on Standardization (CEN), the International Organization for Standardization (ISO), and the IEEE Learning Technology Standards Committee (IEEE LTSC).

Electronic Commerce Policies for Dutch SMEs

Maria-Eugenia Iacob

Telematica Instituut,[1] The Netherlands

INTRODUCTION

Dutch small and medium enterprises (SMEs) are one of The Netherlands' most important sources of wealth creation and employment. No less than 99% of private enterprises consist of medium and small-scale businesses. They provide employment for 2.3 million people (60% of the Dutch labor force) and account for 52% of the national income generated in the private sector (www.mkb.nl/mkbnederland/english.shtml).

Today, the unused potential for SMEs, from adopting electronic commerce, is huge, although this varies by industry, size, and segment of the diverse SMEs. Therefore, enabling the SMEs to engage in the digital economy is one of the key priorities of the Dutch government. This line of thinking is promoted through the "Nederland gaat digitaal" ("The Netherlands go digital") program (www.nederlandgaatdigitaal.nl).

In this article we present an overview of the approach taken by the Dutch government regarding the development of the information society and the diffusion of electronic commerce in small and medium organizations. Our analysis also includes an assessment of the current situation of SMEs with respect to the adoption of electronic commerce and their position with respect to the governmental policies. Furthermore, we refer to policy implementation instruments ("iMPact" and "ASPect" projects) in the area of electronic markets and application service provision.

BACKGROUND: THE PLACE OF SME IN THE ICT POLICY IN THE NETHERLANDS

Policies and Governmental Initiatives

"Nederland gaat digitaal" ("The Netherlands go digital") is the central slogan of a broad campaign the Dutch government started in 2000 with the intention to modernize and change many aspects of Dutch society. The idea of this campaign was to proactively stimulate the use of information and communication technology (ICT) in all the layers of the society: by citizens, government, education, healthcare, and companies. Five ministries are coordinating and financing programs that fall within their areas of responsibility:

- The Ministry of Interior Affairs is taking care of the diffusion of ICT in the relationship between the citizen and the state (e.g., city halls are opening digital offices).
- The Ministry of Justice is coordinating the development of a legal framework that regulates the use of Internet for communication and business.
- The development of a communication infrastructure is under the supervision of the Ministry of Transport, Public Works, and Water Management.
- The Ministry of Education, Culture, and Sciences is coordinating the diffusion of ICT in the educational system.
- The Ministry of Economic Affairs has developed, together with a number of organizations—ECP.NL–Electronic Commerce Platform Netherlands, Syntens,[2] MKB[3] Nederland,[4] and industrial branch organizations—its own SME campaign "Nederland gaat digitaal" (for 2000-2001), aiming to enhance the involvement of SMEs in e-commerce. Furthermore, specific programs were defined to support the industrial branch organizations to develop strategies with respect to ICT, such that these, in their turn, can inform and advise their members accordingly.

During 2001, the Ministry of Economic Affairs collected information from Syntens, MKB Nederland, and other sources showing that there exists a great interest from SMEs for a continuation of the program (see the NIPO Survey, Table 1, Ministerie van Economische Zaken, 2001; NIPO, 2001). The result was that 71% of the SMEs

Table 1. NIPO evaluations (see Snelders & Eecen, 2003)

Category	**4-th quarter 1999 (before the start of "Nederland gaat digitaal")**	**1-st quarter 2001 (half way evaluation)**	**2003**
Percentage of SMEs with internet connection	55%	68%	83%
Percentage of SMEs that do electronic business	18%	36%	66%

were aware of the program and of its goals. Consequently, a second phase of "Nederland gaat digitaal" was initiated.

The new program (2002-2005, 22,7 millions EUR), "The SMEs in the Digital Delta," is targeting companies with less than 100 employees with concrete goals: in the end of the program, two-thirds of the SMEs should be present on the Internet with at least a "shop window" Web site, and two-thirds of the SMEs should do business transactions via the Internet. The plan identifies four obstacles that are in the way of these targets: SMEs do not know what business opportunities the Internet can offer, they don't have in-house *ICT expertise* and knowledge, they don't *trust* the Internet (legally and technologically), and often they are not financially able to support innovation. The approach taken by this new program is dealing only with the first two of the aforementioned problems and in short is the following:

1. To increase the *awareness of SMEs related to ICT opportunities* and to provide them with tailored knowledge, an intensification of the former MKB campaign "Nederland gaat digitaal" is planned. Namely, supplementary founding is directed towards workshops, consultancy, information materials, training and support of branch organizations and of their members, and development of example pilot projects for a number of sectors, also via two projects, iMPact and ASPect, in the areas of e-markets and ASP.
2. With respect to the *enhancement of trust*, the following activities were planned:

   • The government must play an active role in the development of the legal framework for e-commerce. Although, the Dutch legislation can support electronic transactions within acceptable limits (see the white paper on "Legislation for the Electronic Highway," Lower House of Dutch Parliament, 1998), efforts are being made for implementing the EU directives. Several important Internet and e-commerce regulations are already operational, and a number of bills are currently discussed in the Parliament: Distance Sales Act (see Staatsblad, 2000b), Personal Data Protection Act (see Staatsblad, 2000a), Act Regarding the Legal Protection of Databanks, (see Staatsblad, 1999), Electronic Signatures Act (see Staatsblad, 2003), Electronic Commerce Bill (see Lower House of Dutch Parliament, 2001b), Bill regarding Electronic Money (see Lower House of Dutch Parliament, 2001a).

   • Apart from legislation, an important role is reserved for self-regulation. Basically, self-regulation assumes that companies conducting business on the Internet adhere to and act according to a code of conduct. The task of defining and disseminating such a Code of Conduct was carried out in The Netherlands by a non-profit organization, The Electronic Commerce Platform Netherlands (ECP.NL). We will mention here only two of the products that relate ECP.NL to the needs of SMEs: the "*Model Code of Conduct for Electronic Business," version 4.0* (see ECP.NL, 2001; this Dutch initiative was acknowledged as a model by a number of international organizations such as OECD, UN, and the European Commission); and "*Nederland gaat digitaal, netjes volgens het boekje*" ("Netherlands go digital, by the book") (see ECP.NL, Syntens & EZ, 2002, and www.nederlandgaatdigitaal.nl/regels/). The latter explicitly addresses the SMEs. It offers practical guidance related to the e-commerce acts and regulations, by means of questions, answers, and practical examples.

   • The reliability of the communication infrastructure and the security of information exchange over the Internet are targeted in two other national programs (NACOTEL and the campaign "Internet and Security").

The European E-Commerce Policy Landscape

Most of the European governments have recognized the fact that e-business has drawn a clear separation line

Table 2. The use of the Internet in SME–2002 (see CBS, 2002, 2003; Snelders & Eecen, 2003)

between big companies and SMEs. The costs of introducing and maintaining ICT in small companies is significant when compared with their turnover, and therefore they cannot afford experiments and expensive mistakes. Therefore the *rationale* behind all the e-business policy programs was to help SMEs not to make such mistakes and eventually to support them to make the right step towards e-business. Governments (e.g., in the UK, The Netherlands, Greece) have argued the need for such actions based on substantial surveys and large consultations with SMEs, SME (branch) associations, business and IT experts, and academia. Most of these programs have explicitly set as a primary *target* increasing the e-business awareness. Specialized "awareness programs" have been started by several other member states (UK/Scotland—*First Steps Workshop Series*, Austria—*Ecaustria (Let's E-Biz)*, Sweden—*SVEA*, Germany—Lower Saxony (the *B-On-Line Project)*, Spain—*Catalunya on the Net*. In terms of ambitions, each national framework program strives to secure a leading position for that nation in the digital economy.

Significant differences between these programs appear in the selected *implementation* mechanisms, which take various forms: broad consultation forums, consulting, general training, Web-based e-learning tools and toolboxes, tailored e-business strategies, or direct financial support for IT introduction.

MAIN THRUST OF THE ARTICLE: E-COMMERCE AND SMES – THE STATE OF AFFAIRS

In what follows we will present several statistics and figures that will bring some light over the current situation regarding the presence of e-commerce in SMEs.

The introduction of electronic commerce can theoretically lead to three types of improvements in an organization: efficiency (doing things better), effectiveness (doing things differently), and innovation (doing other things).

Table 3. E-commerce innovations (Snelders & Eecen, 2003)

	2002 (%)		2003 (%)	
Category	**5-20 empl.**	**20-100 empl.**	**5-20 empl.**	**20-100 empl.**

- *Efficiency*: In 2003, 75% of the SMEs stated that by using electronic commerce, they have more efficient business processes (in terms of time and lower costs), 58% that they have less administration work, and 12% that for them doing business electronically leads to an increase of the turnover (see Snelder & Eecen, 2003).
- *Effectiveness*: An enhancement of effectiveness almost always assumes a partial or total redesign of the business processes or even an entire new business model. From this point of view, there still is little progress for SMEs (see Table 2): only 34% of them have changed their internal business processes. However, the number of companies that perform some form of electronic transactions (even occasionally) rose in 2003 from 59% to 66% (see Snelders & Eecen, 2003). Most of this growth is due to businesses with less than 20 employees.
- *Innovation:* The most significant novelties brought by e-commerce are those of providing a new transaction channel and accessing new market segments. As a consequence, many companies have reconsidered their strategies with respect to marketing and procurement/sales, and even have developed new products/services to strengthen their position in the market. Still, things are not moving very fast in the SME community. According to MKB Nederland, FHI, and Nederland-ICT (2002), until now most SMEs see e-commerce (in particular having a Web site or an online storefront) only as a cheaper alternative to advertising.

Table 3 gives more detailed information regarding the penetration of the different types of e-commerce innovations among SMEs.

FUTURE TRENDS

Obstacles

Surveys completed during the period 1999-2003 (see NIPO, 2001; MKB Nederland et al., 2002; Snelders & Eecen, 2003) have revealed that SMEs are *still* confronted with several "e-commerce-related" problems. Again, the most important one is the *insufficient expertise and lack of accurate information*: 37% of SMEs still believe that for them this is the biggest obstacle in the way of e-commerce (in 2003 this percentage decreased to 11%; see Snelders & Eecen, 2003). This is perceived as high risk, since SMEs are often not able to express clearly what they need from their ICT suppliers. Moreover, the opinion of SMEs is that the ICT market is not transparent because of a multitude of reasons:

- They cannot have any means to measure the quality of ICT products on the market, and therefore they cannot establish a relation between the price and quality or quantify them.
- They do not understand the ICT-jargon.
- There are too many different ICT products/services.
- They don't know how to compare two IT products and to see how they differ.
- Things are changing too fast and too often in ICT.

The majority (60%) of SMEs think that their ICT suppliers should more seriously consider products tailored to specific branches. With respect to their need for objective information, SMEs have expressed various requests: 20% need more information on ASPs, 22% on e-business, 25% on e-logistics, 34% on administration, and 41% on CRM. However, most need more information on prices and costs (54%) and functionality of ICT products/services (66%).

A second obstacle perceived by 6% of the businesses (Snelders & Eecen, 2003) is the *maintenance of information systems*: half of the SMEs administrate their ICT-infrastructure themselves; a quarter of them use the services of a person, which is either an acquaintance or a hardware supplier; and the rest occasionally hire a system administrator. Although SMEs have declared that in general they are satisfied with government programs like "SME in the Digital Delta," they feel that more attention should also be paid to problems related to internal administration of information systems. SMEs often do not have them completely under control, and if however they decide to transact online, they take great risks.

Finally, SMEs consider that the program of *the government does not stimulate enough the effective implementation* of e-commerce. "Nederland gaat digitaal" succeeded to raise the SMEs interest in electronic commerce (67% of businesses are aware of the program, and 63% acknowledge Syntens as the preferred source of information regarding Internet and e-business; Snelders & Eecen, 2003), but an investment in e-commerce implementations is not part of it.

Policy Implementers: iMPact and ASPect

Providing the Dutch SMEs with tailored knowledge is the most direct way to help them make informed decisions concerning the suitability of conducting business online. For this purpose, the program "SME in the Digital Delta" has (among others) selected two themes:

- The *electronic marketplace model*, as a virtual intermediary between potential buyers and sellers. The government considers that electronic marketplaces can be very attractive for many SMEs, not only because it facilitates potentially more commercial transactions, but also because it makes them more efficient, allowing in many ways significant decreases of costs.
- The *application service providing model*, as a relatively new solution for outsourcing applications and related services and making these applications remotely accessible via the Internet on a rental basis. The ASP model offers a solution for SMEs willing to outsource certain ICT solutions. This will allow them to focus on their core activities, instead of spending resources on the operational administration of ICT applications and the specific requirements (such as expertise, professionals, financial investments, etc.) for it. Besides, such a model can fill the need for otherwise very expensive applications (such as ERP solutions), while paying, in principle, only for the effective usage of them. Finally, SMEs no longer have to worry about acquisition of newer software versions and can easily experiment with new functional features of such updates. Since SMEs have limited abilities to cope with ICT, and considering the aforementioned advantages, the government considers ASP to be an interesting solution.

The two research projects (iMPact and ASPect) developed around these themes are to be carried out over two years (2002-2004) by Telematica Instituut and its partners: Syntens and the branch organizations. Their roles are explained below.

- Telematica Instituut covers the practical research work for the dissemination and introduction of e-marketplace and application service, providing knowledge in the SME sector.
- Syntens is acting as an intermediary between Telematica Instituut and the SMEs. All iMPact and ASPect deliverables are transferred into Syntens hands, which in turn will disseminate them among SMEs via its national SME consultancy network.
- Branch organizations represent the interests of their SME members. On one hand, together with Syntens, they help SMEs to receive all necessary advice regarding e-marketplaces and ASP. On the other hand, they are providing the project research teams with branch-specific information. That will allow them to define a branch strategy for electronic commerce by building pilots and examples tailored to the needs of each branch.

Supporters of these projects are ECP.NL and MKB Nederland.

The work in iMPact and ASPect is carried out along three directions:

1. *Knowledge Management:* This direction is devoted to the development of business, organizational, legal, and technological knowledge.
2. *Education:* This direction will develop training materials and courses for Syntens advisors and staff members of the branch organizations.
3. *Exploration and Analysis of Branches:* Within this direction several industrial branches are surveyed. The aim is to define adequate adoption models for e-marketplaces and ASP. The project teams are attempting to involve primarily large branches in these activities.

CONCLUSION

Without any doubt the policies of the Dutch government are leading to important changes in way the branch organizations, and subsequently the small and medium enterprises, are looking at electronic commerce. However, for SMEs there still is a way to go and several milestones to leave behind. Some of them, such as expertise and skills, can be improved trough projects like iMPact and ASPect. For others, like standardization and security technologies, the ICT forums and industry are striving to find better solutions. Financial obstacles, however, must be taken over by SMEs themselves.
