Scardamalia also indicated that the computer technology also should provide children with the opportunity and the means to make revisions. Without this, she claimed that children will not be able to work continuously to improve the quality, coherence, and the utility of their ideas. One of the major qualities of CHiLE is the ease with which children can revisit and revise the sequences of slides and their accompanying text. The comprehension-modeling tools provided by CHiLE thus promoted idea diversity, improvable ideas, and knowledge-building discourse, three of the sociological and technological determinants of knowledge building identified in Scardamalia (2002).

FUTURE TRENDS

The research in progress reported in the previous two sections indicates that the inclusion of model-eliciting problems and of comprehension-modeling tools (such as CHiLE) into online collaborative learning environments both have the potential to facilitate the establishment and maintenance of online collaborative mathematics knowledge-building communities in schools and higher education institutes.

However, two important issues still need to be addressed before this potential can be realized. First, the set of principles for informing the design of model-eliciting problems developed by Lesh and Doerr (2003) need to be modified to take cognizance of the differences between online collaborative and traditional classroom environments. Second, the theoretical framework informing the design of comprehension-modeling tools needs to be modified to include not just ideas from research into external mathematical representations that were used to inform the design of CHiLE (e.g., Kaput, 1992; Olive, 2000), but also ideas from research conducted in other areas such as online collaboration (e.g., Klopfer & Woodruff, 2002), cognitive science, and multimedia learning (e.g., Mayer, 2001; Sweller, 1999). Both these issues are the foci of a series of design experiments (Bereiter, 2002a) currently being conducted by Nason and Woodruff.

CONCLUSION

In this chapter, we identified two major reasons why mathematics educators have had limited success in establishing and maintaining online knowledge-building communities.

1. The inability of most textbook math problems to elicit ongoing discourse and other knowledge-building activity

2. Limitations inherent in most CSCL environments' math representational tools

We then proposed how these two problems could be overcome, namely, by the inclusion of mathematical problems that children can analyze and describe through a mathematical model (such as the steps necessary to divide two pizzas among three people) and comprehension-modeling tools (that allow observers to later see how the students have solved the problem) within CSCL environments.

We have targeted our discussion within one CSCL groupware product called Knowledge Forum, but we believe the same principles will apply to any online computer-supported collaborative learning system. To that end, we argued that the development of model-eliciting problems suitable for use in online CSCL environments and of comprehension-modeling tools is being restricted by the lack of adequate theoretical frameworks to inform the research and development of these two types of artifacts. Therefore, we have proposed that the development of adequate theoretical frameworks to inform the design of these two types of artifacts should be a major research priority in this field.

KEY TERMS

Comprehension-Modeling Tools: Math representation tools that enable users to (a) generate multiple representations of mathematical concepts and processes, (b) dynamically link the different representations, (c) communicate the mathematical ideas they have constructed, and (d) make movie-like sequences of animation slides that enable others to replay the process used to generate the solution.

Computer-Supported Collaborative Learning: collaborative learning mediated by computers.

CSCL: Acronym for computer-supported collaborative learning.

Knowledge Building: Production and improvement of knowledge objects that can be discussed, tested, compared, hypothetically modified, and so forth, and not simply the completion of school tasks.

Knowledge Forum ®: A single, communal multimedia database designed to facilitate computer-supported collaborative learning.

Mathematical Representations: concrete, pictorial, and symbolic models used to represent mathematical ideas.

Model-Eliciting Problems: Mathematical problems that involve producing models for constructing, describing, explaining, manipulating, predicting, and controlling complex systems (Lesh & Doerr, 2003).

Problem Solving: Situation involving an initial state, a goal (or solution) state, and a blockage between the initial and goal states that requires the construction of new knowledge to proceed from the initial to the goal state.

Innovative Thinking in Software Development

Aybüke Aurum
University of New South Wales, Australia

INTRODUCTION

As we enter the third millennium, organizations have to cope with accelerating rates of change in technology and increased levels of competition on a global scale more than ever before. In order to stay competitive within this changing business environment, organizations are forced to constantly pursue new strategies to differentiate themselves from their competition, such as offering a stream of new products and services (Satzinger et al., 1999). Furthermore, there is growing recognition that an organization's capability to deal with change, improve services and quality, cut costs, develop new products, and compete in a global market will depend upon the level of creative and innovative thinking of its workforce (Covey, 1989). In short, in order to remain competitive in an era of increasing uncertainty and market globalization, organizations must constantly be creative and innovative with their products and services.

Software has been widely considered as central to all sophisticated innovations. In the age of the Internet the challenge is to identify and evaluate new ideas, processes and applications. In many of the fastest growing industries, including computer, entertainment, communications, advertising, logistics and finance, software has been the end product itself, or the highest value component in the end product. In other cases, software has been used to support value creation and innovation processes. The growing importance of software-based innovations suggests the need to improve the creative skills of IT professionals. This need, in turn, requires an appropriate response from the IT education and training sector. Moreover, IT education and training should better nurture students' creativity, so that they can be successful in their future roles as innovative professionals and business people. It is particularly important that IT students be given an opportunity to develop and apply creative and innovative skills to software processes and products.

Given the crucial importance of creativity and innovativeness for success in a knowledge economy, the main purpose of this article is to explore concepts about creativity and how they relate to software development by providing empirical research examples in IT education.

CONCEPT OF CREATIVITY

The literature offers diverse conceptual definitions of creativity. Glass (2001) argues that creativity is hard to define, hard to judge and hard to quantize. Kappel and Rubenstein (1999) reason that this is due to fact that creativity is used to describe a variety of things; that is, supporting the creativity process, the creative person or the creative product present different requirements for the definition of the creativity. Tomas (1999), for example, defines creativity in terms of an original idea. Shalley and Perry-Smith (2001) point out that it is not enough to only be original; also, appropriateness is vital in order to distinguish creative ideas from surreal ideas that may be unique, but have unlawful or highly unrealistic implications.

Central to creativity is the ability to generate ideas. Some psychologists and philosophers have argued that idea formation can be explained by way of association (Mednick & Mednick, 1964). This theory suggests that association occurs when two stimuli take place together (contiguity), when two stimuli are similar to each other (similarity), or when two stimuli are different from each other (contrast). Associations may be stimulated by environmental factors, by previous associations, or may be mediated by ideas related to other associates. Therefore, it is possible to have many combinations and permutations. Associations can vary in strength, depending on how often associated ideas occur together or separately.

Lateral thinking is an aid to creativity when one needs to have diverse ideas. It is a function of knowledge and imagination that may bring out discovery, innovation, imagination, and exploration. Lateral thinking consists of seeking as many alternative options as possible to the extent of one's adventurousness. In other words, it is a mental activity involving making connections between knowledge and ideas that were previously unrelated. The basis of lateral thinking is that since many problems require a different perspective to be solved successfully, individuals should suspend their judgment about what is relevant to a course of action.

CREATIVITY TECHNIQUES

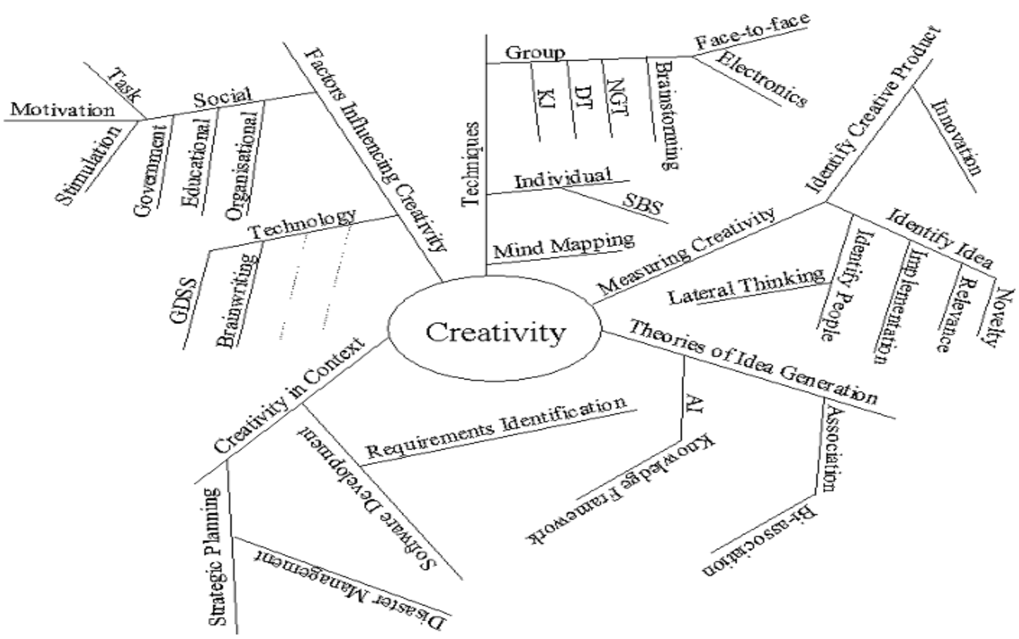
Consistent with the view that creative thinking can be learnt by appropriate stimulation and instruction, a variety of formal techniques have been developed to assist the production of novel ideas including brainstorming, mind mapping or solo brainstorming. Brainstorming and similar idea generation techniques aim to increase the production of novel ideas. The objective is to promote creativity by appropriately managing interaction within group as well as enhancing the creative environment. The procedures involved in the following examples are not difficult and may involve "lateral thinking," where ideas are stimulated by members of the group.

Brainstorming is an idea generation technique that was conceptualized by Walt Disney in the late 1920s and then expanded by Alex Osborn (1957). The objective of brainstorming is to encourage associations. The basic assumption is that it is possible for an individual(s) to generate many ideas, provided that he or she is exposed to stimuli and has experience, knowledge, and the personal flexibility to develop various permutations and combinations, and the capacity to make correct selections. This method initially emphasizes the quantity of ideas generated, leaving the assessment of quality to a later stage. Brainstorming sessions can be conducted electronically or verbally. In electronic brainstorming systems (EBS), group members share their knowledge and ideas by sending their ideas to each other, and by viewing the ideas of other members. Ideas generated from a brainstorming session can be recorded and stored in electronic files, making them easily accessible for printing or later reference (Nunamaker et al., 1991).

Another free association technique is mind mapping. This method begins with writing down a main idea in the centre of the page, and then working outward in all directions, producing a growing and organized structure composed of key words and key images, as illustrated in Figure 1. Mind mapping therefore relies on association (and clustering) of concepts/issues. The association process underling construction of the mind map actually facilitates making connections between concepts, and hence tends to generate new ideas and associations that have not been thought of before.

An example of an individual creativity technique is solo brainstorming (SBS), originally proposed by Aurum (1997). This technique is especially suited to environments where sentential analysis is appropriate, or information sources are document-based (e.g., reports, abstracts). SBS requires the individuals to adhere to a formal protocol, where a series of documents are examined and then edited. The ultimate aim in an SBS session is to determine a sufficient set of issues. As applications of the SBS protocol have been computer-based, all issues are automatically available in electronic form for further analysis. The SBS protocol touches upon an important research issue in the area of knowledge management: whether an increase in an individual's level of domain knowledge will necessarily increase their capacity to be creative within that domain. Central to the SBS protocol is the encourage-

Figure 1. Mind mapping (Aurum & Gardiner, 2003)



ment of participants to use their cognitive abilities by asking them to make "lateral comments".

CREATIVITY IN SOFTWARE DEVELOPMENT

Software engineering is another domain in which creativity plays an important role. The value of creativity is also well recognised in the field of system requirements determination. Robertson (2001) addresses requirements determination as "requirements discovery," which suggests that many users may not even be aware of their true requirements (e.g., unconscious requirements) without application of techniques for reflection and creativity.

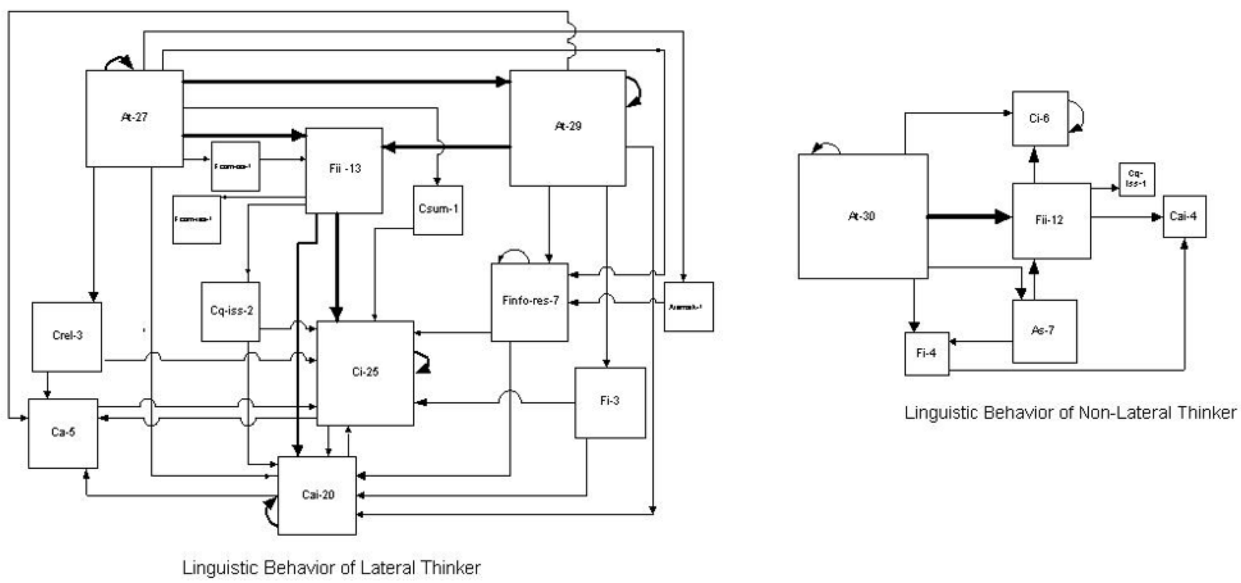
In an experiment focusing upon requirements elicitation, Aurum and Martin (1999) applied the SBS protocol to determine whether application of the protocol would deliver a richer set of requirement statements and insights. An experiment was conducted in which participants were told to adopt the role of a systems analyst retained by a fictitious organization, The Cultural Heritage Authority (CHA), to write requirements specification for their main information systems. The types of documents used as input (external information) to this study included fictitious interviews with users and abstracts from published articles addressing either heritage or marketing issues. Participants' task was to generate ideas and identify issues to be included in CHA's software requirements specification (SRS).

The objective of the research was to investigate whether the application of the SBS protocol had indeed led to a richer level of requirement specifications. The following two research questions are investigated (a) whether application of the protocol would result in identification of more relevant, workable, and original requirements issues, (b) to measure the lateral thinking by examining the linguistic behavior of participants.

The main findings of this study indicated that an SBS-based learning tool had a positive effect on participants' creative performances in development of SRS. This outcome was evident in the originality aspect of task performance, but not relevance and workability. Users were found to generate significantly more original ideas as the result of their interaction with the tool, while maintaining similar levels of relevance and workability (Aurum et al., 2003).

Aurum (1997) suggests that the level of "laterality" for any thought for a given problem can only be assessed with respect to the thoughts generated by others for the same problem. Aurum also found that documents generated from SBS session exhibited some unique characteristics. From linguistic analysis, it was possible to identify those users who were able to think laterally in the SBS session. Furthermore, lateral thinkers displayed a more

Figure 2. Linguistic behavior of SBS participants



complex linguistic pattern than non-lateral thinkers, as illustrated in Figure 2. Participants who generated many ideas and identified many issues were also found to be the lateral thinkers. The findings showed that lateral thinkers wrote many "issue loaded" or "idea loaded" sentences, whereas non-lateral thinkers produced fewer ideas. However, the distinction between these two groups was not clear-cut, but rather a continuum.

The results of this study indicate that the SBS is a promising method for stimulating creative thinking and idea generation in a software development task. Essentially, the brainstorming session helped students uncover ideas without being constrained, stimulate their own thinking by external influences, and capture their thoughts.

These findings also have some important implications for software development and IT education. They demonstrate that creativity can be improved, leading to higher quality software designs. The findings also suggest that the type of tool tested here may be a useful teaching tool in a variety of IT courses involving creative thinking and problem solving. Furthermore, the tool is likely to be most valuable in situations where the problem is unstructured, goals indistinct, and where the outcome of an action cannot always be clearly identified. The tool is a relatively generic one, since it uses a technique that can be applied to a variety of scenarios and can help people process relevant documents whilst identifying issues. These documents act like a 'trigger to stimulate domain-specific ideas from users.

CONCLUSION

Many organizations have come to realize that the creativity of their management and employees is an important source for competitive advantage. However, arguably more can be done within these organizations to promote a creative culture – for example, more organizations should seek to reward management and employees for creative (or divergent) displays, and make creativity supporting technologies more readily available to them.

A number of techniques have been developed to facilitate creativity, with many techniques based upon some form of brainstorming. One theme common to some of the more recent studies on creativity is the importance of a rich source of stimuli to support the creative process, whether the stimuli are: documents, as in Aurum and Martin (1999); group memory, as in Satzinger et al. (1999); or models, as in Shalley and Perry-Smith (2001). Other forms of stimuli include: text, audio, graphics, simulations, video, and so forth (Kletke et al., 2001). Indeed, the effectiveness of the brainstorming technique relies on participants being stimulated by the ideas contributed by others. The potential to cascade ideas is referred to as synergy (Dennis & Valacich, 1993) – that is, the ability of an idea from one participant to trigger in another participant a new idea that would otherwise not have been produced. Another technique is formalizing the creative process through some protocol that can be an effective strategy in terms of supporting the level of intrinsic motivation and mental effort required by participants undertaking a creativity task (Aurum 1999; Paulus & Yang, 2000). Application of a formal protocol is usually at the heart of a creativity technique, and ensures a more systematic and thorough approach to information analysis, which is essential for many creativity tasks.

KEY TERMS

Creativity: There are many views about the definition of creativity. In the context of discovery, creativity is the ability to generate or recognize ideas, alternatives that might be useful solving problems. There are several aspects of creativity, including creative product or value, creative person/people, creative environment, creative symbols and creative process.

Electronic Brainstorming Systems (EBS): A computer-based system that facilitates brainstorming between group members.

Information System (IS): A system that uses IT to capture, transmit, store, retrieve, manipulate or display data for business processes in an organization.

Information Technology (IT): Computer hardware and software, as well as the peripheral devices closely associated with computer-based systems that facilitate data processing tasks, such as capturing, transmitting, storing, retrieving, manipulating or displaying data. IT includes matters concerned with design, development, and implementation of information systems and applications.

Internet: A worldwide network of computer networks that use the TCP/IP network protocols to facilitate data transmission. It provides access to a vast amount of information resources including multimedia (movies, sound, and images), software, text documents, news articles, electronic journal, travel information and so forth. It also provides an environment for buying and selling products and services over a network.

Knowledge Economy: Economic growth is driven by the accumulation of knowledge, which is the basic form of capital. A knowledge driven economy is one in which the generation and exploitation of knowledge plays the predominant part in the creation of wealth.

Knowledge Management (KM): The collection of processes that manage the creation, dissemination, and utilization of knowledge for learning, problem solving, and decision-making. KM often encompasses identifying intellectual assets within organizations. The management of knowledge is regarded as a main source of competitive advantage for organizations. KM brings together three organizational resources: people, process and technologies, and enables the organization to use and share information more effectively

Software Requirements Specification: A document that contains all requirements, for example functional and non-functional requirements and project issues, of the system as agreed upon by customers and software developers.

Instant Messaging Moves from the Home to the Office

Ha Sung Hwang
Temple University, USA

Concetta M. Stewart
Temple University, USA

INTRODUCTION

Instant messaging (IM) quickly established itself as one of the most popular modes of communication, with millions of people logging in at home, at the workplace, and at school. IM is an Internet protocol (IP)-based application that provides convenient communication between people using a variety of different device types. IM enables two people to exchange messages and hold simultaneous conversations without incurring long distance fees, as long as they use the same IM application. While corporate users employ proprietary systems, end users have several commercial services available to them, such as AOL Instant Messenger and Yahoo! Instant Messenger. With IM, users can exchange short text messages simultaneously as well as learn the online status of other users. This is IM's key feature.

While IM is the newest and most popular "near-synchronous" text-based chat technology, other chat technologies, such as multiuser domains (MUDs) and Internet Relay Chat (IRC) have been used for nearly two decades (Grinter & Palen, 2002). However, IM technology distinguishes itself from these previous chat technologies in several ways. While MUDs and IRC technology provide a chat room that allows a group of people to type in messages that are seen by everyone in the room, IM technology allows just two people to exchange messages. IM users adopt a screen name to represent themselves in the messaging service. So, before one can contact someone through IM, he or she must know his or her screen name. Most IM programs also allow users to search for a screen name by e-mail address, name, or area of interest.

HISTORY OF INSTANT MESSAGING

The first IM system, ICQ (I Seek You), was developed in 1996 by Mirabilis. Realizing that millions of people were connected to one huge worldwide network—but were not interconnected with one another—they created a technology that would enable users to locate each other online. They released ICQ in November of 1996, and within 6 months, there were 850,000 ICQ users. AOL acquired ICQ in 1998, but ICQ and AIM are still separate systems. According to a recent report by *Business Wire* (2004), with over 175 million registered users worldwide, ICQ is one of the leading communications communities in the world.

Seeing ICQ's mass appeal and usage, AOL released a free IM software application, named AOL Instant Messenger (AIM) in May 1997. Since 1998, the IM market has exploded: Yahoo launched its own version of IM, Yahoo Messenger, and in 1999, Microsoft's MSN introduced MSN Messenger.

FEATURES OF IM

Upon registering for the IM service, a user adopts a screen name that serves as his or her address for sending and receiving instant messages. Users can use e-mail and other applications when using IM. IM users can also create personal profiles that include the types of people with whom they want to chat. While surfing the Web, IM alerts the user through a window that pops up in one corner of the computer screen when a friend logs in. When not in use, that window can remain hidden until the user wants to send a message to notify that an instant message from a friend or coworker is incoming.

Most IM systems provide awareness technology that allows users to monitor the online state of others, using what is commonly known as a "buddy list." This list displays information about contacts and can be sorted into user-defined categories, such as "friend," "coworker," "classmate," or "family."

The main function of the buddy list is to monitor when friends or coworkers are online. To start a session with a buddy, a user double clicks on the "buddy's" screen name. The service gives or denies authorization to send a pop-up window to the receiver's computer. Such "presence awareness" technology is still growing and developing with more options among IM programs. For instance, MSN Messenger provides several status options to let other users know someone's online presence. Options include *Online*, *Offline*, *Busy*, *Be Right Back*, Away, *Out to Lunch*, and *On The Phone*.

The "blocking" option is another common feature of IM systems. With this feature, a user can control who appears on his or her list. For instance, while chatting with someone, you receive unwanted messages. You can click the *Block* button to refuse all messages from that person. Once that person is blocked, he or she will not be able to send messages to you until you decide to remove that person from your block list. You can add or delete people from your block list. Other common features include variation in fonts and text color, the ability to send files and photos, and Web links to favorite Web sites.

IM ADOPTION AND USE

IM has been widely adopted among the general population, and the number of users worldwide is growing exponentially. While the figures vary among research firms, most studies suggest that the number of worldwide IM users is large and will continue to grow. For instance, Conley (2002) reported that the number of IM users worldwide has already reached over 445 million, with more than 225,000 new users per day. International Data Corporation (IDC) estimated that users sent about 900 million instant messages on a typical day in 2000 and will send about 7 billion a day by 2004. IDC also estimates that the number of global IM users will reach over 500 million by 2005 (as cited in Disababatino, 2001).

The United States has emerged as the leading user of IM, according to Jupiter Media Metrix. Their research revealed that the number of IM users in U.S. homes increased 28%—from 42 million in September 2000 to 53.8 million in September 2001. Jupiter Media Metrix also reported that U.S. IM users at work increased by 34%—from 10 million in September 2000 to 13.4 million in September 2001 (as cited in Woods, 2002).

According to the Pew project (2001), the heaviest users of IM are teenagers and college students for whom IM is part of their daily routine The study showed that almost 13 million teenagers (74% of online teens) use IM, and 69% of teen IM users use IM several times a week. Nielsen/NetRatings (2002) reported that in July, 2002, IM drew 11.5 million kids and teens, with this number representing nearly 24% of the total at-home IM population. According to the Pew project (2002), college Internet users are twice as likely to use IM on any given day compared to the average Internet user. On a typical day, 26% of college students use IM as compared to 12% of other Internet users.

AOL is the predominant IM system in the United States, according to Nielsen/NetRatings (2002). In May of 2002, AOL Instant Messenger became the number one IM application in the United States, attracting more than 22 million users or almost 21% of the total Internet population. Combined, AOL Instant Messenger, MSN Messenger, Yahoo Messenger, and ICQ are the most popular IM services in the United States. Over 41 million American consumers (nearly 40% of the active U.S. online users) used one of these four IM services in the month of May, 2002.

IM IN THE WORKPLACE

After widespread adoption of IM for personal use, IM began to move beyond its consumer-based origins and establish itself as a tool for business communication. In 2002, Jupiter Media Metrix reported that the total number of minutes spent using IM at work increased 110%, from 2.3 billion minutes in September, 2000, to 4.9 billion in September, 2001. By September, 2003, one or more workers in 90% of large U.S. organizations used IM. IM has revolutionized business communication, because it is well suited for communication among dispersed coworkers who face challenges in maintaining ongoing projects. Unlike e-mail, though, IM allows spontaneous interaction among its users, and thereby, facilitates more opportunities for conversation. In this way, IM increases the efficiency of communication among geographically dispersed coworkers.

Studies on IM in the workplace demonstrate IM's value as a tool for supporting brief and informal communication among business partners. However, some studies have found that IM is also used for complex work-related discussions. Nardi et al. (2000) found that IM's primary function is in terms of interaction: quick questioning and clarifications, coordinating work-related activities, scheduling impromptu social meetings, and keeping in touch with friends and family. In particular, they emphasized the utility of IM for facilitating "outeraction"—that is, communication that facilitates further interaction, such as using IM for negotiating availability and scheduling. Muller et al. (2003) found that IM was a means for avoiding certain kinds of communication in the workplace, i.e., to obtain a speedy response to a question, to avoid long telephone conversations, and to seek quick clarification of a question.

Vos et al. (2004) found that most workers used their business IM account mainly on workdays and during work time, and that this IM use was more connected to work-related activities than to personal purposes. Issacs et al. (2002) pointed out the three main characteristics of workplace IM conversations: (1) IM conversations are brief, (2) media switching is prevalent, and (3) multitasking is common. Media switching reveals IM's limitations. When the conversation becomes too complex for the medium of IM, participants agree to switch to phone or face-to-face conversation. Multitasking, however, is considered to be a major benefit of IM. While carrying out other activities, such as e-mailing and talking on the phone, workers can quickly respond to questions from coworkers through IM. They note that frequent users are more likely than infrequent users to utilize IM for a greater variety of tasks.

According to Hansen and Damm (2002), IM is particularly useful for such tasks as problem-solving and creating new software designs, suggesting that IM is an effective "distributed collaboration tool." Other studies suggest how the designs of IM systems might need to evolve to meet the needs of workplace users. Huang et al. (2004), for instance, suggested five factors that affect the adoption of IM use in the workplace: *task specificity and integration*, *tool flexibility and generality*, *visibility and exposure to others' interactions*, *low barriers to use*, and a *dedicated core group of users*.

EMERGING ISSUES FOR IM

A common finding among all of these studies, however, is that the perception of IM as a communication tool among users is mixed. For instance, Herbsleb et al. (2002) indicated that the perception of IM utility is a difficult issue to determine, depending on how users view the importance of informal conversation. According to their study, new users may not see any advantages in IM. Several of their respondents reported that "it's just as easy to pick up a phone and call someone," and others questioned the value of the presence awareness function, "it is not that valuable to know that someone is sitting at their desk" (p. 176).

However, other studies report users who found this presence awareness function useful. Segerstad and Ljungstrand (2002) investigated how awareness of presence affects the content of IM among college students who use the IM service called "Webwho." Key findings included that task-related messages were more often passed among distributed college students in different places, while greeting messages were more often passed among students in the same place, and messages with sexual content were more often sent among students in the same computer lab or at home than among students in different computer labs. The study also suggests that IM is used to support collaborative work and coordinate social activities, as well as to simply keep in touch or have fun.

Teenagers' use of IM has recently emerged as a focus of media research, and these findings suggest that IM is used mainly for the fundamental need to interact with others. Noteworthy here is Grinter and Palen's (2002) finding that exchanging IM messages among teenagers is restricted to those who first met face-to face in a physical setting, such as at school or at summer camp. The study also suggests that for teenagers, peer pressure is an important facilitator in IM adoption.

Though IM has overwhelmingly been the province of teenagers, the Pew project (2003) found that nearly half of all American adults who are active online have sent an instant message at one time or another. The Pew project (2003) showed, however, that when it comes to adults, IM proved to be an activity where experience matters. Compared to those with only a year or less of online experience, those with four or more years of online experience were almost three times as likely to have used IM on an average day.

TRENDS

IM use is expanding dramatically, along with other online activity. The Pew project (2003) reported that between March, 2000, and August, 2003, the American online population expanded from 86 million to 126 million, or by 47%. However, the desire for a sense of control is increasingly influencing the choice of online activity. IM is growing, while other forms of real-time online communications are losing popularity. Although initial adoption of the Internet is in large part due to the popularity of chat rooms, the growth of IM may now be contributing to a decrease in the popularity of chat rooms. With IM, users can exert more control over their social interaction than they can with chat rooms, which may be a factor for populations who feel more vulnerable in open chat room situations, such as with young people and women.

According to the Pew project report (2003), the number of Internet users who have participated in chat rooms grew only 21% (from 24–29 million) between March, 2000, and July, 2002. IM, on the other hand, grew about 33% (from 39–52 million) in the same period. Moreover, American Internet users were almost twice as likely to use IM as they were to participate in a chat room. Compared to chatting, they were also three times as likely to use IM on a typical day.

Most recently, IM has been incorporated into emerging technologies, such as mobile phones and Internet telephony. With this development, IM is poised to expand its reach and convenience even further. For instance, the mobile phone industry has eagerly adopted IM technology by creating a service called "short messaging service." Through this service, millions of short messages are being sent daily to and from mobile phones throughout the world. MSN is preparing to launch Mobile Messenger in Asia (as cited in Peng, 2002). And, AIM now provides the service called "AIM Talk" for online conversations.

AOL seems to be extending its dominance in IM to the wireless world. The owner of ICQ and AOL Instant Messenger (AIM), AOL announced in February, 2003, that its ICQ service would provide messaging services for wireless companies in such countries as Germany, Israel, Taiwan, and Canada (Hu, 2003). ICQ specifically would offer a number of wireless messaging applications on a variety of software platforms, including short message service (SMS), two-way SMS, Wireless Application Protocol (WAP), and Java for cell phones. AOL and Yahoo have also recently established agreements with wireless companies to allow their IM users to send text messages to cell phones (Hu, 2003). Interestingly, however, though mobile IM via SMS has become popular in Europe, it has yet to do the same in the United States.

CONCLUSION

Overall, recent studies on IM use suggest that while young people are still the heaviest users of IM, its popularity has spread across age groups and social settings. Individuals' perceptions of IM utility differ greatly, though. While some IM adopters perceive IM as useful and find it rewarding, some new users do not see any advantages to IM and use other electronic communication media (e.g., telephone and e-mail). For teenagers, though, IM serves as a fundamental tool for socializing with their peers. IM's use, however, goes beyond the social realm and is an increasingly useful tool for workplace communication. In addition to keeping up with friends and family, IM helps with a variety of work-related communication tasks, such as short query, scheduling, and coordinating meetings among distributed business people. IM use has also spread worldwide, moving beyond the borders of the United States, with other countries taking the lead in adopting some of IM's newer features.

KEY TERMS

Blocking: Blocking allows an IM user to control the ability of his or her online status. When you block someone, that person will not be able to send messages to you until you remove that person from your block list.

Buddy List: Presence awareness technology that allows users to monitor the online status of others. A buddy list window shows whether buddies are online or offline. Users double click on a screen name of an active friend, and a message is automatically initiated.

Chat/Chat Room: A real-time online interactive discussion group.

Instant Messaging (IM): Near-synchronous Internet-based one-to-one communication technology. IM allows two users to exchange short text message in real time.

Internet Relay Chat (IRC): Internet-based chat technology that allows a group of people to exchange text messages in real time. To join group chatting, one needs an IRC program to connect to an IRC server. Examples include mIRC, Pirch, and Virc for Windows and Homer or Ircle for Macintosh.

MUD (Multiuser Domains): Network-based text application that was initially developed for role-playing games in which players interact with each other in a computer-created fantasy environment.

Pop-Up Window: A window that suddenly appears (pops up) when a user selects an option. In IM, a pop-up window signals when a users' buddies come "online" and go "offline," while the user is engaged in other computer applications.

Screen Name: This is an IM user name that serves as the address for sending and receiving messages. One can change his or her screen name at any time, and most IM programs also allow users to search for a screen name by e-mail address, name, or area of interest.

Surfing: To navigate the Internet searching for topics of interest, usually considered an undirected form of browsing.

Institutional Dimensions of Information Systems Evaluation[1]

Vassilis Serafeimidis
Atos KPMG Consulting, UK

INTRODUCTION

Information systems (IS) evaluation is a complex organizational and social decision making process. IS evaluation has attracted a lot of interest from the academic community and practitioners during the last few decades. This interest in some way has been generated by the tremendous increase of IT investments and the fact that IT/IS have become an organizational "necessity" in order to, for example, support routine data processing operations, initiatives for competitive advantage, and business transformation exercises.

IS evaluation is highly subjective and context dependent, as well as covering a wide area of situations and activities. A number of good definitions are listed next:

"Evaluation is a series of activities incorporating understanding, measurement, and assessment. It is either a conscious or tacit process which aims to establish the value of or the contribution made by a particular situation. It can also relate to the determination of the worth of an object." (Remenyi & Sherwood-Smith, 1997, p. 46).

"IS evaluation is a process for searching and for making explicit, quantitatively or qualitatively, all the impacts of an IT project and the programme and strategy of which it is a part." (Farbey, Land & Targett, 1999, p. 190)

BACKGROUND

Information Systems Evaluation – The "journey"

In the 1980s organizations started to realize that successful IT outcomes do not occur by default; they are highly uncertain and in order to achieve organizational success, IS have to be managed effectively and be considered broadly within their context. The difficulties in identifying and measuring potential benefits and costs, deriving from current organizational practices, forced many organizations to establish management control mechanisms. Among these mechanisms are the thorough "appraisal" of potential IT investments and the "evaluation" of their expected deliverables.

Evaluation happens in many ways (e.g., formally, informally), uses diverse criteria (e.g., financial, technical, social), follows rigorous methodologies or "gut feelings," and often becomes a political instrument that influences the balance of organizational power and stimulates organizational changes.

The role that evaluation plays as an organizational process varies. It is strongly related to other management and decision making processes. The management expectation from IS evaluation is about establishing by quantitative and/or qualitative means the worth of IT to the organization (Farbey et al., 1993) and IT's contribution to the organizational growth (Bakos & Kemerer, 1992; Hitt & Brynjolfsson, 1996). This can be achieved by effective IS evaluation which ranks alternatives (Clemons, 1991) and forms a central part of a complex and incremental planning, decision-making and control (diagnosis) process (Hawgood & Land, 1988). Evaluation is then a crucial feedback function (Baker, 1995), which helps the organization learn (Walsham, 1993) and thereby reduces the uncertainty of decisions. This feedback helps trace and understand the underlying factors leading to the success or otherwise of an IT investment. In many cases (Farbey et al., 1995) evaluation is a mechanism for gaining commitment and, in highly politically influenced environments, for legitimization, and in some other occasions is a mechanism for exploration and discovery.

In order to understand IS evaluation we have to focus on the why, what, which aspects, when, who and how dimensions. Three different streams of IS evaluation theoretical and practical developments have been dominating this research field: the technical/functional; the economic/financial; and the "interpretive".

The traditional (formal-rational or functionalist) conception sees evaluation as an external judgement of an information system that is treated as if it existed in isolation from its human and organizational components and effects. It also places excessive emphasis on the technological and accounting aspects at the expense of the organizational and social aspects. Therefore, it neglects the organizational context and process of IS development and its content, elements that are critical to the successful application of IT in support of the business. In general, more attention has been focused over the years on pre-scribing how to carry out evaluations (with technically-driven and cost-focused frameworks) rather than analyzing and understanding their role, interactions, effects and organizational impacts (Smithson & Hirschheim, 1998).

Both the *functional and economic* streams promote a logical rationalistic philosophy that searches for the efficiency and effectiveness of an information system in technical and business terms. Developments under these areas have attracted attention for a long period of time as they have addressed necessary questions regarding the performance and the financial aspects of the technical components and their investment returns. These two modes, although necessary and complementary, suffer a number of deficiencies. Their limitations include the:

- limited consideration of the organizational context,
- narrow purposes deriving from the formal/rational paradigm,
- lack of consideration of the new content elements and relevant measures,
- confined and fragmented time horizon,
- neglect of human aspects of evaluation, and
- narrow methodological focus.

Table 1. Summary of the characteristics of the IS evaluation modes (based on Serafeimidis, 2001)

	Technical stream	**Economic stream**	**Interpretive alternatives**
Why - Purpose/ Reasons	• Technical performance (e.g., quality) • Control of resources (e.g., costs)	• Quality and utilization of IS outputs (e.g., accuracy of information)	• Context-sensitive (i.e., contingent, emergent) • Understanding of social actions • Organizational learning
What - The subject of evaluation **Criteria and measurement**	• IT system • Automate - Cost reduction	• IS outputs • Informate - Productivity - Business value - User satisfaction • Uncertainty/Risks	• Broad portfolios of processes and systems • Intermediate relevant measures (e.g., more reliable systems)
When - Time frame	• *Ex ante* and *ex post* in relation to the systems development life cycle	• *Ex ante* and *ex post* in relation to the systems development life cycle	• Continuous benefits management
Who - People	• IT experts	• IT experts • Finance experts • Business managers	• "Evaluation party" including internal and external stakeholders
How – Methodologies /Tools	• Quality-related (e.g., TQM, software metrics) • Cost-related (e.g., COCOMO, function point analysis)	• Economic oriented (e.g., agency theory) • Finance oriented (e.g., CBA, SESAME, DCF, IRR) • Behavioral science driven (e.g., ROM, value analysis)	• Meta-methodologies • Contemporary methods (experimental and exploratory)
Strengths	• Addresses the technical system performance • Assesses the efficiency of IT/IS	• Focuses on financial and economic impact of the investment • Assesses the effectiveness of IT/IS	• Increases the understanding of the role and impact of the investment • Assesses the fit and the contributions of IS/IT within its organizational context
Weaknesses	• Does not address uncertainty of business requirements and the organizational fit of IT • Prescriptive	• Approaches require specialist expertise • Dominated by economic results	• Applicability and use are challenging

As a response to the limitations identified previously, alternative evaluation approaches based on the *interpretive* paradigm have been proposed by authors such as Irani and Love (2001), Symons (1993), and Walsham (1995).

"Interpretive methodologies of evaluation actively analyse the experience of organizational reality, focusing on stakeholder interests and perspectives. ... They increase the effectiveness of organizational activity by ensuring a match between elements of organizational change and the dynamics of organizational culture and politics." (Symons, 1993, p. 74)

The more interpretive approaches come closer to the social and "real" nature of IS and evaluation, but they have not managed to provide a completely "rich picture" of the phenomenon. Moreover, these attempts lack empirical evidence for their wide acceptance by practitioners. A summary of the major issues addressed in each stream is presented in Table 1.

TRENDS IN IS EVALUATION

The latest trends in IS evaluation (Irani & Love, 2001; Smithson & Hirschheim, 1998) recognize the need for multi-dimensional perspectives which consider the dimensions discussed previously but also focus on the social and organizational aspects of an IT/IS investment.

The organizational context (both internal and external) strongly influences the role that evaluation is expected to play and consequently the performance of the evaluation roles. The context includes the organizational characteristics (e.g., culture, norms), structural limitations, the organizational expectations from evaluation and external requirements. All these factors restrict and enable its impacts and contributions. Considering this relationship, four different orientations of IS evaluation can be identified (Serafeimidis & Smithson, 2003): a control; a social learning; a sense making and an exploratory one. The study of IT/IS evaluation through the institutional dimensions offers an alternative approach to the traditional ways. The main principle remains the fact that different evaluation orientations require different treatments in terms of their integration with existing organizational properties.

CONCLUSION

IS evaluation is an important element of the decision making process related to the investments in IT. IS evaluation is a complex, human-centered activity that cannot be divorced from its organizational context and the stakeholders involved. Multiple theories and methodologies have been developed focusing on a variety of areas and dimensions of evaluation, mainly technical, financial and organizational. It is evident that no single method or approach is adequate to provide a complete picture to decision makers. Empirical evidence (Coleman & Jamieson, 1994; Farbey, Land & Targett, 1993; Serafeimidis & Smithson, 2003; Willcocks, 1996) suggests that organizations use different methods and techniques for different types of IT/IS projects depending on the objectives of the evaluation, the time of it and the stakeholder interests. Therefore, a multidimensional consideration which will need to understand the organizational (institutional) dimensions of IS evaluation as well as the needs of the decisions makers at that point in the decision process should be adopted.

KEY TERMS

Economic Evaluation: This approach to evaluation views IT/IS as an investment or a business facilitation project. Therefore, the focus of evaluation shifts from the performance of the IS *per se* to the quality of its outputs (e.g., information) and their utilization (e.g., customer satisfaction, creation of business value). Here the evaluation of IT investments is based on an organizational analysis that emphasizes the achievement of predetermined outcomes as a measure of effectiveness (e.g., critical success factors, business objectives/strategy). In other words the "worth" of an IS is sought in the system's performance and financial profitability.

Institutional Dimensions: Considering the need for integrated evaluation of business ideas/solutions enabled by IT, it is emergent that there are organizational dimensions (or institutions). They include the context where evaluation is integrated (e.g., the system's development life cycle, the IS management practices and processes, the people's roles, the organizational culture) and furthermore, the understanding of stakeholders' behavior within this context.

Interpretive Evaluation: The formal-rational approaches (technical and economic) emphasize the technology features at the expense of the organizational and social aspects. In this context interpretive evaluation is a move towards the "interactionist" role of the technology with the organizational structures, culture and stakeholders. IS evaluation focuses on the analysis and understanding of the social and subjective nature of the phenomenon.

IS/IT Evaluation: There are many definitions in the literature and a few are quoted previously. They are considered as the most representative for the purposes of this article.

Organizational Context: Context is concerned with the multi-level identification of the various systems (e.g., social, political, economic, technical) and structures (e.g., organizational processes, policies, individuals' roles) as well as informal networks and personal relationships within which the organization is "located".

Technical/Functional Evaluation: This type of evaluation focuses on the technical (IT) components. The evaluation is concerned with the relationship between inputs and outputs. Its focal point is on efficiency in terms of the technical performance and the control of resources. Further interests lie around the increased and improved capacity, fewer errors, greater reliability, humanpower savings, and so forth and also in terms of software performance developments and quality (e.g., TQM). The driving force for the timing of evaluation is the traditional system's development life cycle.

A HISTORICAL PERSPECTIVE

The Internet has gone from near invisibility to near ubiquity and penetrated into every aspect of society in the past few years (Department of Commerce, 1998). The application scenarios have also changed dramatically and now demand a more sophisticated service model from the network. In the early 1990s, there was a large-scale experiment in sending digitized voice and video across the Internet through a packet-switched infrastructure (Braden, Clark, & Shenker, 1994). These highly visible experiments have depended upon three enabling technologies: (a) Many modern workstations now come equipped with built-in multimedia hardware, (b) IP multicasting, which was not yet generally available in commercial routers, is available, and (c) highly sophisticated digital audio and video applications have been developed. It became clear from these experiments that an important technical element of the Internet is still missing: Real-time applications often do not work well across the Internet. The Internet, as originally conceived, offers only a very simple quality-of-service (QoS), point-to-point, best-effort data delivery. However, for a real-time application, there are two aspects of the problem with using this service model. If the sender and/or receiver are humans, they simply cannot tolerate arbitrary delays; on the other hand, if the rate at which video and audio arrive is too low, the signal becomes incomprehensible. To support real-time Internet applications, the service model must address those services that relate most directly to the time of delivery of data. Real-time applications like video and audio conferencing typically require stricter guarantees on throughput and delay. The essence of real-time service is the requirement for some service guarantees in terms of timing. In response to these demands of real-time multimedia applications, the Internet Engineering Task Force (IETF) has significantly augmented the Internet protocol stack based on the Internet integrated-services model, which is the focus of this article.

THE INTERNET INTEGRATED-SERVICES MODEL

An Internet *service model* consists of a set of service commitments; that is, in response to a service request, the network commits to deliver some service. The Internet is conventionally designed to offer a very simple service model, best effort, providing no guarantee on the correct and timely delivery of data packets. Each request to send is honored by the network *as best as it can*. This is the worst possible service: Packets are forwarded by routers solely on the basis that there is a known route, irrespective of traffic conditions along that route. This simplicity has probably been one of the main reasons for the success of IP technology. The best-effort service model, combined with an efficient transport-layer protocol (TCP [transmission-control protocol]), is perfectly suited for a large class of applications, which tolerate variable delivery rates and delays. This class of applications is called elastic applications.

However, demanding real-time applications require more sophisticated service models beyond the best effort. There has been a great deal of effort since 1990 by IETF to add a broad range of services to the Internet service model, resulting in the Internet integrated service model (Braden et al., 1994; Crowcroft, Handley, & Wakeman, 1999). The Internet integrated services model defines five classes of services that should satisfy the requirements of the vast majority of future applications.

1. *Best effort*: As described above, this is the traditional service model of the Internet.
2. *Fair*: This is an enhancement of the traditional model where there are no extra requests from the users, but the routers attempt to partition network resources in some fair manner. This is typically implemented by adopting a random-drop policy when encountering overload, possibly combined with some simple round-robin serving of different sources.
3. *Controlled load*: This is an attempt to provide a degree of service guarantee so that a network appears to the user as if there is little other traffic, and it makes no other guarantees. The admission control is usually imposed so that the performance perceived is as if the network were overengineered for those that are admitted.
4. *Predictive service*: This service gives a delay bound that is as low as possible, and at the same time, is stable enough that the receiver can estimate it.
5. *Guaranteed service*: This is where the delay perceived by a particular source or to a group is bounded within some absolute limit. This service model implies that resource reservation and admission control are key building blocks of the service.

The level of QoS provided by these enhanced QoS classes is programmable on a per-flow basis, and end-to-end QoS commitment for the data flow is built using a unified multimedia protocol stack and through resource reservation.

THE INTERNET MULTIMEDIA PROTOCOL ARCHITECTURE

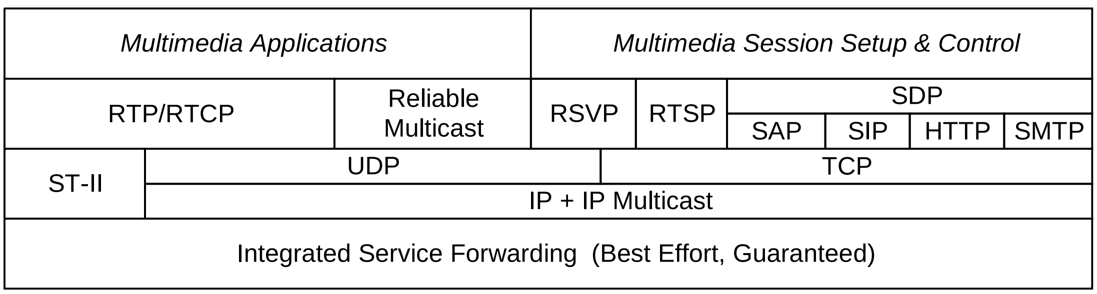
The integrated-services Internet offers a class of service models beyond the TCP/IP's (Internet protocol) best-effort service, and thus it imposes strict new requirements for a new generation of Internet protocols. The set of Internet real-time protocols, which constitute the Internet multimedia protocol architecture, represents a new style of protocols. The new style of protocols follows the proposed principles of *application-level framing* (ALF) and *integrated layer processing* (Clark & Tennenhouse, 1990). In this approach to protocol architecture, the different functions are next to each other, not on top of one another. The Internet multimedia protocol architecture is shown in Figure 1.

As shown in Figure 1, the overall multimedia data and control architecture currently incorporates a set of real-time protocols, which include the real-time transport protocol (RTP) for transporting real-time data and providing QoS feedback, the real-time streaming protocol (RTSP) for controlling delivery of streaming media, the session-announcement protocol (SAP) for advertising multimedia sessions via multicast, and the session-description protocol (SDP) for describing multimedia sessions. In addition, it includes the session-initiation protocol (SIP), which is used to invite the interested parties to join the session. But the functionality and operation of SIP does not depend on any of these protocols. Furthermore, the resource-reservation protocol (RSVP) is designed for reserving network resources. These protocols, together with reliable multicast (Handley, Floyd, Whetten, Kermode, Vicisano, & Luby, 2000), are the underlying support for Internet multimedia applications. While all the protocols above work on top of the IP protocol, the Internet stream protocol, version 2 (ST-II), is an IP-layer protocol that provides end-to-end guaranteed service across the Internet.

The Real Time Transport Protocols: RTP and RTCP

The real-time transport protocol, named as a transport protocol to emphasize that RTP is an end-to-end protocol, is designed to provide end-to-end delivery services for data with real-time characteristics, such as interactive audio and video (Schulzrinne, Casner, Frederick, & Jacobson, 2003). Those services include payload-type identification, sequence numbering, time-stamping, and

Figure 1. Internet protocol architecture for real time applications



nb: For the acronyms, refer to "Key Terms" delivery monitoring. Applications typically run RTP on top of UDP (user datagram protocol) to make use of its multiplexing and checksum services; both protocols contribute parts of the transport protocol functionality. However, RTP may be used with other suitable underlying network or transport protocols. RTP supports data transfer to multiple destinations using multicast distribution if provided by the underlying network.

RTP consists of two closely-linked parts:

- the real-time transport protocol to carry data that has real-time properties, and
- the RTP control protocol (RTCP) to monitor the quality of service and to convey information about the participants in an ongoing session. This functionality may be fully or partially subsumed by a separate session control protocol, which is beyond the scope of this document.

The RTP defines a fixed data-packet header for the set of functions required in common across all the application classes that RTP might support. However, in keeping with the ALF design principle, an extension mechanism is provided to allow the header to be tailored through modifications or additions defined in a profile specification.

RTCP control packets supplement each RTP flow and are periodically transmitted by each participant in an RTP session to all other participants. RTCP performs the following four functions.

1. Provides feedback information to application
2. Identifies RTP source
3. Controls RTCP transmission interval
4. Conveys minimal session-control information

Internet Stream Protocol: ST-II

ST-II has been developed to support efficient delivery of streams of packets to either single or multiple destinations in applications requiring guaranteed data rates and controlled delay characteristics (Schulzrinne, Rao, & Lanphier, 1998). ST-II is an Internet protocol at the same layer as IP (Figure 1). ST-II differs from IP in that every intervening ST-II entity maintains state information for each stream that passes through it. The stream state includes forwarding information, including multicast support for efficiency, and resource information, which allows network or link bandwidth and queues to be assigned to a specific stream. This preallocation of resources allows data packets to be forwarded with low delay, low overhead, and a low probability of loss due to congestion, and thus to support efficient delivery of streams of packets to either single or multiple destinations in applications requiring guaranteed data rates and controlled delay characteristics.

Protocols for Multimedia Session Setup and Control

There are two basic forms of multimedia session-setup mechanisms. These are session advertisement and session invitation. Session advertisements are provided using a session directory, and session invitation (inviting a user to join a session) is provided using a session-invitation protocol such as SIP or packet-based multimedia communication systems standard H.323 (ITU, 1998).

Before a session can be advertised, it must be described using the session-description protocol. SDP describes the content and format of a multimedia session, and the session-announcement protocol is used to distribute it to all potential session recipients.

The Session-Description Protocol

The session-description protocol is used for general real-time multimedia session-description purposes and is purely a format for session description (Handley & Jacobson, 1998). SDP is intended for using different transport protocols as appropriate.

SDP serves two primary purposes. It is a means to communicate the existence of a session, and is a means to convey sufficient information to enable joining and participating in the session. A session description contains the following information.

- Session name and purpose
- The media comprising the session, such as the type of media (video, audio), the transport protocol (RTP/UDP/IP, H.320), and the format of the media (H.261 video, MPEG video)
- Time(s) the session is active.
- Information for receiving those media (addresses, ports, formats, and so on)

The SDP description is announced using the session-announcement protocol.

Session-Announcement Protocol

SAP defines an announcement protocol to be used to assist the advertisement of multicast multimedia conferences and other multicast sessions, and to communicate the relevant session-setup information to prospective participants (Handley, Perkins, & Whelan, 2000). Sessions are described using the session-description protocol, and the session description is the payload of the SAP packet.

SAP supports session announcement and deletion. However, SAP defines no rendezvous mechanism, the SAP announcer is not aware of the presence or absence of any SAP listeners, and no additional reliability is provided over the standard best-effort UDP/IP semantics. A SAP announcer periodically sends an announcement packet to a well-known multicast address and port. A preannounced session can be modified by simply announcing the modified session description. A previously announced session may be deleted.

The announcement contains an authentication header for verifying that changes to a session description or deletion of a session are permitted. It can also be used to authenticate the identity of the session creator.

Session-Initiation Protocol

Not all sessions are advertised, and even those that are advertised may require a mechanism to explicitly invite a user to join a session. The session-initiation protocol is an application-layer control (signaling) protocol that can establish, modify, and terminate multimedia sessions or calls (Rosenberg et al., 2002). SIP can also invite participants to already existing sessions, such as multicast conferences. Media can be added to (and removed from) an existing session. SIP invitations used to create sessions carry session descriptions that allow participants to agree on a set of compatible media types. SIP runs on top of several different transport protocols.

SIP supports five aspects of establishing and terminating multimedia sessions.

- User location: determination of the end system to be used for communication
- User availability: determination of the willingness of the called party to engage in communications
- User capabilities: determination of the media and media parameters to be used
- Session setup: “ringing”; establishment of session parameters at both the called and calling party
- Session management: including transferring and terminating sessions, modifying session parameters, and invoking services

Note that SIP is not a vertically integrated communications system. SIP is, rather, a component that can be used with other Internet protocols to build a complete multimedia architecture (e.g., RTP, RTSP).

Controlling Multimedia Servers: RTSP

A standard way to remotely control multimedia streams delivered, for example, via RTP, is the real-time stream-control protocol. Control includes absolute positioning within the media stream, recording, and possibly device control. RSTP is primarily aimed at Web-based media-on-demand services, but it is also well suited to provide VCR-like controls for audio and video streams, and to provide playback and record functionality of RTP data streams. A client can specify that an RTSP server plays a recorded multimedia session into an existing multicast-based conference, or can specify that the server should join the conference and record it. RTSP acts as a “network remote control” for multimedia servers.

The protocol supports retrieval of media from media servers, the invitation of a media server to a conference, and the addition of media to an existing presentation.

Resource Reservation Protocol

RSVP is an IP resource-reservation setup protocol designed for an integrated-services Internet, and it provides receiver-initiated setup of resource reservations for multicast or unicast data flows that take a significant fraction of the network resources (Braden, Zhang, Berson, Herzog, & Jamin, 1997). Using RSVP, the resources necessary for a multimedia session are reserved, and if no sufficient resource is available, the admission is rejected. The reservations and route setups apply only to packets of a particular session, and RSVP identifies a particular session by the combination of destination address, transport-layer protocol type, and destination port number.

RSVP makes receivers responsible for requesting a specific QoS. A QoS request from a receiver host application is passed to the local RSVP process. The RSVP then carries the request to all the nodes (routers and hosts) along the reverse data path(s) to the data source(s), but only as far as the router where the receiver’s data path joins the multicast distribution tree.

Quality of service for a particular data flow is ensured by mechanisms collectively called *traffic control*, and they are a packet classifier, admission control, and “packet scheduler,” or some other link-layer-dependent mechanism to determine when particular packets are forwarded.

During reservation setup, an RSVP QoS request undergoes *admission control* and *policy control*. Admission control determines whether the node has sufficient available resources to supply the requested QoS. Policy control determines whether the user has administrative permission to make the reservation.

RSVP does not transport application data, but is rather an Internet control protocol. It uses underlying routing protocols to determine where it should carry reservation requests. As routing paths change, RSVP adapts its reservation to new paths if reservations are in place.

THE FUTURE TRENDS

Technically, there are several types of communication networks that are used to provide multimedia communication services, which include data networks, broadband television networks, integrated-services digital networks, and broadband multiservice networks. The Internet is the most widely deployed data network, and significant advancement has been made to provide communication services beyond its original design. This advancement is centered on QoS provisioning on the Internet so that QoS-sensible applications can be supported across the Internet.

Generally, work on QoS-enabled Internet has led to two distinct approaches: (a) the integrated services architecture (often called *Intserv*) and its accompanying signaling protocol, most importantly, RSVP, and (b) the differentiated services architecture (often called *Diffserv*).

As described in this article, the Internet integrated-services architecture is an extension of the Internet architecture and protocols to provide integrated services, that is, to support real-time as well as the current non-real-time service of IP. This extension is necessary to meet the growing need for real-time service for a variety of new applications, including teleconferencing, remote seminars, telescience, and distributed simulation. It allows sources and receivers to exchange signaling messages that establish packet classification and forwarding state on each node along the path between them. In the absence of state aggregation, the amount of state on each node scales in proportion to the number of concurrent reservations, which can be potentially large on high-speed links. Integrated services are considered not scalable and best suited in intranet and LAN (local area network) environments.

In the last few years, we have witnessed the development of other models of service differentiation in order to facilitate the deployment of real-time applications, including the differentiated-services architecture, relative priority marking, service marking, label switching, and static per-hop classification. The differentiated-services architecture has received the most attention in the Internet community.

In contrast to integrated services, which use the more stringent and complex quality-of-service approach, the differentiated-services architecture has emerged as an alternative for implementing scalable service differentiation on the Internet. This architecture achieves scalability by aggregating traffic classification states, which are conveyed by means of IP-layer packet marking. Packets are classified and marked to receive a particular per-hop forwarding behavior on nodes along their path. Sophisticated classification, marking, policing, and shaping operations need only be implemented at network boundaries or hosts. Network resources are allocated to traffic streams by service-provisioning policies that govern how traffic is marked and conditioned upon entry to a differentiated-services-capable network, and how that traffic is forwarded within that network. A wide variety of services can be implemented on top of these building blocks (Blake, Black, Carlson, Davies, Wang, & Weiss, 1998). We can foresee that in the future, support for multimedia applications on the Internet, both integrated services and differentiated services, will be developed and deployed, and will complement each other.

CONCLUSION

The Internet has evolved from a provider of simple TCP/IP best-effort service to an emerging integrated-service Internet. This development provides tremendous opportunities for building real-time multimedia applications over the Internet. The protocol stack necessary for classes of quality of service, including real-time applications, is presented as the Internet integrated-service architecture that supports the various service models. The constituent real-time protocols of this architecture are the foundations and the critical support elements for the building of Internet real-time multimedia applications.

KEY TERMS

Elastic applications: A kind of network applications that will always wait for data to arrive rather than proceed without it.

HTTP: Short for *hypertext transfer protocol*, the underlying protocol used by the World Wide Web.

IP: Abbreviation of *Internet protocol*. IP specifies the format of packets, also called datagrams, and the addressing scheme. Most networks combine IP with a higher level protocol called transmission-control protocol (TCP), forming TCP/IP networks.

Multicast: Means transmitting a single message to a select group of recipients. A simple example of multicasting is sending an e-mail message to a mailing list.

Protocol: A set of rules that govern the operation of functional units to achieve communication.

Protocol architecture: An organization structure of the communication system, which comprises constituent protocols and the relationships among them.

Real-time applications: One class of applications needs the data in each packet by a certain time, and if the data has not arrived by then, the data is essentially worthless.

RSVP: The Internet standard protocol *resource-reservation protocol* (RSVP).

RTP/RTCP: The Internet standard *real-time transport protocol* (RTP) and *RTP control protocol* (RTCP).

RTSP: The Internet standard *real-time streaming protocol* (RTSP) for controlling delivery of streaming of multimedia data.

SAP: The Internet standard *session-announcement protocol* (SAP) for advertising multimedia sessions via multicast.

SDP: The Internet standard *session-description protocol* (SDP) is used for general real-time multimedia session-description purposes and is purely a format for session description.

Service model: Consists of a set of service commitments. In response to a service request, the network commits to deliver some service.

SIP: The Internet standard *session-initiation protocol* (SIP), a signaling protocol for Internet conferencing, telephony, presence, events notification, and instant messaging.

SMTP: Short for *simple mail-transfer protocol*, a protocol for sending e-mail messages between servers. Most e-mail systems that send mail over the Internet use SMTP to send messages from one server to another. In addition, SMTP is generally used to send messages from a mail client to a mail server.

ST-II: The Internet *stream protocol, version 2* (ST-II), an IP-layer protocol that provides end-to-end guaranteed service across the Internet.

TCP: Abbreviation of *transmission-control protocol*, one of the main protocols in TCP/IP networks. Whereas the IP protocol deals only with packets, TCP enables two hosts to establish a connection and exchange streams of data.

UDP: Abbreviation for *user datagram protocol*, a connectionless protocol that, like TCP, runs on top of IP networks. Unlike TCP/IP, UDP/IP provides very few error-recovery services so is less reliable than TCP, offering instead a direct way to send and receive datagrams over an IP network.

Integrating Requirements Engineering Techniques and Formal Methods

María Virginia Mauco
Universidad Nacional del Centro de la Pcia. de Buenos Aires, Argentina

Daniel Riesco
Universidad Nacional de San Luis, Argentina

INTRODUCTION

Formal methods help to develop more reliable and secure software systems, and they are increasingly being accepted by industry. The RAISE[1] Method (George et al., 1995), for example, is intended for use on real developments, not just toy examples. This method includes a large number of techniques and strategies for formal development and proofs, as well as a formal specification language, the RAISE Specification Language (RSL) (George et al., 1992), and a set of tools (George et al., 2001).

Formal specifications may be used throughout the software lifecycle, and they may be manipulated by automated tools for a wide variety of purposes such as model checking, deductive verification, formal reuse of components, and refinement from specification to implementation (van Lamsweerde, 2000a). However, they are not easily accessible to people who are not familiar or comfortable with formal notations. This is particularly inconvenient during the first stages of system development, when interaction with the stakeholders is very important. In common practice, the analysis of a problem often starts from interviews with the stakeholders, and this source of information is heavily based on natural language.

System requirements must be described well enough so that an agreement can be reached between the stakeholders and the system developers on what the system should and should not do. A major challenge with this is that the stakeholders must be able to read and understand the results of requirements capture. To meet this challenge we must use the language of the stakeholders to describe these results (Jacobson, Booch & Rumbaugh, 1999). Stakeholder-oriented requirements engineering techniques help to improve communication among stakeholders and software engineers as they ease the development of a first specification of a system which could be validated with stakeholders and which could be the basis for a formal development. Thus, we could take advantage of both techniques to improve the final product.

Among the techniques proposed to formalize requirements elicitation and modeling, Leite's Requirements Baseline can be mentioned (Leite et al., 1997). Two of its models are the Language Extended Lexicon (LEL) and the Scenario Model. LEL and scenarios provide a detailed description of an application domain, and as they are written in natural language, they are closer to stakeholder's world. However, an important point is how to fruitfully use all this information during the software development process.

To address the problems stated above, we have been working in the integration of stakeholder-oriented requirements engineering techniques with formal methods in order to take advantage of the benefits of both of them. In particular, our work is focused on the Requirements Baseline and the RAISE Method. We have proposed a three-step process to help in the definition of an initial formal specification in RSL of a domain starting from natural language models such as LEL and scenarios. These steps are the derivation of types, the derivation of functions, and the definition of modules. We have developed a preliminary set of heuristics that show how to derive types and functions, and how to structure them in modules by using LEL and scenarios information. We have also proposed to represent the hierarchy of RSL modules obtained using a layered architecture. This layered architecture is then the basis to start applying the steps of the RAISE Method.

BACKGROUND

In spite of the wide variety of formal specification languages and modeling languages, such as the Unified Modeling Language (UML) (Jacobson et al., 1999), natural language is still the method chosen for describing software system requirements (Jacobson et al., 1999; Sommerville & Sawyer, 1998; van Lamsweerde, 2000a). However, the syntax and semantics of natural language, even with its flexibility and expressiveness power, is not formal enough to be used directly for prototyping, implementation, or verification of a system. Thus, the requirements document written in natural language has to be reinterpreted by software engineers into a more formal design on the way to a complete implementation. Some recent works (Lee, 2001; Lee & Bryant, 2002; Moreno Capuchino, Juristo & Van de Riet, 2000; Nuseibeh & Easterbrook, 2000, van Lamsweerde, 2000b) present different strategies for mapping requirements to, for example, object-oriented models or formal specifications.

When using the RAISE Method, writing the initial RSL specification is the most critical task because this specification must capture the requirements in a formal, precise way (George, 2002). RSL specifications of many domains have been developed by starting from informal descriptions containing synopsis (introductory text that informs what the domain is about), narrative (systematic description of all the phenomena of the domain), and terminology (list of concise and informal definitions, alphabetically ordered). Others also include a list of events. They can be found in UNU/IIST´s Web site *(*www.iist.unu.edu*)*. The gap between these kind of descriptions and the corresponding RSL formal specification is large, and thus, for example, it is difficult and not always possible to check whether the formal specification models what the informal description does and vice versa.

As we had some experience in using the Requirements Baseline, and we knew it had been used as the basis to an object conceptual model (Leonardi, 2001), we consider the possibility of using it as the first description of a domain from which a formal specification in RSL could be later derived.

THREE-STEP PROCESS TO DERIVE A FORMAL SPECIFICATION

As an attempt to reduce the gap between stakeholders and the formal methods world, we propose a technique to derive an initial formal specification in RSL from requirements models, such as LEL and scenarios that are closer to stakeholders' language. The derivation of the specification is structured in three steps: Derivation of Types, Derivation of Functions, and Definition of Modules. They are not strictly sequential; they can overlap or be carried out in cycles. For example, function definitions can indicate which type structures are preferable.

Derivation of Types

This step produces a set of abstract as well as concrete types that model the relevant terms in the domain. We perform the derivation of the types in two steps. First we identify the types, and then we decide how to model them. This way of defining types follows one of the key notions of the RAISE Method (George et al., 1995): the step-wise development.

The main goal of the identification step is to determine an initial set of types that are necessary to model the different entities present in the analyzed domain. This initial set will be completed, or even modified, during the remaining steps of the specification derivation. For example, during the Definition of Modules Step, it may be necessary to define a type to reflect the domain state. Also, when defining functions, it may be useful to define some new types to be used as result types of functions. The LEL is the source of information during this step, as LEL subjects and some objects represent the main components or entities of the analyzed domain. In general, LEL subjects and objects will correspond to types in the RSL specification. In some cases, LEL verbs may also give rise to the definition of more types, as when they represent an activity that has its own data to save. However, in order to define just the relevant types, we have suggested some heuristics that can be found in Mauco, Riesco, and George (2001a).

Once a preliminary set of types is defined and in order to remove under-specification, we propose to return to the information contained in the LEL and the Scenario Model. In particular, the analysis of the notion, and sometimes the behavioral response of each symbol that motivated the definition of an abstract type, can help to decide if the type could be developed into a more concrete type. All the developments we suggest satisfy the implementation relation. In Mauco et al. (2001a), some heuristics to assist in this task can be found. During this step, it might be necessary to introduce some type definitions that do not correspond to any entry in the LEL. They appear, in general, when modeling components of some other type. Symbols without an entry in the LEL may represent an omission or a symbol considered outside the application domain language. When an omission is detected, it is necessary to return to the LEL to add the new definition, and update the Scenario Model to maintain the consistency between its vocabulary and the LEL itself.

Definition of Modules

This step helps to organize in modules all the types produced by the Derivation of Types Step in order to obtain a more legible and maintainable specification. These modules would be later completed with the definition of functions in the next step, and probably they will be completed with more type definitions.

A summary of the heuristics we propose to define for the modules can be found in Mauco et al., (2001b). In defining these heuristics, we closely followed the features RSL modules should have according to the RAISE Method (George et al., 1995; George, 2002). For example, each module should have only one type of interest, defining the appropriate functions to create, modify, and observe values of the type, and the collection of modules should be, as far as possible, hierarchically structured.

Then, we identify class expressions to define schemes, and we assemble these schemes defining objects to express dependencies between them.

The modules obtained by applying the heuristics we propose can be hierarchically organized to show the system module structure. In addition, this hierarchy of modules can be represented using a layered architecture composed of three layers (specific layer, general layer, and middleware layer), where each layer is a set of RSL modules that share the same degree of generality (Mauco et al., 2002).

Derivation of Functions

This step results in a set of functions that model the functionality in the application domain. Scenarios are the main source of information when defining functions, as they are natural language descriptions of the functionality in the domain. Each scenario can be classified as modifying or observing depending on whether it produces a change in the domain or not, and so corresponds to a generator or observer function. A scenario that just reports information will be observing.

Functions are usually identified at the top level as scenarios help to generate them there. Functions at one level in the hierarchy of modules frequently have counterparts at lower levels, but with different parameters. For each function in the top level module, we model the necessary functions in lower level modules, in order to simplify the legibility and maintainability of the specification. In Mauco et al. (2001c), we describe some heuristics to derive the functions. These heuristics help to identify and to model the functions by showing how to derive arguments and result types of functions, how to classify functions as partial or total, and how to define function bodies by analyzing the components of scenarios.

FUTURE TRENDS

Formal methods offer a wide spectrum of possible paths towards developing high-quality software. Their successful use for real systems is steadily growing from year to year.

Requirements engineering plays an important role in the development of a software system. Success with requirements capture and modeling is considered crucial as the remainder of the lifecycle activities of the software development process is highly dependent on this early foundation. As we have mentioned before, in the requirements phase, requirements are often specified informally with a language in which stakeholders are familiar.

Then, among the many challenges for the future, bridging the gap between requirements engineering and formal specifications is an important one to work in. The former offers much richer modeling abstractions, while the latter offers many advantages in constructing the software system. So, to take profit of both of them, one should look at ways for mapping the conceptually richer world of requirements engineering to the formal methods world.

CONCLUSION

The advantage of formal methods such as RAISE is they help to avoid requirements ambiguities and misinterpretations, and they provide a correct software development process based on mathematical proofs. However, formal specifications are not easy to understand by stakeholders. LEL and scenarios are valuable for supporting interaction with stakeholders in the initial phases of software development. Then, to contribute to bridging the gap between stakeholders and formal methods specialists, we have defined a three-step process to derive an initial specification in RSL from natural language models. In addition, this process contributes to fruitfully using the large amount of information usually available after problem analysis. We have applied this three-step process to a complete case study (Mauco & George, 2000), the Milk Production System.

The heuristics we have proposed are guidelines on how to start with the definition of an initial specification, taking into account the structured description of a domain provided by LEL and scenarios. The LEL provides structural features of the relevant terms in the domain (Leite, Hadad, Doorn & Kaplan, 2000), thus limiting the definition of types to those that correspond to significant terms in the domain. Using the behavioral description represented in the scenarios, it is possible to identify the main functionality to model in the specification. In addition, the structure proposed in Leite et al. (2000) to describe each scenario makes simpler the derivation of function signatures. However, even though LEL and scenarios have a precise structure and it is established what to write in their components, the same semantics may be usually expressed with many different natural language sentences. But, we think some of the problems found in the derivation, and associated with natural language expressiveness and flexibility, could be overcome if stronger standards or guidelines were imposed to the way of describing LEL symbols and scenarios.

Once the initial specification is derived, the process continues with the steps proposed in the RAISE Method. For example, the initial applicative and partially abstract specification derived could be developed into a concrete one to make use of the SML translator (George, 2001), and thus obtain a quick prototype to validate the specification and get a feeling of what it really does.

We plan to improve the three-step process we proposed by refining and completing the heuristics presented in this work, though obviously a complete automatic derivation is by no means possible, as LEL and scenarios contain all the necessary and unavoidable ambiguity of the real world, while the specification contains decisions about how to model this real world. Besides, a Web-based tool to assist in the derivation process is under development.

KEY TERMS

Formal Methods: The variety of mathematical modeling techniques that are applicable to computer system (software and hardware) design. Formal methods may be used to specify and model the behavior of a system and to mathematically verify that the system design and implementation satisfy system functional and safety properties. These specifications, models, and verifications may be done using a variety of techniques and with various degrees of rigor.

Formal Specification: The expression, in some formal language and at a some level of abstraction, of a collection of properties some system should satisfy. A specification is formal if it is expressed in a language made of three components: the syntax (rules for determining the grammatical well-formedness of sentences), the semantics (rules for interpreting sentences in a precise, meaningful way in the domain considered), and the proof theory (rules for inferring useful information from the specification) (van Lamsweerde, 2000a).

RAISE Method: Encompasses formulating abstract specifications, developing them to successively more concrete specifications, justifying the correctness of the development, and translating the final specification into a programming language. The method is based on a number of principles such as separate development, stepwise development, invent and verify, and rigor. RAISE is an acronym for "Rigorous Approach to Industrial Software Engineering"; it gives its name to a formal specification language, the RAISE Specification Language, the associated method, and a set of tools. (George et al., 1995; George, 2002).

RAISE Specification Language (RSL): A formal specification language intended to support the precise definition of software requirements and reliable development from such definitions to executable implementations. It supports specification and design of large systems in a modular way, and thus it permits separate subsystems to be separately developed. It also provides a range of specification styles (axiomatic and model-based; applicative and imperative; sequential and concurrent), as well as supports specifications ranging from abstract (close to requirements) to concrete (close to implementations) (George et al., 1992).

Requirements: Descriptions of how the system should behave, or of a system property or attribute. They are defined during the early stages of a system development as a specification of what should be implemented. They should be statements of what a system should do rather than a statement of how it should do it (Soomerville & Sawyer, 1998).

Requirements Baseline: A mechanism proposed to formalize requirements elicitation and modeling, or a structure that incorporates descriptions about a desired system in a given application domain. Although it is developed during the requirements engineering process, it continues to evolve during the software development process. It is composed of five complementary views: the Lexicon Model View, the Scenario View, the Basic Model View, the Hypertext View, and the Configuration View (Leite et al., 1997).

Requirements Engineering: Comprehends all the activities involved in eliciting, modeling, documenting, and maintaining a set of requirements for a computer-based system. The term "engineering" implies that systematic and repeatable techniques should be used to ensure that system requirements are consistent, complete, relevant, and so forth (Soomerville & Sawyer, 1998).

ENDNOTE

[1] RAISE is an acronym for Rigorous Approach to Industrial Software Engineering.

Integrating Security in the Development Process with UML

INTRODUCTION

Today, most business processes and communications as well as a lot of everyday life situations involve IT technology. Apart from requirements on functionality, this development of IT systems has increased the need for security. Security issues are reaching the main headlines in the media on a regular basis. Virus, worms, *mis*configuration and program bugs are common problems in a world where new releases and updates are almost as frequently announced as spam e-mail pop-ups in our inboxes.

Having a closer look at the world of IT technology through security-colored glasses, we observe that security is often one step behind functionality. Security issues are mainly addressed as a reaction to existing problems. Like firemen and emergency units, security measures do not come into action before it is too late.

The concept of IT security contains a lot of different aspects. One of the IT security aspects is security risk analysis, in the sequel referred to as security analysis. Security analysis is an inevitable and crucial activity for every system developer, system user or system owner in order to get control over and knowledge about the security level of the actual system.

Security analyses are costly and time consuming and cannot be carried out from scratch every time a system is updated or modified. This motivates the need for specific methodology addressing the integration of security analysis and system development, providing access to, storage of, and maintenance of analysis results.

CORAS (2004) provides such a methodology in the form of so-called “model based security analysis”. The CORAS methodology combines traditional risk analysis techniques like HazOp (Redmill, Chudleigh, & Catmur, 1999), FTA (IEC 1025, 1990) and FMEA (Bouti & Ait Kadi, 1994) with system development techniques like UML (OMG, 2003b) and UP (Jacobson, Rumbaugh, & Booch, 1999). It builds on international standards for risk management: the Australian/New Zealand AS/NZS 4360 (1999), “Risk Management”; the ISO/IEC 17799 (2000), “Code of Practice for Information Security Management”; the ISO/IEC 13335 (2001), “Guidelines for the management of IT Security”; and system documentation in the form of the Reference Model for Open Distributed Processing (RM-ODP) (ISO/IEC 10746, 1995).

BACKGROUND

The CORAS methodology incorporates a documentation framework, a number of closely integrated security analysis techniques, and a risk management process based upon widely accepted standards. It gives detailed recommendations for the use of modeling with UML and similar languages in conjunction with security analysis in the form of guidelines and specified diagrams. Security analysis requires a firm, but nevertheless easily understandable, basis for communication between different groups of stakeholders. Graphical, object-oriented modeling techniques have proven well suited in this respect for requirements capture and analysis. We claim they are as equally suited as part of a language for communication in the case of security analysis. Class diagrams, use case diagrams, sequence diagrams, activity diagrams, dataflow diagrams, and state diagrams represent mature paradigms used daily in the IT industry throughout the world. They are supported by a wide set of sophisticated case tools, are to a large extent complementary, and together support all stages of system development.

The CORAS methodology may be separated into three different components: tools, processes and languages. This is shown in Figure 1. The language part defines common languages to support the methodology. The process part includes instructions for how to "execute" the methodology, that is, descriptions of what should be done, and how and when it should be done. The CORAS methodology for model based security analysis (MBSA) integrates aspects from partly complementary risk analysis methods and state-of-the-art modeling methodology. During execution of the methodology, one may require the use of different tools. The CORAS methodology includes a computerized platform that can be integrated with third party modeling tools and risk analysis tools. It also includes two languages: a UML-based specification language, the UML profile for security analysis (OMG, 2003c), targeting security risk analysis, and an XML markup for exchange of risk analysis data (World Wide Web Consortium, 2000).

In the section called *Model-Based Security Analysis*, the core of model-based security analysis, based on integration of risk management and system development, is explained.

Related Approaches

The CORAS methodology, with its unique approach to security analysis from a modeling point of view, addresses a problem area in which also other methods and technologies exist. Some important ones are mentioned here.

The Common Criteria (CC)

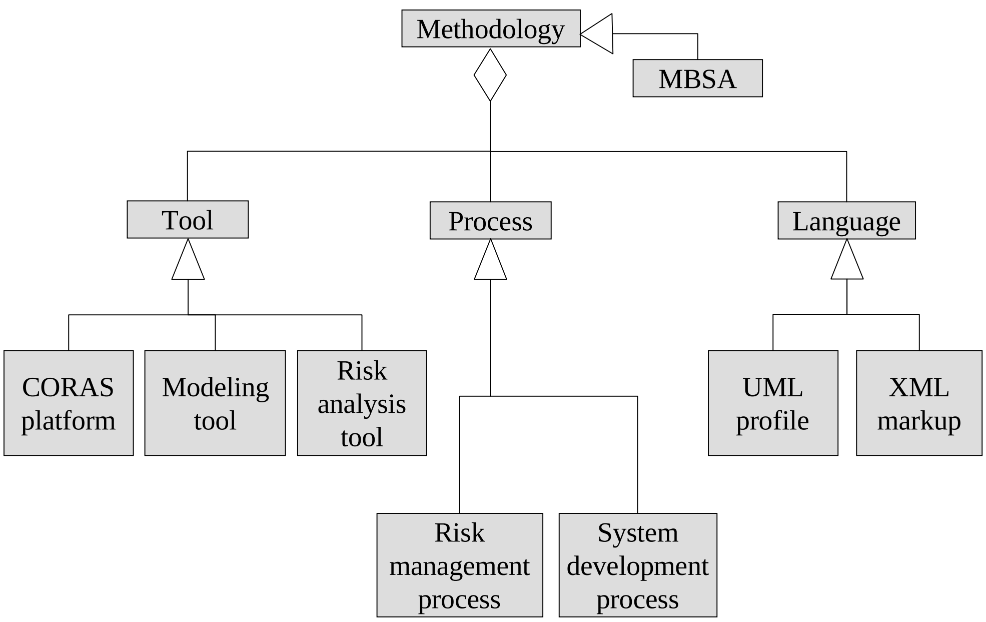
Since 1990, work has been going on to align and develop existing national and international schemes into one mutually accepted framework for testing IT security functionality. The Common Criteria (CC) (CCO, 2002) represents the outcome of this work. The Common Criteria project harmonizes the European "Information Technology Security Evaluation Criteria (ITSEC)" (Communications-Electronics Security Group, 2002), the "Canadian Trusted Computer Product Evaluation Criteria (CTCPEC)", and the American "Trusted Computer System Evaluation Criteria (TCSEC)" and "Federal Criteria (FC)". Increasingly, it is replacing national and regional criteria with a worldwide set accepted by the International Standards Organization (ISO15408) (ISO/IEC, 1999).

The CC and CORAS are orthogonal approaches. The CC provides a common set of requirements for the security functions of IT products and systems as well as a common set of requirements for assurance measures that are applied to the functions of IT products and systems during a security evaluation. CORAS provides a concrete methodology for model based security analysis.

Surety Analysis (SA)

Surety Analysis (SA), developed in Sandia National Laboratories (2003), is a methodology based on the creation of

Figure 1. Structure of the CORAS methodology



an explicit model that covers several aspects of the system's behavior. The modeling framework in SA is proprietary, whereas in CORAS the standardized RM-ODP is used as a common basis. SA supports modeling by means of basic techniques such as interaction, state and dataflow diagrams. CORAS uses the full descriptive power of UML/OCL (Object Constraint Language) (OMG, 2003a) enhanced with aspects of other modeling paradigms specific to security modeling.

COBIT

The control objectives for information and related technology (COBIT) (2003) addresses the management of IT. COBIT and CORAS are orthogonal approaches. COBIT focuses on control objectives defined in a process-oriented manner following the principles of business reengineering.

CRAMM

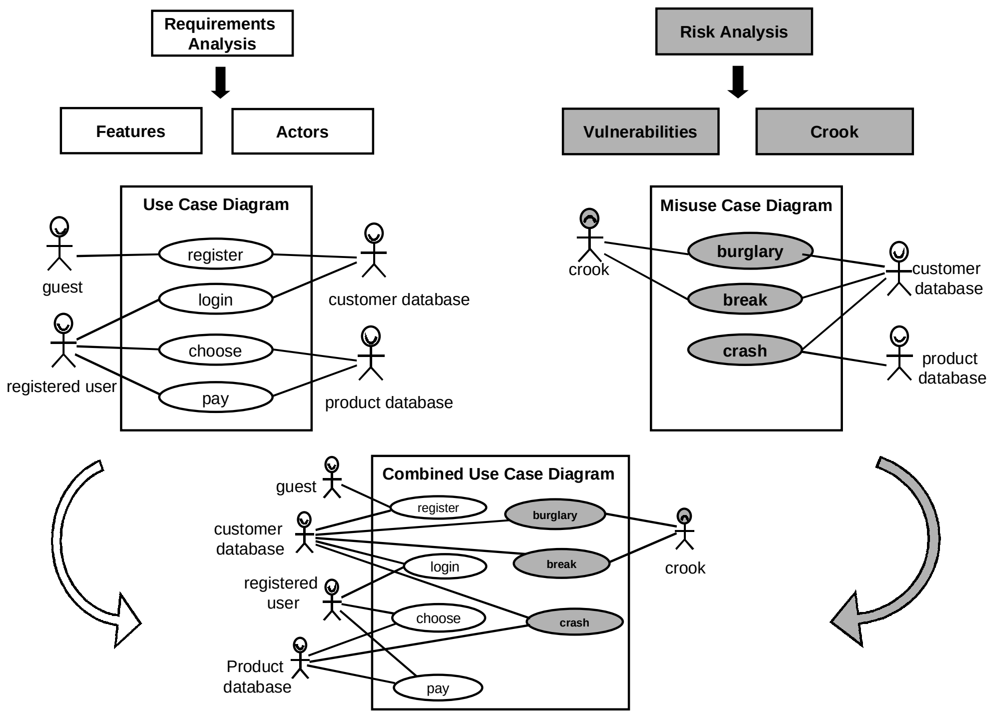
CCTA Risk Analysis and Management Methodology (CRAMM) (Barber & Davey, 1992) was developed by the British Government's Central Computer and Telecommunications Agency (CCTA) with the aim of providing a structured and consistent approach to computer security management for all systems. The UK National Health Service considers CRAMM to be the standard for security analysis of information systems within health care establishments. CRAMM has been an important source of inspiration for CORAS, and aspects of CRAMM have been incorporated in CORAS. Contrary to CRAMM, CORAS provides a security analysis process in which state-of-the-art modeling methodology in the form of UML is tightly integrated.

MODEL-BASED SECURITY ANALYSIS

As mentioned before, "model-based security analysis" is a core concept in the CORAS methodology. This section explains what "model-based security analysis" is, and gives a glimpse on how it is to be applied.

The basis of model-based security analysis is about identifying negative functionality and making this *mis*functionality (Sindre & Opdahl, 2000) visible and known in order to protect the system. This misfunctionality can be everything from vulnerabilities that open for hacker attacks to bad user interface design increasing the chance for crucial mistakes. The idea is that the well-accepted techniques for specification and design of functionality are also suited for model misfunctionality. This is illustrated by Figure 2.

Figure 2. Model-based security analysis



The requirements analysis forms the basis for the traditional kind of modeling (Cockburn, 1997) with focus on desired behavior. Security analysis has a similar role but focuses on unwanted behavior. Every designed system carries its own risks, and it is important that they are known. It is therefore not enough to model only the desired behavior but also the unwanted behavior. In addition, the malicious actors, or crooks, need to be identified just like the normal actors. Model-based security analysis is about documenting the results of traditional risk analysis techniques in the same way as we are used to doing for system requirements. The design process needs to take into account both wanted and unwanted behavior and designed actors and malicious actors. As shown here, UML like graphical techniques can be used for both aspects providing the complete documentation of the system design from both good and bad angles.

UML Profile

The CORAS methodology defines its own UML stereotypes and methods for describing UML models related to security analysis. These specific security related UML aspects are caught in the CORAS UML profile (OMG, 2004). This UML profile for security analysis introduces a meta model that defines an abstract language for supporting model-based security analysis. Furthermore, the profile provides a mapping of classes in the meta model to UML modeling elements by defining so-called stereotypes, and introduces special symbols (icons) for representing the stereotypes in UML diagrams.

The motivation for the profile is the practical use of UML to support security management in general, and security analysis, in particular. In the model-based security analysis methodology of CORAS, UML models are used for three different purposes:

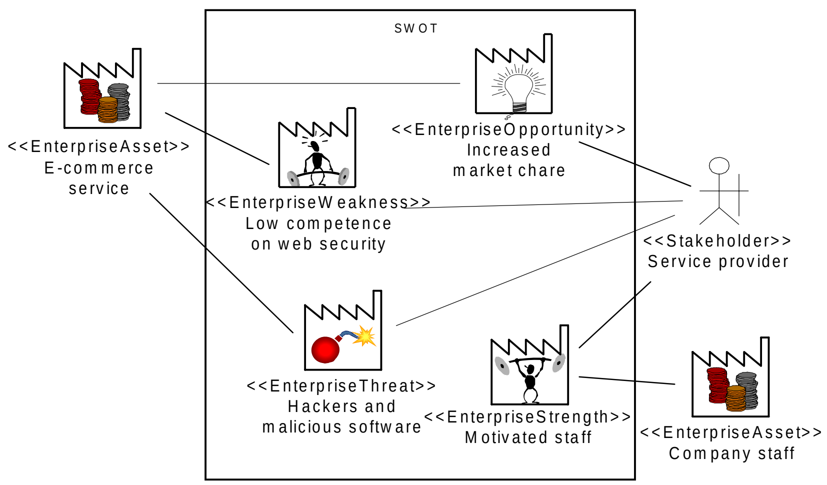
- Target of evaluation: Describing the target of evaluation at the right level of abstraction.
- Communication: Facilitating communication and interaction between different groups of stakeholders involved in a security assessment.
- Documentation: Documenting security assessment results and the assumptions on which these results depend to support reuse and maintenance.

The target of evaluation in a security analysis is a system or part of a system to be assessed, but also the context and assumptions under which the system is assessed. The CORAS profile supports describing the target of evaluation by allowing explicit modeling of the context of assessments, like stakeholders and assets. An example of this is shown in the SWOT diagram in Figure 3, where the assets and stakeholders are directly related to main characteristics of the system to be assessed.

The effectiveness and success of security analysis depends on the extent to which the involved stakeholders and analysts understand and are understood by each other. Users, system developers, decision makers and system managers are different examples of such stakeholders. These will have different backgrounds and competencies, and misunderstandings are likely to occur. The CORAS profile supports communication by introducing easy to understand icons representing the various concepts of the ontology, as shown in the SWOT diagram of Figure 3.

Imagine the following security analysis results generated by a security analysis session as defined in the CORAS methodology.

Figure 3. SWOT (Strength-Weakness-Opportunity-Threat) diagram



"Regarding the availability of service as an important asset of the system, it was identified that some persons with the right knowledge and the wrong intentions could threaten this availability of service by flooding the system. The indicated flooding threat might generate a Denial-of-Service attack which directly affects the availability of service. One way of securing the system against this risk is to apply authentication on requests."

The same results represented in UML using the CORAS profile are shown in Figure 4. Clearly, this representation is easier to communicate and leaves less room for misunderstanding. It also shows how the CORAS methodology allows for specifying discovered risks and treatments related to threats. One might argue that the result in text is just as clear, but this will typically only be the case for relatively simple cases. The CORAS methodology advices to use the given diagrams and modeling techniques, but does not restrict one from using normal text in addition.

In CORAS, security analysis results are documented by the means of elements (diagrams, tables, etc.). Each of these elements belongs to an activity of the risk management process. The CORAS profile supports documentation by introducing types of diagrams supporting various activities of the risk management process being founded in a meta model conforming to the underlying data structure.

The diagrams mentioned here become part of the system documentation and are also stored like that. This documentation process is supported by the CORAS platform, a tool containing both guidance and storage functionality. Recent security analysis results are stored while the process is supported by results from past security analysis experiences. This opens for running the CORAS methodology parallel to the traditional system development process in addition to being able to follow the maintenance and upgrading phases by similarly maintaining and upgrading the security analysis results.

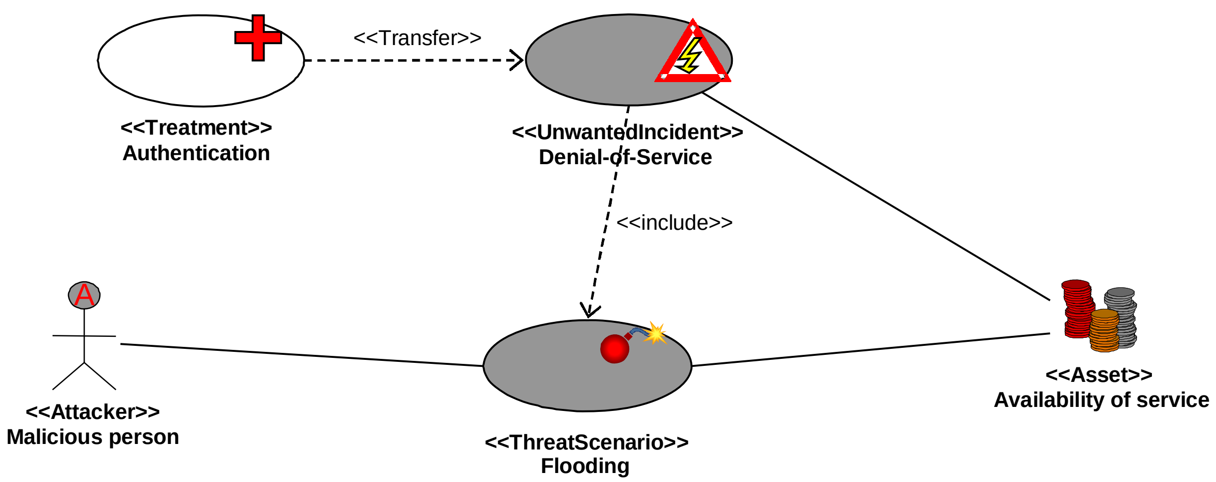
FUTURE TRENDS

A main future trend regarding security analysis is the integration of security in the development process of IT systems. Developers will have to start to think security at the very start of the development process. Today, security and dealing with risks do not always get the attention they deserve: It is often forgotten or simply ignored. Apart from door locks and bank safes, most people let security "live its own life" and often just hope for the best. This attitude is probably necessary in our everyday life: There are so many things that can go wrong, and we cannot worry about all of them. When it comes to IT systems, and especially security critical IT systems, such an attitude could be fatal. We, therefore, need to break the habit of living on hope and turn it into informed, calculated, and constructive actions. To be able to do this, methods and tools are needed to guide us in our security analyses.

CONCLUSION

The CORAS methodology and the corresponding developed CORAS platform help developers in keeping focus on security and provide guidelines on how security analysis can become a natural part of the system development process. The combination of security analysis with system development methodologies like the Unified Process makes security related adjustments possible during all phases of the development process.

Figure 4. Threat diagram



A security analysis identifies and documents the undesirable system behavior. The CORAS UML profile employs the same kind of modeling techniques to document the undesirable behavior that leading system development methodologies employ to capture requirements to the desirable system behavior. For example, as pointed out previously, in the same way as use cases are employed to capture desired functionality, misuse cases may be employed to capture threat scenarios. The fact that the CORAS methodology employs techniques well known to system engineers simplifies security analysis during system development.

The experiences from applying the CORAS methodology in major field trials within e-commerce and telemedicine are promising. The CORAS project involved seven major field trials, each of which made use of the earlier versions of the CORAS methodology and tool to analyze the security of an already existing system or application. The field trials were all of industrial size. Two field trials within telemedicine are documented in Stathiakis et al. (2003) and Stamatiou et al. (2003), while Dimitrakos et al. (2002) and Raptis, Dimitrakos, Gran and Stølen (2002) document field trials within e-commerce. More documentation on the CORAS methodology can be found on the CORAS Web site (CORAS, 2004).

The research on which this article reports has partly been funded by the Research Council of Norway projects COBRA (152209/431) and SECURIS (152839/220) and partly by the 5th Framework EU project CORAS (IST-2000-25031). The CORAS consortium consisted of 11 partners from four countries: CTI (Greece), FORTH (Greece), IFE (Norway), Intracom (Greece), NCT (Norway), NR (Norway), QMUL (UK), RAL (UK), SINTEF (Norway), Solinet (Germany) and Telenor (Norway). The results reported in this article have benefited from the joint efforts of the CORAS consortium.

KEY TERMS

Risk: The chance of something happening that will have an impact upon objectives. It is measured in terms of consequence and likelihood.

Risk Analysis: A systematic use of available information to determine how often specified events may occur and the magnitude of their consequences.

Risk Assessment: The overall process of risk analysis and risk evaluation.

Risk Evaluation: The process used to determine risk management priorities by comparing the level of risk against predetermined standards, target risk levels or other criteria.

Risk Treatment: Selection and implementation of appropriate options for dealing with risk.

Security Analysis: Thorough analysis of a system in order to get a complete picture of its security level. Vulnerabilities, risks, treatments and their costs are identified.

Stakeholders: Those people and organizations who may affect, be affected by, or perceive themselves to be affected by, a decision or activity.

SWOT Analysis: Strength, Weakness, Opportunity and Effect Analysis.

Target of Evaluation (TOE): An IT product or system and its associated administrator and user guidance documentation that is the subject of an evaluation.

Virus: Program that can infect other programs by modifying them; the modification includes a copy of the virus program, which can then go on to infect other programs.

Integration Framework for Complex Systems

Edward Szczerbicki
The University of Newcastle, Australia

INTRODUCTION

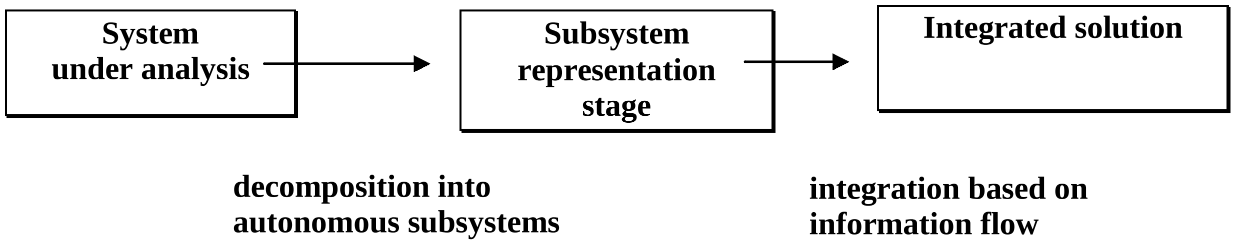
Information is seen as one of the main resources that systems analysts try to use in an optimal way. In this chapter we show how this resource can be used in integration issues. We introduce the problem of information-based integration, propose a solution, and briefly discuss future trends in this area. Systems become increasingly complex. Their decomposition into smaller units is the usual way to overcome the problem of complexity. This has historically led to the development of atomized structures consisting of a limited number of autonomous subsystems that decide about their own information input and output requirements, that is, can be characterized by what is called an information closure. In a real-world context, autonomous subsystems consist of groups of people and/or machines tied by the flow of information both within a given subsystem and between this subsystem and its external environment (Esteve, 2002; Szczerbicki, 2003; Tharumarajah, 1998). Autonomous subsystems can still be interrelated and embedded in larger systems, as autonomy and independence are not equivalent concepts. These ideas are recently gaining very strong interest in both academia and industry, and the atomized approach to complex systems analysis is an idea whose time has certainly come (Liu & Ling, 2003; Orlowski, 2002).

Complex systems (for example manufacturing) are often viewed as sets of components (agents, subsystems) supporting separate functions. Many organizations operate in this highly compartmentalized manner. It appears that the general direction of systems in the future, however, is toward linking together function-specific agents into fully integrated entity. An integrated system is a system that consists of agents/subsystems that efficiently contribute to the task, functional behaviour, and performance of a system as a whole. It is believed that such an integration can be achieved through the flow of information. “Integration,” as used in this article, should not be confused with integration at a physical level by means of computer networks or computer buses. Rather, the semantics of integration is addressed - the information that subsystems should share. While structuring the approach presented, the first consideration was to design some tools that could be easily implemented as components of an intelligent system supporting development of system configurations integrated by the flow of information. Due to the complexity and creativity associated with the early stages of such a development it is quite clear that the way a practicing analyst solves a system configuration problem cannot be easily implemented. This explains the need for new tools and approaches that solve the problem but at the same time can be supported by a computer. Elements of such an approach are presented in this article.

BACKGROUND

We propose a three-stage approach for the development and analysis of complex systems. The involved stages are systems decomposition, subsystem modelling represen-

Figure 1. Overview of a three-stage approach to complex systems integration



tation, and integration at the level of information flow. Figure 1 depicts the general underlying idea behind this approach.

The essence of information-based integration problem can be formulated as follows and illustrated as in Figure 2.

Theoretical framework to provide support for systems integration as outlined includes the following fundamentals:

- the syntax for connections of autonomous subsystems,
- the mechanism for guiding the generation of such connections,
- the integration algorithm.

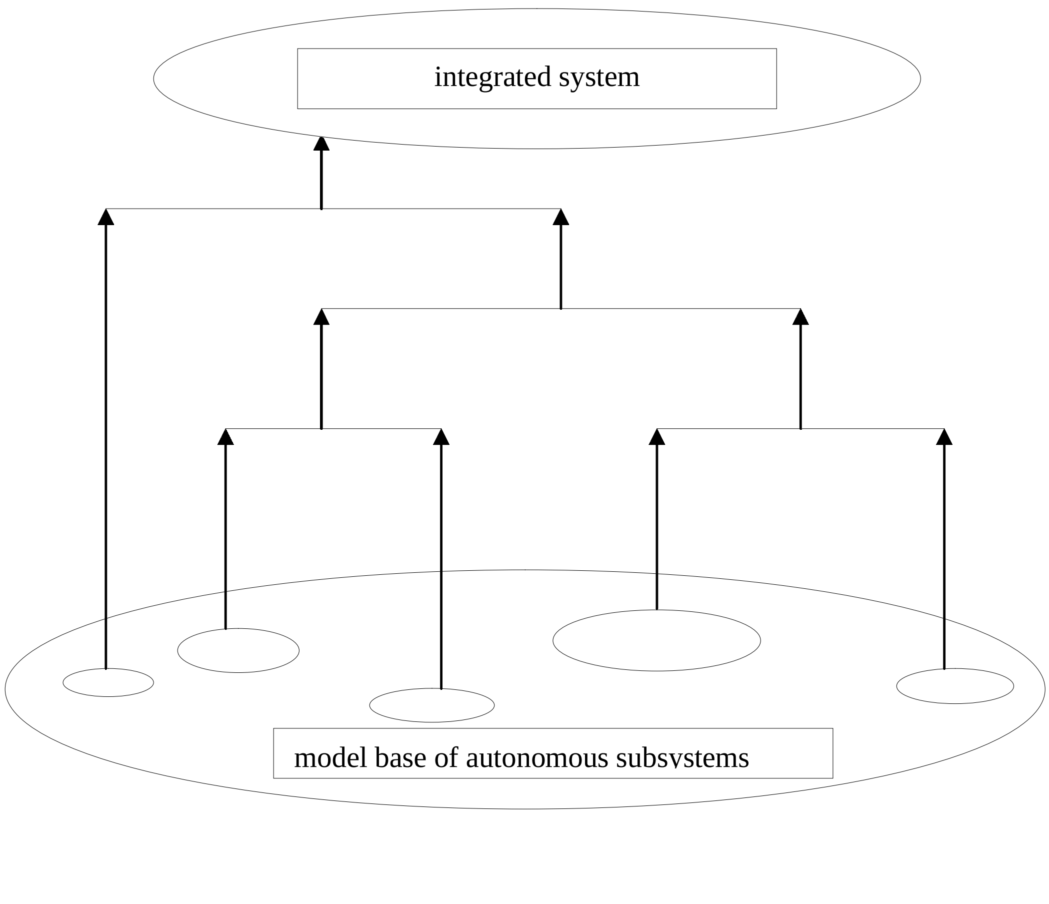
The aim of this article is to briefly outline these fundamentals.

The author, together with his collaborators, has been researching information-based integration issues since the early nineties, starting at The University of Iowa (Kusiak, Szczerbicki & Vujosevic, 1990, 1991), Iowa City, USA, continuing at The GMD FIRST, Berlin, Germany (Szczerbicki, 1994) and currently working on these issues at The University of Newcastle, Newcastle, Australia (Szczerbicki, 2003). The aim of this entry, which is based on previous research publications by the author, is to overview the integration problem from the perspective of the author's experience and to place it among the work of others.

Integration problem is recently gaining very strong interest in both academia and industry. This is particularly apparent in the area of design and modelling of manufacturing systems (O'Grady, 1999). Model development and synthesis (that resembles autonomous systems develop-

Figure 2. Illustrative example of a three-level hierarchical tree of the bottom-up integration process

Given the informational inputs and outputs of autonomous subsystems, find the overall system being designed that meets the desired functions and is integrated through the flow of information.



ment and integration) is frequently based on the general systems theory and it uses hierarchical structures and a number of model base concepts (Esteve, 2002; Rolstadas & Andersen, 2000; Wyzalek 1999). In Raczkowsky and Reithofer (1998), the future development of a hierarchical communication model for coordination of a set of agents performing several functions is addressed. A conceptual modeling approach to represent the complexities in CIM (Computer Integrated Manufacturing) systems, including such issues as information acquisition, storage, dissemination and the time and costs associated with such informational activities is proposed in Tharumarajah (1998). The problem of coordination of multiagent manufacturing systems developed to fulfill their functional requirements advocating a decentralized approach in which each agent has relative autonomy over its own actions is discussed in Pacholski (1998). In O'Grady (1999), the application of modular paradigm to integration of systems in which planning, grouping, and scheduling are the central functional areas is described. The role of the flow of information in the process of integration is discussed in Prakken (2000) and Orlowski (2002). In Kamrani and Sferro (1999), the integration of manufacturing agents (information islands and automation islands) using knowledge-based technology is proposed for the factory of the future.

Traditionally, information system analysts have been solving the integration problem in an ad hoc manner. What we propose through our research is a formal integration approach suitable for computer implementation.

Information-based integration problem should be seen as one of the challenges within the broader, more general aim to enhance systems performance through the flow of information. Engineering, operations research, information science and management science use scientific and engineering processes to design, plan, and schedule increasingly more complex systems in order to enhance their performance. One can argue that systems have grown in complexity over the years, mainly due to increased strive for resource optimization combined with a greater degree of vagueness in the system's environment. Information is seen as one of the main resources that analysts try to use in an optimal way in complex systems. Proper design of information flow, its management, its use, its maintenance, that is, information engineering, is critical in systems' abilities to act appropriately in an uncertain environment – to act intelligently (Baba et al., 2001; Bogdan, 2000; Gunasekaran & Sarhadi, 1997; Morabito, 1997; Prakken, 2000; Tharumarajah, 1998).

INFORMATION BASED INTEGRATION

Autonomous subsystems are matched using informational input and output defined at representation stage (Figure 1). For example, in the domain of environmental engineering, information may represent geographical positioning, urban planning, sources of pollution, traffic data, and the like. In the domain of manufacturing systems, informational inputs and outputs may represent material availability, tool availability, machine availability, number of parts produced, and number of products assembled. After the matching has been accomplished, the informational input variable of a given subsystem represents the value of the informational output variable of the subsystem to which it has been connected. For example, if the input variable X of autonomous subsystem AS2 is matched with the output variable Y of AS1, then the syntax of this connection will be given as:

$$AS1.Y \longrightarrow AS2.X \tag{1}$$

Similar simple syntax can be used for all structures that can be produced during the integration process. These structures are enclosed into higher-level subsystems using ports. The informational input and output ports provide an interface to the subsystem environment. This interface is used to develop hierarchical structures. With the syntax of autonomous subsystems connections in place, the mechanism for guiding the generation of such connections is required. The mechanism needs to represent qualitative system theoretic knowledge, and so it is based on IF... THEN production rules.

Generation of connections between elements in model base of autonomous subsystems is guided by the following production rules (Kusiak, Szczerbicki & Vujosevic, 1990, 1991; Szczerbicki, 2003):

- Rule 1
  IF there is only one element left
  THEN do not generate connections
- Rule 2
  IF a single element that is left includes boundary inputs and outputs only
  THEN it is an overall system
- Rule 3
  IF there are more than one element
  THEN select a connection for an input boundary element
- Rule 4
  IF there are elements other than the boundary elements
  THEN do not specify any connections that involve boundary elements only
- Rule 5
  IF an element is an input boundary element
  THEN it cannot accept an input from any other element

- Rule 6
  IF an element is an output boundary element
  THEN it cannot provide an input to any other element
- Rule 7
  IF two elements have identical output and input variables
  AND there are no production rules that prevent from connecting them
  THEN specify the connections for these elements
- Rule 8
  IF there are no elements with identical input and output variables
  AND there are elements with partially identical input and output variables
  AND there are no production rules that prevent from connecting them
  THEN specify the connection for these elements beginning with the closest match
- Rule 9
  IF a connection for an input boundary element has been specified
  THEN continue with selecting connections for elements that have not been listed in the specifications
- Rule 10
  IF there are boundary elements only
  THEN specify connections between them

These production rules are domain independent and were structured using the underlying general systems theory. The analyst may, however, add domain-based production rules. They may follow, for example, the safety requirements, emission data, traffic data, or other constraints imposed by the analyst.

The last tool needed for simulation of the information-based integration process is an integration algorithm. The algorithm guides the simulation process across various levels of integration illustrated in Figure 2. It was developed with the assumption that in order to enter the next level of integration it is enough to generate just one connection in a given step. Elements taking part in integration that are not matched at integration level i are considered for matching at level $i+1$. The algorithm terminates at the level at which it will no longer be possible to match subsystems into pairs (no connections will be generated). At each integration level, production rules presented previously are fired during simulation process to generate connections between remaining integration elements. The integration algorithm is the last element of fundamentals of a framework to support systems integration process. The algorithm includes the following simple steps (Kusiak, Szczerbicki & Vujosevic, 1990, 1991; Szczerbicki, 2003):

- Define database of autonomous sub systems (bottom level of illustrative example of integration process in Figure 2)
  Set level = 1.
- Generate connections between elements at current•
- If no connections are generated, stop;
  Otherwise, match elements in database into pairs using the existing connections.
- Define informational input and output variables for subsystems generated by the matching process.
- Remove from the database all elements that have taken part in the matching process.
- Add to the database all subsystems generated by the matching process.
- . Set level = level + 1 and go to Step 2.

The presented framework for information-based integration has been applied in numerous real-life based cases in which simulation was used to arrive at integrated problem solution. Some particularly successful applications included system modelling and integration for a coal mine (Szczerbicki & Charlton, 2001), integrated agile manufacturing strategy (Szczerbicki & Williams, 2001), modelling for steel processing (Szczerbicki & Murakami, 2000) and integration of maintenance services (Szczerbicki & White, 2003). In all these cases all three stages of systems decomposition, representation and integration were present (see Figure 1), integration representing the last step in the process of arriving at a systems structure integrated by the flow of information.

FUTURE TRENDS

Information-based system integration is gradually becoming one of the main challenges of our new millennium of information age. The most prominent future trend in this area is focused on using Web-based technologies for tackling problems of integration. Within this trend we have a rapid increase of research efforts towards developing metamodelling architectures and interoperability of Web-enabled information flows (Terrase et al., 2003), semistructured data integration (Liu & Ling, 2003), schema integration (Castana et al., 2003), and Web-based aggregation architectures (Bussler, 2003). The explosive popularity of the Web makes it an ideal integration tool as it opens the possibility to integrate geographically distributed systems. Also, in the future the Web may become a universal platform to synthesize a number of integration approaches (for example like the one presented in this article) into one universal Web-based integration interface.

CONCLUSION

Information flow integration is one of the major activities of the design process of an integrated system. The outcome of the integration process is the overall system integrated through the flow of information.

In this entry, integration problem is formulated as follows: Given the informational inputs and outputs of autonomous subsystems, find the overall system being designed that meets the desired functions and is integrated through the flow of information.

Autonomous subsystems are integrated using an algorithm into an overall system that has a hierarchical structure. General production rules supporting generation of connections for subsystems relate to the underlying systems theory. They are structured independently of the system's domain and cannot be modified by a system analyst. Production rules ensure that only feasible variants of the designed system are explored.

KEY TERMS

Autonomous (Sub)System: A system that decides about its own information input and output requirements.

Complex System: From mathematical perspective a system which is described by differential or difference equations; from informational perspective a system for which information is the main resource and functioning in information rich environment.

General System Theory: Collection of tools, approaches, hypotheses and models that can be used for scientific discovery.

Information Based Integration: Process in which given informational inputs and outputs of autonomous (sub)systems, analyst develops the overall system being designed that meets the desired functions and is interconnected through the flow of information.

Information closure: Boundary defined by information and its sources necessary for autonomous (sub)systems functioning.

Information Engineering: Proper design of information flow, its management, its use, and its maintenance.

Information system: A collection of organised procedures collecting, storing, processing and retrieving data. It provides information to support the organisation.

Intelligence: Ability of a given system to act appropriately (i.e. to increase the probability of the achievement of given aims) in an uncertain and changing environment.

System: A collection of components (subsystems) together with their interrelations.

Integrative Document and Content Management Solutions

Len Asprey
Practical Information Management Solutions Pty Ltd., Australia

Michael Middleton
Queensland University of Technology, Australia

INTRODUCTION

Developments in office automation, which provided multiple end-user authoring applications at the computer desktop, heralded a rapid growth in the production of digital documents and introduced the requirement to manage capture and organization of digital documents, including images. The process of capturing digital documents in managed repositories included metadata to support access and retrieval subsequent to document production (D'Alleyrand, 1989; Ricks, Swafford & Gow, 1992).

The imperatives of documentary support for workflow in enterprises, along with widespread adoption of Web-oriented software on intranets and the Internet World Wide Web (WWW), has given rise to systems that manage the creation, access, routing, and storage of documents, in a more seamless manner for Web presentation. These content management systems are progressively employing document management features such as metadata creation, version control, and renditions (Megill & Schantz, 1999; Wiggins, 2000), along with features for management of content production such as authoring and authorization for internal distribution and publishing (Addey et al., 2002; Boiko, 2002; Hackos, 2002; Nakano, 2002).

If business applications are designed taking into account document and Web content management as integral constructs of enterprise information architecture, then the context of these solutions may be an integrative document and content management (IDCM) model (Asprey & Middleton, 2003). As the name implies, the IDCM model aspires to combine the features of a document management system with the functionality of Web content management. An integrative business and technology framework manages designated documents and their content throughout the continuum of their existence and supports record-keeping requirements.

The IDCM model supports system capabilities for managing digital and physical documents, e-mail, engineering and technical drawings, document images, multimedia, and Web content. These systems may be deployed individually to address a specific requirement. However, due to the volume and varied formats of important documents held in digital format, these systems are often deployed collectively based on a strategic IDCM approach for better managing information assets. An organizational approach to IDCM supports enterprise knowledge strategies by providing the capability to capture, search, and retrieve documented information.

SCOPE

IDCM depends upon effective integration of organizational systems that together are used for managing both digital and physical document types. The scope of this management is across all stages of document lifecycles. It includes provision for distribution of the document content over intranets and the Internet.

Features of enabling IDCM technologies are described in the following section. The technologies may be differentiated into those with core capabilities and supporting technologies.

Core capabilities are: document management; e-mail management; drawing management; document imaging; Web content management; enterprise report management; and workflow. Supporting technologies include: Web services; database management systems; digital signatures; portals; universal interfaces; and network management.

Significant issues that need to be addressed with respect to IDCM solutions include the provision of seamless functionality that may be employed across different capabilities so that currency, integrity, and authority are managed effectively. These in turn must be complemented by user interfaces that provide stylistic consistency and that are augmented by metadata that enhances retrieval capabilities through the supporting technologies.

The following section itemizes the types of features that are required.

SYSTEM FEATURES—CORE TECHNOLOGIES

Document Management

An encompassing approach to document management sees documents within a framework that supports integrity, security, authority, and audit, and that are being managed so that effective descriptions of them are used to support access, presentation, and disposal (Bielawski & Boyle, 1997; Wilkinson et al., 1998). In this context document management applications implement management controls over digital and physical documents. The general capabilities of a document management application are:

- *Document production and capture*—interface with common office productivity software.
- *Classification*—support business classification schemes (e.g., folder structures, document properties).
- *Metadata*—capture of properties that describe document.
- *Check-in/checkout*—maintain document integrity during editing.
- *Version control*—increment versions of document to support integrity.
- *Complex relationships*—manage links and embedded content within digital documents.
- *Security*—implement user/group access permission rights over documents.
- *Document lifecycles*—manage the transition of document states through pre-defined lifecycles.
- *Integrated workflow* to automate review and approvals; controlled distribution of documents.
- *Search and information retrieval*—search metadata or text within documents, or both.
- *Viewing*—view documents in native application or using integrated viewer.

These should be associated with recordkeeping features such as disposal scheduling and archiving.

E-MAIL MANAGEMENT

The growth in e-mail has brought a high demand for solutions that allow enterprises to manage e-mails that have value to the business. The IDCM model offers two types of capabilities:

- *Direct capture*—These applications are often referred to as e-mail archiving applications.
- *End-user capture*—These capabilities are typically offered as a module within document management systems.

Direct capture or archiving facilities intercept incoming and outgoing e-mail. They operate by taking a copy of incoming and outgoing messages that are managed by the e-mail messaging system, and use customized business rules to extract e-mail that may not have a business context. Unwanted e-mail such as spam, or that received from news lists or information bulletins, can be eliminated.

These systems may feature auto-categorization based on metadata such as that contained in e-mail message headers, and possibly also within attachments. Categorization can also occur using the content and context of e-mail by applying techniques such as learning by example from previously processed e-mail. These types of solutions might be valuable for capturing statistical information differentiated by the types of requests made by customers. For example, statistics can aid call centers to monitor turnaround timeframes for responding to e-mail requests, or undertake trend analysis.

Search options include the capabilities to search messages and text attachments. Depending on the capabilities of the system, searches might be invoked from an e-mail client, desktop client application, or Web browser.

Some systems are able to apply rules defined in disposal authorities so that e-mails are purged from the system within a legal framework. In some cases, different retention schedules can be applied to specific categories of e-mail.

End-user capture facilities are adopted by some enterprises to save relevant sent and received e-mails that evidence business transactions into an e-mail management repository, such as a document management system, leaving it up to the user to identify e-mails that need to be saved according to organizational guidelines.

The document management system would need then to integrate effectively with the existing enterprise e-mail client software. This capability would enable end-users to save e-mails and/or attachments to the managed repository, automatically derive metadata from the header of e-mail messages, add custom metadata, and store the e-mail and attachment/s (where appropriate) as a digital record.

DRAWING MANAGEMENT

Many systems for registering or managing drawings have been developed independently of more generic approaches to document management. They may include information systems that enable users to register or index physical drawings in a database, along with generation of transmittals for issue of new documents, and management of the distribution of revisions to drawings and technical documents.

A drawing management system may be differentiated from a registry system in that the software implements automated management controls over the digital drawing objects maintained within a vault-like repository. This capability evolved to support the capture and management of drawings created by Computer Aided Design (CAD) packages. Functionality should include base capabilities such as:

- Integration with CAD tools for capturing electronic drawings.
- Automated features for drawing revision control and revision numbering.
- Management of electronic and hardcopy drawings, technical specifications, and manuals.
- Management of parent-child relationships between multiple drawings.
- Registration and tracking of physical copies of controlled drawings.
- Management of incoming and outgoing transmittals.
- Electronic document review and authorization using integrated workflow.
- Provision of viewing, red line, markup, and annotation functions.
- Maintenance of history logs and audit trails.

Extended capabilities may include automation of drawing numbering, synchronization of digital and physical drawing objects, synchronization of title block and metadata registration and updates, and management of drawing status during engineering change lifecycle transitions.

Drawing management capabilities may be provided by a dedicated drawing management system; as unified functionality within a document management system; as an inbuilt module of an Enterprise Resource Planning (ERP) system, maintenance management system, or similar; or an integral component of a document management application.

DOCUMENT IMAGING

Imaging systems have evolved from the principles of film-based imaging and may now be characterized in two groups for document imaging, these being (a) film-based imaging (micrographics) and (b) digital imaging systems.

In film-based imaging, micrographics technology is used to capture images of physical documents on microfilm, so that the images may subsequently be viewed using a reader, and printed if required. In digital imaging, images of physical documents are captured in a digital file format, with subsequent viewing or printing from the image format.

Digital imaging systems may be differentiated as desktop (ad hoc scanning), workgroup (shared tools in network), or production (high volume, diverse type). IDCM normally implies a workgroup or production environment. Capabilities offered include image manipulation functions such as:

- Capture of hardcopy documents into digital format.
- Capability for scanning and conversion of different sizes, sides (duplex scanning), physical orientation, and physical structure of documents.
- Managing multi-page images as a single entity (e.g., multi-page TIF file).
- Images may be saved to specified file formats. For example, a document might be saved in PDF or JPG for publishing on a Web server, or as a multi-page TIF for viewing/transmission.
- Support for a range of resolution, contrast, threshold, and size settings to meet the diverse requirements of document capture.
- Capture of color and/or grayscale images to suit forms processing and other applications (e.g., colored contour maps).
- Despeckling/deskewing and border removal.
- Multi-level registration capabilities, including batch-, folder-, envelope-, and document-level indexing.

Imaging systems are often integrated with recognition systems to facilitate capture and retrieval. These include technologies for automatically capturing data encoded in barcodes, integration with optical character recognition (OCR and ICR) technologies to enable text information to be extracted from scanned images, and integration with optical mark recognition (OMR).

WEB CONTENT MANAGEMENT

IDCM has the capability to provide a managed environment for the processes associated with publishing Web content. It has been said that a content management system is a concept rather than a product (Browning & Lowndes, 2001). This adds weight to analysis of it within the context of an IDCM model, where documents and their content may be considered more broadly than in terms of Web presentation. Document creation, management, and utilization can thus be undertaken with reference to business requirements and workflow of business processes.

Typically, functionality is characterized in terms of content creation, presentation, and management (Arnold, 2003; Robertson, 2003). Increasingly this functionality is seen to be employed within a unified content strategy for an enterprise (Rockley, Kostur & Manning, 2003).

Content creation functionality includes separation of presentation and content, utilization of elements of documents such as illustrations in different contexts, and continuation of associations between pages after restructuring. Metadata support should also be available, and markup should be transparent to the content creator.

Presentation elements include multiple formats for distribution of internal material such as manuals and business forms over intranets, and for external material such as marketing information and application forms. Other features expected are template availability through style sheets, integration of multiple formats as compound documents, provision of alternative renditions, and personalization of display according to user profiles.

Management features include version control and integrity maintenance among multiple users, and associated security procedures and audit trails. Managed interfaces to other subsystems should provide for dynamic provision of content to pages so that current data can be presented in validated form within compound documents. There should also be utilization of workflow for accommodating distributed users, content review, and approval processes.

These capabilities are shared at least in part with other IDCM systems' functionality. The IDCM environment has the capability to manage Web content within a continuum that includes initial document creation processes, potentially in a distributed environment, through to managed archiving of content.

ENTERPRISE REPORT MANAGEMENT (COLD)

As digital media have been developed, businesses with high volumes of management information reporting have made increasing use of Enterprise Report Management (ERM). These capabilities enable organizations to capture reports from business application databases and store them in a managed repository, to reduce printing, improve information accessibility, and maintain records.

Technologies that provide support for ERM include output reports in a range of formats. Examples of these include text-based digital format (e.g., XML) that is stored and searched via a document management application, and image format such as TIF or JPG that can be captured and accessed via a document management or imaging application. Reports may be captured on optical disk, using a capability known as Computer Output Laser Disk (COLD), which stores digital reports and enables data to be represented with graphical overlays to facilitate interactive communications.

General ERM capabilities are defined as follows:

- Capture of digital report objects to managed repository (document management, imaging, or COLD application).
- Utilization of indexing capabilities for capturing metadata relevant to the report.
- Support for inquiry and retrieval of metadata or report contents (where applicable).
- Management of database growth to support performance.
- Support for repository that can include different data objects.
- Support for document integrity.
- Control of processes through workflow.
- Provision of extraction and use of parts of reports.
- Support for high-volume printing.
- Management of security—user authentication, group and user levels.

WORKFLOW

Workflow management systems are designed to automate and implement controls over a diverse range of business processes, from the initiation of a process through to execution of all tasks, and process closure. The need for transparent interfaces between the workflow management system and IDCM is vital to maintain the integrity of documents or Web content files during their transition through a workflow process.

There are a number of technology options for enterprises that are seeking a workflow management capability. The most suitable workflow engine will depend on the nature and complexity of the requirement and the functionality supported by the workflow technology options. Options for workflow within the context of IDCM are:

- *Messaging/collaboration systems/workflow:* IDCM should support ad hoc and cooperative review and production of documents and reports, and it may be desirable to support integration with electronic forms for recordkeeping purposes.
- *Embedded workflow:* This capability is offered in systems such as document and Web content applications, or in application suites such as ERP systems. The host application provides inbuilt workflow for facilitating document-centric or process-centric modules.
- *Autonomous workflow:* These types are functional without any additional application software, with

the exception of database and message queuing. When used in the context of IDCM, the functionality may support automation of document or Web content review and approval processes.

IDCM ARCHITECTURE

The IDCM system model should feature scalable, flexible, and extensible applications that integrate with the enterprise information architecture, enabling the system to grow with the organization and facilitate knowledge sharing. Some architectural scenarios include:

- Scalability, flexibility, extensibility.
- Intuitive interface, preferably Web based, to facilitate usability, software upgrades, and support.
- Integrate with heterogeneous operating environments (where required).
- Implement three-tier (or "n-tier") client server architecture to facilitate Web client functionality and usability.
- Support distributed computing environment (databases, document/Web content repositories, replication services).
- Support mobile workers—access from remote sites, limited bandwidth.
- Integration with enterprise backup/recovery and business continuity regimes.

REASONS FOR UTILIZING IDCM SOLUTIONS

The business justification for implementing IDCM solutions ranges widely with respect to policy, compliance, and economics. For example, policy initiatives may include support for customer service initiatives, knowledge management (Laugero & Globe 2002), or risk reduction in relation to brand damage. Compliance with legislative requirements may include administrative requirements that support privacy and freedom of information legislation. Economic justification may include support for timely delivery of product to market, reduction in operational costs, continuous process improvement initiatives, and profit maximization strategies.

CRITICAL ISSUES OF DOCUMENT AND CONTENT TECHNOLOGIES

There are critical issues that must be managed, and it is imperative that organizations undertake risk analysis in order to identify risks and develop strategies to mitigate them. Table 1 summarizes some of the critical issues.

Table 1. A summary of critical issues of IDCM technologies

Business Issues	Technology Issues
Executive management lacks resolve Lack of executive management engagement, both at the start and during the project, may impair outcomes.	**Inadequate infrastructure** Client, server, and network architecture needs to be adequate to optimize performance.
Inadequate planning Poor definition of scope and inadequate product and project lifecycle management may impair outcomes.	**Incorrect technology application** Inadequate business definition and failure to examine solution options results in implementation of inappropriate technology solution.
Inadequate specifications Lack of analysis and determination of requirements leads to project complications and inhibits extensibility of applications across enterprise.	**Integrity of metadata** Metadata can be abused in non-validated fields, which may create significant retrievability issues.
Mandated use may cause rejection Document management is often mandated, without appropriate consultation and analysis.	**Security** IDCM solutions contain vital documents and content files, and security should reflect importance.
Lack of process integration Mandated use is often accompanied by failure to integrate capabilities with existing processes, often meaning duplication of effort.	**System incompatibilities** Lack of proven integration capabilities may impact delivery document/content management enabled end-to-end business solutions.

CONCLUSION

The IDCM model supports a business value proposition that aligns enabling systems and technology with an enterprise's strategic, tactical, and operational planning imperatives. The IDCM system architecture provides a range of enabling applications and technologies that support end-to-end business process improvement initiatives and provide a key foundation for knowledge management strategies.

KEY TERMS

Content Management: Implementation of a managed repository for digital assets such as documents, fragments of documents, images, and multimedia that are published to intranet and Internet WWW sites.

Document Capture: Registration of an object into a document, image, or content repository.

Document Imaging: Scanning and conversion of hardcopy documents to either analogue (film) or digital image format.

Document Management: Implements repository management controls over digital documents via integration with standard desktop authoring tools (word processing, spreadsheets, and other tools) and document library functionality. Registers and tracks physical documents.

Drawing Management System: Implements repository management controls over digital drawings by integration with CAD authoring tools and using document library functionality. Registers and tracks physical drawings.

E-Mail Management: Implements management controls over e-mail and attachments. These controls may be implemented by direct capture (e-mail archiving software) or invoked by the end-user in a document management application.

Recognition Technologies: Technologies such as barcode recognition, optical character recognition (OCR), intelligent character recognition (ICR), and optical mark recognition (OMR) that facilitate document registration and retrieval.

Workflow Software: Tools that deal with the automation of business processes in a managed environment.

Intelligent Agents for Competitive Advantage

INTRODUCTION TO MEASUREMENT AND REPORTING SYSTEMS

Since 1494 with the appearance of the double-entry accounting system, developed by Pacioli, those involved in business have attempted to measure business performance in an organized manner. As many accounting functions are repetitive in nature (payroll, inventory, etc.), accounting was one of the first business disciplines to which early computing technology was applied. Today we see comprehensive enterprise models that have been incorporated into ISO Standards in an attempt to build quality, capability, and uniformity into business enterprise systems. Supporting these models and systems is an effort to also launch the Extensible Business Reporting Language (XBRL), such that metadata models gain uniformity and make business information more readily accessible across systems and enterprises.

This article addresses a concept for transitioning from an "end of period" reporting model to one based on "push agents" delivering to the pertinent manager information that is key to managing the enterprise in near real time in order to gain substantive competitive advantage. The high-level model in Figure 1 demonstrates the suggested movement from an "end of period" model to an automated push agent model, with an intermediate step already utilized in some enterprises, that is a "dynamic query model."

Comparing where we are today in business reporting to that of network reporting, Computer Associates, perhaps the first to offer comprehensive, automated agents that forewarn of impending network trouble introduced some time ago neural agents that measure current states as they change against historical databases of past network activity in order to discern conditions that may be reoccurring and are similar to those that caused problems previously. Such detections may involve likely equipment failure to circuits becoming overloaded, with automated warnings and recommendations as to corrective actions being sent to the appropriate manager via the chosen message system (e-mail, voicemail, paging, etc).

Such "heads-up," automated, near-real-time reporting of impending conditions permits network operators to be proactive in addressing problems before they occur. Such real-time network feedback requires an enterprise to develop "key performance indicators" (KPIs), or key measurements that it wishes to track against to plan and run the enterprise. Here, many products are on the market that address the identification of such KPIs and go by the names of "Cockpit Charts," "Digital Dashboards," and "Balanced Scorecards." The secret of the balanced scorecard and the reason it has gained such wide acceptance is primarily due to the fact that it allows organizations to reach their full potential by putting strategy—the key driver of results today—at the center of the management process in organizations facing uncertain equity markets, an accelerating pace of change, and increased expectations for productivity and results. The comparative characteristics of reporting models are listed in Table 1.

Instead of waiting for end-of-period reports, critical measures can be monitored in near real time as a function of the KPIs assigned to each measure, as seen in Figure 2.

Figure 1. Migration of reporting models for competitive advantage

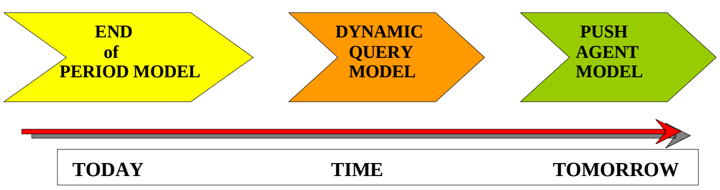

Table 1. Comparative characteristics of reporting models

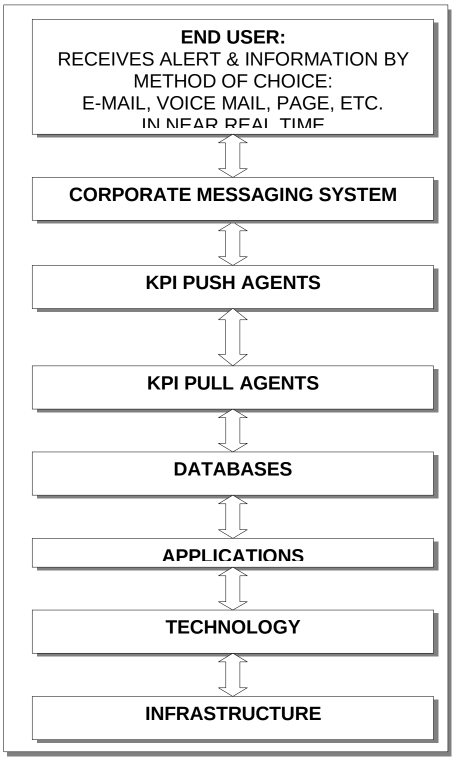
Type of Reporting	End of Period	Dynamic Query	Push/Pull Agents		Pull/Push Agents
Timeliness of Data	Stale	Near Real Time	Near Real Time		Near Real Time
Potential for Managerial Filtering	Yes	No	No		No
Delivery Choice	No	Not Typically	Yes		Yes
Alerts	No	Not typically	Yes		Yes
Silo Issues	No	Possibly	No		No

Figure 2. Simplified intelligent agent push model



BENEFITS OF EMPLOYING A BUSINESS MANAGEMENT PROCESS INTELLIGENT AGENT TOPOLOGY

Erik Thomsen, Distinguished Scientist at Hyperion Solutions Corporation, defines the term "agent" as:

"...a solution-oriented ensemble of capabilities including natural language processing, autonomous reasoning, proactive computing, discourse modeling, knowledge representation, action-oriented semantics, multimodal interaction, environmental awareness, self awareness, and distributed architectures."

He describes the following five areas where the potential impact of intelligent agents on the logical functionality and physical performance of traditional business analytic systems can be positive (Thomsen, 2002):

- Agents should help move business intelligence (BI) from being application centric to being truly process centric, and provide a single point-of-access to distributed information. This is operationalized in intelligent agent solutions by self-description of individual modules that is made available to the system of agents as a whole, and a user's personal agent being able to query all librarian agents responsible for various data sets in an organization for specific information.
- An active dialog is needed between the software and the user to seek out and learn user wants, and be able to anticipate/predict user wants in the future. Thus in addition to tailoring client layers to individual users and enhancing BI applications with options and preferences, the software/intelligent software agent plays an active role in querying the user.
- As attention shifts to business process as much as data states, the number-centric BI applications will have to provide more integrated text and multimedia handling.
- Intelligent software agents can provide personal analytic "coaching" for higher-level business processes by observing, learning about, and interacting with users. Agent applications within an overall BI/Business Process Management (BPM) framework can be deployed to encode horizontal and domain-specific analytic knowledge.

- The server side of most BI applications is very complex due to the changes in the load patterns/ factors and the wide range of physical tuning options. Intelligent physical optimizers can evaluate their own physical organization and, optionally, interact with an administrator before performing any reorganization.

A survey by Lederer, Mirchandani, and Sims (1998) indicates that businesses adopting Web-based information systems (WISs) responded that the most important benefit of being on the Web was to "enhance competitiveness or create strategic advantage." Intelligent online agents can help simplify complex Web environments acting as artificial secretaries (Maes, 1994). Nwana et al. (1998) define agents as "software entities that have been given sufficient autonomy and intelligence to enable them to carry out specified tasks with little or no human supervision." There is no standard definition for intelligent agents, but they are generally described (Decker, Pannu, Sycara & Williamson, 1997; Specter, 1997; Hendler, 1996) as programs that act on behalf of their human users to perform laborious and routine tasks such as locating and accessing necessary information, resolving inconsistencies in the retrieved information, filtering away irrelevant and unwanted information, and integrating information from heterogeneous information sources.

Business intelligence software using intelligent agents and BI technologies such as data marts/warehouses, data mining, Web site analytics, modeling and predictive tools, and data visualization tools can help analyze customer data to make connections that can boost sales, increase efficiency, and retain customers. The BI server connects to the data sources and provides analytical services to clients, which access the BI server through a Web interface or other desktop client. An application server typically provides the Web interface and often runs on the same server as the BI software.

The key benefits of employing a business management process intelligent agent topology are as follows:

- Timeliness of reports
- Automated measurements against planned goals
- Unfiltered information
- Delivery based on the end-user's preference

The key features that should be analyzed when evaluating BI reporting tools are as follows:

- Analysis: The ease in creating reports and the end-user's ability to manipulate the report once distributed.
- Formats and data sources supported.
- Data access: Preferably provide data-attribute-level security.
- Price: This can be compared based on a given number of users, on a specific hardware configuration.

To enable enterprises to better track and manage cross-departmental performance, BI vendors are rolling out frameworks designed to help enterprises integrate and leverage multiple existing BI systems and analytic capabilities. Theoretically, this enables a powerful enterprise-wide management tool for optimizing performance and profits. However, in practice, there are challenges associated with these frameworks that range from data acquisition, cleansing, and metadata management to aligning models and delivering performance management.

POTENTIAL DRAWBACKS OF EMPLOYING A BUSINESS MANAGEMENT PROCESS INTELLIGENT AGENT TOPOLOGY

The pressures on the management team are intense. Executives often struggle to integrate multiple data sources that can then be analyzed and synthesized for financial reporting. For example, inventory data may be stored in the data warehouse while sales information is housed elsewhere. In addition, executives may want to close their books as often as daily, without having to wait until the end of the month to address a problem that could affect revenue or earnings forecasts.

Business intelligence tools are best suited for allowing executives to drill down into the source of financial reports to review their accuracy. For example, if an employee forgets to book an order in an order management system, but makes the adjustment in the general ledger, a BI tool could start investigating further; if anomalies are found, it is critical to drill into the support data to determine the reason. However, a majority of BI systems would be hard-pressed to catch someone intent on committing fraud if the data was entered correctly in the data capture system.

Enterprise application vendors also are adding analytics to back-end financial systems to help companies better leverage raw transactional data. For example, PeopleSoft has embedded analytics in its financial module designed to report to executives on a daily basis the status of KPIs. Executives have little time to analyze data before senior management inquiries begin, and they need visibility across the internal and extended supply chain to have the control in their organization. With a broader audience, the need for more detailed intelligence will drive analytics that are targeted not only at specific vertical industries, but at specific departments and roles. However the dangers of creating more analytic silos cannot be overemphasized.

It is prudent to remember that pressure to act may result in erroneous actions. Business survival depends on an infrastructure that can adapt to changing market conditions. With companies focused on leveraging existing resources and increasing efficiency, infrastructure is no longer just an operational cost of doing business. Solution providers are paying attention to this growing need for intelligent infrastructure, with companies such as Network Appliance Inc. and Web Methods Inc. partnering with BI vendors to bring new abilities—such as storage analytics and business activity monitoring—to their solutions which can help companies realize the full potential of their resources.

CONCLUSION

This article conceptualizes the transition of intelligent agents utilized in network performance management into the field of business and management. A tiered IA system could be implemented at many levels of management and could be the key for successful, timely knowledge management strategies and successes. Such a system would be timely, unbiased, objective, and should provide significant competitive advantages. Moreover, it could leverage existing assets and provide a single objective measure of employee performance at appraisal time.

Although there has been some progress in increasing the number of users in the area of query and reporting, a lot more progress needs to be made between closing the loop between decision making and operations. IA benefits realized in telecommunications networks, grid computing, and data visualization for exploratory analysis connected to simulations should likewise be achievable in business management processes.

KEY TERMS

Data Mart: Database containing data extracted and often summarized from one or more operational systems or from a data warehouse and optimized to support the business analysis needs of a particular unit.

Data Mining: A component of business intelligence decision-support process in which patterns of information in data are discovered through the use of a smart program that automatically searches the database, finds significant patterns and correlations through the use of statistical algorithms, and infers rules from them.

Data Warehouse: A form of data storage geared towards business intelligence. It integrates data from various parts of the company. The data in a data warehouse is read-only and tends to include historical as well as current data so that users can perform trend analysis.

Enterprise Deployment: Term used in the computer industry to describe hardware and software configurations. They are aimed to address the corporation as a whole as opposed to a single department.

ERP: Enterprise resource planning system. Enables the company to integrate data used throughout the organizations in functions such as finance, operations, human resources, and sales. This system extends the pool of information for business intelligence.

Knowledge Management: Application for any business to create, maintain, and share company knowledge. The challenge of capturing collective experience, core values, and expertise of an organization.

Metadata: The information a database or application stores to describe the university's business data and the applications that support it. Refers to the information used to describe a set of data.

Portals: Means entry point. Describes the entry point for users to information available throughout the World Wide Web.

Set-Based Analysis: A recent method that uses groups of sets. It facilitates the examination and comparison of data.

Slice and Dice: Another term for multidimensional analysis. When data has three (or more) dimensions, it can be thought of as being arranged in a cube (or hypercube), with each side representing a dimension. When the data is analyzed, part of the cube can be "sliced" off or "diced" to get to an individual cell.

Intelligent Business Portals

Xue Li
University of Queensland, Australia

INTRODUCTION

Business Portals are now widely used in e-commerce. Intuitively Portals can be regarded as an information gateway for exchanging business information over the Internet. The process of business information exchange requires the services of *security and access control*, *interoperability* over a variety of software of platforms and systems, *interconnectivity* for communications among different data communication networks, and *scalability* for information being sharable on different hardware devices. So, portals can also be regarded as an information carrier for delivering the right information to the right user, at the right time, to the right place, to make the right decisions. A portal is a packaged piece of information with the properties of self-servicing, personalization, and real-time delivery. From a business point of view, a portal is a mobile, self-explanatory, and just-in-time delivered piece of information. In e-commerce, business information is a set of time-stamped transactions that can be triggered by events in business activities. This article will illustrate and explain the architecture of intelligent business portals for Web-enabled business applications.

BACKGROUND

The portal concept was introduced by Merrill Lynch (Shilakes & Tylman 1998). It was estimated that by the year 2002, the portal market value in Business Intelligence will reach US$7 billion(Bergert 2000), in Content Management will reach US$4.5 billion, and in Data Warehousing and Mart will reach US$2.5 billion. This fast growth has been attributed to the World Wide Web on the Internet and the high-speed network infrastructure.

The origination of portals comes from a question on how we could deliver the right information to users. In traditional *pull technology*, individual Web users have to initiate the search operation to find information on the Web, while in *push technology*, information is sent to individual users with or without solicitation. On the other hand, a user may need to interact with a system to provide information (such as filling out a survey form). Thus, there is a need to provide an application-independent mechanism for switching information between information providers and requestors. This requirement has generalized the traditional many-to-one client-server relation into a many-to-many client-server relation. Inevitably, an information explosion is introduced on the Web. Many Web users are frustrated in dealing with the overwhelming information bombardment. To solve the problem, the portal as a packaged piece of information is used for delivering the right information to the right user.

PROPERTIES OF PORTALS

A portal has the properties of self-servicing, personalization, and real-time delivery. For *self-servicing*, a user would be able to use predefined templates to redesign personalized Web pages. For example, an employee in a business organization can be assigned by a predefined Web site according to the business roles played by the individual. The employee can then modify the Web site according to personal interests and preferences. This Web site then is used to conduct the business.

For *personalization*, a user would be able to deliver and receive information that is dedicated to the person. For example, portals are used by university students to select subjects and view personal enrollment information. For *real-time delivery*, a portal is used as a messaging tool to deliver instant messages to an individual.

From a business point of view, a portal provides mobile, self-explanatory, and just-in-time delivered information. Business intelligence is about how to apply knowledge to making business decisions, searching for useful information, or controlling the business processes.

When portals are used as an approach to the fundamental information infrastructure of e-businesses, we need to know how to maximize their usefulness in order to improve our business performance, competitiveness, and viability. Intelligent portals would be portals with knowledge in order to be driven around on an intranet or on the World Wide Web. In other words, by capturing the domain-specific business knowledge, we can deploy portals on the Web and let their behavior be controlled by a knowledge base. In this case, a knowledge management system (Choo,1998; Liebowitz & Wilcox, 1997) would play an important role in an e-business environment.

This article discusses the theoretical issues on the integration of knowledge management systems with portal deployment mechanisms. We will illustrate and explain the technological issues in designing and implementing intelligent business portals for Web-enabled business applications.

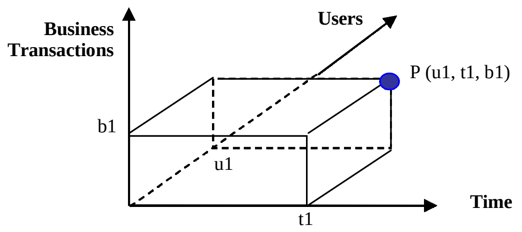
INTELLIGENT PORTALS

Intelligence is the execution of knowledge. When a reasoning mechanism is invoked by a question or a problem, the relevant knowledge is retrieved and a possible answer or solution is then concluded. Intelligence also implies the capability of finding the best solution for a problem. In a business environment, knowledge can be in different forms. It could be a set of if-then production rules for decision-making problems, a set of facts for corporate infrastructure descriptions, or a set of procedural descriptions for the business transactions. Business activities are event driven, so the timely execution of certain business processes is crucial to the success of business. This research area is mainly covered by workflow management (Marin, 2001; WfMC, 1996).

A portal in this context is an information feeder that will satisfy the information needs of different users at different times for different business processes. In Figure 1, it can be seen that a point *P* in the 3-D space is the information about *who is doing what at what time*. Since the business activities can be the predefined workflows (like an application for an insurance policy will go through a step-by-step process to get an approval), a workflow control system should be able to check the information requirements for a particular business process and a particular person. For example, in Figure 1, point *P* may be interpreted as a person "John" on "Monday, 3 Nov, 2003" at "9am" is "placing an order to buy a product".

In an e-business, if a Web site is designed for online ordering, while a user is online, the system should be able to deliver context sensitive information to the order form (e.g., user account number, best sales, etc). Furthermore, a reasoning mechanism may be triggered for context-sensitive reasoning and decision making. In this case, an intelligent portal is a context-sensitive information/service supplier that will accompany the user through the lifetime of the transaction. The 3-D space of the workflow control illustrated in Figure 1 shows the demands of the intelligent portals.

Figure 1. Three-dimensional space for the workflow control



PORTALS VS. AGENTS

Here we need to differentiate intelligent portals from intelligent agents. Intelligent agents (Knoblock & Ambite, 1997) are mobile software programs and are task oriented, while intelligent portals are information carriers and are content based. By using agents, we get things done; by using portals, we know what happened and what information should be supplied. One of the advantages of intelligent portals over intelligent agents concerns the acceptance by general users: agents are the programs to be executed on the clients' machines, while intelligent portals are the pieces of information driven by knowledge to deliver Web services. Consequently, there is no fear from users about potential virus attacks.

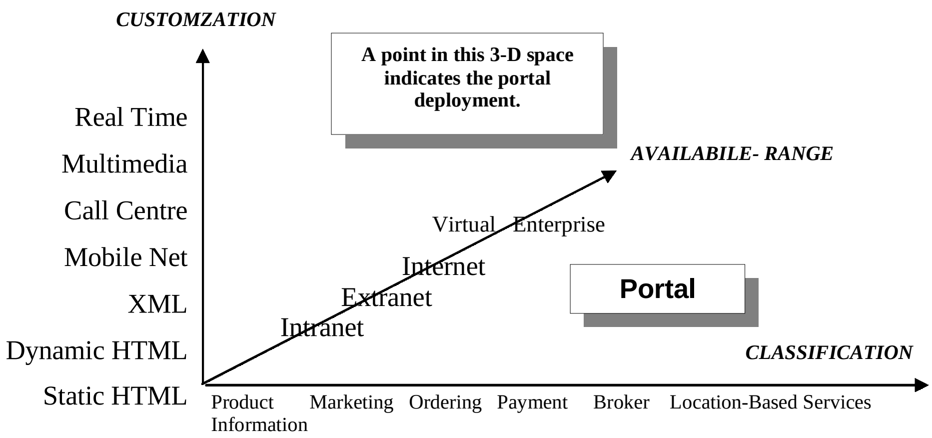
KNOWLEDGE MANAGEMENT WITH PORTALS

In a business environment, knowledge management has many aspects, from low-level, day-to-day business process control to high-level, executive decision making. A knowledge management system should be able to collect relevant knowledge, store knowledge in a sharable enterprise memory, communicate the knowledge with parties, and maintain consistencies. In all these activities, a portal can play an important role within an enterprise, that is, as an information carrier to shift information around the organization.

One important task relating to portals in knowledge management is Workflow Management (Allen, 2001; WfMC, 1996). Workflow management involves:

- *Specification* of process control for business transactions, which concerns data coordination, exception handling, recovery, etc. The workflow specifications provide execution plans.
- *Verification* of the feasibility and correctness of a design, while allowing for re-design and implementations for coping with changes.
- *Execution control* for carrying out business transactions. A Workflow Engine is responsible for execution of the processes. During any given execution, a workflow plan may be applied to many individual users. As a result, many concurrent workflow

Figure 2. Deployment of intelligent business portals



instances will be generated. The Workflow Engine is responsible for concurrency control (process dependencies), exception handling, and recovery.

In Workflow Management, portals can be used as basic constructs to build workflow tasks (Marin, 2001). For example, in processing a procurement request (e.g., purchasing a laptop computer), one may need information about competing offers from different suppliers. In this context, a portal should play a role not unlike a real-life broker who can assess the buyer's requests and evaluate the seller's offers in order to make a deal.

Portals Deployment

Knowledge about portals is presented from three aspects: ontological services, applicability services, and directory services. These three services answer the questions of what portals are, where they are used, and for what they are used. Ontological services are facilities that categorize business information into a searchable, indexed structure with the meaning of the data (e.g., Classification dimension in Figure 2). Availability services provide maps of portals over the Internet for their availability (e.g., Available-Range dimension in Figure 2). Directory services are a view of the information tailored for personalized service (e.g., Customization dimension in Figure 2, as well as location-sensitive services such as those portals for the mobile phone and PDA users. These three aspects are orthogonal in the sense that they make up the key information required for providing business data over the Internet. Figure 2 shows the idea of the deployment of the intelligent portals.

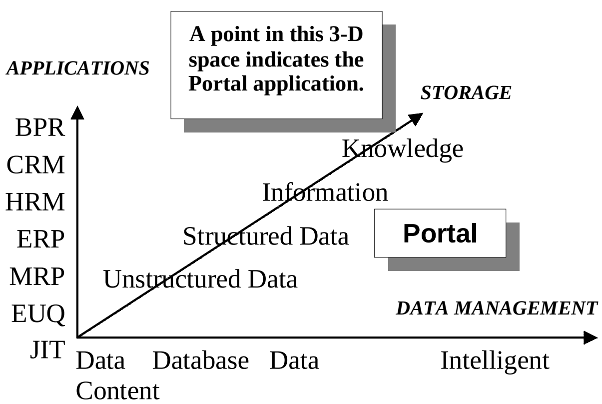
It should be pointed out that the security services and access control for the intelligent portals are embedded in all dimensions of the above discussions.

Portals Development

In Figure 3, we show the intelligent portals in a three-dimensional paradigm for representation purposes. In the Storage dimension, the business data are packaged as structured data, unstructured data, or knowledge in a ready-to-use format. In the Data Management dimension, the business data are the objects managed within databases, data warehouses, intelligent applications, and content-management systems. In the Applications dimension, the business data are the objects in Business Process Restructuring (BPR), Customer Resource Management (CRM), Enterprise Resource Planning (ERP), Material Resource Planning (MRP), or Just-in-time Delivery (JID), etc. applications.

By identifying these three dimensions of business portals, we will be able to design and manage portals in a way that they are "intelligent" – i.e., the portals as

Figure 3. Development of intelligent business portals



packaged business data will be "living" in a business transaction management environment and will be "clever" enough to deliver the business data on the Internet at the right time, to the right places.

In order to use intelligent portals, we need to design the business workflow so that an event-driven workflow engine can be integrated with a portal delivery system.

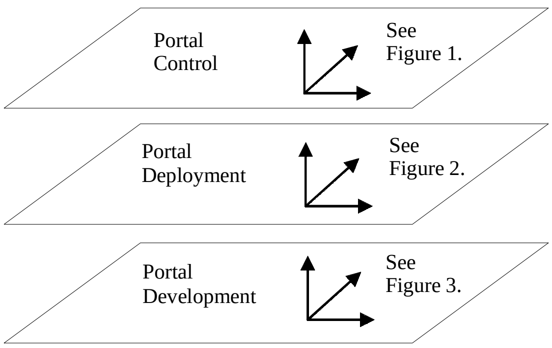
A LAYERED ARCHITECTURE

We identify that intelligent portals are organized in three layers (see Figure 4). From the top, the Portal Control Layer is used to describe the Portal's application logic, which concerns how and when Portals are used in e-Business applications. Figure 1 shows this aspect in a 3-D space. The Portal Control Layer provides information to applications. The middle layer is the Portal Deployment Layer. The Portal Development Layer concerns how and where Portals are deployed. Figure 2 details a 3-D space for portal deployment. At the bottom layer, we discuss portal development. The portal is conceptualized in a 3-D space in order to package data into highly structured and managed pieces of information.

KEY COMPONENT: INFORMATION BROKER

The intelligence of portals relies on the performance of a kernel system component called the Information Broker (see Figure 5). It is responsible for pushing portals to users at the right time. The Information Broker is also capable of searching information for user needs. It is an executor of business workflows that is context sensitive to user requests for information. Its input consists of the User Profile (UP) and the stored information of the Business Workflow (BW). By using UP, the system knows the requirements of individual users. By using BW, the system knows how and when to deliver what information. Figure 5 shows the architecture of a Web site that uses the Information Broker as a key component of portals.

Figure 4. Three layers of intelligent portals



BUILDING INTELLIGENT PORTALS

In order to build intelligent portals, we need to select the right tools to put them together. However, there is currently no consensus on a standard for portals or intelligent portals. In the following discussion, we provide some suggestions from currently available tools.

Figure 6 shows the architecture of the Information Broker – the key component that needs to be built. It is an integrated system that carries out information brokering. The Workflow Engine is a sub-system with knowledge on how portals are used. The Search Engine is a sub-system that knows where to find and collect information, while Portal Management is a sub-system that knows what information is available. The implementation of this component relies on the proper usage of the Web services that can support the distributed information management and the information subscriber/provider architectures.

Portals can be implemented in XML. Many tools provided by major companies (e.g., Microsoft, Oracle, IBM, etc.) are now supporting XML (Finkelstein & Aiken, 2000) used for portals. As that of SQL can be used to represent inference rules, when using XML to represent knowledge, the domain structural knowledge must be specified in a standard Document Type Definition (DTD) as a set of rules to validate the portals. There are many specialized XML in business applications (e.g., FXML, see http://www.finxml.org.). Also, OML/CKML (Kent, 1999) provides a conceptual knowledge framework to specify the

Figure 5. Architecture of a Web site that uses intelligent portals

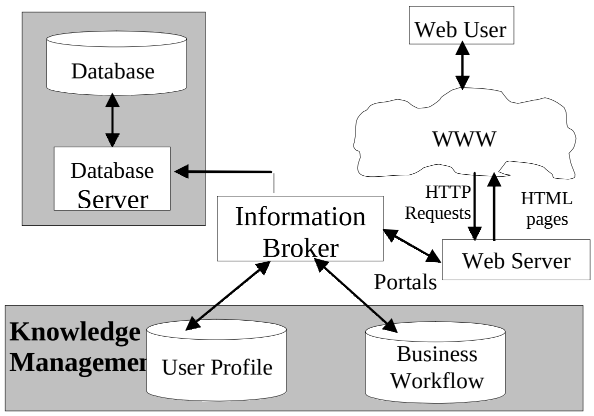


Figure 6. Architecture of information broker

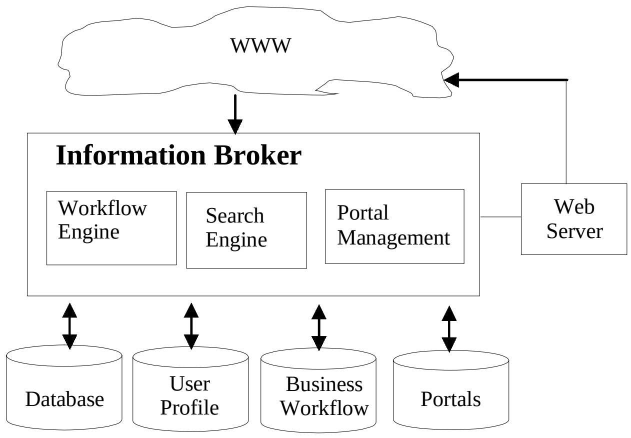

ontological and schematic structures and domain knowledge of data analysis, information flow, and concept lattice (Sowa, 1999). Portals as a content-based approach is becoming a major application of XML.

FUTURE TRENDS

More and more service or content providers are now changing from free services to paid subscriptions. This change requires business portals to play a main role in business applications. As portals are capable of packaging information for its intelligent delivery, the future of this technology can be characterized as follows:

- **Personalized services.** Portals will be more and more used as a vehicle carrying around timely information to users on the World Wide Web. Personalization is a way that different users would be served with the special needs.
- **Self-explainable information services.** With the maturity of Web-enabled business ontology, portals are to be used as a semantic tool to make effective communications among different applications.
- **Uniform interactivities.** XML has provided a language to specify contents, while portals are used to answer the question on how contents are delivered. By using portals, the first class citizen of the WWW would be those well-organized and purposely packaged pieces of information communicating through the protocols such as UDDI, SOAP, and WSDL.
- **Harmonizing business transactions and workflow.** With a large amount of information transmitting on the Internet is now a part of business transactions in situations such as B2B, B2G, etc., portals will be regarded as intelligent because of their ability to be transactional.

The architecture of portals, as illustrated in Figures 5 and 6, will evolve from traditional client-server of many-to-one service pattern to the flexible services patterns such as P2P or many-to-many client-server patterns.

CONCLUSION

Currently the contents on the World Wide Web are evolving from passive hypertext documents to active distributed services (Li, 2000; Zirpins, Weinreich, Bartelt, & Lamersdorf, 2001). By providing self-servicing, personalization, and real-time delivery, portals can actively deliver information to Web users. In this article, we have discussed the following problems:

- What are intelligent business portals?
- What potential do they provide?
- What is the architecture of intelligent portals?
- What are the technical issues in implementing them?

In order to implement intelligent portals, we have discussed a three-layer architecture that reflects the usage of the modern information technology infrastructure. At the development layer, portals are packaged according to the needs. At the deployment layer, portals are allocated to their applications. At the top control layer, portals become knowledgeable and know how, where, and when to deliver their services. The key component in our architecture is the Information Broker who is responsible for implementing the three-layer intelligent portal architecture.

KEY TERMS

Business Intelligence: Business information systems have transitioned from function-oriented to knowledge-oriented systems. Business intelligence is a study of business rules that are the best in practice. Intelligence is the execution of knowledge. Business intelligence is related to the knowledge acquisition, repository, sharing, and application in the activities of an organization. Business intelligence is becoming a necessity to the most business organizations to be carried out in their business procedures and functions. Business intelligence has now emerged as a sharable commodity embodied in commercial software and no longer something that could only be possessed by a small bunch of experts.

Information Broker: A key software component that supports intelligent portals. Information Broker has ability to coordinate between search engine, workflow engine, and portal management. Without an Information Broker, an individual user's profile would not be managed and consequently would not be serviced by context-sensitive portals. Information Broker may work behind the Web server to provide the personalized services for Web users. It may also work directly with WWW for searching Web services online.

Intelligent Portal: Portal designed for decision-making purposes. Intelligent Portal is not an agent program but a content-based information package that *knows* what it is used for and how it can achieve its goal. In practice, intelligent portals are supported by a software component, namely, *Information Broker* running on application servers over the Internet. The intelligence comes from the mechanisms that support the portals to deliver information at right time to the right place.

Personalization: From the service provider's viewpoint, any service provided to a user should be personalized. Personalization is a process through which the system utilizes the knowledge about a user to tailor the service to suit the online user with a flavor of the individuality. An automated personalization may promote the service provider's image and improve the effectiveness of the system functions.

Portal: A self-addressed information package with the ability to be *pushed* or *pulled* among Internet applications. It is self-contained with meta data for its information structure and presentation. Compared with the concept of *datagram* on the Internet, portal can be regarded as a kind of *information-gram* on the Internet for its properties of self-service, personalization, and real-time delivery. Mostly portals are implemented in XML.

Self-Service: One of the major differences between traditional business information system and current Web-enabled business information systems is that the user does not need to be trained and is assumed to have sophisticated prerequisite knowledge to be able to use the system. A Self-Service system is a new trend of business systems that is Web-enabled and has a user-configurable interface. A system is deployed on the Web with a generic user interface. Self-Service allows online users to select system functions to construct a Web information system in a way that is best suited for the user's information needs.

User Profile: With a large number of customers, a service provider may need to analyze its customers in terms of a list of identified business-critical factors. A user profile is a dynamically maintained data repository that groups user behaviors and classifies them into different categories according to their attributes such as age, gender, profession, etc., so that the user profile may be used as a resource of business intelligence.

Workflow Engine: A software component defined by WfMC (WfMC, 1996). Workflow engine is application independent. When a workflow plan is executed, there may be multiple workflow instances concurrently running at different states. Workflow engine is responsible for resolving the problems such as resource/data dependency, process dependency, live-lock or deadlock, event-trigger handling, etc.

Intelligent Metabusiness

Luiz Antonio Joia
Brazilian School of Public and Business Administration of Getulio Vargas Foundation and Rio de Janeiro State University, Brazil

INTRODUCTION

In 1994, the Sloan School of Management at MIT inaugurated a multi-year research and education initiative called "Inventing the Organizations of the 21st Century", headed by Thomas Malone, Director, Center for Coordination Science. One of the key activities of this initiative has been developing a series of coherent scenarios of possible future organizations. The Scenario Working Group considered a wide variety of possible driving forces, major uncertainties, and logics that might shape 21st century organizations. Two scenarios were then created addressing the size and the *modus-operandi* of the future organizations: "Small Companies, Large Networks", as the one found in Northern Italy (Textile Production in the Prato region of Italy), and "Virtual Countries", as more mergers and acquisitions are turning up worldwide (e.g., Exxon and Mobil) (Laubacher & Malone, 1997).

One of the greatest challenges of the new knowledge economy is to deal with new organizational forms, that is, the ones that challenge traditional notions of structure, coordination and control, such as the companies derived from the "Small Companies, Large Networks" scenario. When all of the tasks and processes of an enterprise are centralized in just one company, it is far from difficult to organize and manage the knowledge accrued from a project. However, a lot of different players can now be involved in major projects. Hence, how is it possible to manage and store the knowledge generated during an enterprise, so as to use it during the current project and not to lose it at all for future projects?

Some very important researchers addressed some features on this issue, such as Badaracco (1991), Bahrami (1992) and Baker (1994), just to name a few.

Notwithstanding being very important in their realm, this research just taps on how to create, deploy, transfer, store and retrieve the intelligence of an enterprise encompassing a lot of different companies, in different places, with different " although important " duties. Therefore, the next logical step includes expanding the research to ongoing and ad-hoc intraorganizational groups. In order to accomplish this, it is paramount to understand how information technology can leverage and strengthen the knowledge links among the players of a major project involving a lot of subcontractors, suppliers, and other firms, namely a metabusiness.

BACKGROUND

Metabusiness

A metabusiness or a relational company is a *quasi*-firm created through digital links among several companies, in such a way that it is almost impossible to know exactly its boundaries (Keen, 1991). A metabusiness is also independent of its organizational structure, as each node has its own structure that can be changed without interfering in other nodes' structures.

"The Organization is its Formal Structure" and "Structure follows Strategy" are two paradigms challenged by metabusinesses that wisely use information technologies.

This overview presents the role and impact of information technologies in three branches of a metabusiness: its degree of connectivity, its degree of sharing and its degree of structuring (Haeckel & Nolan, 1993). According to the latter authors, these three parameters are considered vital to establish the intelligence of a metabusiness and its expertise to manage the involved knowledge.

The connectivity issue addresses the "degree of reach" of the metabusiness, that is, if and how the involved companies are linked within the metabusiness in order to transmit data and information among themselves.

The sharing issue addresses the "degree of range" of the metabusiness, that is, the type of transactions developed within the metabusiness, and the way the companies are working together, in order to set up a workgroup environment.

Finally, the structuring issue deals with the ability that the companies have to extract knowledge from the data and information retrieved and shared by them. As is known, knowledge " either tacit or explicit " is much more than data and information, and according to the Autopoiesis Theory (Maturana & Varela, 1980) is created when a "structural coupling" occurs with the workers (see also, Kim, 1998). This overview shows that this issue is a key point for the success of an enterprise, and the one where the major flaws and drawbacks occurred. People have great difficulty to transform raw data and information into knowledge, as well as tacit to explicit knowledge, notwithstanding several frameworks explaining how this can be processed, as the Knowledge Spiral from Nonaka and Takeuchi (1995). The current educational system hinders workers to learn how to learn, making it difficult for them not to create standardized mental models to deal with new knowledge.

Hence, different technologies such as Electronic Data Interchange (EDI), Electronic Document Management Systems (EDMS), Workflow Systems, Internet/intranet/extranet and mainly Web-Based Instruction (WBI), just to name a few, are integrated to leverage the metabusiness' intelligence.

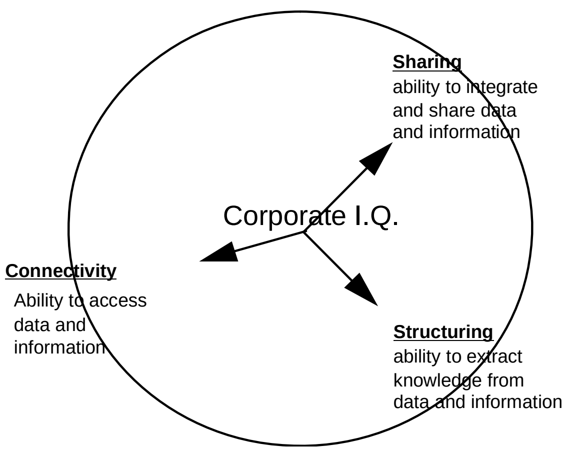
Intelligent Metabusiness

As was already said, metabusiness is a quasi-firm created through digital links among several companies, in such a way that it is almost impossible to know exactly its boundaries (Keen, 1991). This definition matches the "Small Companies, Large Networks" scenario of MIT Scenario Working Group (Laubacher & Malone, 1997). In a metabusiness, the integrator keeps the core competency of the business, outsourcing most of the other productive processes. The integrator is in charge of managing dependencies and restrains among the players and their due processes, coordinating the transactions among the involved partners.

According to Prusak (1997), some trends are forcing companies to be engaged in a metabusiness:

a) the globalization of the economy and the terrific pressure on firms for increased adaptability, innovation and process speed;
b) the awareness of the value of specialized knowledge, as embedded in organizational processes and routines of the nodes of a metabusiness;
c) the awareness of knowledge as a distinct factor of production; and
d) cheap networked computing, which is at last giving us a tool to work and learn with each other.

Figure 1. Corporate I.Q.



During the development of an enterprise, data and information are exchanged among the players compounding the metabusiness. Data and information are not knowledge, although often considered as such. There is great misunderstanding and confusion about the differences between data, information and knowledge.

Data means a set of discrete and objective facts concerning events. Therefore, it can be understood as a structured record of transactions within an organization (Davenport & Prusak, 1998).

Information is data that makes difference and is relevant, or as Peter Drucker says: "information is data with attributes of relevance and purpose" (cited in Davenport & Prusak, 1998, p.4). Normally, information is understood as a message, usually having the format of a document or visual and/or audible messages. Information is, above all, context-based.

Knowledge is linked to the capacity of action (Sveiby, 1997). It is intuitive, therefore hard to be defined. It is linked to the user's values and experience, being strongly connected to pattern recognition, analogies and implicit rules. Most of the time, knowledge within an organization is located both inside employees' heads (tacit knowledge) and in documents (explicit knowledge). This can explain why too much confusion has arisen between document management and knowledge management.

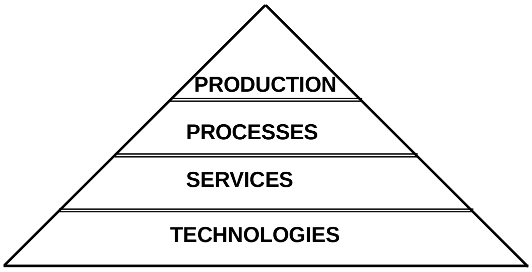
Although it is a generally accepted distinction, doubts have been cast recently over the tacit-explicit dichotomy (Polanyi, 1958). According to the autopoietic epistemology school (Varela, Thompson, & Rosch, 1992), knowledge is a private, personal thing, and so an organization cannot possess it. Hence, knowledge cannot be explicit, only tacit: Explicit knowledge is actually data and/or information which help other people to create their own knowledge through what is known as "structural coupling". However, this overview will accept the tacit-explicit distinction, which will enable us to reach more interesting conclusions.

Then, assuming the tacit-explicit dichotomy, the following mathematical formulas depict what was said (Joia, 1999):

INFORMATION = DATA + $\sum$(Attributes, Relevance, Context)
KNOWLEDGE = INFORMATION + $\sum$(Experience, Values, Patterns, Implicit Rules)

The main question is to know how knowledge can be transformed into metabusiness intelligence. Using the I.Q. metaphor (notwithstanding its flaws), it can be said that the metabusiness I.Q. (Haeckel & Nolan, 1993) can be

Figure 2. Taxonomy of the integrated model



evaluated through the enterprise's capability of connectivity (ability to access data and information through internal link and link with its partners), sharing (data and information shared among its personnel, and its partners) and structuring (ability to extract knowledge from information and raw data). Figure 1 (Joia, 1999) depicts this concept.

AN INTEGRATED MODEL FOR INTELLIGENT METABUSINESS

To integrate all of the technologies in a structured taxonomy for intelligent metabusinesses, it is taken for granted that technologies are important as they can allow services to be deployed, and services are important as they convey to productive processes, according to the following formula: TECHNOLOGIES => SERVICES => PROCESSES => PRODUCTION , as shown in Figure 2, according to Joia (2001).

Therefore, Table 1 (Joia, 2001) can present more deeply the idea shown in Figure 2, relating the Connectivity, Sharing and Structuring issues " the three facets of an intelligent metabusiness " with the needed services and productive processes within a relational enterprise.

Barriers, Causes and Solutions

Notwithstanding the great advances in the connectivity and sharing technologies and services, the same can not be said concerning the structuring technologies and services. Although great advances have been made lately, such as the development of the data mining technology, this realm is the bottleneck for the effective development of the metabusiness' intelligence. Structuring, as said before, is about creating meaning (or knowledge) for lots of data and information. Some research shows that the overload of information does not necessarily convey to adequate knowledge creation (Joia, 1999) and is the main cause of problems in complex enterprises developed in a metabusiness way. The

Table 1. Integrated model for intelligent metabusiness

	CONNECTING	SHARING	STRUCTURING
TECHNOLOGIES	Client-Server Based Intranet, Extranets, LAN, WAN, Satellite Links, Dedicated Links, Fiber-Optics Network	Internet, Groupware, Electronic Data Interchange (EDI), EDMS, Workflow, Video-Conferencing and Distributed Data Base	Web-Based Instruction Systems, Data Mining, Expert System
SERVICES	Physical Link among the players (Star Topology with the Integrator as the Hub)	Data and Information Transactions, Forms Exchange, Documents Life-Cycle Control and Tracking	Education Anytime, Anywhere Just-in-Time Education, Knowledge Acquisition, Pattern Recognition
PROCESSES	PRODUCT INNOVATION; OPERATION MANAGEMENT; PLAYERS' COORDINATION (management of restrains and dependencies); QUALITY CONTROL OF THE NODES OF THE METABUSINESS

PRODUCTION

Table 2. Barriers, causes and solutions within an intelligent metabusiness

BARRIERS	CAUSES	SOLUTIONS
Structural		
Focus only on direct man-power and indexes	Obsolete decision criteria	Deep analysis of the costs and benefits involved
Failure to perceive the actual benefits	Lack of measures to intangible benefits	Intangible and tangible productive analysis
High risk for the managers	Reward system not considering innovation	Different reward systems for managers
Lack of coordination and cooperation	Organizational fragmentation	Systems to allow coordination/cooperation
High expectation and hidden costs	Selling of an unreal system	Planning strategic objectives
Human		
To avoid the risk	Fear of change and uncertainty	Communication and involvement
Resistance	Fear of loss of power and status	Board engaged in project implementation
Unplanned decisions and fear of being made redundant	Orientation and Action: lack of patience with planning	Pilot Project planning: long-range objectives
Technical		
Incompatibility of systems	Purchase of different hardware and software platforms	Purchase of only one integrated system; write own system; neutral transfer files

metabusiness is intelligent if and only if their nodes and respective personnel are intelligent too.

Besides, a generic table with the main problems arisen to build and maintain an intelligent metabusiness, their causes and some possible solutions, is shown in Table 2, according to Joia (2001).

FUTURE TRENDS

As it is known, the knowledge can be either explicit or tacit. Also, a metabusiness is intelligent if and only if its nodes also have intelligence. Intelligence is the ability of using knowledge to create new knowledge (Drucker, 1998). But if it is hard to convince the professionals within a company to externalize their knowledge, both because they do not know how to structure it and because of lack of confidence in the firm, what about a lot of professionals working together for the first time and belonging to different companies, geographically dispersed, tied digitally?

Hence, the first trend is the need companies have to create mechanisms that reward their professionals involved in metabusinesses, to externalize their strategic knowledge, as is already done in some management consulting companies, as Bain and Mckinsey (Hansen, Nohria, & Tierney, 1999). It is necessary to develop an environment of trust where this is possible (von Krogh, 1998). According to Venkatraman & Henderson (1998), it is important to develop new ways of managing knowledge workers, as the human resource policies are geared toward production and administrative workers. Hence, it is necessary to create incentives and compensation practices to attract and keep knowledge workers.

A second trend is to have technology used in a more comprehensive way. As McKenney, Zack, and Doherty (1992) realized:

"- managers use electronic mail for efficient communication in well-defined contexts - monitoring task status, coordinating efforts, exchanging factual

information, sending alerts, and broadcasting information.

- managers use face-to-face interaction for defining and discussing problems and solutions, building a shared understanding of the situation, discussing shifting priorities and external pressures, interpreting ambiguous signals, and socialization of members."

Once again, the solution passes through the overcoming of organizational and cultural barriers, rather than technical ones. Also, the technology must increase the employment of the tacit knowledge, as it has been used to leverage and deploy the explicit one.

The third trend is to homogenize the technological platform of all the nodes involved in a metabusiness, defining a "bottom-line" platform, as just one node with an inadequate platform can jeopardize the intelligence of the metabusiness altogether.

Finally, the fourth and more important trend, is to give the employees of an intelligent metabusiness a digital thinking in order they have their structuring skill effectively developed, that is, to give them:

- ability to decodify and structure data and information, in order to transform them in knowledge;
- identify, enunciate and solve problems by themselves;
- have the fundamentals to research, evaluate, criticize and select information among complex knowledge networks;
- be creative;
- have the ability to work in teams, most of time geographically dispersed, and have the ability of self-management;
- ability to work in digital and, often, virtual environments.

So, investments must be made in the development of customized Web-based instruction systems, so as to allow the increasing of the human capital of the firms and by consequence the intellectual capital of the metabusiness, as well as to develop a trust-based environment among the companies and the employees.

CONCLUSION

The metabusiness is an extreme case that challenges our general understanding of the management of knowledge development processes in virtual organizations through the use of technology. The intelligence of a metabusiness depends on its degree of "reach" and "range", or in other words, on its degree of connectivity, sharing and structuring.

Technology, itself, does not create either knowledge or intelligence. Technology is just an enabler to achieve this stage. Notwithstanding that a lot of information technologies are already available to be used to increase the connectivity, sharing and structuring issues of a metabusiness in order to make it intelligent and with a high degree of "reach" and "range", the organizational and cultural obstacles are still very high to be smoothly overcome, and the causes and solutions must be analyzed.

The attitude is dangerous that drives management towards strong investments in information technology, possibly at the expense of investments in human capital. The danger lies on an IT-driven knowledge management strategy that may end up objectifying and calcifying knowledge into static, inert information, thus disregarding altogether the role of tacit knowledge. It can be mentioned that the major problem Volkswagen has faced in its newly built truck plant in Resende, Brazil "regarded as the most advanced automobile production process implemented in the world" has come from problems with the quality of the products/services delivered by its partners. As part of the enterprise, VW built a Training Center in Angra dos Reis, near Resende, close to the factory, where all of the metabusiness' nodes employees are trained before being engaged in the production network. However, the quality problems still remain, mainly due to the lack of employees' structuring skills, which hinders them for creating their own knowledge through the training process. Notwithstanding that the main players of this metabusiness work in the same geographical place, without certain physical boundaries, this innovative project has shown the need of investing in the leverage of the human capital of all the companies, otherwise all of the enterprise can be jeopardized.

The knowledge society with its knowledge workers demands new organizational forms (Laubacher & Malone, 2002), organic, flexible, seemingly almost anarchic, but coordinated enough to allow knowledge to be created, stored, retrieved and reused. Development and improvements in the newly created coordination science (Malone & Crowston, 1994) is paramount to spread intelligent metabusinesses as the "knowledge-based organizational structure" in compliance with the "Small Companies-Large Networks" scenario of the MIT Group for Organizations of the 21st Century.

KEY TERMS

Corporate I.Q.: Enterprise's capability of connectivity (internal link and link with its partners), sharing (data and information shared among its personnel, and its partners) and structuring (ability to extract knowledge from information and raw data).

Data: A set of discrete and objective facts concerning events.

Degree of Range: Type of transactions developed within the metabusiness, and the way the companies are working together, in order to set up a workgroup environment.

Degree of Reach: How the involved companies are linked within the metabusiness in order to transmit data and information among themselves.

Degree of Structuring: Deals with the ability that the companies have to extract knowledge from the data and information retrieved and shared by them.

Digital Thinking: Creation of a new mental model that is based on an assynchronous mental model and on the ability of linking, combining and associating different, or even opposite ideas.

Information: Data with attributes of relevance and purpose.

Intelligent Metabusiness: A metabusiness with a high degree of reach, range and structuring.

Knowledge: User's values and experience, being strongly connected to pattern recognition, analogies and implicit rules.

Metabusiness: A *quasi*-firm created through digital links among several companies, in such a way that it is almost impossible to know exactly its boundaries.

Intelligent Software Agents

Roger Tagg
University of South Australia, Australia

INTRODUCTION

An agent, in traditional use of the word, is a person that acts on behalf of another person or group of persons. In software, the term *agent* is broadly used to describe software that carries out a specialist range of tasks, on behalf of either a human user or other pieces of software. Such a concept is not new in computing. Similar things have been said about subroutines, re-usable objects, components and Web services. So what makes agents more than just another computer technology buzzword and research fashion?

BACKGROUND

The idea of intelligent agents in computing goes back several decades. Foner (1993, p. 1) dates the first research on software agents to the late 1950s and early 1960s. However, with the breakthrough of the Internet, intelligent agents have become more intensively researched since the early 1990s. In spite of this long heritage, the uptake of these ideas in practice has been patchy, although the perceived situation may be partly clouded by commercial secrecy considerations. Even today, the many different notions of the term *software agent* suggest that the computing profession has not yet reached a generally accepted understanding of exactly what an agent is.

DEFINITIONS AND CLASSIFICATIONS

According to Jennings et al. (1998, p. 8), "an agent is a computer system, *situated* in some environment that is capable of *flexible autonomous* action in order to meet its design objectives".

- S*ituated:* the agent interacts directly with its environment. It receives inputs from the environment and it performs activities with external effects.
- *Autonomous:* the agent is in charge of its own internal status and actions. Thus, it can perform without explicit interference of a user or other agents.
- *Flexible:* the agent is responsive to its environment and, at the same time, proactive. The agent should show social behaviour and should feature the ability to interact with external entities.

Furthermore, many agents show intelligence, in that they "carry out some set of operations on behalf of a user or another program with some degree of independence or autonomy, and in doing so, employ some knowledge or representation of the user's goals or desire" (Gilbert et al., 1995, p. 2f).

The research literature discusses many different types of agents, carrying out all sorts of functions with what can be termed primary and secondary characteristics. Primary characteristics include autonomy, cooperation and learning, while secondary characteristics include aspects like multi-functionality, goodwill or trustiness.

A typology of software agents has been proposed by Nwana (1996, pp. 7-38):

- Collaborative agents feature a high degree of cooperation and autonomy. They are determined by the idea of distributed artificial intelligence and by the concept of task sharing, cooperation and negotiation between agents.
- Interface agents focus on the characteristics of learning and autonomy. By collaborating with the user and by sharing knowledge with other agents they learn a user's behaviour and are trained to take the initiative to act appropriately.
- Mobile agents are not static but have the ability to travel. This entails non-functional benefits such as freeing local resources, showing more flexibility and enabling an asynchronous work scenario.

- Information or Internet agents emphasise managing enormous amounts of information. Their main task is to know where to search for information, how to retrieve it and how to aggregate it.
- Reactive agents are showing a stimulus-response manner as opposed to acting deliberatively. Since they are based in the physical world and only react to present changes, their behaviour is not predetermined.
- Hybrid agents comprise more than one agent philosophy and benefit from the combination of different architectures.

Wooldridge and Jennings (1995, pp. 24-30) offer a two-way classification, based on contrasting approaches to building agents. They distinguish the following representative architectures:

- Deliberative agent architecture. This classical agent architecture consists of one definite, symbolic world model with all decisions being made on the basis of logical reasoning. Challenges of this approach are the translation of the real world into an accurate model and the establishment of an efficient reasoning.
- Reactive agent architecture. In contrast to the deliberative agent architecture this alternative approach is lacking an explicit and symbolic model of the world as well as extensive reasoning.

Wooldridge and Jennings also allow for hybrid agent architectures that are built as a hierarchy of deliberative and reactive agent architecture layers.

DISCUSSION

Four aspects are of particular interest when trying to understand how agents work and could be successfully employed in applications and environments. Discussed next are: agent knowledge, agent applications, agent standards and multi-agent systems.

Agent Knowledge

To operate autonomously, any software agent must build up a collection of knowledge, typically data and rules that enable it to serve the human or client software it is acting for. According to Maes (1994, p. 2f), an agent's knowledge base should be built up gradually by learning from users and other agents. The key issues are competence and trust. To be competent, the agent must have a knowledge base that is comprehensive and flexible enough to adapt to the user's profile. For an agent to be trusted, a human user must feel comfortable when accepting help from the agent or when delegating tasks to it. Generally, an agent can only learn from its user and other agents if their actions show an iterative pattern. Maes suggests four different ways of training an agent to build up competence: observation and imitation of the user's habits, user feedback, training by examples and training by other agents.

However, Nwana and Ndumu (1999, p. 10) have criticized Maes' approach, claiming that an agent would not only need to know all peculiarities of the deployed operating system but also must understand all tasks its user is engaged in. Furthermore, the agent would need to be capable of gathering the user's intent at any time, thus continuously modelling its user. Nwana and Ndumu identify four main competences for an agent: domain knowledge about the application, a model of its user, strategies for assistance and a catalogue of typical problems that users face in the environment.

Agent Applications

Software agents can be employed in many fields of information technology. One role for agents is to act as an assistant or helper to an individual user who is working with a complex computer system or physical equipment. Examples are:

- Information agents (Davies et al., 1996, pp. 105-108) that help a human researcher in finding the most relevant material, from many sources and possibly through different search engines.
- Decision support agents that help a user assess alternative courses of action; functions include filtering and summarisation of data, optimising algorithms, heuristics and so forth.
- E-mail agents (Maes, 1994, p. 5f), which filter spam, allocate incoming mail to folders, and work out addresses to which outgoing mail should be sent.
- Buying and selling agents, which assist a user in finding good deals in Internet marketplaces or bidding agents, which assist participants in auctions. These agents have characteristics of information agents as well as of decision support agents.

A second group of applications is where the agent acts as a coordinator of activities, or "virtual manager". Any workflow management system could qualify for this category. Other examples include meeting scheduling agents (Kozierok, 1993, p. 5), and dynamic scheduling agents that are able to re-allocate resources to meet the goals of a business process (Lander et al., 1999, p. 1ff).

Delegation agents are another example in this category, although they could also be regarded as individual support.

A third group of applications is where the agent continually monitors data and rules in an organisation, and on that organisation's behalf alerts, or sends messages to, human recipients. Examples are advertising agents, notification agents, recommendation agents and selling agents. Such agents are at work when you receive an e-mail from Amazon.com about a book that might interest you.

Other agents act as a third party between two humans, or pieces of software, that need to co-operate. Examples include brokering agents, negotiation agents, mediation agents and ontology agents (Helal et al., 2001; Pivk & Gams, 2000).

Many humans, computer systems and even other agents depend on one particular specialised task, which is a common agent or subagent, especially useful in an era of information overload. This is a categorisation agent (Segal, 2000, p. 2f). Such an agent has the task of applying, and where necessary building up, a classification structure for incoming data. This structure may be particular to an individual (e.g., for e-mail filtering and filing) or it may be for an organisational unit.

Agent Standards

Intelligent agents are intended in order to function in heterogeneous system environments. To interact smoothly and efficiently in such environments, standardisation is essential.

Although agent technology is relatively immature and many researchers still have their own definition of agents, professional bodies have been developing standards for agents since the late 1990s.

These organisations include (Dickinson, 1997):

- ARPA Knowledge Sharing Effort (KSE)
- Agent Society
- OMG Mobile Agent System Interoperability Facility (MASIF)
- The Foundation for Intelligent Physical Agents (FIPA)

The FIPA and MASIF standards are regarded as of special importance for intelligent agents. While the FIPA Standard has its origins in the intelligent agent community and has been influenced by the KQML (Knowledge Query and Manipulation Language), MASIF deals primarily with agent mobility.

The FIPA 2000 standard (*http:www.fipa.org*) specification deals with mobility and tries to integrate MASIF (Milojicic et al., 1998, pp. 50-67). Therefore this specification bridges the gap between the intelligent and mobile agent communities. FIPA's specification is divided into five main categories: applications, abstract architecture, agent communication, agent management and agent message transport.

Multi-Agent Systems

Much of the recent literature on agents envisages a system with a community of agents that cooperate in some way to achieve an overall set of goals. According to Jennings et al. (1998, p. 9, p. 17f), "Multi-agent systems are ideally suited to representing problems that have multiple problem-solving methods, multiple perspectives and/or multiple problem solving entities". Since each agent has a restricted view of any problem and only limited information, multi-agent systems feature a flexible and advanced infrastructure to solve issues beyond individual capabilities. Thus, the system can benefit from every agent's expert knowledge. Other characteristics of multi-agent systems are decentralised data, asynchronous computation and the lack of a central control system.

A major challenge of multi-agent systems is clearly the means of coordination between agents. Nwana et al. (1997, pp. 33-55) have identified the following key components in such coordination: foreseeable structures of agent interaction; defined agent behaviour and social structures; flexibility and dynamics; and the knowledge and reasoning to utilise the above.

Possible coordination techniques are:

- Organisational structuring. The agents' roles, responsibilities, their communication chains and paths of authority are defined beforehand.
- Contracting. All tasks and resources distributed amongst agents are controlled by a contract net protocol.
- Multi-agent planning approach. Agents decide on a detailed and interlaced plan of all activities and goals. Multi-agent planning can be centralised, with one agent reviewing all individual plans and coordinating them into a single – or a distributed - multi-agent plan.

When agents are interacting in a multi-agent system, they may have to negotiate in order to fulfil their interests. Nwana et al. suggest two different negotiation theories:

- In the *game theory-based negotiation* approach, each agent holds a utility matrix that lists how much a certain interaction or goal is worth. During the negotiation process, which is defined by a negotiation protocol, the parties exchange bids and counter-offers following their strategies.

- In the *plan-based negotiation* theory, each agent schedules its actions individually before all plans are coordinated. This is similar to the multi-agent planning coordination approach, but any agent can play the role of central coordinator.

FUTURE TRENDS

We believe that the area of support for human users in the carrying out of highly heterogeneous workloads represents a promising area for the development of agent applications. The current support for users who work with a mixture of word processing, e-mail, spreadsheets, databases, digital libraries and Web search tools is very primitive. The user has to do most of the work in correlating the different sources, and current tools are poor at learning the user's commonly repeated work patterns. The authors of this article feel that agents are the most promising technology to redress this shortcoming, and have worked on architecture for linking agents with tools such as Groupware and Workflow.

CONCLUSION

In spite of a considerable amount of research, the killer application for intelligent agents is still somewhat elusive. The IT industry has still not reached a consensus about the use of agents now and in the future. Nwana and Ndumu (1999, p. 14) are even more critical, claiming that "not much discernible progress has been made post 1994". The main reason might be that intelligent agent theory integrates some of the most challenging concepts in science: for example, artificial intelligence, data mining or contract theory. Agent technology can be considered as another new demanding application of these concepts and will succeed or fail depending on any progress in these areas. The take-up of agent technology is therefore likely to suffer the same ups and downs that AI has experienced in recent decades. In the longer term, however, there is a large area of opportunity for agents supporting human users of computer systems, which has yet to be fully developed.

KEY TERMS

Artificial Intelligence: Computer systems that feature automated human-intelligent, rational behaviour and employ knowledge representation and reasoning methods.

Business Process: A process at the business layer of an organisation. Since the 1990s, the focus of any business reengineering project and one of the central inputs for IT design. It is sometimes also used as a synonym for workflow.

Categorisation: The process of deducing, from the content of an artefact, the potentially multiple ways in which the artefact can be classified for the purpose of later retrieval from a database, library, collection or physical storage system.

Contract Theory: Contract theory deals with aspects of negotiation and contracting between two or more parties.

Data Mining: Integrating statistics, database technology, pattern recognition, and machine learning, to generate additional value and strategic advantages.

Game Theory: Mathematical theory of rational behaviour for situations involving conflicts of interest.

Workflow: The automation of a business process, in whole or part, during which documents, information or tasks are passed from one participant to another for action, according to a set of procedural rules (WFMC.org) (sometimes also used as a synonym for business process).

Intelligent Software Agents in E-Commerce

INTRODUCTION

Agent technology is one of the most widely discussed topics in information systems and computer science literature. New software products are being introduced each day. A growing number of computer information professionals recognize that there are definite issues surrounding intelligent agent terminology. These must be resolved if agent technology is to continue to develop and establish.

Current research on intelligent agent software technology can be categorized as two main areas: technological and social. In the excitement of emergent technology, people often forget to scrutinize how new technology may impact their lives. The social dimension of technological progress is the driving force and most central concern of technology. Technology is not created for its own sake as a technological imperative. This article critiques the current state of software intelligent agents by examining technological issues and the social implications of intelligent agent software technology.

TECHNOLOGICAL ISSUES

An attempt to arrive at a generally accepted definition is the first hurdle. In order for this term to have any effectiveness, there must first be a universal definition that can be agreed upon and used consistently. Unfortunately, there is none. Many proposals for defining an "intelligent agent" have been put forth, but none has received wide acceptance. Some of these proposals are the following:

- "An agent is anything that can be viewed as perceiving its environment through sensors and acting upon that environment through effectors." Russell and Norvig (1995)
- "Let us define an agent as a persistent software entity dedicated to a specific purpose. 'Persistent' distinguishes agents from subroutines; agents have their own ideas about how to accomplish tasks, their own agendas. 'Special purpose' distinguishes them from other entire multifunction applications; agents are typically much smaller."
- "An autonomous agent is a system situated within and a part of an environment that senses that environment and acts on it, over time, in pursuit of its own agenda and so as to effect what it senses in the future." Franklin and Graesser (1996)

While these terms attempt to describe characteristics of intelligent agents, no comprehensive and generic description for these agents has gained wide recognition as the definitive description of a software agent. A consensus definition has not yet been achieved. As Franklin and Graesser (1996) indicate, most of the definitions proposed are derived from conceptualizations peculiar to the subjective views of the individuals. It is important to note that it is this intuitive aspect of an "intelligent agent" which makes it difficult to establish a broadly accepted formal definition. Ironically, it facilitates marketing of intelligent agent software technology.

A second reason for a lack of a consensus definition is that much of the agent research is proprietary. Companies that make investments to sponsor such research do not wish to reveal their competitive edge nor give away the value of their work. Standardization of new technology is difficult. Uncertainty will continue until the companies and individuals with the proprietary information recognize that sharing knowledge benefits everyone.

A third reason for the difficulty for the lack of a generally approved definition of an intelligent software agent, and probably the most important reason of the three outlined in this article, is that intelligent agent software does not seem to be qualitatively different from other software. "Is it an agent, or just a program?" Franklin and Graesser (1996) ask and observe, correctly, that all software agents are programs. The authors also state that not all programs are agents. The implication is that some programs are, in fact, agents. If an "intelligent agent" were just an added complex program, the term "intelligent agent" would simply mean that a software program was simply extended, made more composite and possibly more useful than other typical programs. An intelligent agent differs from a procedural program in two ways. First, it is an agent and broadly speaking, it is defined as someone or something that acts. To be able to act, the entity must have a purpose or a goal. A computer program can only perform a prescribed set of instructions. An intelligent software agent has the same capability and is similar to a computer program in this respect.

Computer programs act utilizing a relatively low level of logic. These programs cannot act autonomously. For any entity to act with autonomy there must be concomitant independence and freedom. Procedural computer programs do not have volition, because whatever is written into the program is executed. The key factor is logic bound and a closed program. The term "react" is an inherent limitation of closed computer programs. An agent, in the true sense of the word, initiates action. The several reasons illustrate why some time is required for an acceptable definition of software agent. This process is likely to be somewhat similar to the emergence of the distinction between artificial intelligence, expert systems and decision support systems, which became clear gradually with more widespread usage of this distinctive software.

We do not demean the effort that has been invested into these products. Systems that are based on the detection of patterns in conjunction with explicit user commands and preferences are based on straightforward computational mathematics and logic. Technical challenges exist in the areas of security, connectivity, storage, peer group collaboration, network-based services, user interface, stability and standards (Bantz et al., 2003). Park and Park (2003) propose an agent-based system for merchandise management and verify its application in a duty-free shop, which performs evaluating and selecting merchandise and predicting seasons and building purchase schedules autonomously in place of human merchandise managers under a business-to-business (B2B) electronic commerce (EC) environment. In order to facilitate the agent's intelligent behavior, several analysis tools such as data envelopment analysis (DEA), genetic algorithm (GA), linear regression and rule induction algorithm are incorporated into the system.

E-mail and filters reject messages that do not comply to the user's defined preferences. Help engines and data warehousing tools search for built-in patterns. Patterns are pre-built into the engines, which are limited by the closed logic bounds specified by the designs. News and searching tools have a great potential, albeit they pose a concern. The dilemma is if many users have news searching intelligent agent tools constantly searching for information on the Internet, the Internet may possibly be clogged up by too many of these searching tools. Imagine if one of these intelligent agents had a built-in error (bug) that caused the program to continuously spawn even more agents to search the Internet. Moreover, some intelligent agents searching the Internet for information could get lost and not return with the requested information. Thus, one can see the latent technical threat in employing such ill-designed intelligent agents. These "lost" agents may create severe bottlenecks on the Internet.

Although intelligence means people thinking, it may be possible to replicate the same set of behaviors using computation. This idea was discussed by Turing in the 1940s. In 1950 he proposed a test, now called the Turing Test (TT), for computational intelligence. In the test, a human judgment must be made concerning whether a set of observed behaviors is sufficiently similar to human behaviors that the same word - intelligent - can justifiably be used. Feigenbaum (2003) discuss the challenges for computational intelligence, including: 1. an alternative to TT that tests the facet of quality (the complexity, the depth) of reasoning, 2. building a large knowledge base by reading text, thus reducing knowledge engineering effort, and 3. distilling from the WWW a huge knowledge base, thus reducing the cost of knowledge engineering.

Olin et al. (2001) suggest that although tools in the shape of distributed artificial intelligence will be available and be particularly applicable to the complexities of decision-making in the typical global enterprise, a number of issues will arise in the next few years as intelligent agents become the mainstream enablers of "real-time" enterprise process, such as the need to ensure continuity in the transition phase by careful integration of intelligent agent systems in to a legacy systems.

Van Den Heuvel and Maamar (2003) propose a framework for contract-based support to establish virtual collaboration using loosely coupled and heterogeneous intelligent Web services (IWS) in which contracts encapsulate the control information for IWSs engaged in e-business transactions. Since IWS technology is still in its infancy, several important issues must be addressed before agentified Web services can be successfully deployed at e-marketplaces, such as the integration of IWSs with wrapped legacy systems, the semantic integration of Web services, and the integration of Web services into e-commerce transactions (Van Den Heuvel & Maamar, 2003).

While search engines have become the major decision support tools for the Internet, there is a growing disparity between the image of the World Wide Web stored in search engine repositories and the actual dynamic, distributed nature of Web data. The traditional static methods in which search and retrieval are disjoint seem limited. Menczer (2003) proposes using an adaptive population of intelligent agents mining the Web online at query time and presents a public Web intelligence tool called MySpiders, a threaded multi-agent system designed for information discovery and augmenting search engines with adaptive populations of intelligent search agents for significant competitive advantage. Weippl et al. (2003) describe the manifold security threats that occur in mobile agent systems. For instance, when masquerading, an agent claims the identity of another agent and tries to gain unauthorized access to resources. A possible solution to this security flaw is signing agent code with digital signatures such as those provided by the Java cryptographic extension (JCE 1.2.1). Mobile agents could launch denial of service attacks since too many agents could flood the Java runtime environment. Another relevant issue that needs to be addressed in the future is database intelligent agents' independence of the Java agent platform used for transport agents. Due to the lack of support offered by major Java agent platforms, the unconfined employment of standardized interfaces is not yet possible. Finally the issue of multiple, heterogeneous data warehouse islands that need to be made interoperable is being investigated by using intelligent agents to realize the federation. For instance, Xu et al. (2003) propose a two-layer approach for the formal modeling of logical agent mobility (LAM) using predicate/transition (PrT) nets in which a mobile agent system is viewed as a set of agent spaces and agents could migrate from one space to another.

SOCIAL IMPLICATIONS

The social implications, as with any new technology, include both positive and negative aspects. We are aware that the current literature debate and research on intelligent agent software technology deals in moderation with the topic of the social and ethical implications. Technologies are human artifacts, developed, presumably, for the benefit of humankind and the improvement of the quality of life. New technologies must, however, be tested to determine if the product meets these. Most important is to check if the new technology is significantly different from the existing ones.

One of the major benefits from using intelligent agents is the potential for liberating humans from the tedious task of searching for information on the Internet. The intelligent agent can aid in the search by filtering information that has little or no value. Unfortunately, intelligent agents also have the potential for damage. First, with excessive reliance on intelligent agents, humans can risk an excessive loss of choice. According to Lanier (1999), confining to an artificial world created by a programmer(s) can limit human potential for innovation. Another objection Lanier raises is that human beings degrade themselves by using intelligent agents. When individuals begin to think of computers anthropomorphically, as actually possessing intelligence and autonomy, people will tend to relate to computers as if they were human. The opposite is true too. This is a serious dilemma that must be avoided. An additional technical problem that Lanier (1999) raises is that info-consumers see the world through agents' eyes. The point is that if intelligent agents are used to find useful information, the agents themselves may be manipulated.

FUTURE TRENDS

The technological, social, and ethical issues notwithstanding, the new business environment is characterized not only by a rapid pace of change but also the dynamically discontinuous nature of such change. The issues such as lack of standardization in mobile agents may cause lack of identity traceability due to multiple transfers among networks. The security concerns relate to machine protection without artificially limiting agent access rights. Finally, there are issues surrounding performance and scalability, such as the performance effects that high levels of security would have on the network, as well as the effects of having multiple mobile agents in the same system. The emergence of intelligent mobile/software agents not only will change the way that we communicate across networks, but also have a profound impact on the way that we accomplish many tasks.

CONCLUSION

In conclusion, while intelligent agent technology has the potential for being useful to humankind, many fundamental issues remain unsolved. These problems are technical, social and/or ethical and require careful thought and consideration by developers. This discussion is critical of the current state of intelligent agent software technology and research, in the hope of encouraging developers to be aware of spillover effects. Unfortunately, issues raised by authors such as Lanier (1999) are often thrust aside as being extremist. Intelligent agent software technology has advanced, but greater progress must be made socially and ethically before these agents can be accepted as tools for the improvement of the quality of human life.

KEY TERMS

Agent: A program designed to provide specialized and well defined services. Agent can be *static* – executing on the computer where it was installed, or *mobile* – executing on computer nodes in a network.

Autonomous Agent: A system situated within and a part of an environment that senses that environment and acts on it, over time, in pursuit of its own agenda and so as to effect what it senses in the future.

Bottlenecks: A stage in a process that causes the entire process to slow down or stop.

Data Warehousing: A form of data storage geared towards business intelligence. It integrates data from various parts of the company. The data in a data warehouse are read-only and tend to include historical as well as current data so that users can perform trend analysis.

Decision Support Systems: A specific class of computerized information system that supports business and organizational decision-making activities. DSS is an interactive software-based system that compiles useful information from raw data, documents, personal knowledge, and/or business models to identify and solve problems and make decisions

Expert Systems: A computer system that facilitates solving problems in a given field or application by drawing inference from a knowledge base developed from human expertise. Some expert systems are able to improve their knowledge base and develop new inference rules based on their experience with previous problems.

Intelligent Agent: A program that gathers information or performs some other service without your immediate presence and on some regular schedule.

Turing Test (TT), for computational intelligence: In the test, a human judgment must be made concerning whether a set of observed behaviors is sufficiently similar to human behaviors that the same word - intelligent - can justifiably be used.

Interactivity and Amusement in Electronic Commerce

Yuan Gao
Ramapo College of New Jersey, USA

INTRODUCTION

The use of structural features such as text size, font, graphics, color, animation, video and audio has been widely explored in the traditional media. Similar uses of such features have also been found in the online environment (Rodgers & Thorson, 2000). Factors related to consumer's behavior, attitude, and perceptions regarding Web sites have been examined in academic literature (Chen & Wells, 1999; Coyle & Thorson, 2001; Ducoffe, 1996; Eighmey, 1997; Koufaris, 2002; Koufaris, Kambil, & Labarbera, 2001; Vijayasarathy, 2003). They include the investigation of effects of interactive features on Web site appeal (Ghose & Dou, 1998), and e-store characteristics on site traffic and sales (Lohse & Spiller, 1998). Some experimental studies examined the effects of animation and image maps on perceived telepresence and consumer attitude (e.g., Coyle & Thorson, 2001), and the use of pop-up windows on consumer decision-making processes (Xia & Sudharshan, 2000).

BACKGROUND

The current literature is gradually expanding on the study of using interactive features to provide visitors a more realistic experience, and the exploration of using amusement techniques to enhance entertainment value of a Web site. Recent literature has also extended Resnik and Stern's (1977) content analytical method to examine Web site information content and design features (Ghose & Dou, 1996; Huizingh, 2000; Palmer & Griffith, 1998; Philport & Arbittier, 1997). Mitra (2003) argues that institutions find themselves dwelling at the intersection of the real and the virtual, and are consequently faced with a more complex act than developing a Web site in order to make its appearance in cyberspace attractive. Thus, more aspects of a Web-based communications message, especially attributes related to interactivity, entertainment, and amusement need to be explored.

INTERACTIVITY

An important attribute of using a Web site to disseminate product information and conduct e-commerce is its ability to engage customers in interacting with the Web site. Interactive functions include text-based email inquiries, feedback forms, and multimedia components that attempt to retain customers at the site for longer visits. Entertaining features in the hypermedia include pictures, virtual reality displays of products, multimedia shows, online games, and the use of cartoons and humor. A Web site is a mix of direct selling and advertising with characteristics of both general product display and interactive involvement with customers (Berthon, Pitt, & Watson, 1996). In addition to providing product information, a Web site can engage visitors in dialogues such as inquiries, suggestions, order status tracking, new product proposal, and online problem diagnostics (Ghose & Dou, 1998). This medium affords a rich collection of formats that are available to the marketer in the presentation of products.

One such format is the personalization (e.g., yahoo.com) and customization (e.g., NikeID.com) offered by informational and corporate portals. Such features as intelligent agents, online help functions, recommender systems, custom-tailored news tickers and personalized home pages made it easy for online firms to service specific shopping needs of consumers (Andre & Rist, 2002). Research showed that a company's willingness to customize its products and services had a positive impact on customer trust in the company both online and off-line (Doney & Cannon, 1997; Koufaris & Hampton-Sosa, 2004).

Interactivity is an important dimension of features that distinguish the Internet from other media. Though the concept of interactivity can be conceptualized in many different ways, defining it as a medium characteristic best reflects the exchange between a Web user and the site (Lombard & Snyder-Duch, 2001). According to Steuer (1992), interactivity is "the extent to which users can participate in modifying the form and content of a mediated environment in real time" (p. 84). Interactive functions allow the user to participate actively in the exchange and persuasion process through direct manipulation of the structural elements of a site (Rodgers & Thorson, 2000). Like television, the interactivity of this medium provides the potential to deliver information in an entertaining form.

Hypermedia is multimedia. Animation, video and audio complement traditional text and graphics when used judiciously. Entertainment supports experiential flow of surfers who engage in "shallow, sensory-level, peripheral processing of the executional aspects of the message" (Singh & Dalal, 1999, p.95). In addition to traditional features such as color, size, typeface, product class, appeal type, animation, audio, sound level, sound clarity, and movement, new design elements like vividness, realism, and interactivity need to be considered in the context of the Web (Rodgers & Thorson, 2000). In a study of 651 companies from Yahoo! and Dutch Yellow Pages, Huizingh (2000) finds that larger sites tend to contain more forms of entertainment features such as pictures, jokes, cartoons, games, and video clips than smaller sites.

A picture is worth a thousand words. Certain types of animation used to display a product from a multi-dimensional perspective and activated upon user request derive benefits at least comparable to large pictures that are often available upon user clicks at most online shopping sites. Animated product displays enhance the directness of user product experience, which has been found to produce more confidently held and more enduring attitudes (Smith & Swinyard, 1983). With animation, product detail can be presented from more angles than with still pictures. Graphics, animation, and video clips might be some of the elements that prevent a casual visitor from simply clicking away from a site.

AMUSEMENT

In addition to product display, animation also provides amusement through imparting motion and activity in products and cartoons that could consequently be perceived as lively, active, or spirited. The use of humor has also been widely explored in advertising as well as computer-mediated communications (Morkes, Kernal, & Nass, 1999; Weinberger & Gulas, 1992). Research has shown that humor attracts attention and seems to be most effective in ads promoting low-risk routine purchases. In a series of field studies, Scott, Klein, and Bryant (1990) found that humorous fliers increased attendance at social events like neighborhood picnics and clambakes, though having little effect on attendance of business gatherings.

When a Web surfer is engaged in low-risk message processing, peripheral cues like animation and humor may be used and can succeed in gaining visitor attention as they do in traditional media (Weinberger, Spotts, Campbell, & Parsons, 1995). A more likable interface will also encourage visitors to visit more pages and stay longer, hence nurturing a more positive attitude.

Humor fulfills audience's needs for escapism, diversion, aesthetic enjoyment, and emotional release. Humor's intention is to amuse and entertain people, to make them laugh, and to convey light-hearted enjoyment through "an incongruous comment that is recognized by the receiver as an attempt to amuse and that succeeds at amusing" (Morkes et al., 1999, p.403). In addition to entertainment, humor also helps gain attention and comprehension, especially when humor is related to the products presented (Speck, 1991).

Web site designers for apparent reasons have examined amusement features in a great length. A first-time visitor judges a site by its look: eye-catching graphics and animations, along with navigation buttons and company logos. Software packages intended to enhance Web site appeal have been developed by many vendors, and software technologies such as Flash® and LiveMotion® have been used by many Web sites as entrance pages for the purpose of entertainment and amusement.

RESEARCH ON EFFECTS OF INTERACTIVITY AND AMUSEMENT

The study of interactive and amusement Web techniques and their effects have been conducted in both advertising and information systems research. This section briefly summarizes the research findings reported in the current literature.

Philport and Arbittier (1997) studied the content of over 2000 commercial communications messages across TV, magazines, newspapers, and the Internet, and found no distinguishing characteristics in Web advertising, that is, banner ads were not particularly different in any dimension. This observation suggests to us that we probably should look at an entire Web site in the study of techniques and effects in the hypermedia. Ghose and Dou (1998) found that greater degrees of interactivity, defined by the total count of interactive functions considered in their research, related positively to Web site appeal.

Coyle and Thorson (2001) argue that interactivity and vividness are the two main factors affecting perceived telepresence, and consequently attitude toward the site. In addition, they found that the presence of image maps, audio and animation influence perceived telepresence and attitude toward the site. Higher perceived interactivity of a Web site also leads to a more positive attitude toward the site (Jee & Lee, 2002).

A user profile study found that, in addition to information, structure and design of a Web site are important factors contributing to better perceptions by the visitor (Eighmey, 1997). Relating to site features, Lohse and Spiller (1998) performed a study measuring 32 user interface features at 28 online retail stores against store traffic and sales. They conclude that online store traffic and sales are influenced by the presence of such interface elements as an FAQ page, promotional activities, and better organization of the product menu. Li and Bukovac (1999) find that the size and animation on a banner ad make a difference in viewer responses. Large animated banners were found to be more attention getting than smaller and static banners and thus assist recall of the advertising. A research addressing the impact of different digital retailing interfaces by Westland and Au (1998) finds that virtual reality storefronts increase a consumer's time spent searching for products but do not significantly increase sales.

In a study linking the use of interruption implemented via pop-up windows, Xia and Sudharshan (2000) manipulated the frequency of interruptions and found that interruptions had a negative impact on consumer shopping experiences. Intrusive formats of advertising like interstitials are found to have "backlash risks" in this new medium (Johnson, Slack, & Keane, 1999).

In traditional humor research, Wells, Leavitt, & McConville (1971) find that along with vigor, personal relevance, and irritation, humor is a major perceptual dimension in their profiling of user responses to TV commercials. The adjectives that accounted for this factor include jolly, merry, playful, humorous and amusing. They concluded that humor contributes to perceived entertainment. From a pool of 600 adjectives, Aaker and Bruzzone (1985) identify four factors that explain the majority of variance in predicting informative, enjoyable, annoying, or offensive ads. In particular, the amusing/humorous variable contributed to 37.6% of the variance explained by the factor "entertainment". In an experimental study of computer-mediated communications, humor was found to enhance the likability of the computer interface, as well as to have a positive effect on user cooperation (Morkes et al., 1999). Animated product displays were found to have a significant effect on perceived entertainment, while the use of humor was found to have a marginally significant effect on perceived entertainment (Gao, 2002).

FUTURE TRENDS

Research in Web marketing and user interface design undertakes both observational and experimental approaches. Observational research has provided a high degree of external validity by taking advantage of the existing real-world Web sites (e.g., Chen & Wells, 1999; Eighmey, 1997; Koufaris, 2002; Lohse & Spiller, 1998). On the other hand, experimental studies perform carefully designed and controlled hypermedia-based stimuli in an attempt to answer the questions of what causal effect a certain Web-based technique may have on perceptual, attitudinal, or behavioral outcomes through between-subjects comparisons (e.g., Coyle & Thorson, 2001; Gao, 2002; Li & Bukovac, 1999; Xia & Sudharshan, 2000). Future research may explore various combinations of presentation attributes like interactive features and humor as fixed factors. Researchers should take advantage of the convenience of Web-based survey techniques, and consider non-intrusive means of collecting usage and exploration data through click streams.

CONCLUSION

In summary, this article provides an overview of the current state of Web interactivity and amusement features and their effects reported in past research. This article advocates a research paradigm that goes beyond observational research and user profiling, and suggests potential future directions in the study of the effects of interactive techniques and amusement features in electronic commerce. Doing business online is constantly evolving. It is necessary to take a rigorous and scientific look at the various components that go into this environment, in order to help electronic business grow in a structured, efficient, and effective way.

KEY TERMS

Amusement: The state of being amused, entertained, or pleased.

Animation: Technique of imparting motion and activity in graphic images of such objects as products and cartoons to create a condition of being alive, active, or spirited.

Attitude Toward the Site (Ast): A Web user's predisposition to respond either favorably or unfavorably to a Web site in a natural exposure situation.

Entertainment: Something that fulfills a visitor's need for aesthetic enjoyment, escapism, diversion, or emotional release.

Humor: Techniques such as cartoons and jokes that are intended to induce laughter or amusement.

Interactive Advertising: Advertising that simulates a one-on-one interaction to give consumers more control over their experience with product information than do traditional media ads.

Interactivity: A characteristic of a medium in which the user can influence the form and content of the mediated presentation or experience.

Web Marketing: The dissemination of information, promotion of products and services, execution of sales transactions, and enhancement of customer support via a company's Web site.

Interface Design Issues for Mobile Commerce

Susy S. Chan
DePaul University, USA

Xiaowen Fang
DePaul University, USA

INTRODUCTION

Effective interface design for mobile handheld devices facilitates user adoption of mobile commerce (m-commerce). Current wireless technology poses many constraints for effective interface design. These constraints include limited connectivity and bandwidth, diverse yet simplistic devices, the dominance of proprietary tools and languages, and the absence of common standards for application development.

The convergence of mobile Internet and wireless communications has not yet resulted in major growth in mobile commerce. Consumer adoption of m-commerce has been slow even in countries such as Finland, which have broadly adopted wireless technology (Anckar & D'Incau, 2002). An international study of mobile handheld devices and services suggests that mobile commerce is at a crossroads (Jarvenpaa, Lang, Takeda & Tuunainen, 2003). The enterprise and business use of wireless technology holds greater promise, but it demands the transformation of business processes and infrastructure. Poor usability of mobile Internet sites and wireless applications for commerce activities stands out as a major obstacle for the adoption of mobile solutions. For example, even with the latest 3G phones in Japan, consumers still find the small screen display and small buttons on these devices difficult to use (Belson, 2002).

BACKGROUND

Mobile Commerce

Mobile commerce broadly refers to the use of wireless technology, particularly handheld mobile devices and mobile Internet, to facilitate transaction, information search, and user task performance in business-to-consumer, business-to-business, and intra-enterprise communications (Chan & Fang, 2003). Researchers have proposed several frameworks for the study of m-commerce. Varshney and Vetter's framework (2001) presents 12 classes of m-commerce applications, ranging from retail and online shopping, auction, mobile office, and entertainment to mobile inventory emphasizing the potential of mobile B2B and intra-enterprise applications. The framework by Kannan, Chang, and Whinston (2001) groups mobile services into goods, services, content for consumer e-commerce, and activities among trading partners.

Waters (2000) proposes two visions for the potential and opportunities of m-commerce. One perspective argues that the mobile, wireless channel should be viewed as an extension of the current e-commerce channel or as part of a company's multi-channel strategies for reaching customers, employees, and partners. The second, more radical view suggests that m-commerce can create markets and business models.

Recent development in m-commerce has substantiated the first perspective. Major e-commerce sites have implemented their mobile Internet sites as an extension of wired e-commerce to support existing customers (Chan & Lam, 2004; Chan et al., 2002). Consumers have shown relatively low willingness to use m-commerce, but adopters of e-commerce are more likely to embrace this new technology (Anckar & D'Incau, 2002). Furthermore, perceived difficulty of use can affect consumers' choice of m-commerce as a distribution channel (Shim, Bekkering & Hall, 2002). These findings suggest that in a multi-channel environment, m-commerce *supplements* e-commerce instead of becoming a *substitute* for e-commerce.

Enterprise and business applications of m-commerce technologies seem to hold greater promise, because it is easier for companies to standardize and customize applications and devices to enhance current work processes. An Ernst & Young study (2001) of the largest companies in Sweden shows that, except for the retail industry sector, most industries have viewed m-commerce as being vital for growth and efficiency strategies, but not necessarily for generating new revenue. However, integrating the wireless platform in an enterprise requires significant structural transformation and process redesign.

Research on Wireless Interface Design

Several recent studies have examined interface design for mobile applications using handheld devices. Researchers have found that direct access methods were more effective for retrieval tasks with small displays (Jones, Marsden, Mohd-Nasir, Boone & Buchanan, 1999). Novice WAP phone users perform better when using links instead of action screens for navigation among cards, and when using lists of links instead of selection screens for single-choice lists (Chittaro & Cin, 2001). Ramsay and Nielsen (2000) note that many WAP usability problems echo issues identified during the early stage of Web site development for desktop computers, and could be alleviated by applying good user interface design. Such design guidelines for WAP applications include: (1) short links and direct access to content, (2) backward navigation on every card, (3) minimal level of menu hierarchy, (4) reduced vertical scrolling, (5) reduced keystrokes, and (6) headlines for each card (Colafigi, Inverard & Martriccian, 2001; Buchanan et al., 2001). Buyukkokten, Garcia-Molina, and Paepcke (2001) have found that a combination of keyword and summary was the best method for Web browsing on PDA-like handheld devices.

Diverse form factors have different interface requirements. The study by Chan et al. (2002) of 10 wireless Web sites across multiple form factors reveals that user tasks for the wireless sites were designed with steps similar to the wired e-commerce sites, and were primarily geared towards experienced users. Many usability problems, such as long download and broken connections, information overload, and excessive horizontal and vertical scrolling, are common to three form factors—WAP phone, wireless PDA, and Pocket PC. Interface design flaws are platform independent, but the more limitations imposed on the form factors, the more acute the design problems become.

Mobile users access information from different sources and often experience a wide range of network connectivity. Context factors have a particular impact on the usability of mobile applications. Based on a usability study conducted in Korea, three use context factors—hand (one or two hands), leg (walking or stopping), and colocation (alone or with others)—may result in different usability problems (Kim, Kim, Lee, Chae & Choi, 2002). Therefore, the user interface design has to consider various use contexts. Researchers also suggest a systems-level usability approach to incorporating hardware, software, "netware," and "bizware" in the design of user-friendly wireless applications (Palen & Salzman, 2002). Perry, O'Hara, Sellen, Brown, and Harper (2001) have identified four factors in "anytime anywhere" information access for mobile work: the role of planning, working in "dead time," accessing remote technological and informational resources, and monitoring the activities of remote colleagues.

Multimodal interfaces are gaining importance. The MobileGuiding project developed in Spain is aimed at building a European interactive guide network on a common, multimodal, and multilingual platform in which contributors will provide leisure information and cultural events in their locations (Aliprandi et al., 2003). Furthermore, there has been a study conducted in Finland that addresses the design and evaluation of a speech-operated calendar application in a mobile usage context (Ronkainen, Kela & Marila, 2003).

MAIN THRUST OF THIS ARTICLE

Five issues are essential to the interface design for mobile commerce applications, including: (a) technology issues, (b) user goals and tasks, (c) content preparation, (d) application development, and (e) the relationship between m- and e-commerce.

Technology Issues

Limitation of Bandwidth

Most mobile communication standards only support data rates that are less than 28.8 kbps. Connections to the wireless service base stations are unstable because signal strength changes from place to place, especially on the move. These constraints limit the amount of information exchanged between device and base station. Indication of the download progress and friendly recovery from broken connections are necessary to help users gain a better sense of control.

Form Factor

Mobile commerce services are accessible through four common platforms: wireless PDA devices using Palm OS, Pocket PCs running Microsoft Windows CE/Pocket PC OS, WAP phone, and two-way pagers. Within the same platform, different form factors may offer different functionalities. A developer should consider the form factor's unique characteristics when developing m-commerce applications.

User Goals and Tasks

Mobile users can spare only limited time and cognitive resources in performing a task. Services that emphasize mobile values, and time-critical and spontaneous needs, add more value for m-commerce users. These mobile services may include the ability to check flight schedules, check stock prices, and submit bids for auction (Anckar & D'Incau, 2002). In addition, mobile tasks that demonstrate a high level of perceived usefulness, playfulness, and security are the ones most likely to be adopted by users (Fang, Chan, Brzezinski & Xu, 2003).

Content Preparation

Constraints in bandwidth and small screen size demand different design guidelines. Most design guidelines for e-commerce (e.g., Nielsen, Farrell, Snyder & Molich, 2000) support the development of rich product information sets and a complete shopping process. In contrast, wireless Web sites have to simplify their content presentation.

Amount of Information

Content adaptation is necessary to convert information for the mobile Web (Zhou & Chan, 2003). However, users should have sufficient, if not rich, information to accomplish the goals for the application.

Navigation

Navigation systems vary from one form factor to another because the design of handheld devices differs. Currently, there is no consensus on which functions or features should be provided by the application, or built into the device itself.

Depth of Site Structure

Since mobile users have limited time for browsing wireless applications, the organization of information is critical. A flatter structure with fewer steps for wireless applications would allow users to review more options in the same step, and to locate the desired information more quickly.

Graphics or Text

Text is a better choice for displaying information on small screen browsers. However, better technology may improve the screen quality of handheld devices to display more complicated graphics. When determining the format of information to present, it is important to consider the form factor, because it may pose additional constraints on the format.

Development Environment

Mobile computing alters the assumption of "fixed" context of use for interface design and usability testing (Johnson, 1998). Traditional means of user interviews or usability testing in a laboratory environment cannot reveal insights into users' activities and mobility in real life. Contextual consideration is critical for gathering information about user requirements. For example, when developing and testing a mobile application for grocery shoppers, user requirement gathering and prototype evaluation should be conducted in a grocery store (Newcomb, Pashley & Stasko, 2003). The method of contextual inquiry can augment user interface design by exploring the versatility of usage patterns and usage context (Väänänen-Vainio-Mattila & Ruuska, 1998). While contextual inquiry may help developers gain a realistic understanding of contextual factors affecting user behaviors in motion, it is difficult to conduct non-obtrusive observations and inquiries. Developers for mobile applications need to consider the application context surrounding the relationship between the mobile device and user goals and tasks.

Relationship Between M-Commerce and E-Commerce

The wireless channel for e-commerce has raised many new questions regarding coordination between interactions with users across multiple channels. Some researchers suggest that because of the "transaction aware" and "location aware" characteristics of the wireless technology, mobile consumers may increase impulse purchases, especially in low-value, low-involvement product categories, such as books and CDs (Kannan et al., 2001). At present, many Web sites have extended the wireless channel to leverage relationships with exiting customers (Chan et al., 2002). The current state of technology and poor usability of mobile Web sites makes it difficult to expand m-commerce as an independent channel. Many analysts believe that the wireless channel is promising for customer relationship management (CRM) because of its ability to: (1) personalize content and services; (2) track consumers or users across media and over time; (3) provide content and service at the point of need; and (4) provide content with highly engaging characteristics (Kannan et al., 2001). The challenge is how to coordinate interface and content across multiple channels so that experienced users and repeat customers can handle multiple media and platforms with satisfaction.

FUTURE TRENDS

Technology Trends

User interface design for mobile commerce will likely be influenced by four trends. First, multiple standards for wireless communication will not be resolved quickly, especially in North America. Second, the high cost of third-generation (3G) technology may delay the availability of broadband technology for complex functionality and content distribution for mobile applications. Third, instead of the convergence of functionalities into a universal mobile handheld device, there may be a variety of communication devices operating in harmony to support users in their everyday lives. Fourth, input and output format may expand to incorporate voice and other formats, as well as expandable keyboards. The introduction of the voice-based interfaces may complement the text-based interface and remedy some of the information input/display problems of the handheld devices. These trends suggest opportunities to conceptualize wireless user interface beyond text-based interaction. The new challenges are to design better multimodal interfaces for inter-device communication in order to simplify tasks for mobile users.

Development Trends

Alternative methods for interface design and evaluation will be necessary to support m-commerce applications development. First, requirement analysis should focus on the context of mobile users' behaviors and tasks. Contextual inquiry and other methods may be developed to facilitate the understanding of interactions between mobility and usability. Second, usability testing should be conducted with an understanding of contextual variables beyond user behavior. Third, mapping form factors, user tasks, data needs, and content across multiple channels and platforms is necessary to synchronize content and coordinate functionality in a distributed system. Fourth, user-centered design guidelines for mobile applications will be important. These trends require a fresh look at current methodology and will help determine new ways of incorporating user interface design and usability testing for distributed wireless application development. The reference framework proposed by Lee and Benbasat (2003) may be useful in this regard. Their framework incorporates seven design elements for m-commerce interface: context, content, community, customization, communication, connection, and commerce.

M-Commerce Business Models

Wireless technology for m-commerce is likely to evolve in two areas. For intra-enterprise and business-to-business uses, wireless technology provides location-aware and mobility-aware solutions for mobile workers. There is a broad range of possibilities for B2B applications because such deployment can be controlled more easily. Content distribution may be integrated with the enterprise systems. Context-based applications, interfaces, functionality, and even devices can be customized according to the mobile tasks and user groups in the B2B context. This approach makes application development, deployment, and integration easier to manage. In contrast, it is far more challenging to manage the design, development, and deployment of wireless applications for customers. Wireless technology's capability for personalization seems to be the strongest argument for m-CRM services to enhance customer retention (Chan & Lam, 2004). A careful mapping of tasks, data, form factors, and the CRM process is essential for user interface design.

CONCLUSIONS

Wireless technology and the mobile Internet continues to evolve. Until the technology matures and bandwidth improves, wireless applications will be geared toward users requiring limited bandwidth, short exchange of data and text, and simple functionality. Two areas of wireless applications, CRM and enterprise efficiency, may reap greater success. Consumer e-commerce Web sites should focus on the selection of tasks that are most suitable for the wireless channel and demonstrate mobile values, especially for experienced users. Such mapping process requires a solid understanding of the CRM strategy, user preferences, and the constraints imposed by a mobile environment. For enterprise adoption, consolidating the wireless platforms and form factors will facilitate interface design. In either case, additional research to improve usability for mobile commerce is essential.

KEY TERMS

Contextual Inquiry: This interface design method employs an ethnographic approach such as observing user activities in a realistic context.

Fixed Context of Use: Traditional user interface design and testing assumes a single domain, with the users always using the same computer to undertake tasks alone or in collaboration with others.

Form Factor: This platform or operating system runs on a handheld device. Major form factors include Palm, Pocket PC, and WAP.

Interface Design: Design of the interactions between humans and computers.

Location-Aware Service: Mobile services that provide information based on a user's location through the support of a global positioning system. Such services include mobile maps, weather, restaurants, and movie directories.

M-CRM: Interactions between a company and its customers for marketing, sales, and support services through the mobile Web and wireless channel.

Multimodal Interface: An interface that communicates with users through multiple modes.

Usability: Usability refers to how well an application is designed for users to perform desired tasks easily and effectively.

International Digital Studies Approach for Examining International Online Interactions

Kirk St.Amant
Texas Tech University, USA

INTRODUCTION

As global access to the Internet increases, so does the potential for miscommunication in international online interactions (IOIs). Unfortunately, many models for examining cross-cultural communication focus on conventional (offline) interactions or settings. As a result, researchers lack a mechanism for examining how cultural factors could affect online discourse.

This article presents an approach—international digital studies—for examining how cultural factors could affect IOIs. The purpose of this approach is to identify points of contention or areas where online media can create conflicts in cultural expectations associated with credibility. Once identified, these points of contention can serve as the subject of future research related to culture and communication.

BACKGROUND

Creating credibility, or ethos, is not a random process. Rather, audiences use certain factors, or *ethos conditions*, to develop a checklist for determining if a presentation is credible (worthy of attention). That is, audiences come to a particular presentation situation thinking, “This individual must do x, y, and z if I am to consider him or her credible/worth listening to.” If all of these expectations are met (can be “checked off”), then the presenter and his or her ideas will be considered credible. If one or more ethos conditions are not met, then audiences will be less likely to view a presenter as credible (see St.Amant, 2002a, for a more in-depth discussion of this concept).

The ethos conditions one expects to encounter can vary from culture to culture, and such differences have been noted at a variety of levels (Campbell, 1998; Tebeaux, 1999; Lewis, 2001). Persons from different cultures, for example, often use different organizational structures (e.g., stated vs. implied conclusions) and different methods of citing sources to establish the credibility of a presentation (Woolever, 2001; Lewis, 2001; Hofstede, 1997). Cultures can also associate different credibility expectations with sentence length. Southern Europeans, for example, associate longer sentences with credible presentations, while Americans view shorter and more direct sentences as being more credible (Ulijn & Strother, 1995). Additionally, the kind of relationship associated with the use of a particular word can cause cross-cultural credibility problems (Li & Koole, 1998; Li, 1999).

Online media complicate cross-cultural interactions by creating conditions that affect credibility expectations. In many cases, online media reduce human interaction to typed words. Typed online messages, however, tend to follow patterns related to spoken discourse. This mix of written and spoken communication creates a new and interesting situation, for recipients of online text messages do not obtain nonverbal identity cues key to communicating in spoken exchanges. The sender of an online message therefore seems faceless and anonymous (Gauntlett, 2000; St.Amant, 2002b).

As a result, notions of authority, identity, and credibility take on new forms in cyberspace. As Fernback (1999) notes, in online exchanges, the markers of credibility—marks that draw others to listen to you—are not, “brawn, money, or political clout,” but are rather “wit, and tenacity, and intelligence” (p. 213). Thus, wit, tenacity, and intelligence become ethos conditions individuals can use to appear more authoritative or more credible than other participants in an online exchange. These factors therefore become *digital ethos conditions*, for individuals come to expect them when assessing the credibility of online presentations. These digital ethos conditions, however, can conflict with the communication expectations of different cultural groups.

Understanding how cultural factors can affect online exchanges can be a complicated and seemingly overwhelming process. Yet, now that more of the world is getting online, it is becoming increasingly important to understand IOI situations so that miscommunications and mistakes can be avoided. (Such culture-related mistakes, moreover, could affect everything from online social exchanges to international outsourcing and international e-commerce activities.) For this reason, researchers can benefit from an approach that helps them focus their analysis of IOIs on a more manageable set of topics. The international digital studies approach is designed to establish such a focus.

MAIN THRUST OF THE ARTICLE

International digital studies is a research approach used to examine how cultural groups differ in their responses to digital ethos conditions. According to this perspective, the objective of the researcher is two-fold:

- First, the researcher must identify *actual* digital ethos conditions—presentation factors that actually contribute to a presenter's credibility in online exchanges. Once isolated, these digital ethos conditions can become variables used to evaluate how different cultures communicate online.
- Second, the researcher must determine if a digital ethos condition is also a factor that varies in relation to cultural communication expectations. That is, researchers need to determine if cultures would differ observably in how they responded to a particular digital ethos condition.

The key to this line of research becomes identifying variables that could affect communication in IOIs. To achieve this objective, researchers must use a two-part literature review involving the fields of Internet studies and intercultural communication.

The purpose of the dual-field literature review is to determine how factors of medium and of culture might create conflicting expectations of ethos conditions in IOIs. To identify these situations, individuals must first survey the research literature in Internet studies in order to identify digital ethos conditions in direct, two-way interactions online. The focus of this review is to isolate behavior resulting from online communication conditions vs. the transfer of communication patterns from more traditional media to an online setting. Name-dropping, for example, can be used to create credibility in both print and online media; the use of emoticons to create credibility, however, is more restricted to online communication.

After researchers identify digital ethos conditions, they must determine if these factors could cause confusion or conflict in cross-cultural exchanges. The goal then becomes evaluating if a particular digital ethos condition is also a *point of contention*—or a situation in which the communication patterns documented in the literature of one field (Internet studies) conflict with patterns noted in the literature of another field (intercultural communication).

To identify points of contention, the second part of the international digital studies process involves a review of the research literature in intercultural communication. In this second review, the researcher would look specifically for indications that digital ethos conditions identified in the initial (Internet studies) literature review relate to findings reported in the intercultural communication literature. If little or no mention of this factor is made, or if this variable appears to cause no real conflict in cross-cultural exchanges, then that variable would be a *weak* point of contention. If, for example, different cultural groups did not react differently to uses of wit (a key ethos condition noted in Internet studies), then uses of wit would be a weak point of contention, for there is little evidence of different cultural behavior related to this digital ethos condition. If, however, the intercultural literature review reports that the ethos condition noted in the Internet studies literature can cause problems in cross-cultural interactions, then that factor would be a *strong* point of contention that could affect IOIs.

Researchers must next determine if a strong point of contention could actually cause problems in IOIs. That is, just because the two-part literature review indicates a particular ethos condition could be a point of contention.

- Does that ethos condition actually affect discourse in IOIs?
- Do reactions to that ethos condition vary along cultural lines in IOI? (e.g., Do some cultures use it more than others? Are some cultures more confused by its use than others?)
- Can researchers develop a ranking system to compare how specific cultural groups vary in relation to uses of and responses to a particular ethos condition?

To answer these questions, researchers must use strong points of contention as the foundation for experiments that test if and how a strong point of contention can affect IOIs. In this way, the international digital studies approach helps researchers identify suitable topics for conducting further research into IOIs.

FUTURE TRENDS

An application of international digital studies indicates that the concept of identity could be a key problem area in future IOIs. For this reason, it is important that researchers understand how aspects and perceptions of identity could cause problems in online exchanges involving individuals from different cultures.

A review of the Internet studies literature reveals identity is a factor that affects discourse in online forums. Many researchers note that, in cyberspace exchanges, identity is neither fixed nor stable; rather, it can easily change because of online media that reduce interactions to typing words (Gauntlett, 2000; St.Amant, 2002b). By reducing identity to texts, online media allow individuals to create their online identity on their own terms (Arnold & Plymire, 2000).

Other researchers note that by limiting identity to texts, online media allow other users to co-opt or to change someone else's online identity by cutting and pasting another person's words into a different message (Warnick, 1998). Cutting and pasting parts of a message allows individuals to separate what was said from who said it (Warnick, 1998). The ability to separate authors from their original online message gives presenters a great deal of liberty, for they can:

- attribute segments of forwarded messages to whomever they wish, thus altering the online identity of someone else;
- create new identities for themselves by co-opting the words or ideas of another;
- alter what another said, creating a new online identity for that author by "putting words in that person's mouth."

In all three cases, altering textual factors allows one individual to change the online identity of another person. The question then becomes: Could this plasticity of online identity result in reactions that vary along cultural lines? To answer this question, the researcher must review the intercultural communication literature in search of information relating to identity.

A review of the intercultural communication literature reveals that a fixed or verifiable identity is often essential to creating credible messages (Weiss, 1998; Ferraro, 2002; Ng & Van Dyne, 2001). In some cultures, one's identity is not based on the claims or the proof that the individual himself or herself presents, but is rather based on the claims of others. For example, in certain cultures, people interact within relatively large and complex social networks. These networks are often formed from long-term relationships developed between individuals over time, or from strong familial ties based on trust and senses of family duty and family honor (Hofstede, 1997; Weiss, 1998; Richmond, 1995).

In social network cultures, the identity of the presenter often determines if others will listen to or ignore information presented by that individual (Hofstede, 1997; Weiss, 1998; Richmond, 1995). The distinction is essentially one of in-group vs. out-group. If one can be identified as a member of the in-group as confirmed by someone else in the social network, then certain behaviors are expected and a certain level of credibility is awarded. Additionally, a special authority—or credibility—is given to the information that "identified" individual presents. If one is viewed as a member of the out-group (his or her identity cannot be confirmed by someone else in the social network), different behaviors are expected and different, more restricted levels of trust and disclosure are granted.

Also, in social network cultures, outsiders (members of a different culture) tend to be viewed with suspicion, and being "heard" or "listened to" often becomes a matter of having the proper introduction (Richmond, 1995; Hofstede, 1997; Scharf & MacMathuna, 1998). In such systems, if a person who is part of the network (has a known identity) says an outsider should be listened to, then that outsider is identified as "credible" by other members of the network. In this case, the identity of the outsider gains credibility by being associated with a particular individual who is known and is trusted by members of that system (Hofstede, 1997; Scharf & MacMathuna, 1998; Weiss, 1998). Success in such a cultural communication system becomes a matter of identity. That is, does the recipient of a message know the identity of the presenter and how do factors of identity affect perceptions of credibility?

Social network perspectives on identity might affect how individuals from such cultures use online communication technologies. For example, when an individual from a social network culture receives an e-mail message that lacks identity cues, will that individual trust the identity of the sender? Moreover, if individuals from such cultures (cultures in which a person's word is often that person's bond) see how easily online messages can be altered and reposted, would those individuals be willing to use online media to introduce new people or present new ideas? And how would resistance to disclosing information in cyberspace be perceived by individuals from cultures in which a fixed identity is not as important?

According to such cultural expectations, the identity of the presenter affects his or her credibility. This perceived credibility affects the degree of access an individual has to certain kinds of information in social network cultures. Persons with a solid and an easy-to-confirm identity are considered credible and gain access to information. Individuals with a limited/text-based identity, however, might be viewed as non-credible and would be limited in the information they could obtain. In such cases, identity = trust/credibility, and lack of identity = doubt.

The limited identity resulting from IOIs could therefore undermine the credibility of some participants in IOIs. This situation could lead to "unexpected" behaviors or reactions from members of social network cultures. (These behaviors might include ignoring important communiqués because the identity, and thus the credibility, of the sender is "suspect.") Such unexpected behavior could, in turn, lead to confusion or even offense.

This two-part literature review reveals instances where cultural perceptions of identity could cause problems in

IOIs. As a result, identity appears to be a strong point of contention that merits further examination. From this point, researchers can use different methods to examine how this strong point of contention might affect discourse patterns in IOIs. For example, some researchers might conduct online case studies to observe how individuals from different cultural groups act and interact in online environments where identity remains restricted to texts. Other researchers might conduct controlled experiments in which different cultural groups interact in situations where identity is known and stable, and in situations where identity is limited and text based.

The purpose of these approaches would be to determine if identity actually affects how cultural groups interact in IOIs. Such research could also be used to establish a comparative system for determining how specific cultures differ according to this particular point of contention. The overall objective would therefore be to determine if a strong point of contention could allow for a relativistic comparison of cultural behavior according to a similar concept. The results of such research could provide important insights that could be used to shape everything from international e-commerce strategies to communication protocols used in international outsourcing projects.

CONCLUSION

The rapid evolution of online communication technologies is constantly changing how people think about space and time. Now, international communication often transpires in seconds or minutes, not days or weeks. This new degree of proximity, however, could lead to an increase in cross-cultural misunderstanding as many aspects of online interactions contradict the communication expectations of certain cultures. This essay has overviewed how the international digital studies approach can serve as a foundation for examining international online interactions. It now becomes the task of researchers to examine culture, technology, and communication in order to explore the true nature of IOIs.

KEY TERMS

Cross-Cultural: Situations where individuals from different cultures interact with or exchange information with one another; interchangeable with the term "intercultural."

Digital Ethos Conditions: Factors individuals use to assess the credibility or the worth of an online presentation of information.

Ethos Conditions: Factors individuals use to asses the credibility or the worth of a presentation.

Intercultural: Situations where individuals from different cultures interact with or exchange information with one another; interchangeable with the term "cross-cultural."

International Online Interaction (IOI): Situation in which individuals from two or more cultures use an online medium to interact directly with one another.

Literature Review: Reviewing the research findings reported by a certain field of research; the process usually involves the examination of articles published in the research journals of a particular field.

Point of Contention: A communication factor that is found to be positive (contribute to one's credibility) in the research of one field, but is found to be negative (detract from one's credibility) in the research of another field.

Presentation: The sharing of information with other via spoken, written, or online media.

Internet Abuse and Addiction in the Workplace

Mark Griffiths
Nottingham Trent University, UK

INTRODUCTION

As with the introduction of other mass communication technologies, issues surrounding Internet use, abuse and addiction have surfaced. This article has a number of objectives. It will first introduce readers to the concept of Internet addiction before going on to look at the wider issue of Internet abuse in the workplace. In this section, generic types of Internet abuse will be described, in addition to further examination of the reasons why Internet abuse occurs. The chapter ends with some guidelines and recommendations for employers and human resources departments.

BACKGROUND: INTERNET ADDICTION

There have been a growing number of academic papers about excessive use of the Internet. These can roughly be divided into four categories:

- Studies that compare excessive Internet users with non-excessive users (e.g., Brenner, 1997; Young, 1998)
- Studies that have examined vulnerable groups of excessive Internet use; for example, students (e.g., Nalwa & Anand, 2003; Scherer & Bost, 1997)
- Case studies of excessive Internet users (Catalano, Catalano, Embi & Frankel, 1999; Griffiths, 2000a; Tsai & Lin, 2003; Young, 1996)
- Studies that examine the psychometric properties of excessive Internet use (e.g., Armstrong, Phillips & Saling, 2000; Charlton, 2002; Pratarelli et al., 1999).
- Studies examining the relationship of excessive Internet use with other behaviors; for example, psychiatric problems, depression, loneliness, academic performance and so forth (e.g., Kubey, Lavin & Barrows, 2001; Nie & Ebring, 2000; Shapira, Goldsmith, Keck, Khosla & McElroy, 2000)

Despite the predominance of drug-based definitions of addiction, there is now a growing movement that views a number of behaviors as potentially addictive, including those which do not involve the ingestion of a psychoactive drug (e.g., gambling, computer game playing, exercise, sex, and now the Internet) (Orford, 2001). Research has suggested that social pathologies are beginning to surface in cyberspace. These have been termed "technological addictions" (Griffiths, 1996a) and have been operationally defined as non-chemical (behavioral) addictions that involve excessive human-machine interaction. They can thus be viewed as a subset of behavioral addictions (Marks, 1990) and feature core components of addiction (Brown, 1993; Griffiths, 1996a); that is, salience, mood modification, tolerance, withdrawal, conflict and relapse. Young (1999) claims Internet addiction is a broad term that covers a wide variety of behaviors and impulse control problems. This is categorized by five specific subtypes:

- Cybersexual addiction: compulsive use of adult Web sites for cybersex and cyberporn
- Cyber-relationship addiction: over-involvement in online relationships
- Net compulsions: obsessive online gambling, shopping or day-trading
- Information overload: compulsive Web surfing or database searches.
- Computer addiction: obsessive computer game playing (e.g., Doom, Myst, Solitaire, etc.)

In reply to Young, Griffiths (2000a) has argued that many of these excessive users are not "Internet addicts" but just use the Internet excessively as a medium to fuel other addictions. Put very simply, a gambling addict or a computer game addict who engages in their chosen behavior online is not addicted to the Internet. The Internet is just the place where they engage in the behavior. However, in contrast to this, there are case study reports of individuals who appear to be addicted to the Internet itself (e.g., Young, 1996; 2000b). These are usually people who use Internet chat rooms or play fantasy role playing games - activities that they would not engage in except on the Internet itself. These individuals to some extent are engaged in text-based virtual realities and take on other social personas and social identities as a way of feeling good about themselves.

In these cases, the Internet may provide an alternative reality to the user and allow them feelings of immersion and anonymity that may lead to an altered state of consciousness. This in itself may be highly psychologically and/or physiologically rewarding. There are many factors that make the Internet seductive. It is clear from research in the area of computer-mediated communication that virtual environments have the potential to provide short-term comfort, excitement, and/or distraction (Griffiths, 2000a). These reasons alone provide compelling reasons alone why employees may engage in non-work related Internet use. There are also other reasons that are outlined in more detail in the next section on Internet abuse.

Case study accounts (e.g., Griffiths, 2000b; Tsai & Lin, 2003; Young, 1996) have shown that the Internet can be used to counteract other deficiencies in the person's life (e.g., relationships, lack of friends, physical appearance, disability, coping, etc.). Internet addiction appears to be a bona fide problem to a small minority of people but evidence suggests the problem is so small that few employers take it seriously. It may be that Internet abuse (rather than Internet addiction) is the issue that employers should be more concerned about.

TYPES OF WORKPLACE INTERNET ABUSE

It is clear that the issue of Internet abuse and Internet addiction are related but they are not the same thing. Furthermore, the long-term effects of Internet abuse may have more far-reaching effects for the company that the Internet abuser works for than the individual himself or herself. Abuse also suggests that there may not necessarily be any negative effects for the user other than a decrease in work productivity.

As seen in the previous section, Young (1999) claims Internet addiction is a broad term that covers a wide variety of behaviors and impulse control problems categorized by five specific subtypes. These can be adapted and refined to produce a typology of Internet abuse within the workplace. These are cybersexual Internet abuse, online friendship/relationship abuse, Internet activity abuse, online information abuse, criminal Internet abuse, and miscellaneous Internet abuse. These are examined in more detail below.

- Cybersexual Internet abuse: this involves the abuse of adult Web sites for cybersex and cyberporn during work hours. Such online sexual services include the conventional (e.g., Internet versions of widely available pornographic magazines like Playboy), the not so conventional (Internet versions of very hardcore pornographic magazines) and what can only be described as the bizarre (various discussion groups). There are also pornographic picture libraries (commercial and free-access), videos and video clips, live strip shows, live sex shows and voyeuristic Web-cam sites (Cooper, 2000; Griffiths, 2001).
- Online friendship/relationship abuse: this involves the conducting of an online friendship and/or relationship during work hours. Such a category could also include the use of e-mailing friends and/or engaging in discussion groups, as well as maintenance of online emotional relationships. Such people may also abuse the Internet by using it to explore gender and identity roles by swapping gender or creating other personas and forming online relationships or engaging in cybersex (see above) (Griffiths, 2001; Whitty, 2003).
- Internet activity abuse: this involves the use of the Internet during work hours in which other non-work related activities are done (e.g., online gambling, online shopping, online travel booking, online computer gaming, online day-trading, etc.). This may be one of the most common forms of Internet abuse in the workplace.
- Online information abuse: this involves the abuse of Internet search engines and databases. Typically, this involves individuals who search for work-related information on databases and so forth but who end up wasting hours of time with little relevant information gathered. This may be deliberate work-avoidance but may also be accidental and/or non-intentional. It may also involve people who seek out general educational information, information for self-help/diagnosis (including online therapy) and/or scientific research for non-work purposes.
- Criminal Internet abuse: this involves seeking out individuals who then become victims of sexually-related Internet crime (e.g., online sexual harassment, cyberstalking, paedophilic "grooming" of children). The fact that these types of abuse involve criminal acts may have severe implications for employers.
- Miscellaneous Internet abuse: this involves any activity not found in the above categories such as the digital manipulation of images on the Internet for entertainment and/or masturbatory purposes (e.g., creating celebrity fake photographs where heads of famous people are superimposed onto someone else's naked body) (Griffiths, 2001).

WHY DOES INTERNET ABUSE OCCUR?

There are many factors that make Internet abuse in the workplace seductive. It is clear from research in the area of computer-mediated communication that virtual environments have the potential to provide short-term comfort, excitement, and/or distraction (Griffiths, 2000a). These reasons alone provide compelling reasons why employees may engage in non-work related Internet use. There are also other reasons (opportunity, access, affordability, anonymity, convenience, escape, disinhibition, social acceptance, and longer working hours), which are briefly examined next:

- Opportunity and access – Obvious pre-cursors to potential Internet abuse include both opportunity and access to the Internet. Clearly, the Internet is now commonplace and widespread, and is almost integral to most workplace environments. Given that prevalence of undesirable behaviors is strongly correlated with increased access to the activity, it is not surprising that the development of Internet abuse appears to be increasing across the population.
- Affordability - Given the wide accessibility of the Internet, it is now becoming cheaper and cheaper to use the online services on offer. Furthermore, for almost all employees, Internet access is totally free of charge and the only costs will be time and the financial costs of some particular activities (e.g., online sexual services, online gambling, etc.).
- Anonymity - The anonymity of the Internet allows users to privately engage in their behaviors of choice in the belief that the fear of being caught by their employer is minimal. This anonymity may also provide the user with a greater sense of perceived control over the content, tone, and nature of their online experiences. The anonymity of the Internet often facilitates more honest and open communication with other users and can be an important factor in the development of online relationships that may begin in the workplace. Anonymity may also increase feelings of comfort since there is a decreased ability to look for, and thus detect, signs of insincerity, disapproval, or judgment in facial expression, as would be typical in face-to-face interactions.
- Convenience - Interactive online applications such as e-mail, chat rooms, newsgroups, or role-playing games provide convenient mediums to meet others without having to leave one's work desk. Online abuse will usually occur in the familiar and comfortable environment of home or workplace, thus reducing the feeling of risk and allowing even more adventurous behaviors.
- Escape - For some, the primary reinforcement of particular kinds of Internet abuse (e.g., to engage in an online affair and/or cybersex) is the sexual gratification they experience online. In the case of behaviors like cybersex and online gambling, the experiences online may be reinforced through a subjectively and/or objectively experienced "high". The pursuit of mood-modifying experiences is characteristic of addictions. The mood-modifying experience has the potential to provide an emotional or mental escape and further serves to reinforce the behavior. Abusive and/or excessive involvement in this escapist activity may lead to problems (e.g., online addictions). Online behavior can provide a potent escape from the stresses and strains of real life.
- Disinhibition – Disinhibition is clearly one of the Internet's key appeals, as there is little doubt that the Internet makes people less inhibited (Joinson, 1998). Online users appear to open up more quickly online and reveal themselves emotionally much faster than in the offline world. What might take months or years in an offline relationship may only takes days or weeks online. As some have pointed out (e.g., Cooper & Sportolari, 1997), the perception of trust, intimacy and acceptance has the potential to encourage online users to use these relationships as a primary source of companionship and comfort.
- Social acceptability – The social acceptability and perception of being online has changed over the last 10 years (e.g., the "nerdish" image of the Internet is almost obsolete). It may also be a sign of increased acceptance as young children are exposed to technology earlier and so become used to socializing using computers as tools. For instance, laying the foundations for an online relationship in this way has become far more socially acceptable and will continue to be so. Internet interaction takes away the social isolation that we can all sometimes feel and there are no boundaries of geography, class or nationality.

FUTURE TRENDS: GUIDELINES FOR MANAGERS AND HUMAN RESOURCES DEPARTMENTS

As has been demonstrated, being able to spot someone who is an Internet addict or an Internet abuser can be very difficult. However, there are some practical steps that can be taken to help minimize the potential problem.

- Develop an "Internet Abuse At Work" policy. Many organizations have policies for behaviors such as smoking or drinking alcohol. Employers should develop their own Internet abuse policies by liaison between personnel services and local technology councils and/or health and safety executives.

- Take the issue of Internet abuse/addiction seriously. Internet abuse and addiction in all their varieties are only just being considered as potentially serious occupational issues. Managers, in conjunction with personnel departments, need to ensure they are aware of the issues involved and the potential risks it can bring to both their employees and the whole organization. They also need to be aware that for employees who deal with finances, the consequences of some forms of Internet abuse/addiction (e.g., Internet gambling) for the company can be very great.
- Raise awareness of Internet abuse/addiction issues at work. This can be done through e-mail circulation, leaflets, and posters on general notice boards. Some countries will have national and /or local agencies (e.g., technology councils, health and safety organizations, etc.) that can supply useful educational literature (including posters). Telephone numbers for these organizations can usually be found in most telephone directories.
- Ask employees to be vigilant. Internet abuse/addiction at work can have serious repercussions not only for the individual but also for those employees who befriend Internet abusers and addicts, and the organization itself. Fellow staff need to know the basic signs and symptoms of Internet abuse and addiction. Employee behaviors such as continual use the Internet for non-work purposes might be indicative of an Internet abuse problem.
- Give employees access to diagnostic checklists. Make sure that any literature or poster within the workplace includes a self-diagnostic checklist so that employees can check themselves to see if they might have (or be developing) an Internet problem.
- Monitor Internet use of your staff that you suspect may have problems. Those staff with an Internet-related problem are likely to spend great amounts of time engaged in non-work activities on the Internet. Should an employer suspect such a person, they should get the company's IT specialists to look at their Internet surfing history, as the computer's hard disc will have information about everything they have ever accessed. The fact that specific individuals may be monitored should be outlined in the organization's "Internet Abuse At Work" policy so that employees are aware they may be monitored.
- Check Internet "bookmarks" of your staff. In some jurisdictions across the world, employers can legally access the e-mails and Internet content of their employees. One simple check is to simply look at an employee's list of "bookmarked" Web sites. If they are spending a lot of employment time engaged in non-work activities, many bookmarks will be completely non-work related (e.g., online dating agencies, gambling sites).
- Give support to identified problem users. Most large organizations have counseling services and other forms of support for employees who find themselves in difficulties. In some (but not all) situations, problems associated with Internet use need to be treated sympathetically (and like other more bona fide addictions such as alcoholism). Employee support services must also be educated about the potential problems of Internet abuse and addiction in the workplace.

CONCLUSION

In this chapter, major issues that surround Internet abuse/addiction issues in the workplace have been highlighted. Internet abuse/addiction can clearly be a hidden activity and the growing availability of Internet facilities in the workplace is making it easier for abuse to occur in lots of different forms. Thankfully, it would appear that for most people Internet abuse is not a serious individual problem, although for large companies, small levels of Internet abuse multiplied across the workforce raises serious issues about work productivity. For those whose Internet abuse starts to become more of a problem, it can affect many levels including the individual, their work colleagues and the organization itself.

Managers clearly need to have their awareness of this issue raised, and once this has happened, they need to raise awareness of the issue among the work force. Knowledge of such issues can then be applied individually to organizations in the hope that they can develop an Internet abuse policy in the same way that many organizations have introduced smoking and alcohol policies. Furthermore, employers need to let employees know exactly which behaviors on the Internet are reasonable (e.g., the occasional e-mail to a friend) and those that are unacceptable (e.g., online gaming, cybersex, etc.). Internet abuse has the potential to be a social issue, a health issue *and* an occupational issue and needs to be taken seriously by all those employers who utilize the Internet in their day-to-day business.

KEY TERMS

Conflict: This refers to the conflicts between the addict and those around them (interpersonal conflict), conflicts with other activities (job, social life, hobbies and interests) or from within the individual themselves (intrapsychic conflict) that are concerned with the particular activity.

Cybersex: The act of computer-mediated sex either in an online or virtual environment. Examples include two consenting adults engaging in an e-mail or real-time chat sex session. The advantages to this are that two people who are at opposite ends of the globe can maintain a relationship.

Internet Addiction: This is a term used to describe excessive Internet use and has been also been referred to as Internet addiction disorder (IAD), Internet addiction syndrome (IAD) and pathological Internet use. As with other addictions, Internet addiction features the core components of other addictive behaviors (salience, mood modification, tolerance, withdrawal, conflict and relapse) and can be defined as a repetitive habit pattern that increases the risk of disease and/or associated personal and social problems. It is often experienced subjectively as "loss of control" and these habit patterns are typically characterized by immediate gratification (short-term rewards), often coupled with delayed, deleterious effects (long-term costs). Attempts to change an addictive behavior (via treatment or by self-initiation) are typically marked by high relapse rates (see also technological addictions).

Mood Modification: This refers to the subjective experiences that people report as a consequence of engaging in the particular activity and can be seen as a coping strategy (i.e., they experience an arousing "buzz" or a "high" or paradoxically, tranquilizing feel of "escape" or "numbing").

Relapse: This is the tendency for repeated reversions to earlier patterns of the particular activity to recur and for even the most extreme patterns typical of the height of the addiction to be quickly restored after many years of abstinence or control.

Salience: This occurs when the particular activity becomes the most important activity in the person's life and dominates their thinking (preoccupations and cognitive distortions), feelings (cravings) and behavior (deterioration of socialized behavior). For instance, even if the person is not actually engaged in the behavior they will be thinking about the next time they will be.

Technological Addictions: These addictions are operationally defined as non-chemical (behavioral) addictions that involve human-machine interaction. They can either be passive (e.g., television) or active (e.g., computer games, Internet), and usually contain inducing and reinforcing features which may contribute to the promotion of addictive tendencies. Technological addictions can be viewed as a subset of behavioral addictions and feature core components of addiction, that is, salience, mood modification, tolerance, withdrawal, conflict and relapse.

Tolerance: This is the process whereby increasing amounts of the particular activity are required to achieve the former effects. For instance, a gambler may have to gradually have to increase the size of the bet to experience a euphoric effect that was initially obtained by a much smaller bet.

Withdrawal Symptoms: These are the unpleasant feeling states and/or physical effects that occur when the particular activity is discontinued or suddenly reduced, for example, the shakes, moodiness, irritability and so forth.

Internet Data Mining Using Statistical Techniques

Kuldeep Kumar
Bond University, Australia

INTRODUCTION

Data mining has emerged as one of the hottest topics in recent years. It is an extraordinarily broad area and is growing in several directions. With the advancement of the Internet and cheap availability of powerful computers, data is flooding the market at a tremendous pace. However, the technology for navigating, exploring, visualising, and summarising large databases is still in its infancy. Internet data mining is the process of collecting, analysing, and decision making while the data is being collected on the Internet. In most of the financial applications, data is updated every second or minute or hour. By using Internet data-mining tools, a decision can be made as soon as data are updated.

The quantity and diversity of data available to make decisions have increased dramatically during the past decade. Large databases are being built to hold and deliver these data. Data mining is defined as the process of seeking interesting or valuable information within large data sets. Some examples of data mining applications in the area of management science are analysis of direct mailing strategies, sales data analysis for customer segmentation, credit card fraud detection, mass customization, and so forth. With the advancement of the Internet and World Wide Web, both management scientists and interested end users can get large data sets for their research from this source. The Web not only contains a vast amount of useful information, but also provides a powerful infrastructure for communication and information sharing. For example, Ma, Liu, and Wong (2000) have developed a system called DS-Web that uses the Web to help data mining. A recent survey on Web-mining research can be seen in the paper by Kosala and Blockeel (2000).

Both statistics and data mining are concerned with drawing inferences from data. The aim of inference may be to understand the patterns of correlation and causal links among the data values (explanation) or making predications for the future data values (generalization). At present, data-mining practitioners and statisticians seem to have different approaches to solving problems of a similar nature. It appears that statisticians and data miners can profit by studying each other's methods and using a judiciously chosen combination of them.

Data-mining techniques can be broadly classified into four areas.

1. **Exploratory Data Analysis (EDA) and Inferential Techniques:** As opposed to traditional hypothesis testing designed to verify an a priori hypothesis about relations between variables, EDA is used to identify systemic relationships between variables when there are no a priori expectations as to the nature of those relations. Computational EDA includes both simple and basic statistics and more advanced, multivariate exploratory techniques designed to identify patterns in multivariate data sets.
2. **Sampling Techniques:** Where an incomplete data set is available, sampling techniques are used to make generalizations about the data. Various considerations need to be accounted for when drawing a sample, not the least of which is any a priori knowledge about the nature of the population.
3. **Neural Networks:** Neural networks are analytical techniques modeled after the process of learning in the cognitive system and the neurological functions of the brain. These techniques are capable of predicting new observations from other observations after executing a process of so-called learning from data. One of the major advantages of neural networks is that they are capable of approximating any continuous function and the researcher does not need to have any hypothesis about the underlying model or even, to some extent, which variables matter.
4. **Decision-Tree Techniques:** These techniques successively split the data into subgroups in order to improve the prediction or classification of the dependent variable. These techniques can handle a large number of independent variables and, being nonparametric in nature, can capture the relationship where traditional statistical techniques fail.

EXPLORATORY DATA ANALYSIS AND DATA-MINING TECHNIQUES

Keogh and Kasetty (2003) have published a survey on time series data mining. References of these techniques can be seen in Flury (1997), Kumar and Baker (2001), McLachlan (1992), Mendenhall and Sincich (2003), and so forth.

SAMPLING TECHNIQUES FOR DATA MINING

Sampling techniques are essential tools for business data mining. Although there are several sampling techniques, simple random sampling is commonly used in practice. There are quite a few drawbacks of using simple random sampling, and it may not be an appropriate technique in many situations. In this section we have reviewed various sampling techniques with their relative merits and demerits. We have also proposed a new sampling technique.

Sampling techniques play a key role in data mining. These techniques are also widely used in market research, economics, finance, and system analysis and design. Sampling is the process of selecting representative elements of a population from a huge database. When these selected elements are examined closely, it is assumed that the selected sample will reveal useful information about the whole database.

For example, given a huge database of customers, it may be difficult to interview each and every one because of the enormous cost and it will also take lots of time. Obviously, the best way is to draw a small representative sample and interview these customers to assess the preferential pattern of consumers for different types of products, the potential demand for a new product, scope for any diversification in the production schedule, and so forth. Similarly, the system analyst has to make a decision on two key issues: first, the selection of the documents generated by the members of the organization, and second, the fact that a great many employees can be affected by the proposed information system. Which people should the system analyst interview, seek information from via a questionnaire, or observe? Obviously, he or she will need a representative sample.

Rocke and Dai (2003) describe a clustering method for unsupervised classification of objects in large data sets. Grabmeier (2002) has given an overview of clustering analysis techniques from a data-mining point of view. There are quite a few techniques available for selecting a sample, but only the simple random sampling technique is widely used in selecting samples from a database. A summary of these techniques is given in Table 2.

Neural networks are very sophisticated modeling techniques, capable of modeling extremely complex functions. In particular, neural networks are nonlinear and moreover, they are distribution free. For many years, linear modeling had been the commonly used technique in most modeling domains since linear models had well-known optimisation strategies. Where the linear approximation was not valid, the models suffered accordingly.

Neural networks learn by example. The user gathers representative data, and then involves training algorithms to automatically learn the structure of the data. Thus, the user needs only to have knowledge of

- how to select and prepare data,
- how to select an appropriate neural network, and
- how to interpret the results.

Thus, the level of user knowledge needed to successfully apply neural networks is much lower than would be the case using traditional statistical methods.

The type of problems amenable to solution by a neural network is defined by the way they work and the way they are trained. Neural networks work by feeding in some input variables and producing some output variables. They can therefore be used where you have some known information and would like to predict the value of some unknown information. For example, to analyse form in horse racing, the factors to be taken into account might include times, weights, distance suitability, barriers, beating and winning margins, the class of race, and the overall field strength. The output information would be some guide as to the likelihood of success in a particular race (e.g., a prediction of the expected time that a given horse would take to run the race). There are a number of sites where this type of information is available for a fee. The user then has to decide which components of the data they will present to the neural network and the parameters of processing that they want the network to use. Neural networks have been successfully applied across a range of problem domains in areas as diverse as finance, medicine, engineering, geology, and physics. Indeed, anywhere that there are problems of prediction, classification, or control, neural networks are being introduced. This success can be attributed to three key factors.

- **Power:** Neural networks are very sophisticated modeling techniques, capable of modeling extremely complex functions. In particular, neural networks are nonlinear. For many years, linear modeling had been the commonly used technique in most modeling domains since linear models had well-known optimisation strategies. Where the linear approximation was not valid, the models suffered accordingly. Neural networks also keep in check the curse of the dimensionality problem that bedevils attempts to model nonlinear functions with a large number of variables. Quite often, the back propagation method is used for training the neural network.
- **Ease of Use:** Neural networks learn by example. The neural-network user gathers representative data, and then involves training algorithms to automatically learn the structure of the data. Although the user does need to have some heuristic knowledge of how to select and prepare data, how to select an appropriate neural network, and how to interpret the results, the level of user knowledge needed to successfully apply neural networks is much lower than would be the case using more traditional statistical methods.
- **Reasonable Processing Time:** The key performance objective of the ANN will be to achieve the highest possible success rate. A further objective is to achieve this success rate without the ANN processing time being unacceptably slow. These two performance objectives may counteract each

Table 2. A summary of sampling techniques

- Stratified Random Sampling
- Systematic Sampling
- Cluster Sampling
- Two-Stage Sampling
- Sampling Proportional to Size

other but can often be traded off against one another through the design of the ANN.

DECISION TREE TECHNIQUES

Classification and regression tree (CART) techniques were developed by Dan Steinberg. These techniques are robust and easy-to-use decision-tree tools that automatically sift large databases, searching for and isolating significant patterns and relationships in the data. These relationships are then used to generate prediction models for applications such as profiting customers, detecting frauds, and managing credit rules. CART's output can also be used as input to improve prediction accuracy of neural nets. This technique can also handle missing values in the database. CART can also accommodate situations in which some misclassifications are more serious than others. Multivariate adaptive regression splines (MARS), developed by Jerry Friedman, is another variation of CART. It is a high-speed prediction-modeling solution that provides superior forecasting accuracy by deployment of an accurate and easy-to-understand regression model. MARS can find optimal variable transformation and interactions. Every variable selected for entry into the model is checked for a nonlinear response. It can be used for forecasting and also for understanding the prediction model. There are several other decision-tree techniques; for example, SPSS uses a CHAID- (chi-square automatic interaction detection) tree-based statistical method.

FUTURE TRENDS

The flow diagram given can be used for data mining. It illustrates the five steps mentioned in SAS Enterprise Miner.

- **Sample:** The most important thing is to draw a representative sample from a large database. The details of drawing the sample are given in "Sampling Techniques for Data Mining."
- **Explore:** By exploring, we mean calculating various statistics as mentioned in "Exploratory Data Analysis and Data-Mining Techniques."
- **Modify:** This consists of creating new variables or adding some new variables to clarify the data.
- **Model:** This consists of choosing the best available model for estimation or forecasting.
- **Assess:** At this stage we need to make sure that various assumptions inherent in the model are satisfied.

Recent Developments in Data Mining

Data mining has become an essential analytical skill in e-commerce. Business organizations are using data-mining techniques to increase profit. Some authors (e.g., Fayyad, 1997) see data mining as a single step in a larger process that we call knowledge discovery in database. Some other interesting open problems in data mining, for example, finding interesting patterns, spurious relationships, contaminated data, and so forth, is given in the paper by Hand (1998). A new journal named *Data Mining and Knowledge Discovery* covers recent developments in this area. Also, *IEEE Intelligent Systems and their Applications* has a special issue on data mining (March 2000) that gives some important developments in special topics like knowledge design and feature mining. Some recent books on data mining are by Giudice (2003), who uses statistical methods, Nemati and Barko (2003), writing on organizational data mining, Chakrabarti (2002), writing on Web mining, Freitas (2002), whose book is on data mining with evolutionary algorithms, and Kloesgen and Zytkow (2002), writing on data mining and knowledge discovery. Kosala and Blockeel (2000) have given a survey of the research in the area of Web mining. Ma et al. (2000) have presented a system called DS-Web that uses Web to help data mining.

Packages for Data Mining

As mentioned by Hand (1998), because of commercial interest in data mining, a number of software tools have appeared in the market. Some are general tools that are good enough to do statistical analysis like SPSS, SAS,

Table 3. Packages for data mining

- Clementine (SPSS)

- Data Scope
- Explora
- IBM Visualization Data Explorer
- Model Quest Enterprise
- Nuggets
- Partek
- The Data Mining Suite
- Tooldaiag
- XpertRule

MINITAB, and so forth, while others are special tools built for data mining, for example, EXPLORA (Klosgen, 1996) and Interactive Data Exploration and Analysis Systems (Selfridge, Srivastava, & Wilson, 1996). These packages, for example, can segment market data and analyse the effect of new promotions and advertisements. Two special packages developed by Salford Systems are CART and MARS. Some of the automatic forecasting packages, which do not require specialist knowledge, are AUTOBOX and FORECAST PRO. A review of these packages including some other packages is given in Kumar (1995).

CONCLUSION

Data mining is a very general term that refers to the things that people do to understand and explore data. In this paper we have outlined some of the techniques for data mining. We have not looked at data mining from the point of view of database architecture and data warehouse. Internet data mining is different from ordinary data mining in the sense that data mining is done over the Internet and results keep on changing. With the commercial interest growing in data mining, we feel that there is a good scope for developing an automated Internet data-mining package using the tools mentioned in the paper, which could be easy enough to understand and to make decisions. This will help managers to quickly make a decision as soon as the data is updated on the Internet.

KEY TERMS

Back Propagation: A training method used to calculate the weight in a neural net from the data

Classification Tree: A decision tree that places categorical variables into classes

Data Mining: A process of seeking interesting and valuable information from a large database using a combination of methods

Discriminant Analysis: A multivariate statistical method that separates the data into categories

Internet Data: Data collected through Internet by an organization

MARS: Multivariate adaptive regression splines that are a generalization of decision trees

Neural Network: A complex, nonlinear modeling technique based on a model of the human neuron

Outlier: Data items that did not come from the assumed population of data

Sampling: Part of the data selected to represent the whole population

Time Series Model: A model that forecasts future values of the time series based on past data

Internet Diffusion in the Hospitality Industry

Luiz Augusto Machado Mendes-Filho

Universidade Federal do Rio Grande do Norte, Brazil

INTRODUCTION

Tourism is the most important industry in the world in terms of the numbers of employees and its effect on the social and economical development of a region or country. Holjevac (2003) believes that, by the year 2050, tourism will by far be the largest industry worldwide, with 2 billion tourists and US$24 billion in domestic and international receipts. Moreover, the major tourist destinations will be India, China, Indonesia, and Brazil.

The use of information technologies for basic functions—conferences, business meetings in distant places, training, designed routes and airlines, reservations and tickets purchased through computer systems, tourist shops, restaurants—is becoming usual in tourism. All these services have led tourist companies to adopt more updated methods in order to increase competition. Consumers, who are already becoming familiar with new technologies, demand more flexible, interactive, and specialized products and services, bringing new management techniques from the intelligent use of IT used to accomplish tour company business processes (Buhalis, 2000).

The hotels depend progressively on the resources of new information technology to follow and update the tools which allow an efficient development of activities in each section of the company, leading to better results for its management (Mendes-Filho & Ramos, 2003a). To Phillips and Moutinho (1998), information technology (IT) is one of the critical factors of success in the hotel industry.

According to studies and data, the use of technological tools will allow a bigger competitiveness for hotels (Cline, 1999). Technology will be the catalyst of change, a source of growing connectivity and one of the most important factors in distinguishing success among hotel companies. Few issues have greater importance to the business of hospitality than the technological decisions that will be made in the coming years (Buhalis, 2000; Mendes-Filho & Ramos, 2004; Olsen & Connoly, 2000).

The hotel industry is one of the most important kinds of Web commerce. The data shows that all major companies linked to the tourism industry (hotels, agencies, air companies, and rentals) possess some kind of e-commerce activity through the Web (O'Connor, 1999; Scottish Executive, 2000; Werthner & Klein, 1999).

BACKGROUND

Decades ago, before the use of the computer in the accommodation sector, those charged with making reservations performed their service by checking availability tables exposed on the wall or in large, updated, handwritten lists (O'Connor, 1999). The hotels received innumerous telephone calls, letters, and telex from potential clients, sometimes larger than that of the hotel's reception, and worked to select correspondence, type letters, send telegrams, and deal with other demands. The delays were frequent, the cost of correspondence writing went sky-high, and specialized typists were in demand (World Tourism Organization, 2003).

A way found by the American hotel chains to streamline the reservation services was to centralize this function in a main office, serving the consumer better and offering a valuable service to the hotels belonging to that chain. O'Connor (1999) states that the reservation process in hotels in the USA was made even easier with the introduction of free telephone services in the mid-'60s, which permitted potential clients to perform an only call to obtain information or make reservations in any of the hotels of that chain in the world.

Although the reservation area became faster and more efficient, two large costs remained, those of telecommunications (free telephone service payment) and labor costs of the reservation agents necessary to answer the phones. With the increase in trips during the 1960s, the airline companies developed the computer reservation system (CRS), which pressured the hotel sector to develop its own (O'Connor, 1999).

The main focus in hotel and restaurant management has always been the maximization of consumer satisfaction and personalized attention. The use if IT has, at times, seemed incompatible with this objective, and the hotel sector has, in a way, delayed the application of IT in its operations. The technology has been viewed as a hindrance to personalized service because it creates an impersonal, mechanical, and cold environment with the clients.

However, the change of this belief is being changed within the hotel sector. Nowadays, according to Sheldon (1997), the establishments are noticing that IT can bring efficiency to the hotel, besides reducing costs and offering a great potential to increase the levels of personalized service to the clients.

In a survey performed by financial managers of American hotels, all stated that IT increased the hotel's productivity (David, Grabski, & Kasavana, 1996). The motives used to justify this statement were the following: Technology reduces the administration costs, decreases the amount of paperwork between sectors, minimizes operational errors, increases the earnings/profits of the hotel, and makes the reservation management more efficient. This same survey proved that IT is not only used to increase the hotel's productivity but also to improve the service, as well as to offer new services to the guests.

According to Namasivayam, Enz, and Siguaw (2000), IT can also be employed to reach business objectives. American and European hotel executives have plans to use the technology to reduce operational costs, increase sales, improve the service to the client, increase employees' productivity, and increase hotel earnings.

In research performed by Van Hoof et al. (1995), 550 American hotel managers answered questions about their perceptions of the use and implementation of technology in their establishments. Those responding identified the front office (reception and reservations) of the hotel as the sector that can benefit the most from the use of the technology, followed by sales and marketing, accounting, and the food and drink sector. According to Van Hoof et al. , having a quality service is a challenge to the hotel industry, which has high employee turnover indexes, employee salary increase, and low age of the most qualified people. Consequently, technological applications have been developed in hotels to increase this quality in the services and improve the interaction of the hotel employees with the guests.

IMPACTS OF THE INTERNET IN HOTEL INDUSTRY

During the '80s and '90s several authors from companies and universities had already foreseen that as new technologies were increasingly used, hotels could benefit from that in a great range of situations, for example: better qualified services for customers, increased sales and profits, efficiency in operation and integration of hotel sectors, rapid communication, and cost reduction (Laudon & Laudon, 1999).

Technological applications enable information and knowledge to bring a competitive advantage to the future profile of the hotel. The "Information Age" idea is that the most modern companies will build their success upon the amount of knowledge they have about their clients as well as information on their products and services and how they will make a profit in this new environment (Olsen & Connoly, 2000).

With the Internet being used as a means of communication, this brings several advantages or benefits compared to other vehicles. Flecha and Damiani (2000) state that when it comes to the tourist area, the main points are: the new relationship between consumers and companies, marketing for actively participating consumers, the importance of detailed information, self-service application, credibility, and agility of communication.

The use of the Internet and World Wide Web is spreading quickly in most consumer access areas to travel database developments. There are hundreds of thousands of suppliers' homepages, associations, e-news, newsgroups, and chats for the travel and tourism community. This group of technologies provides many opportunities for the industry to interact with its consumers and suppliers. It is also possible that, through information technology, products and services may be personalized according to the tourist's needs and thus may become a differential feature for those who adopt it (Buhalis, 2000; Sheldon, 1997).

The purchase of products and services through the Internet is revolutionizing the world of business and people's lives as well. For some clients it is more comfortable to book an e-ticket through the company home page rather than going to the travel agency (Franco, 2001).

As the Internet began and grew, the use of such technologies at home or work and also the new opportunities that arose from the lower costs in telecommunication equipment made it possible for suppliers to distribute information to their clients and process reservations directly with the clients (O'Connor, 1999).

According to Jeong and Lambert (2001), the Internet has already modified the competitive strategy of some hotels. It is through the Internet that the client can have a "self-understanding" in a service that is being offered to him in a more efficient way. In hotels, check-in processes can already be totally automatic, from the Internet booking until the moment the client takes his keys in an automatic dispenser. The result is that clients can become more informed and willing to have quick answers from the orders online. Though many experts and businessmen agree that the Internet is probably the most important technological tool, it is still relatively new and misused in the hotel industry (Van Hoof & Verbeeten, 1997).

Several authors have identified impediments to the growth of the Internet in the industry and, hence, have reservations about the willingness of hotel operators to adopt the Internet wholeheartedly (Wei et al., 2001). These problems include user-friendliness, the quality and accuracy of information obtained from the Web, and the issue of data security (Wei et al.). Here are other difficulties found by Lituchy and Rail (2000) in their research: problems in updating new information in hotel Web pages, annoyance expressed at inaccessible Webmasters by managers, hard to find hotel Web sites, lack of knowledge on the employees' part of how to use the technology, and the impersonality of the medium. Because of these, consumers have been slow to adopt the Internet as a means of making hotel reservations. Only 4% of reservations are made online (Maselli, 2002).

Namasivayam et al. (2000) summarize that almost 60% of the hotels in their study had few technologies. To Feiertag (2000), a lack of proper training, high turnover rates, and limited financial resources were major barriers to the successful use and implementation of new technologies.

In addition to this, many hotels still believe that conventional means of advertising, such as radio, television, and printed material, are the most effective way of promoting their properties. The share of reservations received through the Internet remains minute compared to reservations received through conventional means, such as phone, fax, or mail (Van Hoof & Combrink, 1998). However, these problems are diminishing with the increase of the number of Internet users. And if customers become accustomed to browsing for rooms and making reservations through the Internet, more and more properties will be forced to get on the Internet as well (Mendes-Filho & Ramos, 2002).

In a specific way, the Internet provides an expansion of hotel services, changing this industry and giving new opportunities to clients, thus being a new channel to be developed. Besides online reservation services, the Internet allows hotels to sell their services and charge them electronically as well as offer new products through the World Wide Web (Blank, 2000; Laudon & Laudon, 1999).

Through the Web the customer can check hotel location, compare rates, see pictures and watch videos, get information about tourist destinations and other facilities, check room availability, and book and confirm reservations for the amount of time he wants to stay, among other services. Hence, the interactivity of the Web provides an ideal medium for distributing accommodations online, consolidating itself as a very adequate platform for bringing information and services to the client in a very straightforward, efficient, and quick way (Flecha & Damiani, 2000; Hotels, 2001).

Marriot, Hospitality Services of America, and Hilton are some of the hospitality industry's members that have successfully used marketing on the Internet to reach new markets, track customers, take online reservations, and offer information about their products and services (Lituchy & Rail, 2000).

FUTURE TRENDS

A hotel chain's success has always depended on excellent services performed by operation, marketing, and human resources sectors. For Withiam (2000) in the 21st century an essential factor will be technological support, making it possible for computers to process information of reservation systems, affinity programs, and marketing data banks.

Improvements in integration, centralized data banks, and the use of Web sites are some of the tendencies in the development of software for hotels (Adams, 2001). Therefore, the connection of a hotel system to the Internet will integrate information of the internal system with the Web site, and this will make a lot of information available to managers. The new systems are being developed with this integration with the Web site.

With the increasing demand of information in the tourist sector, the importance of IT use in this industry will only tend to increase in the future. Therefore, the tourist businesses must understand, incorporate, and use IT strategically to serve the target markets, improve their efficiency, maximize profitability, perfect services, and maintain the profitability in the long term (Buhalis, 2000).

To Olsen and Connoly (2000), the volume of information about the guests collected electronically is too large for the directors to be able to manage without the help of technology. Data warehousing and data mining are technologies that are gaining popularity to analyze information about clients. These technologies may be used to help hotel keepers construct good relationships with their guests, increasing their loyalty to them.

Using the Internet in the hotel industry has good prospects of growth, though in many hotels the use of such technology is still moving slowly. On the other hand, there are some hotels using and steadily setting the trend. It will be an important and strategic issue for businessmen to stimulate such Internet use policies inside the tourist trade so that they become wired to this new reality and can work on even terms with their competitors.

CONCLUSION

The Internet has decreased expenses and enabled small businesses to conduct international business from home (Lituchy & Rail, 2000). Small inns and bed and breakfasts are advertising on the Web and are therefore becoming a presence in the global market. So, they face the likelihood of serving foreign customers that may have different hospitality expectations.

Despite the fact that Internet use is very common, the proportion of reservations received from the Internet is small. The public could still be concerned about issues of

security for financial transactions or could not be satisfied with its inability to synchronize inquiries. A low reservation rate from the Internet may also be partly attributed to the lack of certain relevant information, such as room availability and virtual tours of the property not commonly included in the homepage (Wei et al., 2001).

In general, the Internet does enable tourist companies to increase their competitiveness. IT can improve the efficiency of suppliers and provide tools for the development and delivery of different tourist products (Mendes-Filho & Ramos, 2003b). One of the benefits reached is the reduction of the dependence on the middlemen in the distribution of tourist products. Hotel owners should invest more money in technology besides concentrating more time and attention to subjects in that area. IT affects all aspects of a hotel chain's value, going far beyond sectors and departments. As technology will be intrinsically linked to hotel business, its executives will insert technology in all their strategic decisions for the facility. That implies all the employees (including managers and directors) need to have enough knowledge to extract the potential the technology provides.

KEY TERMS

Bed and Breakfast: An establishment (as an inn) offering lodging and breakfast.

Computer Reservation System: A computer system that manages the distribution of the tourist products to transportation, lodging, and entertainment companies.

Data Mining: The process of analyzing data to determine relationships undiscovered by previous analyses.

Data Warehouse: A data warehouse is a central repository for all or significant parts of the data that an enterprise's various business systems collect.

E-Ticket: An e-ticket (electronic ticket) is a paperless electronic document used for ticketing passengers, particularly in the commercial airline industry. Virtually all major airlines now use this method of ticketing.

Front Office: The department of the hotel that deals directly with clients. Normally, it involves the reception and the reservation sector of the hotel.

Middleman: A dealer or agent intermediate between the producer of goods and the consumer or retailer.

Internet Support for Knowledge Management Systems

Murray E. Jennex
San Diego State University, USA

INTRODUCTION

Organizations are building and maintaining systems for managing organizational knowledge and memory. Users of these systems may not be at the same location; in many cases they are distributed across large geographical distances and multiple offices. Key to this task is developing an infrastructure that facilitates distributed access and utilization of the retained knowledge and memory. Connectivity and easy to use interfaces are main concerns. Jennex (2000) found that using the Internet as a common communications platform (either as an Intranet or an Extranet) and Web browsers as an interface is a viable, low cost solution. Newell, et al. (1999) found that Intranets not only supported distributed knowledge processes but also enhanced users' abilities to capture and control knowledge. Stenmark (2002) proposes that using a multiple perspective of the Internet— information, awareness, and communication—allows developers to build successful Internet-based knowledge management systems, KMS. This article discusses how the Internet can be effectively used as an infrastructure for knowledge management/organizational memory systems, KMS/OMS.

BACKGROUND

The OMS consists of the processes and information system components used to capture, store, search, retrieve, display, and manipulate knowledge. The KMS consists of the tools and processes used by knowledge workers to interface with the knowledge contained in the OMS. Knowledge is managed and used through a combination of the KMS and OMS. Jennex and Olfman (2002) identified the KMS-OMS model in Figure 1 as a representation of the relationships between the OMS, KMS, and organizational learning. Organizational learning, OL, is identified as a quantifiable improvement in activities, increased available knowledge for decision-making, or sustainable competitive advantage (Cavaleri, 1994; Dodgson, 1993; Easterby-Smith, 1997; Miller, 1996).

There are two approaches to building a KMS as discussed by Hansen et al. (1999), Morrison and Weiser (1996), and Stenmark (2002). These can be described as a process/task approach and the infrastructure/generic approach. The process/task approach focuses on the use of knowledge/OM by participants in a process, task or project in order to improve the effectiveness of that process, task or project. This approach identifies the information and knowledge needs of the process, where they are located, and who needs them. This approach requires the KMS to capture less context, as users are assumed to understand the knowledge that is captured and used.

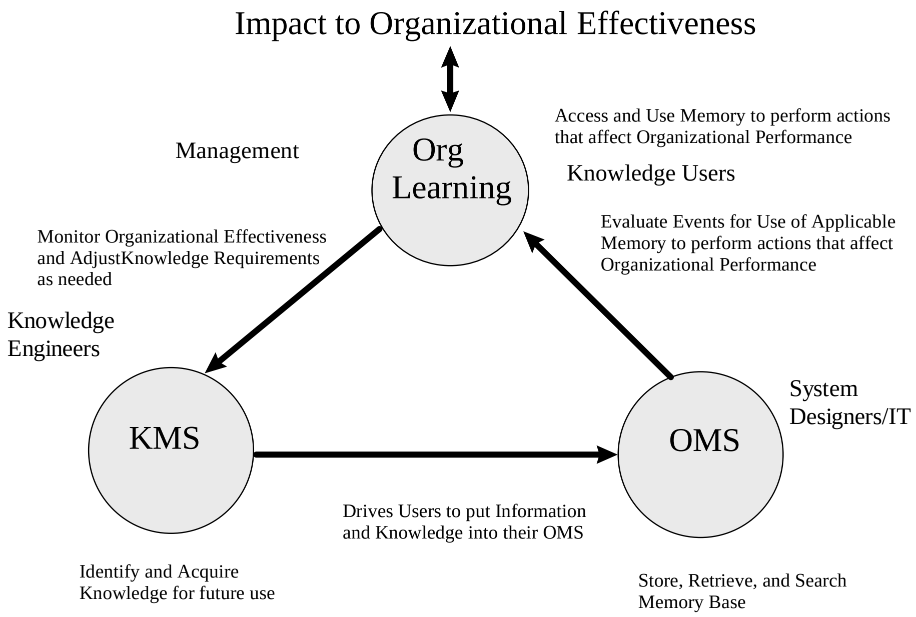
The infrastructure/generic approach focuses on building a system to capture and distribute knowledge/OM for use throughout the organization. Concern is with the capturing of context to explain the captured knowledge and the technical details needed to provide good mnemonic functions associated with the identification, retrieval, and use of knowledge/OM. The approach focuses on network capacity, database structure and organization, and knowledge/information classification.

Both approaches may be used to create a complete KMS. The process/task approach supports specific work activities, while the infrastructure/generic approach integrates organizational knowledge into a single system that can be leveraged over the total organization instead of just a process or project.

Jennex and Olfman (2001) developed a set of design recommendations for enabling KM/OM in systems. The recommendations, Table 1, are based on studies of KMS/OMS success factors. One recommendation calls for use of a common infrastructure. The Internet is suggested for this due to its widespread availability, open architecture, and developed interfaces. This also assists in standardizing software across the organization through the use of browsers and Web applications.

The Internet meets several of these recommendations. It provides a common network that is global. Use of common browsers aids in standardizing software. Ease of use of browsers and in building and maintaining Internet-based systems empowers users (Newell et al., 1999) and simplifies incorporating the KMS into everyday processes. Ease in handling unstructured data as well as databases simplifies knowledge representation, capture, and dissemination. Table 2 lists Internet tools and features that expand the ability of the Internet to serve as the infrastructure for a KMS. Some of these features are expanded in the following.

Figure 1. The Jennex-Olfman KMS-OMS model



Gandon et al. (2000) propose using XML to encode memory and knowledge, and suggest using a multi-agent system that can exploit this technology. The proposed system would have improved search capabilities and would improve the disorganization and poor search capability normally associated with Web pages. Chamberlin et al. (2001) and Robie et al. (1998) discuss using XML query language to search and retrieve XML encoded documents.

Dunlop (2000) proposes using clustering techniques to group people around critical knowledge links. As individual links go dead due to people leaving the organization, the clustered links will provide a linkage to people who are familiar with the knowledge of the departed employee. Lindgren (2002) proposes the use of Competence Visualizer to track skills and competencies of teams and organizations.

Te'eni and Feldman (2001) propose using task-adapted Web sites to facilitate searches. This approach requires the site be used specifically for a KMS. Research has shown that some tailored sites, such as those dedicated to products or communities, have been highly effective.

Eppler (2001), Smolnik and Nastansky (2002), and Abramowicz et al. (2002) use knowledge maps to graphically display knowledge architecture. This technique uses an intranet hypertext clickable map to visually display the architecture of a knowledge domain. Knowledge maps are also known as topic maps and skill maps. Knowledge maps are useful, as they create an easy to use standard graphical interface for the Intranet users and an easily understandable directory to the knowledge.

The use of ontologies and taxonomies to classify and organize knowledge domains is growing. Zhou et al. (2002) propose the use of ROD, rapid ontology development, as a means of developing an ontology for an undeveloped knowledge domain.

FUTURE TRENDS

Although there is strong support for using the Internet as a knowledge infrastructure, there are areas that current research is improving. Chief among these is the difficulty in organizing and searching large quantities of knowledge in varying knowledge formats and structures. Knowledge can be stored as documents, audio, images, databases, and spreadsheets. Lack of standard structure can make organizing knowledge difficult, while the lack of standard terms and naming conventions makes searching difficult. An example is Ernst & Young UK, who in early 2000 had in excess of one million documents in its KMS (Ezingeard et al., 2000). Another concern is the tendency to not to use the system. Jennex and Olfman (2002) fount that voluntary use is enhanced if the system provides near and long-term job benefits, is not too complex, and the organization's culture supports sharing and using knowledge and the system. Other significant issues requiring resolution are summarized in Table 3 and include security, having ad-

Table 1. KMS design recommendations

- Use a common network structure, such as the Internet.
- Add KM/OM skills to the tech support skill set.
- Use high-end PCs and/or clients.
- Standardize hardware and software across the organization.
- Incorporate the KMS into everyday processes and IS.
- Use an enterprise-wide data dictionary to design knowledge base.
- Allocate maintenance resources for KMS.
- Train users on use and content of the KMS.
- Create and implement a KM strategy/process for identifying/maintaining the knowledge base.
- Expand system models/life cycles to include the knowledge process.
- Assess system/process changes for impact to the KMS.
- Automate data capture.
- Design security into the knowledge base.
- Incorporate KM into personnel evaluation processes.
- Implement KMS use/satisfaction metrics.
- Identify organizational culture concerns that could inhibit KMS usage.

equate bandwidth for the expected use, maintaining content in large sites, and system incompatibilities between distributed offices/users.

CONCLUSION

The conclusion is that the Internet is an effective infrastructure for a KMS. However, there are issues associated with using the Internet that KMS designers need to be aware of. Chief among these are knowledge representation and search. Several tools such as knowledge maps, XML, adaptive Web sites, clustering, and examples of effective Internet-based KMSs were discussed that addressed these issues. However, as knowledge bases grow, designers need to be aware of increasing search times as well as a variety of knowledge artifacts. This is perhaps the most important area for future research. Developing ontologies and taxonomies to aid in classifying and structuring knowledge domains is critical.

Maintaining a site is critical. User, organizational, and/or project needs for knowledge change over time, requiring the KMS to change its knowledge content. Also, knowledge has a life cycle and eventually reaches

Table 2. Internet features/technologies that support KMS

- Common Architecture and Interfaces
- Easy to Use Front-end Systems (Browser User Interface)
- Trends Towards Internet-Based Processes
- Back-end Systems that Provide Database Access to Users
- XML wrapping of documents and other data
- Powerful Search Engines
- Virtual Private Networks
- Internet Opportunities Include:
  - Ability to push time-sensitive data quickly to a wide audience
  - To answer frequently asked questions
  - To create 24-hour service
  - To make knowledge additions/updates available quickly
  - To allow feedback from users
  - To service both specialized teams/users and generic users

Table 3. A summary of issues for future trends of Internet-based KMS

Bandwidth Restrictions and Latency
Improving transmission and methods to enable large numbers of users to receive knowledge from the KMS

Organizing Knowledge
Creating standard ontologies and taxonomies to enable standard knowledge structures

Flooding of the Web with content
Improving knowledge acquisition so that content not helpful to the users is captured

Maintenance and integrity of data
Keeping Web maintenance up-to-date and accurate knowledge on the site for users

Exposure Points/Security
Creating secure systems that allow remote access yet keep unauthorized user access out

System incompatibilities
Improving cross-platform compatibility to improve system integrations and access

a point where it is no longer useful. Organizations must allocate resources to update and maintain every KMS.

Securing the KMS is also critical, as knowledge is valuable. KMS/OMS designers need to ensure the security of captured knowledge and use of secure connections is a viable alternative. This may be the greatest impediment to the development of Internet-based KMSs.

The final issue is the tendency of people not to use the computer portion of a KMS. Jennex and Olfman (2002) found that this is a tendency of new members and suggest that this is a matter of context. New members do not understand the context under which the knowledge was created and stored so do not know how to retrieve and use the knowledge. As these members gain experience they gain context and rely more upon the computer and less upon their peers.

KEY TERMS

Knowledge: An evolving mix of framed experience, values, contextual information and expert insight that provides a framework for evaluating and incorporating new experiences and information (Davenport & Prusak, 1998).

Knowledge Management: The process established to capture and use knowledge in an organization for the purpose of improving organizational performance (Malhotra, 1998).

Knowledge Management System: The system created for users to interact with the organizational memory system.

Knowledge Map: An Intranet hypertext-clickable map to visually display the architecture of a knowledge domain. Knowledge maps are also known as topic maps and skill maps.

Knowledge Ontology: Common definitions established for captured knowledge, similar to key words, used to capture and express a common context for search, retrieval, and use of knowledge.

Knowledge Taxonomy: The hierarchical organization of knowledge categories within a knowledge management system.

Organizational Learning: The process by which an organization assimilates experiences of its members and uses that experience to modify the organization's potential actions (Jennex & Olfman, 2003).

Organizational Memory: The means by which knowledge from the past is brought to bear on present activities resulting in higher or lower levels of organizational effectiveness (Stein & Zwass, 1995; Walsh & Ungson, 1991).

Organizational Memory System: The system created to capture, store, search, and retrieve knowledge from a repository.

Interoperability in Geospatial Information Systems

Hassan A. Karimi

INTRODUCTION

Geospatial information systems (GIS) are an important sector of the information industry, as well as an essential component of the information technology infrastructure (Lo & Yeung, 2002). They are a type of computerized information system specifically designed and used to solve *geospatial* problems, those which are related to locations on the surface of the earth (Longley, Goodchild, Maguire, & Rhind, 2001). The extent of usefulness of GIS has been proven across many diverse applications in many disciplines. They have long been used in traditional application settings, such as land management and natural resources, and have recently become an important element in emerging applications, for example, in ubiquitous mobile computing environments.

Since the mid-1990s, the focus of computing has shifted from stand-alone and locally networked environments to wide-scale, distributed, heterogeneous computing infrastructures. This coupled with the exponential growth in the use of the Internet has enabled and compelled new ways of using GIS. A wide range of GIS applications are now widely available on the Internet for users from anywhere in the world. In addition, the proliferation of wireless and mobile computing technologies, such as cellular phones and Personal Digital Assistants (PDA), has provided new platforms and paved the way for the emergence of new GIS applications. Because of the advances in computing, GIS applications are now designed, implemented, and applied very differently from their predecessors.

Contrary to their past monolithic design and implementation, GIS are now becoming an integral component of many diverse software packages specifically designed for solving problems in different application domains. In addition, current computing trends suggest that future GIS will be multitiered and used in heterogeneous network environments, where computers of different platforms coexist and tasks are performed in a distributed manner. Consequently, future GIS will have to be *interoperable*—they will have to be able to work together in a seamless fashion.

BACKGROUND

Efficient and effective use of GIS to solve geospatial problems generally requires special skills. Today's GIS platforms are mostly designed for workstations or personal computers and provide generic "toolbox" *geoprocessing* operations that can be broadly applied to many problems in different application domains. To utilize these packages, the users must possess certain knowledge and skills. First, they must have knowledge about how real-world objects are represented in GIS; for example, the boundary of a county is represented as a set of points that defines a polygon, and a railroad is represented as a line object. Second, the users must know the range of available geoprocessing operations in GIS and how they are applied to solve geospatial problems. For example, the users must know that in order to determine if a railroad crosses a county boundary, a geometric intersection operation using a polygon and a line that define the county boundary and the railroad, respectively, should be applied. In addition, knowledge about geospatial data sources, geospatial data storage, and methods of obtaining geospatial data are also needed. To solve the problem of county boundaries, the users must have knowledge about the sources of data sets for polygons representing county boundaries. They must also know the format and structure in which the data sets are stored. Lastly, the users must know how a GIS software package operates and how to use it to solve problems. For example, they must know how to operate the ArcInfo GIS software package and be familiar with the methodology in ArcInfo for incorporating data sets into the project, including format conversion, coordinate transformation, and importing procedures. They must also know the specific commands and syntax for invoking geoprocessing operations in ArcInfo as well as the specific behavior of each operation (e.g., Does the "intersect" operation provided by ArcInfo partially, or fully, solve the problem?).

These difficulties in using GIS are due to a number of historical and practical reasons. GIS software packages generally approach geospatial problems in terms of abstract geometrical objects and operations, that is, computations on points, lines, and polygons. This imposes a heavy burden on the users because the first task in solving any problem with GIS is to map real-world problems into an environment where GIS techniques and tools can be used. This task is further complicated by the fact that problems in different application domains are often treated differently in GIS. For example, applications in ecology usually involve large-scale raster data and spatiotemporal analysis for visualization purposes, while applications in urban navigation generally involve a smaller geographic extent and are concerned mainly with real-time decision information. In addition, GIS software packages have historically been developed independently with little regard to data sharing (Goodchild, Egenhofer, & Fegeas, 1998). Different GIS software packages use their own proprietary formats, schemas, and terminologies to represent geospatial data and concepts. This has exacerbated the issue of data use, especially when they are to be shared, requiring manual conversions or availability of import and export tools. This process is often nontrivial and, considering the large volumes of data commonly required in GIS projects, is also very time consuming.

MAIN THRUST OF THE ARTICLE

Information Heterogeneity

The aforementioned issues are related to interoperability. The basis for problems related to interoperability is *information heterogeneity*, which is divided into three levels (Sheth, 1999): *syntactic heterogeneity*, which refers to the differences in formats and data types; s*tructural heterogeneity*, which deals with the differences in data-modeling constructs and schemas; and *semantic heterogeneity*, which refers to the variations of the intended meanings of concepts and terminologies. Table 1 provides examples of information heterogeneity in GIS.

The issues of syntactic and structural heterogeneities have been extensively addressed in the past within the computer and information science discipline. Recently, much research has been focused on addressing the issue of semantic heterogeneity, which is a significant problem in the field of GIS. In general, semantic heterogeneity is a result of different conceptualizations and representations of things in the world and can be distinguished into two types (Bishr, 1998).

Cognitive heterogeneity, which arises when two groups of people from different disciplines conceptualize the same real-world facts differently. As an example, a geologist thinks of hill slopes as areas where soil erosion or landslides can occur, but a tourist manager may think of hill slopes as areas where skiing is possible (Dehn, Gartner, & Kikau, 1999).

Naming heterogeneity, which arises when different names are used for identical concepts of real-world facts. For example, *hill slope* is also known as *valley side*, *mountain flank*, or simply *slope*.

Due to the widespread use of GIS by users both within and across disciplines, semantic heterogeneity in GIS is increasingly becoming an important issue in the GIS community. In the first example illustrated by Lutz, Riedemann, and Probst (2003), the semantic of the *touch* topological operator in the GeoMedia Professional GIS software package is different from that of Oracle 9i Release 2 Spatial (Table 2.). In GeoMedia, two polygons would satisfy the touch operator if their boundaries and/or interiors intersect. In Oracle, on the other hand, two polygons would satisfy the touch operator only if their boundaries, and not their interiors, intersect.

Furthermore, two GIS software packages may use

Table 1. Information heterogeneity in GIS

Information Heterogeneity	**Examples**
Semantic	Different behaviors of the "intersect" operation from different GIS software packages Different interpretations of the word "within" in a user's query
Structural	Different data dictionaries when merging two or more data sets Different metadata standards
Syntactic	Different data formats (e.g., Shapefile, ASCII [American Standard Code for Information Interchange], XML [eXtensible Markup Language])

Table 2. Topological relationships between two polygons and whether they satisfy the "touch" operator invoked in two different GIS software packages

		
GeoMedia Professional GIS	YES	YES
Oracle 9i Release 2 Spatial	YES	NO

different names for the same spatial operation. For example, the operation for aggregating polygons based on an attribute is called *dissolve* in the ArcGIS software package, but may be known by others as a *merge* operation (Figure 1).

These occurrences of semantic heterogeneity can lead to confusion and unexpected outcomes for users who need to deal with multiple GIS platforms or interact with other users who use different GIS platforms. The reconciliation of the differences in semantics must be accomplished by all parties involved in order for them to interoperate.

In another example of semantic heterogeneity, a German motorist in 1998 drove his car into a river after following instructions given by its navigation system. Though there may be other factors that led to the accident, Raubal and Kuhn (2004) hypothesize that the technical factor was that the in-car navigation computer did not make the distinction between a *bridge*, which is a permanent pathway, and a *ferry*, which is a transport carrying cars across a river. Though both a bridge and a ferry are pathways that can be used for route computations, a crucial semantic distinction must be made between them when instructions are given to drivers to account for the nonpermanent nature of the ferry.

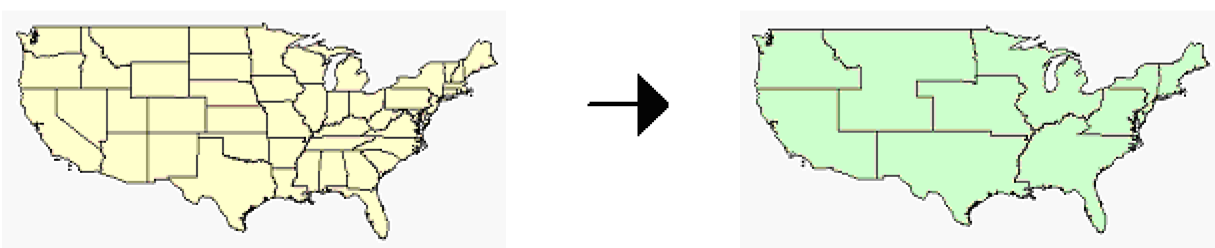
To overcome information heterogeneity in GIS and provide interoperability in GIS platforms, users, and data, there needs to be an agreement among the parties involved.

The Open GIS Consortium Standards

Many standards have been defined for the GIS domain to allow interoperability among different GIS platforms. However, currently the most prominent standard body for GIS is the Open Geospatial Consortium (http://www.opengeospatial.org). OGC is an organization consisting of companies, government agencies, and universities participating in a consensus process to develop publicly available geoprocessing specifications that result in interoperability among diverse GIS platforms. The creation of the OGC was to address interoperability issues among different GIS platforms, particularly when they are used in the Internet environment. The development process of the OGC involves the creation of abstract specifications and implementation specifications.

The purpose of abstract specifications is to create the conceptual foundation that facilitates understanding of real-world geospatial phenomena, and allow for the development of implementation specifications by precisely capturing and stating requirements and knowledge of the abstract geospatial domain. Essentially, abstract specifications describe how "ideal" software should work, and they include, but are not limited to, topics on feature geometry, topology, coordinate reference systems, and geospatial metadata. Abstract specifications mainly concern abstract geospatial objects and concepts applicable to GIS (e.g., point, line, and polygon) and do not specifically address real-world, application-

Figure 1. Operation for aggregating areas based on an attribute may be called differently in different GIS software packages



context concepts and terminologies (e.g., street, river, forest). For example, the topic *Feature Geometry*, which is also a draft international standard (ISO 19107 Spatial Schema; Herring, 2001), is the standard that specifies geometrical and topological objects as well as operations which can be applied on them.

Implementation specifications provide programmers with specific programming rules and advice for implementing interfaces and protocols that enable interoperability between different GIS platforms. They are engineering specifications that implement part of the abstract specification for particular distributed computing platforms. For example, the Web Map Service (WMS) Implementation Specification specifies the interface for providing mapping services over the Web (Beaujardiere, 2002). Another example, the Geography Markup Language (GML), is a language designed to be a general data format for modeling, transporting, and storing geospatial information (Cox, Daisey, Lake, Portele, & Whiteside, 2003). GML is an XML (eXtensible Markup Language) grammar written in XML schema that provides a variety of kinds of objects for describing geography as defined in abstract specifications, including features, coordinate reference systems, geometry, topology, time, and units of measurement.

Although the OGC standards address many aspects of information heterogeneity in geoprocessing, they are designed by GIS experts for use by GIS experts in implementing GIS projects. Missing from the OGC standards, however, is the issue of how to allow non-expert users to realize the potential of GIS by making the task of geospatial problem solving easier through semantic interoperability in the application-domain context.

Ontological-Based GIS

There are two key aspects related to semantic interoperability in GIS. First, there is a need for semantic agreement on geospatial data models (e.g., point, line, polygon) and geoprocessing operations (e.g., buffering, intersection). Second, there is a need for semantic agreement about real-world, application-level geographic objects, concepts, and terminologies used in geospatial problem solving. The OGC standards address the first aspect of semantic interoperability by providing a uniform definition and behavior of abstract geometrical objects and geoprocessing operations. However, it does not address the second aspect of semantic agreement regarding the geographic world and application-domain contexts. As previously discussed, one difficulty in using GIS is the mapping of real-world problems into a form which GIS understand. This is arguably the first and most important task of problem solving in GIS, and current technology does not have a means to automate it.

An approach to address the problem is by incorporating *ontologies* into GIS, which would provide shared bodies of semantic knowledge of the geospatial domain. An ontology is a specification of a conceptualization (Gruber, 1993) that allows parties who agreed to an *ontological commitment* to communicate with one another and share knowledge. It may include a dictionary of terms and a specification of their intended meanings. The concepts defined in an ontology and how they are interrelated collectively impose a structure on the domain and constrain the possible interpretations of terms (Uschold & Jasper, 1999). In the information-system context, ontologies are machine-processable bodies of knowledge. As such, an ontological-based GIS would allow the use of geospatial information based primarily on its meaning (Fonseca, Egenhofer, Agouris, & Camara, 2002).

In an ontological-based GIS, an ontology would include concepts and terminology about an application domain that users can directly relate to and use. For example, an ontology would define terms specific to the application domain of ecology and how they can be interpreted. This ontology can then be used by the users to formulate their geospatial queries that would conform to the knowledge defined in the ontology. Furthermore, the OGC geoprocessing standards can be considered as another distinct ontology that constrains the meaning and behavior of geometrical objects and operations. Since solving geospatial problems using GIS involves mapping real-world queries into geometries and operations, bridging the two ontologies would provide the means for interpretation of geospatial queries by computers.

Recent research efforts on geospatial ontology include cognitive and philosophical aspects on how the real world should be modeled and formalized into ontologies (Mark, Freksa, Hirtle, Lloyd, & Tversky, 1999; Mark, Smith, & Tversky, 1999; Smith & Mark, 1998, 2001), as well as how to use ontologies in GIS (Fonseca et al., 2002; Karimi, Akinci, Boukamp, & Peachavanish, 2003; Kuhn, 2001; Raubal & Kuhn, 2004; Visser, Stuckenschmidt, Schuster, & Vogele, 2002).

FUTURE TRENDS

One of the goals of GIS research, explicitly stated or not, is to advance the technology to a point where it can be used as decision-support systems assisting users in solving a wide variety of problems in many applications. We consider GIS to be decision-support systems when they are easy to use by all users with different backgrounds, able to solve complex problems that otherwise are handled inefficiently, semantically interoperable, and equipped with knowledge and reasoning to provide automated decision-making tasks, especially in real-time applications.

This need is evident by the proliferation of application-specific GIS on the Internet (e.g., Web sites that provide driving directions) and in other distributed environments (e.g., location-based wireless real-time services). To thrive in these heterogeneous, distributed environments, GIS platforms must support interoperability. Additionally, much research is still needed to unlock the potential of GIS to ordinary users for solving complex problems. For instance, semantic integration into GIS through ontologies is a research area that would facilitate interoperability at a higher level, allowing the use of GIS by many users with little GIS background, lowering geoprocessing costs, and increasing the usefulness of GIS in general.

CONCLUSION

GIS have come a long way from being simple stand-alone tools that facilitated digital mapping and primitive geoprocessing to information systems capable of performing sophisticated geoprocessing on stand-alone or distributed platforms. This evolution took over 4 decades and was made possible through advances in computer geometry, database systems, personal computers, Internet, and other techniques and technologies. During the same period, the number of applications that adopted GIS technology increased. Today, numerous applications utilize GIS technology to solve a range of simple to complex problems. However, despite the complex operations current GIS support and the widespread applications in which they are employed, they markedly lack the ability to interoperate due to various historical and practical reasons. Advances in key areas are needed before GIS become more interoperable and accessible to all users, novice or expert, paving the way for the emergence of new applications.

KEY TERMS

Geoprocessing: Operations in GIS for integrating, analyzing, computing, and presenting geospatial data.

Geospatial Data: Data representing objects on or near the surface of the earth.

Geospatial Information Systems (GIS): Information systems capable of storing, managing, computing, and displaying geospatial data for solving geospatial problems.

Geospatial Problems: Problems involving geospatial data, objects, and phenomena.

Information Heterogeneity: The differences in syntax, structure, and semantics used in different information systems.

Interoperability: The ability of two or more heterogeneous systems to work together in a seamless manner.

Ontology: A conceptualization and representation of objects and phenomena and the relationships among them in a domain.

Standard: An agreed-upon set of concepts, terminologies, and methodologies by a given community.

Interoperability of Information Systems

Christophe Nicolle

Kokou Yétongnon
Université de Bourgogne, France

INTRODUCTION

An information system is a multilevel system characterized by a "data" level, a "behavioral" level, and a "communication" level. The data level represents the data stored by the system. The behavioral level represents management and production processes carried out by the system. The processes can interact with the data level to extract, generate, and store data. The communication level relates to the network used to exchange data and activate processes between geographically distant users or machines.

Information system interoperation has emerged as a central design issue in Web-based information systems to allow data and service sharing among heterogeneous systems. Data heterogeneity stemming from the diversity of data formats or models used to represent and store information in the Web is a major obstacle to information systems interoperability. These data models range from the structured data models [network, relational, object oriented (OO)] found in traditional databases to flat files and emerging Web-oriented semistructured models. Information system interoperability aims at supporting the amalgamation of autonomous heterogeneous systems to create integrated virtual environments or architectures in which information from multiple disparate sources can be accessed in a transparent and efficient manner. As an example of such integrated virtual systems, consider an airline reservation system based on the integration of a group of airlines reservation and ticket sale information systems. The specific airline systems provide various types of fares and special discount trips that can be searched and compared to respond to user queries for finding the best available prices for specified flights.

BACKGROUND

Database interoperability issues have been extensively studied in the past. Several approaches, including database translation, distributed systems, federations, language-based multidatabase, ontology, and mediation, have been proposed to bridge the semantic gaps among heterogeneous information systems.

The database translation approach is a point-to-point solution based on direct data mappings between pairs of information systems. The mappings are used to resolve data discrepancies among the systems (Yan & Ling, 1992). The database translation approach is most appropriate for a small-scale information-processing environment with a reduced number of participants. The number of translators grows with the square of the number of components in the integrated system. For example, consider two information systems IS1 and IS2 in the travel agency example above. The corresponding translators must be placed between the information systems as shown in Figure 1. Information in IS1 is represented by vertical lines, while the information in IS2 is shown as horizontal lines.

In the standardization approach (Figure 2), the information sources use the same model or standard for data representation and communication. The standard model can be a comprehensive metamodel capable of integrating the requirements of the models of the different components (Atzeni & Torlone, 1997). The use of a standard metamodel reduces the number of translators (this number grows linearly with the number of components) to resolve semantic differences. However, the construction of a comprehensive metamodel is difficult; the manipulation of high-level languages is complex; and there are no unified database interfaces. In our example, the travel agencies must define a common model to export their data. A centralized information system can be built to replace the original information systems (IS1, IS2). The global centralized schema is a combination of the data (horizontal and vertical lines) contained in IS1 and IS2.

Federated systems (Figure 3) consist of a set of heterogeneous databases in which federation users can access and manipulate data transparently without knowledge of the data location (Sheth & Larson, 1990). Each federation database includes a federated schema that incorporates the data exported by one or more remote

Figure 1. Database translation approach

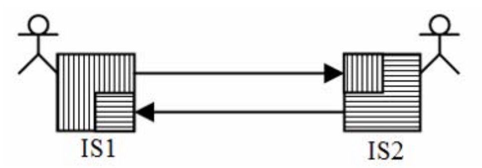

Figure 2. Standardization approach

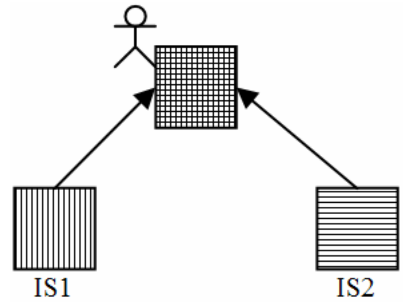

Figure 3. Federated systems

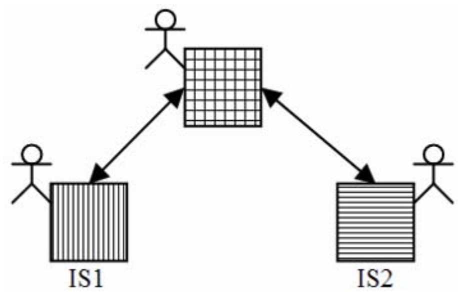

Figure 4. Multibase systems

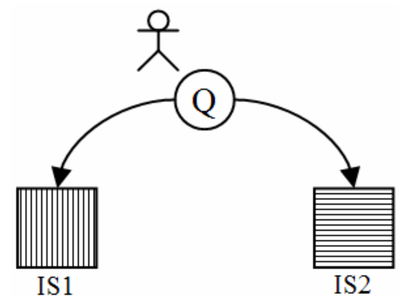

Figure 5. Ontology approach

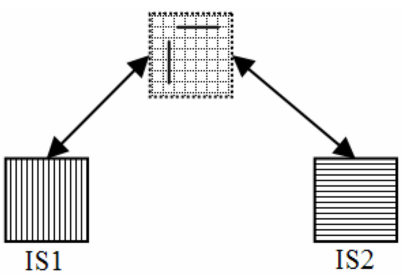

Figure 6. Mediation approach

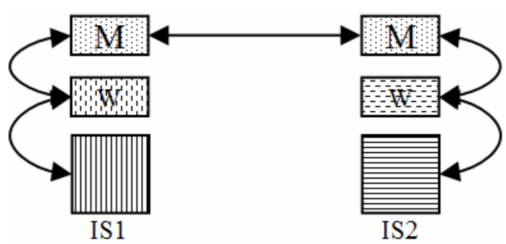


information systems. There are two types of federations. A tightly coupled federation is based on a global federated schema that combines all participant schemas. The federated schema is constructed and maintained by the federation administrator. A loosely coupled federation includes one or more federated schema that are created by users or the local database administrator. The federated schema incorporates a subset of the schema available in the federation. This approach becomes rapidly complex when the number of translators required becomes large. In our example, the existing information systems are completely operational for local users. Only the shared data are integrated in the federated schema. The federated system is made only of horizontal and vertical lines that IS1 and IS2 want to exchange.

Language-based multibase systems (Figure 4) consist of a loosely connected collection of databases in which a common query language is used to access the contents of the local and remote databases (Keim, Kriegel, & Miethsam, 1994). In this approach, in contrast to the distributed and federated systems, the burden of creating the federated schema is placed on the users, who must discover and understand the semantics of the remote databases. In our example, the various companies have to define a global common language (Q) to query their information systems (IS1, IS2). This solution is well adapted for information systems that are based on the same family of data models and do not require complex query translators.

The ontology-based interoperability approach (Figure 5) uses ontology to provide an explicit conceptualization of the common domain of a collection of information systems (Benslimane, Leclercq, Savonnet, Terrasse, & Yétongnon, 2000). An ontology defines a common vocabulary that can be used by users from different systems. The construction of an ontology for a domain is a difficult task and often requires merging existing overlapping ontologies. The interoperability solutions based on ontology describe the semantics of information rather than their organization or their format. In our example, the companies have to define ontology to capture the semantics of their domain of activity.

The mediation approach (Figure 6) is based on two main components: mediator and wrapper. The mediator is used to create and support an integrated view of data over multiple sources. It provides various services to support query processing. For instance, a mediator can cooperate with other mediators to decompose a query into subqueries and generates an execution plan based on the resources of the cooperating sites. The wrapper is used to map the local databases into a common federation data model. The wrapper component provides the basic data access functions (Garcia-Molina, Hammer, Ireland, Papakonstantinou, Ullman, & Widow, 1995). In our example, a translator, which acts as a wrapper, is placed between the conceptual representation of the mediator and the local description of each information source.

Table 1. Overview of architectures for interoperable information systems

Systems	**Advantages**	**Limits**	**Tools or methods used**	**Levels**
Translation	• Better control of point-to-point translation	• Requires a large number of translators in open environments • Adding a new information system requires 2(*n* - 1) translators	Required *n**(*n* - 1) translators	☑ D ☐ B ☐ C
Standard-ization	• Use of pivot, canonical model or metamodel • Reduce the number of translators	• Definition of a common standard accepted by all IS • The construction of a comprehensive metamodel is difficult	Required 2*n* translators	☑ D ☐ B ☐ C
Federation	• Derived from standardization • Local IS are autonomous	• Use of a global, static federated schema • The construction of an integrated federal schema is difficult • New addition requires redesign of federated schema	Required 2*n* translators	☑ D ☐ B ☐ C
Multi-base	• Used of a single language for many IS	• The common interoperating language does not export local system semantics • Users need to discover and understand the semantics of remote IS	Query based	☑ D ☑ B ☐ C
Ontology	• Semantic-oriented solution	• Extensive ontologies are voluminous • Requires meta-level translation	Semantic	☑ D ☐ B ☐ C
Mediation	• Combine translation and semantic • Local IS are autonomous	• Difficult to construct automatic mediator process	Required 2*n* semantic translators	☑ D ☑ B ☐ C

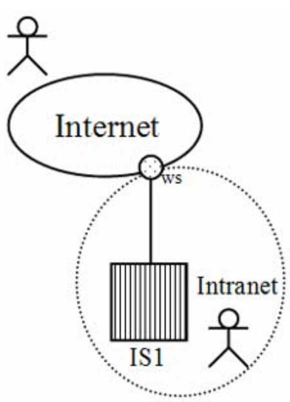
Table 1 summarizes the various architectures for the interoperation of information systems. In this table, a brief presentation of the advantages and limits of each approach is given.

FUTURE TRENDS

As new data models are developed for Web-based information systems, there is a need to extend interoperability solutions to take into account requirements and specifications of the new models. For instance, *XML* (XML, 2004) emerged as an important model for describing and sharing Web-based data. This importance stems from two major factors. First, XML is becoming a de facto data standard supported by many software vendors and applications developers. Second, XML is based on a relatively simple structure that is both user and machine readable and that can be used by nonexpert database administrators. The existing Web technologies are not initially intended to address some of the issues involved in database integration. For instance, the Web-browsing paradigm is efficient for data lookup in a large environment, but it is inadequate for database integration support. To use this paradigm to locate and merge data requires costly applications that are often tailored to specific integration needs. New challenges have arisen from the development of Web-based information systems. One of the challenges is the need to develop Web-oriented tools to support information integration and allow access to local as well as remote information sources.

Recently, Web services (WS) have been proposed as a method to address some of the challenges of Web-based integrated systems. A Web service can be viewed as a set of layers contained in a stack (Figure 7). The layers are dynamically defined following user needs and are called through a set of Internet protocols. The protocols are different than those proposed for various network architectures. However, in all Web service architectures, a base set of protocols is always used (W3C, 2002). This base set is composed of SOAP (SOAP, 2003), WSDL (WSDL, 2003), and UDDI (UDDI, 2002). They allow for the discovery, description, and information exchanges between Web services.

Figure 7. WS approach



SOAP is a mechanism that uses XML for the exchange of structured and typed information between several actors in a decentralized and distributed environment. SOAP does not define the semantics of the application but provides a mechanism for expressing semantics by proposing a modular template and mechanisms for data coding.

WSDL uses XML syntax to describe the methods and parameters of Web services. These parameters include protocols, servers, ports, input and output messages format, and exceptions format. With WSDL, an application using SOAP can autoconfigure the Web services exchanges, masking the majority of the low-level technical details.

UDDI is a Web-based company, world directory, combining “white pages” (information such as name, address, telephone number, and other contact information of a given business), “yellow pages” (information that categorizes businesses). and “green pages” (technical information about the Web services provided by a given business). UDDI allows Web service references by automating all search procedures. Table 2 presents the advantages and limits of Web services.

In our example, a set of Web services can be built from each information system independent from the other information systems. The Web services become a standard interface to access the local information system. These Web services can be used by customers and partners via the Internet and by local users via an intranet. This solution is flexible and reduces the complexity of the heterogeneity problem.

To achieve a Web service architecture, several industrial tools have been developed. Four main actors in the industrial world share the market. The solutions proposed by Microsoft and SUN are language oriented, while the solutions proposed by IBM and BEA are platform oriented.

Microsoft .NET proposes a software platform on which companies can exchange data and services on the Internet based on an ASP model (application provider service). Most Microsoft products can be extended to use Web services developed with the .NET. The philosophy of this solution can be resumed by “one OS, many languages.”

The *SUN J2EE* is developed by the Java Community Process. It is a set of services and specifications containing JDBC (Java database connector), JMS (Java Message Services), JSP (Java Server Pages), EJB (Enterprise Java Beans), etc. J2EE 1.4 includes Web service specifications

Table 2. Web services, new architecture for interoperability

Systems	Advantages	Limits	Tools or methods used	Levels
Web services	• Resolved format level • Resolved process translation • All levels of IS are managed • Normalized solution • Developed by industrials and researchers	• Security mechanism not finalized • Combination of Web services not resolved\	Protocol SOAP, WSDL, UDDI	☑ D ☑ B ☑ C

using an open-source framework called AXIS (used by IBM WebSphere). In response to the Microsoft .NET solution, SUN proposes ONE, which groups the set of SUN Web services propositions. The philosophy of this solution can be resumed by "many OS, one language."

IBM WebSphere is a set of components allowing the creation of interoperable information systems based on Web services. These components include Interchange Server, which allows process integration; MQ Integrator Broker, which allows data integration; MQ Workflow, which allows processes management, etc. IBM WebSphere uses the SUN JAVA language for the development of its Web services.

The *BEA WebLogic Server* is based on the Java Connectors architecture. This tool uses the notion of components and connectors that can be integrated between them. The integration of the connectors is carried out by the Application Integration framework and the Adapter Development Kit. To manage the resulting architecture, business process management is used in coordination with the business-to-business (B2B) integration tool. This tool exploits standards, such as XML, HTTP, or SSL, and semantic solutions, such as RosettaNet, cXML, ebXML, and EDI.

CONCLUSION

For the past 20 years or so, the need to exchange information between various partners pushed researchers to develop architectures for the interoperability of information systems. The proposed architectures have addressed several key interoperability issues, ranging from the resolution of data format heterogeneity using translations-based architecture and the reduction of the number of required translators in standardization-based architecture to the resolution of semantic heterogeneity based on ontology, and the resolution of process heterogeneity with mediation-based architecture.

Nowadays, information systems can be integrated or disassociated depending on the market trends of enterprise mergers. The Web-service-based architecture allows the development of this type of interoperability by proposing a standard data format with XML, a standard communication architecture based on the SOAP protocol, and a standard description of processes using WSDL and UDDI. The next major challenge in the Web service world is to extend Web services to include security, data owner, and semantics.

KEY TERMS

Interoperability: The ability of heterogeneous software and hardware to communicate and share information.

Ontology: An explicit formal specification of how to represent the objects, concepts, and entities existing in some area of interest and the relationships among them.

SOAP (Simple Object Access Protocol): An XML-based message protocol used to encode information in Web service requests and response messages before sending them over a network. SOAP messages are independent of any operating system or protocol and may be transported using Internet protocols (SMTP, MIME, and HTTP).

UDDI (Universal Description, Discovery, and Integration): A Web-based distributed directory for discovery of Web services offered by companies. It is similar to a traditional phone book's yellow and white pages.

Web Service: A software system designed to support interoperable machine-to-machine interaction over a network. It has an interface described in a machine-readable format (specifically, WSDL). Other systems interact with the Web service in a manner prescribed by its description using SOAP messages, typically conveyed using HTTP with an XML serialization in conjunction with other Web-related standards.

WSDL (Web Services Language Description): An XML-formatted language used to describe a Web service's capabilities as collections of communication endpoints capable of exchanging messages.

XML: A language for creating markup languages. There are two kinds of XML documents: well-formed and valid. The first respects the XML standard for the inclusion and the names of the tags. The second must be well-formed and uses a grammar to define the structure and the types of data described by the document.

Intranet Use and the Emergence of Networks of Practice

Emmanuelle Vaast
Long Island University, USA

INTRODUCTION

Communities of practice (CoPs) are key to today's knowledge management (Schultze & Leidner, 2002; Von Krogh, 2002). Moreover, the capability of exchanging professional knowledge beyond distance has become a strategic asset for innovative firms. How can members of local CoPs exchange knowledge with remote colleagues and create networks of practice (NoPs)? This article contends that the use of information technology (IT), and more specifically, of intranet systems, is especially suited to link local CoPs to an overall network of practice.

BACKGROUND

Communities of practice are social groupings whose members work in the same material context, interact frequently, acquire common knowledge, and experience similar professional concerns (Brown & Duguid, 1991; Lave & Wenger, 1991; Wenger, 1998). Members of CoPs work together and achieve activities that are for some similar and for others complementary (Gherardi & Nicolini, 2000). As they share the same work environment, they have frequent occasions to discuss directly about their job and unusual issues (Orr, 1990). Communities of practice unfold from a shared situation that creates a context favorable to direct encounters, mutual assistance in practice, and collective goals (Iverson & McPhee, 2002). Even though members of a CoP may not spontaneously name their workgroup a community, they usually acknowledge their membership to their occupational group and value its rules and principles.

CoPs display three distinguishing features: mutual engagement, joint enterprise, and common repository (Wenger, 1998).

- *Mutual engagement*: People join a CoP by committing themselves in actions whose meaning is mutually negotiated. Members of a CoP are related to each other through their mutual engagement in social practices.
- *Joint enterprise*: The community exists and provides social support and identity to its members to favor the achievement of common goals. These objectives may be explicit or not, officially defined or not, but members of the community engage themselves to complete them.
- *Common repository*: Over time, shared practices, repeated interactions, and the emergence of a shared culture provide traces of the community. Its members may refer to a common repository to deal with daily or more unusual issues. This repository may be material and concrete (files, forms) or more intangible (routines, specific idioms).

The network of practice extends the notion of CoPs beyond geographical distance. NoPs relate local CoPs whose respective members share occupational competences, job duties, and tasks, but who do not directly interact because of geographical distance (Brown & Duguid, 2000, 2001). As the literature on this notion is extremely recent, the appellation has not been stabilized yet. Some refer to "constellations of practice" or to "virtual communities of practice" (Gherardi & Nicolini, 2000). This article relies on the notion of "network of practice" as the most direct extension of CoPs beyond geographical distance. This phrase also explicitly accounts for the practice foundation of both communities and networks of practice.

People who are not collocated and do not necessarily know each other, but still achieve the same kinds of activities and experiment with similar identification processes belong to an NoP (Vaast, 2004). The relationships among members of an NoP are looser than the ones that characterize CoPs. Members of the NoP can nevertheless exchange on occupational issues. Although each local community displays idiosyncratic features, the overall network is characterized by shared knowledge, culture, and patterns of action. To some extent, the NoP also experiments mutual engagement, joint enterprise, and common repository.

The ways in which local CoPs may get connected to each other and favor the emergence of an NoP are, however, anything but obvious. Given that CoPs rely heavily on the sharing of a material context and on situated recurrent direct interactions, how may these local CoPs get connected into a network of practice?

It has been proposed that specific IS may favor CoPs (Brown, 1998) and may help spread knowledge among communities (Pan & Leidner, 2003). More specifically, the use of intranet systems seems especially suited to relate communities and networks of practice (Vaast, 2004).

INTRANETS, IDEAL TOOLS FOR COPS AND NOPS

Intranets are internal networks based on Web standards that aggregate and integrate various computing applications, such as e-mail, databases, groupware systems, or forums (Bansler, Damsgaard, Scheepers, Havn & Thommesen, 2000; Curry & Stancich, 2000; Ryan, 1998). Since 1995, intranets have represented a major growth area in corporate computing thanks to the availability of standard network technologies like Ethernet, TCP/IP, Web browsers, and servers. They have become increasingly more sophisticated and have integrated dynamic databases and various occupational applications. *Intranets* are private networks that favor flows of information and applications among members of an organization or parts of it (Newell, Scarbrough & Swan, 2001). Specific groups may implement and appropriate their own intranet, and protect it with passwords and various levels of security. Moreover, intranets may easily be customized to various contexts and end-user needs.

Key features of intranets seem appropriate to fulfill the needs of CoPs and NoPs:

Interoperability: Based on universal Web standards, intranets connect local computing networks and unify multiple software systems. Interoperability is useful to connect various local groups, to create room for communication, and to share applications among members of diverse communities.

Cost- and time-efficiency: The wide availability of standard TCP/IP protocols and of other network standards have recently made the implementation of intranets easy, fast, and reasonably priced. Basic intranets only require the availability of one server and of local computers equipped with a browser and connected to the network. Thus, even informal communities may implement and appropriate their own intranet. This ensures that the specific needs of occupational groups are taken into account in the system.

Flexibility: Typical of the new generation of information systems, intranets are also highly flexible and may include multiple applications. IT professionals as well as end-users may thus customize them to take into account the specific needs of their occupational groups. Flexible intranets may also be transformed and enriched over time. As agents become more familiar with the network, they can upgrade or introduce changes. Moreover, the flexibility of intranets makes it possible to adapt them, along with the emergence of an NoP from local CoPs. In particular, as the NoP emerges, communication features (through e-mail, FAQ or forum systems, chat) may become increasingly critical to create and maintain links among local communities.

Privacy: Intranets are private networks. Their design and architecture restrict access to authorized users. For instance, firewalls screen requests to the servers to make sure that they come from acceptable domain names and IP addresses. Mobile users may access the private network thanks to secure logon procedures and authentication certificates. Various levels of confidentiality also ensure that members of CoPs feel that their computing network is to be used only by peers and that outsiders will not intrude into the most private parts of the system (such as the ones that deal with occupational applications). Moreover, access rights and authentication procedures allow for differentiated uses by localized employees. For instance, an intranet may simultaneously present information relevant to all local CoPs and include sub-parts or folders dedicated to specific CoPs. Discriminate access in and among local communities favors the exchange of information and encourages the building of trust throughout the NoP.

User-friendliness: Based on hypertext interfaces and on graphical commands, most intranet systems are intuitive to use. Thus, no matter whether end-users are computer literate or not, they can easily learn how to make good use of the resources the intranet systems provide. As human-computer interactions are made easier and more intuitive, even members of CoPs who are not familiar with computers and computing networks may nevertheless consequently spontaneously appropriate their intranet. User-friendliness also favors end-users' willingness to improve features of the system and to adapt it to fit the communication needs of the NoP.

Two Examples of Intranet Use Creating Links Between CoPs and NoPs

The following examples show how an NoP emerges from the use of an intranet system by members of local CoPs.

Insurance Company Vendors

Thirty-five hundred vendors of an insurance company were geographically dispersed and worked in local teams of about 15 people. Vendors in any one team had many activities in common with vendors in other teams, but traditionally most felt that they were in competition with other teams from the same geographical area. The central headquarters of the company introduced an intranet system dedicated to these professionals. The intranet was not widely used at first, because of limited IT competencies of salespersons and because of the perceived competition among teams. Gradually however, newcomers started to use the intranet and transmitted their expertise in browsing the intranet to old-timers. Members of local teams thus socialized around the intranet. Also, over time, the intranet was used to exchange professional experiences among local teams. It then favored the emergence of a feeling of membership to the same occupation beyond geographical distance.

Buyers of a Railroad Company

Buyers of a railroad company (about 2,500 employees working in local teams) implemented an intranet site dedicated to their work. They directly fully integrated use of an intranet into their daily business. Buyers used the intranet to order supplies and to get information about their shipments. By making it possible for distant local buyers to aggregate their orders, use of the intranet reinforced a pre-existing trend towards the greater centralization of procurement. It also deeply affected work processes and tasks: buyers' practices became more transparent to the other departments of the railroad company. The intranet also made buyers become more aware that, even though they worked in dispersed local services, they all belonged to the same occupational group. Finally, exchanges of experiences and electronic messages resulted in new communications among distant colleagues and favored the exchange of professional experiences and mutual learning.

THE USE OF INTRANETS RELATES COPS AND NOPS

The use of intranets favors the overlapping of local CoPs. When members of various situated CoPs appropriate an intranet system, they become aware that their occupational group is not restricted to their local community. Thanks to common repositories, shared databases, and the possibility to exchange electronically, members of different CoPs start interacting with remote colleagues. Intranet systems allow members of distant communities who share professional concerns to exchange knowledge and experiences with each other. Local communities remain geographically separate and their respective members do not interact directly, but the use of an intranet contributes to the overlapping of local CoPs and to the emergence of NoPs, as it increases the visibility of shared practice and favors more frequent electronic communications.

Furthermore, the availability of an intranet dedicated to a specific occupation favors identification to this occupation thanks to the external and internal recognition of the work accomplished by these professionals. As the intranet is visible (if not entirely open, because of security issues) to the overall organization, it publicizes the occupation throughout the organization. On the other hand, the availability of common information and applications increases the feeling of occupational membership by members of local CoPs and thus also increases the internal recognition of the occupation.

Specific features of intranets strengthen the links among CoPs and favor the emergence of NoPs thanks to the geographical extension of mutual engagement, joint enterprise, and shared repertoire from the community to the network level. Table 1 presents these features.

FUTURE TRENDS

Managers should be especially careful in their attempt to implement and manage intranets to relate CoPs and NoPs. In particular, managers have to deal with three delicate dilemmas: initiative vs. control, sharing vs. competitive emulation, and official vs. emergent processes.

Defining the intranet too tightly and preventing the expression of local initiatives presents obvious drawbacks, as members of CoPs will not appropriate systems that are imposed on them and that they are unable to customize. However, if too much room is left for local initiatives, multiple fragmented intranet sites may be created which do not favor the establishment of links among CoPs. Alternate phases in the management of the intranet may thus prove useful to deal with this dilemma between initiative and control. Initially, light management—as well as relative freedom of implementation and use—favors the appropriation of the intranet. Later, more control encourages expected positive outcomes at the level of the overall NoP.

The sense of community in CoPs and NoPs provides support to their members, but it does not always encourage the search of improved practices or new knowledge. Healthy emulation among members of CoPs thus fosters the continuous improvement of work process and the pursuit of innovation. On the other hand, leaving too much room for competition and for the expression of political struggles in the CoPs or the NoPs is detrimental to the sharing of valuable knowledge. It therefore seems important to ensure that a basic level of knowledge, practices, and rules are established at the network level to make the dialog among local communities possible *and* to provide incentives for competition and sharing throughout the NoP, notably through different sections of the intranet.

Table 1. Three dimensions of CoPs and NoPs favored by intranet use

	Intranet Applications and Features	***Links Between CoPs and NoPs***
Mutual Engagement	**Repertory:** Index of all users of the intranet, of all members of the profession.	Access to all members of the profession beyond geographical distance. Repertory with name, phone number, e-mail, localization, competences.
	Forum: Discussion application where any end-users freely ask questions, answer, and react.	Discussions on occupational topics taking place at the level of the NoP, and not just of the CoP. Complementary to direct conversations.
	FAQ: List of answers to usual questions. Answers made by experts on covered topics.	Members of local groupings have access to competent and validated knowledge from experts from the whole network.
	E-mail system: Link from the intranet to the e-mail system.	Members of local CoPs may electronically get in touch with remote colleagues. Related to the repertory feature.
Joint Enterprise	**Homepage:** First page of the site that provides information on the site and links to applications.	Presentation of the overall purpose of the work of local CoPs and NoPs. General information on the CoPs and the NoP.
	Occupational applications: Migration of these applications to the intranet.	Members of local CoPs accomplish parts of their job by using the intranet. Nourishes sense of commonality of work throughout the NoP.

The official management may be unaware of emergent and improvisational dynamics of change that contribute to the richness of real-world practices. The lack of official support, however, weakens the legitimacy and visibility of local CoPs or of the overall NoP. Coaches at various levels therefore appear as useful intermediaries between informal workgroups and the management. They make it possible to connect CoPs, NoPs, and the official management of the firm. Coaches may also help deal with the two preceding dilemmas. In particular, they may decide when and how to introduce more control or more freedom in the management of the intranet. They may also know how to favor the sense of community and the emulation among members of the network thanks to initiatives on the intranet.

CONCLUSION

Intranet features and use constitute useful links between CoPs and NoPs. They make their users aware that, beyond geographical distance, they belong to an overall occupational network. Intranet use also makes it possible to store and exchange information throughout the network and to improve professional practices.

One would expect these occupational networks to expand even more as technologies such as extranets become more available. The extension of networks of practice from the intra- to the extra-organizational level will undoubtedly present new challenges and opportunities to knowledge management.

KEY TERMS

Browser: A client software program used for searching and viewing various kinds of resources such as information on a Web site or on an intranet.

Computer Literacy: The ability confidently and competently to make good or optimum use of the facilities that computers provide.

Extranet: A private network that uses Internet protocols and the public tele-communications system to share a business's information, data, or operations with external suppliers, vendors, or customers.

Firewall: The set of related programs, located at a network gateway server, that protects the resources of a private network from users from other networks. Basically, a firewall, working closely with a router program, filters all network packets to determine whether to forward them toward their destination. A firewall is often installed away from the rest of the network so that no incoming request can get directly at private network resources.

Flexibility: The ease with which a system or component can be modified for use in applications or environments other than those for which it was originally designed. A flexible system may be transformed by IT professionals and customized by end-users.

Intranet: A private network inside a company or organization that is based on Web standards (i.e., TCP/IP protocols) and offers various applications for members of a specified group.

Server: The computer on a network that is dedicated to a particular purpose, and stores all information and performs the critical functions for that purpose. For example, a Web server would store all files related to a Web site and perform all work necessary for hosting the Web site.

User-Friendliness: Quality of a program or user-interface that is easy to use and appropriate for end-users. With graphical interfaces, in particular, human-computer interaction is made easier and more intuitive for end-users.

Introducing Java to the IT Master's Curriculum

Wendy Lucas
Bentley College, USA

INTRODUCTION

The object-oriented programming paradigm has gained popularity in both industry and academia, and Java is becoming the language of choice. Yet, it can be a difficult language to learn, with many hurdles for novice programmers. This overview describes how Java was successfully introduced as the first programming language in an information technology master's program at Bentley College. Careful consideration was given to a variety of factors, including when to introduce object-oriented concepts, which integrated development environment to use, and how to support students with minimal prior programming experience. The impact of these choices on the learning experience and the factors that led to the successful implementation of Java as a first programming language are described.

BACKGROUND

The Java programming language was developed at Sun Microsystems in 1991 for use in consumer electronics devices, such as television sets and VCRs. It, therefore, needed to be both small and portable. While the language has grown in size with each new release, the Java Virtual Machine continues to ensure implementation-independent code that can be run under a variety of operating systems. Coupling this capability with the ability to run Java applets from Web pages was what first attracted interest in the language when it was initially released in 1995. Since that time, Java has developed into a general-purpose language used throughout enterprise-wide distributed applications.

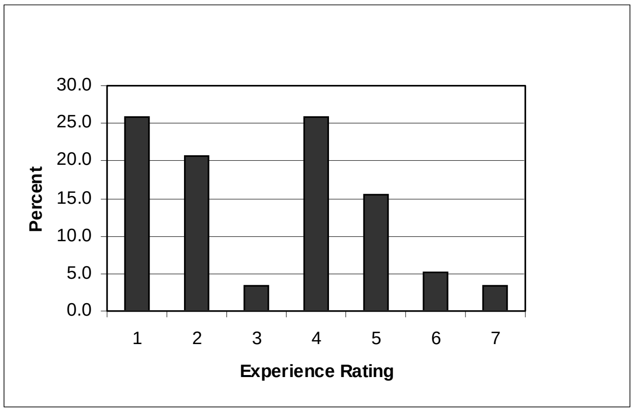
While Java has gained acceptance and widespread use in industry, it has also made inroads into academia. It is now taught extensively in intermediate programming courses and has been widely adopted as the first programming language. Its inclusion in introductory courses, however, has been problematic due to inherent complexities in the language. In comparing Java to C++, for example, it soon becomes clear that many of Java's "simplifications" are not correlated with a simpler learning experience for beginning programmers. Although Java does not support multiple inheritance, a difficult concept for students learning C++, it does allow classes to extend multiple interfaces, which is similar in purpose and complexity. Java does not permit pointer arithmetic and hides pointers from the user, but beginning programmers must understand the concept of references in order to work with objects and arrays. Other problems include: the library documentation is often ambiguous; the encapsulation model is actually more complicated than that of C++; and a large number of methods in the class library throw exceptions that must be caught or passed to a caller. Benander, Benander, and Lin (2003) found that, while professionally employed programmers understand the importance of catching exceptions, many students fail to appreciate Java's exception handling approach. Even capturing keyboard input from the user is difficult, as Java does not provide basic support for such input in non-GUI programs. As a result, authors typically provide their own methods, requiring students to develop a basic understanding of packages, classes, and methods at a very early stage (see, for example, Lewis & Loftus, 2003; Savitch, 2004). One way in which Java is truly simpler than C++ is in providing automatic memory management in the form of a garbage collector.

Given the difficulties new programmers must overcome in learning Java, some educators, such as Collins (2002), have reached the conclusion that it is not reasonable to expose students to this language in their first programming course. Others have sought means for shielding students from some of Java's complexities. Roberts (2001) describes the use of the MiniJava environment, which contains a subset of the standard Java release along with simplifying enhancements that make it easier to use. Another development environment, BlueJ, was specifically designed with teaching in mind (Poplawski, 2001; Sanders, Heeler & Spradling, 2001). It provides an easy-to-use interface with customizable templates for class skeletons, and allows the user to instantiate objects and test methods without having to write a driver program. Kölling and Rosenberg (2001) used this environment during three semesters of an introductory object-oriented programming course. The system supports an "objects first" approach, provides visual representations that help students understand the relationship between classes and objects, and supports student experimentation, thereby promoting frequent and early testing of code. Lewis and Watkins (2001) also found that BlueJ helped them explain and demonstrate object-oriented concepts from the beginning of their introductory programming course within the MSc in Computing program, in which the majority of students were graduates from other disciplines. Barnes (2002) also described an objects-early approach to teaching introductory Java through the use of LEGO® MINDSTORMS™ kits. Providing physical models was found to enhance and support the introductory programming course experience.

The debate between following an object-oriented or procedural paradigm when first teaching Java has persisted from the earliest days of its inclusion in programming courses. Results of a survey of sixty-one students who had taken or were taking a Java programming course showed that while object-based programming was not considered particularly difficult to learn, object-oriented programming concepts were difficult (Madden & Chambers, 2002). A recurring objection to "objects first" is that students must proceed on faith that the concepts and structures, which they make use of early on, will be explained to them and understood later in the course. Based on the premise that students should gradually build upward from primitive data types and control structures in order to free them from the immediate conceptual load associated with abstract data types, Cecchi, Crescenzi, and Innocenti (2003) follow a "structured programming before object-oriented programming" approach in their CS1 course. An automated development tool called JavaMM was used in this course to remove the burden of creating the complex structure of Java programs from the student. A preliminary evaluation indicated that the tool was very useful in improving the success rate of students.

Little research exists on the use of Java as a first programming language in graduate information systems (IS) or information technology (IT) programs. While these programs face a number of the same issues as those

Figure 1. Self-ranking of prior programming experience



mentioned earlier, there are significant differences between IT graduate and undergraduate students. For the former, their first programming course may well be the only one they take. In addition, many of them expect to see environments and applications similar to those they have been exposed to in the workplace. They may also have a broader range of prior programming experience. It was necessary to take these differences into account when designing the course described next.

OBJECT-ORIENTED PROGRAMMING COURSE

The graduate level object-oriented programming course within the master's level IT program was taught for the first time in the fall of 2001 to 58 graduate students in three sections. On a scale from one (*novice/beginner*) to seven (*expert*), the average student prior programming experience level at that time was 3.14 ± 1.78. Figure 1 shows the distribution.

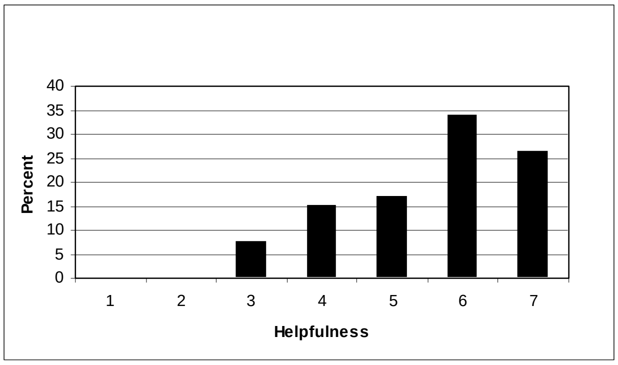
A proactive approach is taken to support students in what, for many, is their first exposure to programming. The following are descriptions of choices that have been made for enhancing the learning experience without adding to student anxiety over learning to program in Java.

Supporting Materials

One critical decision concerned which integrated development environment (IDE) to use. After extensive trials with a number of environments, the Borland® JBuilder IDE was selected due to the strength of its built-in help facilities and its tools for writing, running, and debugging code. While it could be confusing at first, JBuilder is easier to use than most of the professional environments found in the industry (Savitch, 2001). Plus, several students had expressed interest in working with JBuilder because it was being used in their own work environments. JBuilder was installed on the computers in all of the technology classrooms and computer labs, and students were encouraged to download their own copies from the Web.

A review of several textbooks led to the selection of *Computing with Java: Programs, Objects, and Graphics* by Gittleman (2001). This book was chosen for its in-depth coverage of critical course concepts, the clarity of its text, and its frequent and easy to follow code examples. The course Web site provides access to weekly lecture notes, assignments, individualized grades and comments, source code for programming examples from the lecture, and links to other relevant sites, such as Java's class libraries.

Figure 2. Student ranking of JBuilder



Course Organization

The course is taught over a fifteen-week semester, and is organized as weekly, 2-hour and 15-minute lectures with ten programming assignments, a midterm exam, and a final exam. The lecture notes, which are projected during class, allow students to focus on understanding concepts and programming examples, rather than on taking notes. A portion of the lecture is devoted to problem solving, with students writing code both individually and together. Working individually provides an opportunity for the instructor to observe the various approaches being taken and comment on their effectiveness and efficiency. Either the instructor (earlier in the term) or a student (later in the term) will then type a solution into the classroom computer using JBuilder's editor. It is often more educational when a student's code fails to run properly, as the class will then need to determine and correct the errors.

Programming assignments reinforce the concepts covered in the lectures. Assignments are completed on an individual basis, with students encouraged to seek the help of lab assistants for questions involving syntax or the IDE, or the instructor for more complex questions.

The first seven assignments are all one week in length and are primarily logic-intensive. Short, focused assignments force the students to stay up-to-date with the material and to practice what they have been learning. The last three assignments are each two weeks in length, and encourage creativity and investigation of Java's class libraries. Assignments account for 30% of the grade. Midterm and final exams make up 30% and 35%, respectively, and the remaining 5% is for class participation.

Course Content

The content of both lectures and assignments begins at a rudimentary level and increases in complexity throughout the semester. The first few weeks focus on basic programming concepts, including data types, operators, and control structures. Class and object concepts are then introduced using built-in classes and arrays. User-defined classes come next, followed by the object-oriented concepts of inheritance, polymorphism, and encapsulation. Additional topics such as dynamic data structures, exception handling, and file I/O are also covered.

Students are initially guided through Java's class libraries and then, as the weeks progress, are encouraged to explore the libraries to find classes and methods for use in assignments. In the last few weeks, graphics and event handling are taught using applets, which require an understanding of a predefined startup sequence of method calls, system-defined and system-passed arguments, and inheritance that is gained throughout the course.

Survey Results

Mid-way through the fall 2001 semester, the 58 students enrolled in the course completed a course survey. A total of 143 students from six preceding semesters of the programming course taught using Visual Basic (VB) had filled out a similar survey. In the following sections, the results of the Java survey are presented and contrasted to the results from the VB survey, wherever possible.

SUPPORTING MATERIALS

Students were in general pleased with the supporting materials provided for this course. The use of JBuilder was only required for one assignment, yet the majority of students (86%) continued using this IDE throughout the term. Its average rating was 5.57 ± 1.25 on a seven-point

Figure 3. Student ranking of the course Web site

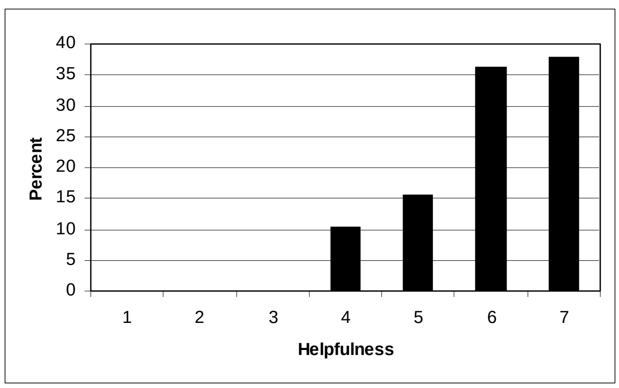


Figure 4. Student ranking of the textbook

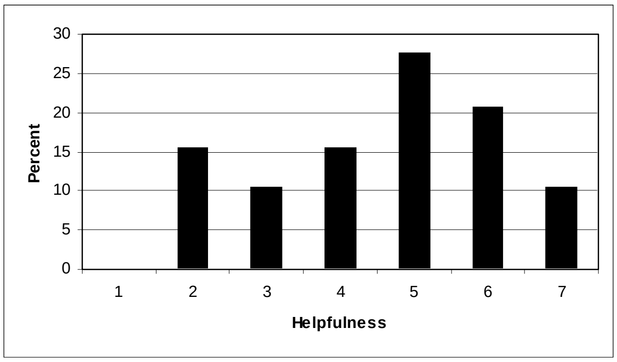

scale ranging from one (*no value*) to seven (*high value*). Figure 2 shows the distribution.

The course Web site was highly valued, with an overall helpfulness rating of 6.02 ± 0.98 on the same seven-point scale (see Figure 3). The average rating of the text was lower (4.59 ± 1.57) and showed more variation in responses (see Figure 4). This was still considered a positive finding, however, because students are typically unenthusiastic about technically-oriented textbooks and generally rate them poorly.

Course Content

The average difficulty of the course was rated on a seven-point scale as 4.79 ± 1.14, where *one* represents *not challenging*, and *seven* represents *very demanding*. Figure 5 contrasts the difficulty ratings to those for the prior programming course taught in VB. The average difficulty rating for the VB course was 4.69 ± 1.15. The mean difference between the two groups is not significant.

The mean difference in perceived difficulty for students in the Java course with prior programming experience versus those without is significant at the 0.05 level. Figure 6 shows this relationship, where *little* refers to those who rated their experience as either a one or a two, *somewhat* refers to those in the three-to-five range, and *very* is for a rating of six or seven.

It should be noted that the survey was distributed before many of the more advanced object-oriented concepts had been introduced. As the course proceeded, even those students with prior procedural programming experience had difficulty with some of the object-oriented concepts, based on their performance on assignments and the final exam. This agrees with the findings of Mehic and Hasan (2001) that prior procedural language experience can actually create an obstacle for students learning object-oriented design.

Figure 5. Comparison of VB course difficulty to Java course difficulty

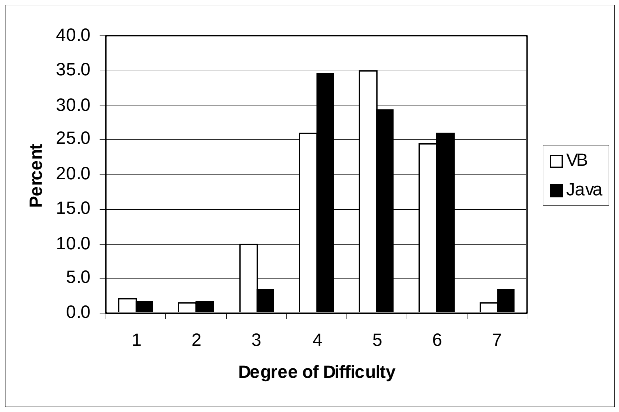

Figure 6. Java course difficulty as a function of prior experience

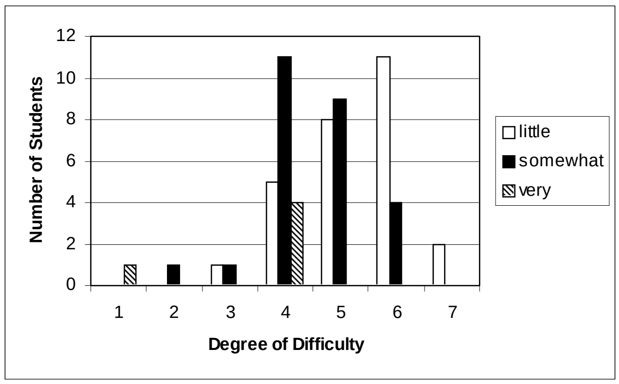

Figure 7. Hours worked in the Java course as a function of prior experience

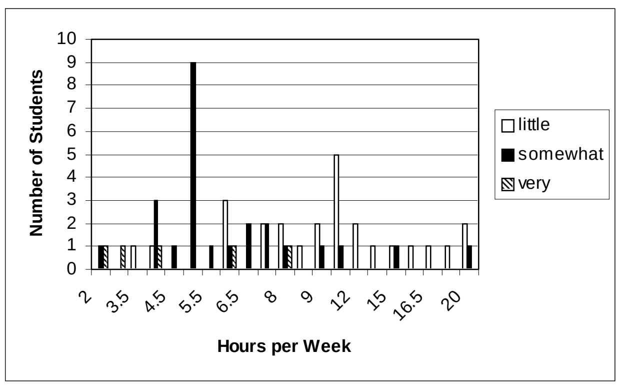

The average number of hours worked per week was 8.24 ± 4.62, while the average for the VB course had been 6.59 ± 4.35. The mean difference between the two is significant at the 0.05 level. There was also a significant difference between means for those students with prior experience versus those without, as shown in Figure 7.

FUTURE TRENDS

Given the continued popularity of Java in both industry and academia (with the latter evidenced by the decision of the College Board to have the Advanced Placement® Computer Science Examination be administered in Java, beginning with the 2003-2004 academic year), the trend toward teaching Java as the first programming language gives no indication of abating. Nonetheless, the inherent complexities associated with Java will continue to make it a difficult first language to learn. There is, therefore, a continuing need for research into factors that can positively affect the likelihood of success for students in introductory programming courses built upon the Java platform.

CONCLUSIONS

There are several factors that have led to the successful implementation of this Java course. Students particularly enjoy the frequent programming assignments, which reinforce their understanding of course material. Earlier assignments boost confidence in their ability to write functioning code. Those successes help students maintain a positive attitude when the level of complexity increases. The incremental dependence upon Java's class libraries also assists students in learning to navigate the extensive documentation without becoming overwhelmed.

The support structure for the students definitely has a positive impact. JBuilder's debugging environment is very helpful, and the IDE as a whole has been well received. Finally, access to lecture notes, code, and grades from the course Web site is highly appreciated and contributes to the positive view of the course held by most of the students.

In summation, the benefits of frequent programming assignments to reinforce learning, a carefully structured, well thought-out curriculum, and a strong support structure have helped ease the transition to the Java programming language and continue to make this course a successful and vital component of the MSIT curriculum.

KEY TERMS

Abstract Windows Toolkit (AWT): Library of classes for writing window interfaces.

Byte-code: This machine-independent code is translated into the machine language of the computer on which it is running.

Encapsulation: Data and actions are packaged together in a class, with the details of the implementation hidden from other classes.

Inheritance: A way of organizing classes so that properties can be defined once and applied to a whole collection of classes, with a general class defining those properties and specialized classes inheriting them.

Instantiation: Creation of an object, or class instance, from a class.

Java Virtual Machine (JVM): A platform-independent execution environment that converts Java byte-code into machine language and then executes it.

Methods: Actions performed by objects.

Polymorphism: One method name can cause different actions to occur, depending on the kind of object performing the action.

IS Implementation in the UK Health Sector

Stuart J. Barnes
Victoria University of Wellington, New Zealand

INTRODUCTION

Since the mid-1980s, the UK public sector has been the subject of wide-ranging reforms involving the introduction of IS and IT. Change has been sought in the ways that services are managed and delivered, the evaluation of the quality of aforesaid services, and in accountability and costing. One of the most predominant of such changes has been the introduction of competition for services, the motivation of which has been to invite efficiency, effectiveness, and related benefits ensuing from the accrual of economies.

Pivotal to such change has been an explosion in the introduction of a variety of information systems to meet such challenges. Focusing on health care, a large part of the work of the health service involves collecting and handling information, from lists of people in the population to medical records (including images such as X-ray pictures), to prescriptions, letters, staffing rosters and huge numbers of administrative forms. Yet until recently, the health service has been woefully backward in its use of the technology to handle information by the standards of private industry.

This has been quickly changing in recent years and by 2003 the National Health Service (NHS) spent £2.8 billion annually on capital in hospitals (Department of Health, 2003a), around 10% of which was for IT. In the last 20 years, IT has added 2% to overall health expenditure (Wanless, 2001). This investment is still small by the standards of the private sector, but is all the more significant when we consider that health care is an industry which has been slow to adopt IT and one which presents some of the biggest IT opportunities (Department of Health, 2002).

BACKGROUND: INFORMATION SYSTEMS IN THE NHS

The implementation of IT in the UK health sector has been fraught with difficulties. In fact, estimates suggest that problems with the first wave of projects in the public sector, from the mid-1980s to mid-1990s, cost over £5 billion (Collins, 1994). There are a number of high-profile examples of IS failure in the NHS, including that of Wessex Regional Health Authority's Regional Information Systems Plan (£63 million), the London Ambulance Service's Computer Aided Dispatch system (£1.1 to £1.5 million), and more recently, various Resource Management Initiative (RMI) Case Mix failures (£1 to £3 million) (Barnes & Targett, 1999).

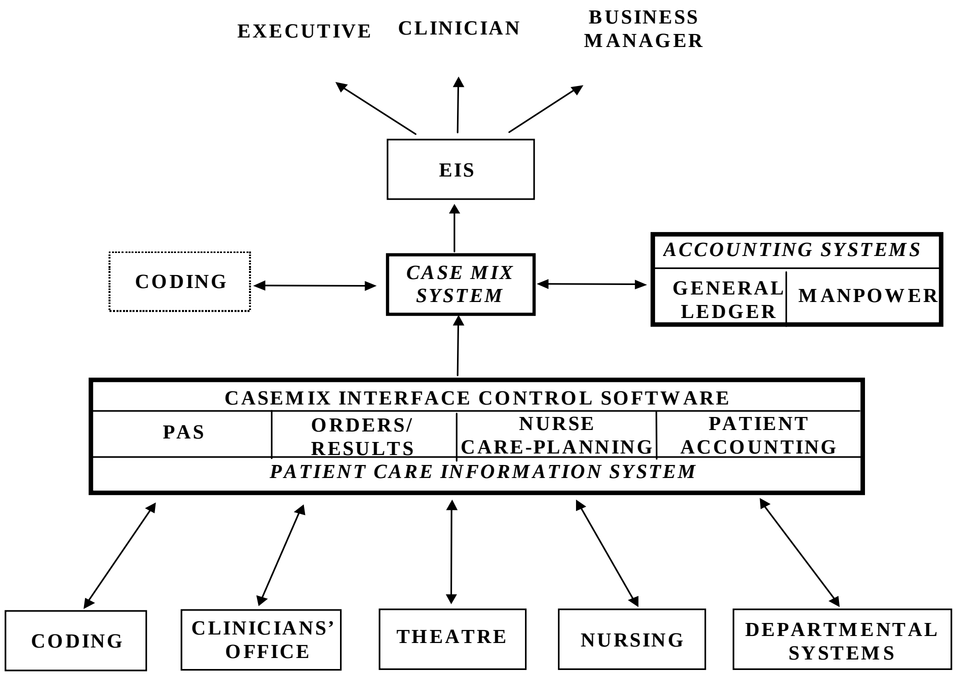
In this section we will focus on RMI and Case Mix as an illustration, since this was one of the first initiatives for wide reaching IT-induced organizational transformation and information integration in the health sector. The systems implemented have been an important support for financial developments in the management of UK hospitals. During 2003, the importance of Case Mix systems has again come to the fore as the NHS has attempted to implement prospective payment systems (PPS) (Department of Health, 2003b).

RMI was a driving force in the move towards information systems and cultural change in the NHS. First announced in 1986, RMI was going to help clinicians and other hospital managers to make better-informed judgments surrounding how the resources they control can be used most effectively (DHSS, 1986). The Initiative was not only aimed at persuading clinicians to own the management process, but to provide them with accurate, up-to-date and relevant information which could be used to cost medical activities and improve patient care. The response to this need for improved information services available to hospital units was the development and implementation of a sophisticated and extensive package of IT referred to as the "Case Mix" information system (CMIS), an idea borrowed from the U.S., with the purpose of clinical and management audit.

Prior to RMI, the introduction of IT in the NHS was patchy and limited. Where systems existed, the technology was very varied, incompatible, archaic, and dependent upon regional computer departments to deliver necessary operational systems. The development of CMIS, with its dependence on data fed from other systems such as the Patient Administration System (PAS), radiology, pathology, theatre and nursing systems, provided a catalyst for the adoption of operational systems throughout the hospital (Barnes, 2001).

CMIS takes a central position in the hospitals' IT infrastructure, as shown in Figure 1 (an illustrative example - specifications may vary depending upon the hospital), providing a tool for collecting and analyzing data from all areas of hospital operations using an execu-

Figure 1. The role of case mix in NHS hospitals



tive information system (EIS). As we can see from Figure 1, there are two main types of data feed: financial and medical. The financial feed consists of pulling data from the general ledger and humanpower systems, particularly standard costs and budgets. This contrasts with the other main feed to CMIS, that of the "patient care information system" - a label given to the array of feeder sub-systems providing information on all aspects of patient treatment and care.

Each of the feeder systems is interfaced with CMIS, so as to provide appropriate data in an acceptable format. Such data are accumulated by CMIS within the care profile sub-system: this stores the actual tests, treatments, costs, number of cases and so on to be compared with expected "ideal" profiles or projected activity levels as drawn from the financial data, enabling financial audit. Regarding clinical audit, CMIS provides the tool for assessment of the professional clinical practices of each clinician.

EXPERIENCES IN INFORMATION SYSTEMS IMPLEMENTATION

In addition to traditional problems of IS implementation, RMI also reveals a number of interesting and contrasting influences on the early implementation of strategic IS in UK hospitals:

- *Central influence* - Regional authorities (RAs) had a substantial influence on the development of systems in a number of areas, for example investment justification, what to procure, objectives, financing, and project management milestones. Importantly, the original "standard" systems were not sensitive to the needs of individual hospitals, affecting stakeholder support and the need for project redefinition. Where relationships with RAs were tenuous, RMI was looked upon with suspicion. Initiatives imposed subsequently changed the shape and direction of the project, and created other priorities within hospitals, while recommendations about clinical coding were never clear. Central influence is, interestingly, both a reason for the existence of the project, and for many of its problems: paradoxically, it is both an enabler and an inhibitor.
- *Project purpose* - The problems in communicating the purpose of CMIS, and in approaching locally sensitive designs, affected the attitudes of stakeholders: the project was very much an imposed directive. Many individuals were unclear about the rationale for CMIS, and this was compounded by the traditional absence of IT within hospitals. While RM was aimed at improving resource allocation, ironically, many saw IT spending as a waste of money as opposed to direct patient care.
- *Clinicians, management and CMIS* - Hospitals are distributed organizations, with a variety of frag-

mented groups and cultures, each with their own defined roles. RMI and CMIS cut a swathe through many of these, particularly clinicians and management, and sat uncomfortably in hospitals. Where the system impinged upon the territory of individuals or groups, friction was encountered. Hospitals, for many years without IT, and with a defined structure and set of roles, found change difficult. While politics occurred in a variety of areas, the clinician-management divide is perhaps the most interesting. Each of these groups found it difficult to adjust to a new culture and structure, and for apparently conflicting reasons: top management was often opposed to devolvement, while clinicians were wary of CMIS as a "tool of management" and a control device. Thus, paradoxically, CMIS was seen both as a tool of centralization and of devolution.

CONCLUSIONS AND FUTURE TRENDS

The complexities surrounding RMI compounded early experiences in strategic IS implementation in the NHS. Evidence suggests that success has been difficult to achieve, and that hospitals found it difficult to achieve any tangible benefits (e.g., see Barnes, 2001; Barnes & Targett, 1999; Lock, 1996). Evaluating investments is made all the more difficult by the fact that published evidence is scarce. Lock (1996) found that only 5% (by value) of all investments were the subject of published assessment, which may be an indicator of the poor value of such investments. Even published studies are far from conclusive: the "official" resource management evaluation conducted by Brunel University found "no measurable patient benefits" in its review of the six pilot sites, while costs were more than double those expected (Heath Economics Research Group, 1991).

One of the key impacts of case mix has been on the financial management of hospitals. The sustainable financial management of hospitals has recently come into question (Audit Commission, 2003). During 2003, the UK Department of Health has outlined the Government's desire to implement PPS, as outlined in its *Payment by Results* White Paper (Department of Health, 2003b). This would allow the trust financial regime (TFR) of hospitals to carry deficits and surpluses, spurring greater efficiency. This has led to some concerns that it may lead to under-investment and reduction in quality (Medicare Payment Advisory Commission, 2003; Rosenberg & Browne, 2001; Topping, 1997). On balance, the evidence from the U.S. and elsewhere seems to suggest that these systems are not detrimental to the quality of health care (Dismuke & Guimaraes, 2002; Shen, 2003).

KEY TERMS

Case Mix: On admission to a hospital, the individual patient is provided with a variety of services, each of which expends resources. Each encounter or episode has a mix of, for example, tests, treatments, accommodation, and so on. Case mix refers the combination of services and resources used for each patient episode.

Case Mix Information System (CMIS): An information system, fed with data from an array of hospital subsystems, for the principal purpose of clinical and financial audit of patient cases. Further developments to CMIS have seen other functionality added, such as contract planning, quality assurance, waiting lists, and clinical support.

Clinical Audit: The assessment of professional clinical practices. General information routinely provided includes lengths of stay, deaths and re-admissions. More specific information such as drugs administered and operative procedures performed are available via the appropriate feeder systems. The data allow aspects of case mix, clinical management, diagnostic accuracy and patient outcomes to be compared.

Clinical Coding: Categorises diagnoses and procedures for patient episodes according to a detailed clinical standard index. The most common standard is the International Classification of Diseases (ICD), particularly for financial audit, but a UK standard, Read, is very popular with medical staff. These are grouped to provide aggregate information for audit.

Executive Information System (EIS): An IS that provides high-level information tailored to the needs of decision-makers. Typically a graphics-oriented system, in the context of CMIS the EIS aggregates and uses summary data to present information to clinicians, executives and business managers in the form of graphs, histograms, pie charts, tables and so on.

Financial Audit: The budgetary assessment of the cost of hospital care. CMIS collects data on the actual tests, treatments, costs, number of cases and so on. These are then compared with expected "ideal" profiles or projected activity levels as drawn from the financial data, typically based on best practices or historical data.

Resource Management Initiative (RMI): A UK initiative providing clinicians and other hospital managers with information required to use resources to maximum effect, generally by the introduction of new IT. This was aimed at encouraging clinicians to take more interest and involvement in the management of hospital and community units, making them responsible for operational and strategic decisions.

IS Project Management Contemporary Research Challenges

Maggie McPherson
University of Sheffield, UK

INTRODUCTION

Although project management is often said to have its roots in other traditional fields, such as construction, Morris (2002) asserts that modern project management practices have their origins in the 1950s US aerospace agencies. Much has been written about Information System (IS) / Information Technology (IT) project initiatives in both the public and private sectors. In fact, many information systems frequently fall short of their requirements, and are, more often than not, costlier and arrive later than anticipated, if indeed they are completed at all. For instance, according to a report for the Organization for Economic Co-operation and Development (2001), failures of major IT investments and key systems development projects have raised concerns for the achievement of service improvement through information technology. Additionally, it has been argued that failures in IT projects are more common than failures in any other aspect of modern business (Nulden, 1996). The widely-cited Standish Group (1994) study, carried out in the US, classified IT projects as follows:

- **Resolution Type 1 (Project Success)**: The project is completed on-time and on-budget, with all features and functions as initially specified.
- **Resolution Type 2 (Project Challenged)**: The project is completed and operational but over-budget, over the time estimate, and offers fewer features and functions than originally specified.
- **Resolution Type 3 (Project Impaired)**: The project is cancelled at some point during the development cycle.

The report estimated the success rate was only 16.2%, while challenged projects accounted for 52.7%, and impaired projects (cancelled) amounted to 31.1%. Since large complex projects in any area are difficult to organize, it could be said that the level of abstraction required often leads to a lack of understanding between all stakeholders involved with the project. Callahan and Moretton (2001) describe software design as being "in the code". They assert that since it is not visible, it makes it hard to use software design as a focal point for development project coordination and integration, unlike many physical designs which can be made visible to all project participants. As a result of this "invisibility", managing the development of an IS project is arguably more problematic than project management within the manufacturing sector because software development is often a highly conceptual and complex process.

Indeed, a lack of adequate project management knowledge could be said to be a major contributing factor to unsuccessful IS projects. For instance, as project managers should be aware, unless specific objectives and clear-cut end points have been set, it can be difficult to know if a milestone has been reached and indeed if the required end-product has been produced. However, making use of proprietary tools such as Microsoft™ Project is sometimes mistakenly thought of as project management, whereas real project management expertise goes beyond the mere production of Gantt or Pert (Program Evaluation Review Technique) charts, which simply represent project activities in the form of bar charts or flow diagrams. As Mandl-Striegnitz et al. (1998) point out, important project management techniques include estimation of costs and explicit identification of risks. Clearly, there is a need for more in-depth research to gain a better understanding relating to the complex role of project management within the whole IS design and development process. This discussion considers how these problems affect contemporary IS project management research and explores the methodological approaches open to researchers carrying out investigations in this area.

BACKGROUND

In order to better understand the challenges facing researchers of Information Systems Project Management (ISPM), it is necessary to explore what is meant by some of these terms. As stated by the American National Standard for Telecommunications (2000), an IS is "an organized assembly of resources and procedures united and regulated by interaction or interdependence to accomplish a set of specific functions, whether automated or manual, that comprises people, machines, and/or methods organized to collect, process, transmit, and disseminate data that represent user information". In its simplest terms, an IS can be described as a human activity or social system, which may or may not involve the use of computer systems; although, these days the former is more likely. According to Stoner et al. (1994), management can be regarded as a process of planning, organizing, leading and controlling the efforts of staff and other resources in order to achieve organizational goals, and the Association for Project Management (2000) describes a project as a distinct set of coordinated activities "… with definite starting and finishing points, undertaken by an individual or organization to meet specific objectives within defined time, cost and performance parameters". By combining these terms, a definition for ISPM could be said to be the process of managing the creation of an IS through the establishment of project goals; organizing, leading, co-coordinating the efforts of staff processes and tasks; and controlling other resources to achieve a set of agreed objectives.

Since IS projects are frequently comprised of multi-disciplinary teams of people, a definition of what is meant by a team in this particular context is called for. Geddes et al. (1993), regard a team as comprising those individuals who have a significant contribution to make to the successful achievement of the project, whether this is through technical or specialist expertise; sponsorship, political support or sponsorship; or expectation of, and interest in, outcomes. Programmers and associated staff are often selected according to their ability to demonstrate the appropriate technical knowledge, which does not guarantee proficiency in managing successful projects. Despite the emphasis on team leadership ability, senior developers/project managers are often promoted from the programming team, with a continued emphasis on technical expertise (Mandl-Striegnitz et al., 1998).

In reality, IS project managers must not only be able to plan and break activities down into components that can be understood and to control tasks and monitor risks, but must additionally be able to consider people and process issues requiring significant team-building skills. Although IS may be implemented by staff with technical competence, they may well lack the necessary abilities to evaluate organizational contexts and analyze corresponding behaviors.

Nevertheless, since 1994 there has been an improvement in project management outcomes. By 2001, the Standish Group published another report stating that project time and cost overruns had reduced significantly. Although this improvement in project results was confirmed by a UK-based survey (Saur & Cuthbertson, 2004), the authors acknowledged that their sample could have been unrepresentatively experienced, signifying a continued need for further research.

CRITERIA FOR ISPM SUCCESS

Referring to the Standish Group report "Extreme Chaos" (2001), it seems that lessons can be learned from the successes and failures of past projects which warrant further study. From extensive research, the Standish Group identified ten criteria for project success:

1. Executive support
2. User involvement
3. Experienced project managers
4. Clear business objectives
5. Minimize scope
6. Standard software infrastructure
7. Firm basic requirements
8. Formal methodology
9. Reliable estimates
10. Other criteria such as small milestones, proper planning, competent staff and ownership

In the UK based study, Sauer and Cuthbertson (2004) reported a higher project success rate than the US Standish Report (1994). Nevertheless, Sauer and Cuthbertson suggested that in order to continue this general improvement, the following recommendations ought to be adhered to:

- Project managers should:
  - Structure projects into smaller units
  - Select the right team and involving them in decision making
  - Invest time and effort in self-development
- Senior IT managers should:
  - Establish a project management focus in the organization
  - Identify the right person for project management role
  - Create appropriate career paths
  - Be accountable through more effective performance management
- Senior business managers/sponsors should:
  - Develop client understanding of project management
  - Engage more actively with projects for which they have responsibility

Some reasons for the improvements described above were costs being cut, better tools being created to monitor and control processes and, not least, project managers becoming better skilled with better management processes being used, giving rise to optimism for the future of project management. Despite the change for the better as highlighted above, the Standish Group (2001) considered "Nirvana" still to be a long way off, indicating a need for continued research. In order to select more appropriate research approaches to investigate ISPM, it is necessary to explore some of the issues specifically related to this particular field.

INFORMATION SYSTEMS PROJECT MANAGEMENT RESEARCH ISSUES

Prior to the 1950s, computing was primarily associated with scientific applications. Even after computer installation began in business environments for data-processing tasks, associated research had a tendency to be dominated by scientific approaches. Thus, despite the increasing importance of IS within modern businesses, for historical reasons the close association of IS development with IT induced many researchers to consider IS problems using methods from the natural sciences (Baskerville & Wood-Harper, 1996; Garcia & Quek, 1997) that are more suited to science laboratories. As a consequence of this scientific tradition, investigations within the field of IS appear to have had a predominance of both positivist and technical points of view, despite major criticisms (op.cit.) that may these research methods might be not always be wholly appropriate.

Keen (1984) stressed that IS is not simply the installation of a technical system in an organization. He suggested that successful implementation needs to consider institutional issues affecting its use in the ongoing context of jobs, formal and informal structures, as well as personal and group processes. Hughes and Wood-Harper (2000) concurred, rejecting the notion that the process is exclusively technical and rational. In their view, IS research should not merely pay attention to the technology and called for IS development to be understood in its situated context, i.e. to consider the domain, the organizational constraints, the social actors and the politics in situ.

ISPM RESEARCH METHODS

The debate as to whether to adopt quantitative or qualitative research methods is well-documented and will only be touched on lightly here. However, as described by Wilson (2002), one of the most contentious debates is whether to adopt the positivist view of the nature of social reality, in which social facts can be known with certainty and in which laws of cause and effect can be discovered, or whether to apply humanistic approaches which generally see social reality as constructed through social action on the part of people who undertake those acts because they have meaning for them. Conventional "scientific" research can run the risk of being reductionist (Lincoln & Guba, 1985), since complex problems are condensed in order to produce models that can provide a simplified simulation of reality. Bryman (1988) suggests that the basic choice of methodological approach is largely influenced by the type of research question being asked and according to Yin (1994) a researcher's choice of methodological approach depends on the problem at hand and the control that the researcher has over the behavioral events. Given that many researchers now believe IS to be socially constructed in particular contexts, it is thought to be important to extend research methodologies for ISPM problems beyond the positivist paradigm in order to uncover rich qualitative data.

FUTURE TRENDS

Mumford et al. (1985) argued for a methodological pluralism within IS research domains, asserting that scientific proof was being regarded as the only valid method despite the fact that many IS problems were not susceptible to these systematic methods. A decade later, Allen (1995) agreed that research methods from different paradigms can be used simultaneously or consecutively and are equally valid. Despite the historical emphasis on positivist methods in IS research, there is increasing support for developing this type of methodological mix and this is equally applicable to project management research. This is demonstrated by the fact that although the data for the Standish Group (1994) project management research was primarily collected through a survey, focus groups were conducted to augment the survey results.

In fact, Myers (1997) argues that all studies are based on some underlying assumptions about what constitutes "valid" research and it is this which should dictate which research methods are appropriate. Avegerou (2000), writing about alternative reasoning for IS, notes that the development literature argues that developing societies need to recognize the limitations of the validity of techno-economic rationality and that they ought to pursue rationalities stemming from their own value systems. IS professional roles have been based and legitimated mostly on technocratic logic, without an obligation to consider the validity of the requirements, which are normally based on the social context (Avegerou, 2000). Morris (2002) concurs, stating that project management is not a science in the full or proper sense of the word. This is contrary to the view of Khazanchi and Munkvold (2000) who believe that methodological and philosophical diversity do not preclude researchers from making scientific inquiries into the fundamental nature of IS phenomena.

Nevertheless, Morris believes that it is a discipline worthy of theoretical study, with various questions susceptible to the methods of scientific enquiry, whilst other areas will always have a large element of unpredictability. He therefore considers that some knowledge of this field will always be personal and experiential. Following this line of reasoning, prominent researchers such as Galliers (1992) have proposed that an interpretative stance for IS research would be wholly applicable. Correspondingly, other researchers have explored and recommended various interpretivist approaches as being particularly suitable. These methodologies include case study research (Yin, 1994), where the researcher interprets data without direct involvement, and action research (Baskerville, 1999), where the researcher is actively involved.

However, Garcia and Quek (1997) stress the need for further critical awareness, stating that importing methods into the IS field is not a simple task. They warn that without critical awareness, there is a danger of methods becoming stereotyped or distorted. Nonetheless, they supported the use of multiple methods to correspond with the complexity of research investigation which will allow a better understanding of the different aspects involved in the constitution of the object under investigation.

CONCLUSION

If one accepts that IS are socially constructed, as many researchers now appear to do, then it follows that evaluative research of IS projects needs to be situated in contextualized and authentic settings. It would therefore seem highly appropriate to set aside the positivist versus interpretivist debate, since Marcella and Knox (2004) suggest that "…it is only based upon a much fuller and more precise understanding of the complex and multifaceted needs of all users, internal and external, in all functional areas of the institution, that systems will be developed which are truly responsive and which function to meet overall … objectives". With this in mind, it seems reasonable to suggest that it is worthwhile combining diverse research methods, as endorsed by Fitzgerald and Howcroft (1998), with a view to maximizing their complementary strengths. This would seem to be particularly appropriate to address many of the concerns and issues relating to ISPM as highlighted in this discussion.

KEY TERMS

Case Study Research: An in-depth investigation that attempts to captures lessons learned through studying the environment, procedures, results, achievements, and failures of a particular project or set of circumstances.

Development Literature: Literature about impoverished countries of the world that are trying to modernize or to find different ways of supporting their populations.

Focus Group: A small group interview, conducted by a moderator, which is used to discuss one or more issues.

Humanism: A philosophical approach that focuses on human value, thought, and actions.

Information Systems Project Management: The process of managing the creation of an IS through the establishment of project goals; organizing, leading, co-coordinating the efforts of staff processes and tasks; and controlling other resources to achieve a set of agreed objectives.

Interpretivism: A research approach that attempts to reach an understanding of social action in order to arrive at a causal explanation of its course and effects.

Positivism: A belief that natural science, based on observation, comprises the whole of human knowledge.

Project Team: All individuals who have made a significant contribution to make to the successful achievement of the project.

Project: A distinct set of coordinated activities with definite starting and finishing points, undertaken by an individual or organization to meet specific objectives within defined time, cost and performance parameters.

Techno-Economic Rationality: Logical justification for making a connection between technical advances and economic growth.

Isochronous Distributed Multimedia Synchronization

INTRODUCTION

A multimedia system is characterized by the integrated computer-controlled generation, manipulation, presentation, storage, and communication of independent discrete and continuous media data. The presentation of any data and the synchronization between various kinds of media data are the key issues for this integration (Georganas, Steinmetz, & Nakagawa, 1996). Clearly, multimedia systems have to precisely coordinate the relationships among all media that include temporal and spatial relationships. Temporal relationships are the presentation schedule of media, and spatial relationships are the location arrangements of media. Multimedia synchronization is a process of maintaining these relationships by employing appropriate synchronization mechanisms and algorithms. Multimedia synchronization is traditionally challenging, especially in distributed environments.

Three types of multimedia synchronization can be distinguished: intrastream synchronization, interstream synchronization, and intermedia synchronization (Crowcroft, Handley, & Wakeman, 1999). The approaches used for interstream synchronization can also be used for intermedia synchronization.

The word *synchronization* refers to time. The easiest way of synchronizing between streams at different sites is to use a single time reference. There are several ways to provide this time reference.

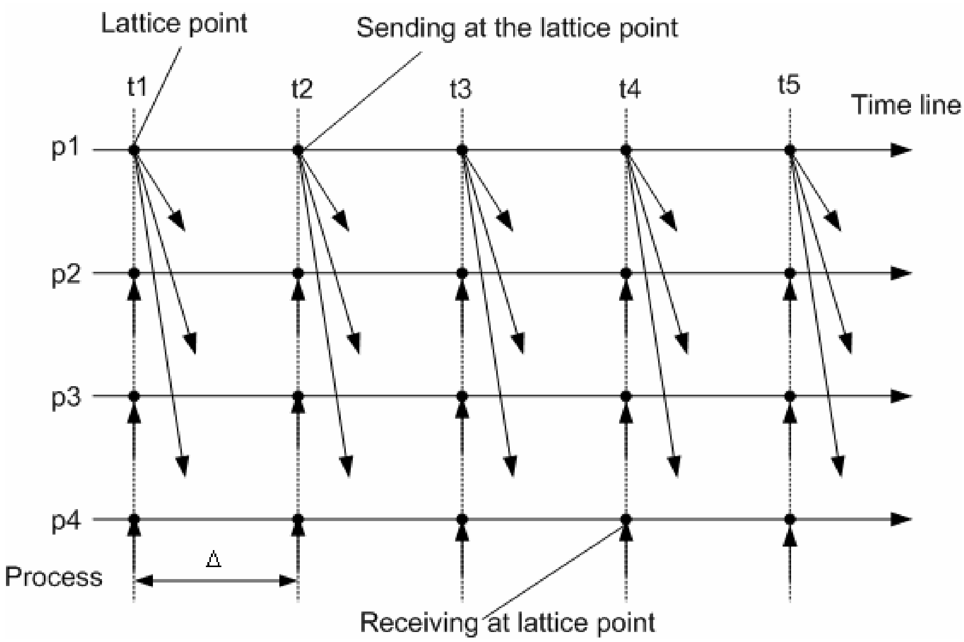
- The network will have a clock serve as a single reference. This approach is used in H.261/ISDN- (integrated services digital network) based systems. A single clock time is propagated around a set of codecs and multipoint control units (MCSs).
- The network deploys a clock-synchronization protocol, such as NTP (the network time protocol; Mills, 1993). The time stamps of media packets will be derived from the globally synchronized clocks. The isochronous synchronization approach as described in this article heavily relies on this time reference.

AN ISOCHRONOUS SYNCHRONIZATION APPROACH

The isochronous synchronization approach employs a clock-driven protocol for achieving multimedia synchronization (any one of three types of synchronization; Yang, Gay, Sun, Siew, & Sattar, 2002). This approach is particularly suitable for distributed collaborative multimedia environments where many-to-many multimedia communication is the basic interaction pattern. In this approach, multimedia synchronization is based on the use of synchronized physical clock time instead of any form of logical clock or sequence numbers, and thus clock synchronization across the distributed system is assumed. A real-time (synchronized) clock is incorporated in the system as a mechanism used for initiating significant events (actions) as a function of real time.

With globally synchronized clocks that satisfy the granularity condition, we can construct an *action lattice* (or *event lattice*; Kopetz, 1992). One dimension of this lattice represents the progression of time, the other dimension is the processes in the system (Figure 1). Processes in the system are designed to execute a simple *clock-driven protocol*, which requires that the events of sending and receiving messages are restricted to only

Figure 1. Lattice structure



occur at the lattice point of the globally synchronized space-time lattice (Figure 1). Thus, whenever an action has to be taken, it has to be delayed until the next lattice point of the event lattice.

This lattice structure greatly simplifies multimedia synchronization and readily maintains the temporal and causal relationship among the media.

The idea behind the clock-driven, isochronous synchronization is very simple and intuitive in that the easiest way to synchronize processes is to get them all to do the same thing at the same time. Using the simple mechanism based on the synchronized clock without requiring complex algorithms, the approach can equally well be applied to various multimedia applications in distributed environments, including live multimedia applications (live teleconferencing and CSCW) and stored media applications.

THE ORDERING PROPERTIES OF THE SYNCHRONIZATION PROTOCOL

In essence, what is really required for distributed multimedia synchronization is *order*; that is, a synchronization protocol must ensure that multimedia messages or streams are sent, delivered, and presented in an order that is consistent with the expected behavior of the distributed multimedia system as a whole. Clearly, multimedia systems have to precisely coordinate the relationships among all media. These relationships include temporal and spatial relationships. Temporal relationships are the presentation schedule of media, and spatial relationships are the location arrangements of media.

There are two specific cases concerning temporal order: *causal order* and *Δ-causal order*. These ordering concepts are derived from a happens-before relation, which is a more fundamental notion in distributed computing. The expression $a \rightarrow b$ is read as "a happens before b" and means that all processes agree that first, event a occurs, then afterward, event b occurs. The happens-before relation can be observed directly in two situations in a distributed environment: (a) If a and b are events in the same process and a occurs before b, then $a \rightarrow b$ is true, and (b) if a is the event of a message being sent by one process and b is the event of the message being received by another process, then $a \rightarrow b$ is also true. Obviously, a message cannot be received before it is sent or even at the same time it is sent since it takes a finite, nonzero amount of time to arrive. Note that happens-before is a transitive relation, so if $a \rightarrow b$ and $b \rightarrow c$, then $a \rightarrow c$.

The notion of causal order, as introduced by Birman and Joseph (1994), states that for any process, the order in which it delivers messages must respect the happens-before relation of the corresponding sending of the messages. More formally, a distributed computation E, all of whose messages is denoted as a set $M(E)$, respects causal order if for any two messages $m1$ and $m2$ and corresponding message-sending events $send(m1)$ and $send(m\_2)$, $send(m1) \rightarrow send(m2)$. If $m1$ and $m2$ have the same destination process, then for the message delivering events, $deliver(m1) \rightarrow deliver(m2)$.

In the definition of causal order, nothing is mentioned about the time at which the messages are delivered; also, it does not prescribe what to do with the cases of message loss and late arrival. However, in a distributed multimedia system, messages have limited *validity time*, after which the messages become useless and are allowed to be discarded. Messages that arrive at its destination within its validity time must be delivered within the expiration of its validity time and in its causal order. This motivates the notion of Δ-causal order, introduced in Yavatkar (1992) and formalized in Baldoni, Mostefaoui, and Raynal (1996). The Δ-causal order is defined as follows. A distributed computation respects Δ-causal order if (a) all messages in $M(E)$ that arrive within a time interval Δ are delivered within Δ and all the others are never delivered (they are lost or discarded), and (b) all delivery events respect causal order. That is, for any two messages $m1$ and $m2$ in $M(E)$ that arrive within Δ we have, if $send(m1) \rightarrow send(m2)$ and $m1$ and $m2$ have the same destination process, then $deliver(m1) \rightarrow deliver(m2)$.

The clock-based isochronous synchronization protocol requires the following ordering property be respected.

- **Same order:** The multimedia messages are delivered to the destinations in the same order.
- **Temporal order:** Different destinations see the different messages in the temporal order.
- **Simultaneity:** Different destinations see the same messages at about the same time.

Note that the temporal order is a prerequisite for the causal order. If and only if the occurrence of an event e_1 has preceded the occurrence of an event e_2 in the domain of real time, it is possible that e_1 has an effect on e_2. On the other hand, if it can be established that e_2 has occurred after e_1, e_2 cannot be the cause of e_1.

The basic mechanism is to use clock values as event time stamps to preserve temporal ordering of events and to achieve synchronization, and clocks in the system must have sufficient granularity or resolution. The granularity g of a synchronized clock is defined as the real-time duration between two consecutive global ticks. Obviously, the temporal order of two or more events, which occur between any two consecutive ticks of the synchronized clock, cannot be reestablished from their time stamps. This is a fundamental limit when using clock time for temporal ordering.

With globally synchronized clocks having sufficient granularity, we can construct an action lattice (or event lattice) as described above; that is, one dimension of this lattice represents the progression of time, and the other dimension is the processes in the system (Figure 1). Processes in the system are designed to execute a simple clock-driven protocol (an isochronous protocol below), which requires that the events of sending and receiving messages are restricted to only occur at the lattice point of the globally synchronized space-time lattice. Thus, whenever an action has to be taken, it has to be delayed until the next lattice point of the event lattice. This delay is the price we have to pay for the simple and intuitive synchronization protocols.

This lattice is a basic mechanism for the isochronous approach to multimedia synchronization. The lattice interval, Δ, is an important design parameter for the synchronization protocols. The following factors will affect how to choose Δ.

- The bounded end-to-end communication delay
- The validity time of multimedia, beyond which the multimedia objects become useless
- The granularity g and precision p of clock synchronization

As a general guideline, Δ must be large enough to accommodate all these factors; it must also be small enough not to unduly delay events.

AN ISOCHRONOUS SYNCHRONIZATION PROTOCOL

We now describe a general clock-driven, isochronous protocol to achieve desired multimedia synchronization. The protocol seeks to guarantee that in a time period, a set of processes will deliver the same messages at the same time and in the same temporal order. Here, "same time" must be understood to be limited by the clock skew (clock-synchronization precision) as much as π, meaning that two processes undertaking to perform the same action at the same time may in fact do so as much as π time units apart.

The protocol executes its events on every clock tick (i.e., at the lattice point), and executes a *No-Op* event by doing nothing if there is no communication event to take place on a clock tick. In practice, operations on a clock tick can be implemented by an interrupt-driven program; for example, the receipt of a message time-stamped T causes the setting of a clock interruption for $T+\Delta$, which in turn will cause the message to be processed at that time. When a process disseminates a message, it will not do so immediately; rather, it will wait until the next tick (i.e., next lattice point) on its clock and then time-stamp the message using its clock reading and send out the message. When the message arrives at its destination, it is not sufficient for the destination process to handle messages that have been received in ascending order by time-stamp. We must ensure that a process delivers messages only if no message with a smaller time stamp can be subsequently received. We say that a message is *stable for p* once no message with a lower time stamp can be delivered to the process *p*. Clearly, a message should be processed only after it becomes stable.

The lattice structure for the protocol operation provides a convenient way of establishing message stability. Here, testing the stability of a message can be accomplished by exploiting the bounds on delivery delays (i.e., the next lattice point) and process clocks. A message time-stamped T by process p will be received by $T+\Delta$ at every other process in the system according to each process' local clock, which is synchronized with the others. The message that arrives later than $T+\Delta$ is considered useless and discarded (because the multimedia message is beyond its validity time).

The isochronous synchronization protocol follows the following rules.

- **Sending Rule:** A process sends out the message at every clock tick; if there is no message to send, the process will do nothing (or you can think of it as sending out a null message) at the clock tick.
- **Stability Rule:** A message is stable at process p_i if the time stamp on the message is T and the clock at p has a value equal or greater than $T+\Delta$.
- **Delivery Rule:** Stable messages are delivered to the application in ascending order by time stamp.
- **Tie-Breaking Rule:** Two messages with the same time stamp from different processes are ordered according to the process ID, which is assumed to be unique.

Note that the ordering properties as required by the synchronization are guaranteed by executing this protocol. Noticeably, the temporal order, causal order, and Δ-causal order are all respected without requiring additional sophisticated algorithms. In executing this protocol, all processes have a consistent behavior toward messages.

The isochronous synchronization approach assumes globally synchronized clocks in distributed systems. The improved NTP (version 3) enjoys synchronization to within a few tens of milliseconds in the global Internet of today; the clock synchronization for LANs (local area networks) can obtain accuracy as high as a few microseconds. The introduction of the Global Positioning System (GPS) in the 1990s has further advanced the clock-synchronization technique (Herring, 1996). GPS has introduced an inexpensive way to obtain accurate information (including time information) using a radio receiver, which consists of nothing more than a GPS receiver and a network interface. Time obtained in this manner is accurate to a few tens of microseconds. Accuracy such as this is adequate for even the most demanding real-time applications. With this development and such an accurate timing source in place, we believe that the clock-based isochronous distributed synchronization, as advocated by Lamport (1984), provides a promising yet simple and intuitive alternative.

ACHIEVING ISOCHRONOUS SYNCHRONIZATION USING RTP/ RTCP

RTP (a transport protocol for real-time applications) is the real-time transport protocol within an Internet integrated-service architecture, which is designed to provide a quality-of-service guarantee beyond the current TCP/IP (transmission-control protocol/Internet protocol) best-effort service model. RTP provides end-to-end network transport functions suitable for applications transmitting real-time data (e.g., audio, video, or simulation data) over multicast or unicast network services. The data transport is augmented by a control protocol (RTCP) to allow monitoring of the data delivery in a manner scaleable to large multicast networks, and to provide minimal control and identification functionality. RTP and RTCP are designed to be independent of the underlying transport and network layers.

The noticeable feature associated with media synchronization is the 32-bit time stamp field in RTP data packets, the 64-bit NTP time stamp field, and the 32-bit RTP timestamp field in RTCP control packets. Although RTP does not mandate running the NTP to provide clock synchronization, running NTP is very useful for synchronizing streams transmitted from separate hosts. The mechanisms incorporated in RTP/RTCP enable the isochronous synchronization protocol.

One of primary functions of RTCP is to provide feedback in RTCP control packets (sender report, SR, and receiver report, RR) on the quality of the data distribution and information for intermedia synchronization. The RTP standard requires that the NTP time stamp (based on synchronized clocks) and corresponding RTP time stamp (based on data-packet sampling) are included in RTCP packets by data senders. This correspondence between the RTP time stamp and NTP time stamp may be used for intra- and intermedia synchronization for sources whose NTP time stamps are synchronized. Using the time-stamp mechanisms in RTP/RTCP and the lattice structure described in this chapter, our isochronous approach can be readily applied to multimedia systems, particularly in distributed many-to-many conferencing environments.

CONCLUSION

In distributed multimedia systems, there exist two approaches to protocol design, event driven and clock driven, and most protocols have taken an event-driven approach. While using physical time based on globally synchronized clocks for obtaining synchronization was advocated a long time ago, the clock-driven approach has not been popular in the distributed-system research community. In conjunction with the lattice structure, the isochronous protocol achieves the required synchronization, which guarantees the temporal order, including causal order and Δ-causal order, without additional sophisticated algorithms for respecting causality. The only assumption of the isochronous protocol is the synchronized clocks in a distributed system and the known bounds of the network communication delays. These assumptions can readily be satisfied with the deployment of modern networks. The mechanisms incorporated in the Internet standard real-time protocols such as RTP/RTCP make the isochronous synchronization approach readily applicable.

KEY TERMS

Clock Synchronization: Physical clocks in a network are synchronized to within certain precision and accuracy. The precision refers to the difference between readings of clocks, and the accuracy refers to the difference between the clock reading and the universal standard time.

Intrastream Synchronization: This, also called playout synchronization, ensures that the receiver plays out the medium a fixed time after it was generated at the source and it experienced variable end-to-end delay. In other words, intrastream synchronization assures that a constant-rate source at the sender again becomes a constant-rate source at the receiver despite delay jitter in the network.

Intermedia Synchronization: This is concerned with maintaining the requirements of the temporal relationships between two or more media. Lip synchronization between video and audio is an example of interstream synchronization where the display of video must synchronize with audio.

Interstream Synchronization: This ensures that all receivers play the same segment of a medium at the same time. Interstream synchronization may be needed in collaborative environments. For example, in a collaborative session, the same media information may be reacted upon by several participants.

Isochronous: The term refers to time-dependent processes where data must be delivered within certain time constraints. For example, multimedia streams require an isochronous transport mechanism to ensure that data is delivered as fast as it is displayed, and to ensure that the audio is synchronized with the video. Isochronous processes can be contrasted with asynchronous processes, which refers to processes in which data streams can be broken by random intervals, and synchronous processes, in which data streams can be delivered only at specific intervals. Isochronous service is not as rigid as synchronous service, but not as lenient as asynchronous service.

Multimedia: This term is used to indicate that the information and data being transferred over the network may be composed of one or more of the following media types: text, images, audio, and video.

NTP: NTP stands for network time protocol, and it is a standard Internet protocol used to synchronize the clocks of computers to some time reference.

Stream: This technique is for transferring data such that it can be processed as a steady and continuous stream. Streaming technologies are becoming increasingly important with the growth of the Internet because most users do not have fast-enough access to download large multimedia files quickly. If the stream is for transferring multimedia data, it is called a *multimedia stream*.

Validity Time: This is a time interval within which the message remains valid, available, and useful to its recipients. After the validity time of a message, the message becomes useless and may be discarded. The notion of validity time is important in multimedia communication.

Isoluminance Contours for Animated Visualization

Marion Cottingham
The University of Western Australia, Australia

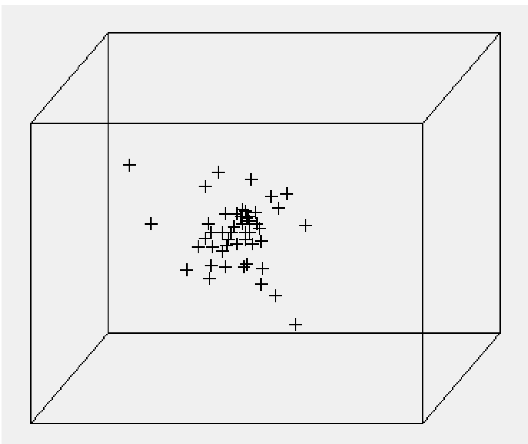
EVOLUTION OF THE ISOLUMINANCE CONTOURS MODEL

Visualization software applications were introduced to enable the sheer volume of data produced by computers worldwide to be viewed in picture form. Visualization makes it easier for the human visual system to pick up trends, patterns, and relationships in the data. The first wave of these applications typically generated simple two-dimensional line graphs, bar charts, and pie charts on expensive graphics workstations.

The second generation enabled three-dimensional images, with single data points typically denoted by dots or crosses, as shown in Figure 1. Axes lines or boxes enclosing the data were typically displayed. The whole image could then be rotated with the data points to give some indication of their orientation to each other. Since the majority of computers were not fast enough to perform the rotation in real-time, there was often some confusion in the picture's interpretation.

Graphics software applications became available, such as OpenGL or DirectX, containing functions for creating simple solid objects such as cubes, cylinders, cones, and spheres, and researchers could now attempt their own visualization. Most of these graphical applications were based on the polyhedral representation and did not provide any control over the number of patches representing each solid. Being able to animate the data points in real-time enhances trends and relationships in the data that are not easily identified in a still image. Since time is crucial in animation, representing solids with the minimum number of patches is of utmost importance.

Figure 1. Data cloud with data points denoted by crosses



The Isoluminance Contour model (IC model) was introduced in 1980 (Cottingham, 1981) as a means of representing these simple solids. It provides realistic results that far outweigh those produced using traditional methods, and in a fraction of the time. The amount of data used to generate an image can be easily adapted to suit each frame making real-time animation possible even on slow PCs.

Generating Images Using Traditional Graphics Techniques

Traditional graphics techniques adopt a divide-and-conquer approach to rendering solid objects. Each solid's surface is subdivided into planar patches that are generated one-by-one to produce the image while balancing speed with realism.

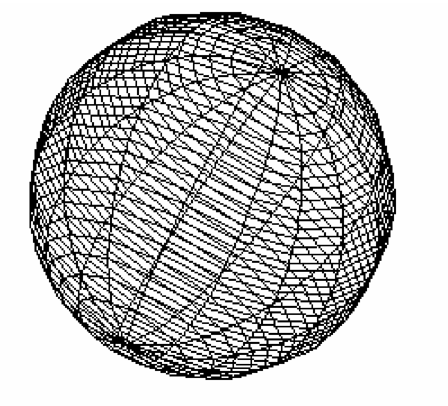
Storage Considerations

Each surface patch consists of four edges, each defined by two vertices specified in three-dimensional space. Topological information defines how edges and vertices are connected. Because surface patches from the simple solids form complete rows and columns, the topology can be implied by the order of storage using the Compressed Data Structure (CDS) (Cottingham, 1985; 1987).

Figure 2 shows a sphere represented by 640 facets, stored in 41 rows of 17 columns and generated by drawing lines to connect vertices stored at adjacent columns and rows. This is termed a wire frame drawing.

For speed, wire-frame drawings with only the edges of patches drawn are often used for quick previewing, but these do not provide much realism. At the next level, patches are flat shaded by calling a polygon fill function. However, in general, only triangular surfaces patches are guaranteed to be planar, so it is common practice for surface patches to be triangulated in an attempt to im-

Figure 2. Wire-frame sphere



prove the degree of realism—this doubles the number of patches. Figure 3 shows a sphere defined by 11 rows and 21 columns of vertices that specify 400 triangular patches or 400 quadrilateral patches.

Isoluminance Contour Model (IC Model)

The Isoluminance Contour (IC) model takes an entirely different approach by representing solids by planar contours that are defined by a collection of perimeter points. Points that share the same orientation to the light source are chosen, therefore, they all share the same constant chromaticity. To generate a contour, the illumination model needs to be called only once before calling a polygon fill function. Contours are rendered in depth order. For speed, you can also simply apply linearly spaced chromaticity values without calling an illumination model at all and select one that achieves the required effect.

Using the Isoluminance Contour model, each contour is defined by a single row of vertices from the CDS array, so there is no need to connect vertices from adjoining rows. Figure 4 shows the planar contours drawn as a wire-frame image and Figure 5 shows the planar contours filled with color.

Using the IC model, hidden surface elimination is automatically performed by generating contours in depth order (Painter's algorithm). The illumination model can be minimized to deciding on a range of color values and evaluating a contour's color according to its distance from the light source. For optimum realism, a complex illumination model can be applied. This would achieve results indistinguishable to those produced using ray casting. Ray casting is considered to give the highest degree of realism of all the traditional rendering techniques available. It generates images pixel by pixel and is renowned for the vast amounts of CPU time it consumes. However, the Isoluminance Contour Model produces identical results, give or take a pixel, yet can produce images in a fraction of the time taken to produce even wire-frame.

Comparison of Image Generation Speeds

Table 1 compares the CPU cycles taken to perform a single image containing a thousand spheres using traditional rendering methods on polyhedra with equivalent images produced using the IC model. For this comparison, each sphere was defined by 1250 patches—25 circular planes defined by 50 vertices, and the image was generated on a slow Pentium 400 PC. Although different hardware configurations will yield different results, the relative proportions of these times will remain constant.

For wire-frame drawings, all the edges for the polyhedral representation were drawn, displaying mainly quad-

Figure 3. Flat-shaded sphere represented by triangulated patches

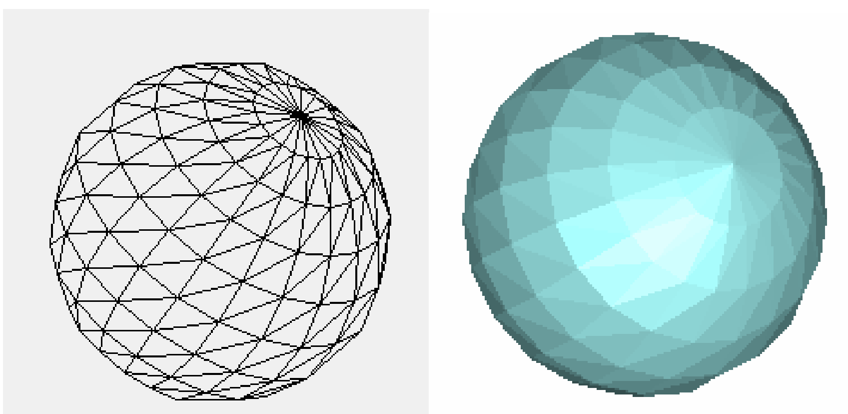


Figure 4. Isoluminance contour represents a sphere by a collection of planar contours

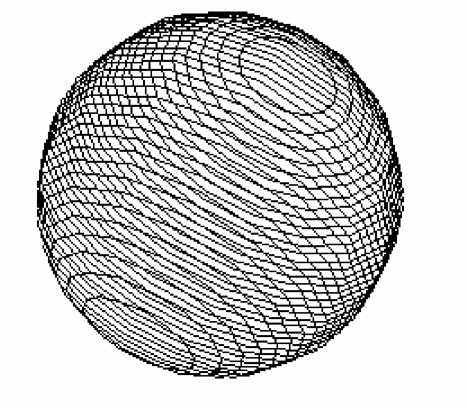

Figure 5. Filled isoluminance contours

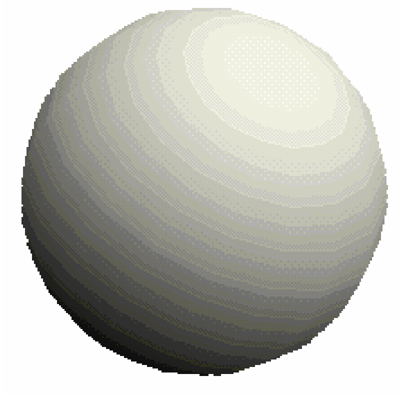

rilateral patches; the IC model displays circular planes and avoids drawing the edges connecting the poles, as shown in Figure 4.

Different traditional techniques were applied to render the shaded images, each producing different levels of realism. The IC model used in the flat-shading timing included the specular reflection calculation, which is an add-on when required rather than part of the illumination model. The specular area shown in Figure 6 is the circular umbra that would appear if the light source was at the same angle as the viewing direction; this becomes more elliptical as the light is moved around. A higher level of realism would also require the penumbra to be displayed.

Using the IC model, a realistic image can be produced faster than even the simplest wire-frame image can be rendered by traditional methods. One reason is that only one normal and illumination calculation is required by the IC model for each of the 25 circular planes. In comparison, shading the polyhedral representation requires calculating the normals and illumination values for each of the 1250 vertices. In addition, when Gouraud's smooth-shading method (1971) is used, these illumination values have to be interpolated at every pixel lying inside each patch. The slowest time used Phong's (1975) method that requires the normals for every vertex to be interpolated and the illumination values calculated at every pixel lying inside each patch.

Figure 6 shows the images of one of the spheres rendered for this timing comparison. The top three spheres all use the polyhedral representation. From left to right, the polygons were rendered to produce a full wire-frame drawing, a wire-frame drawing with hidden lines re-

Figure 6. Spheres generated during the timing stage

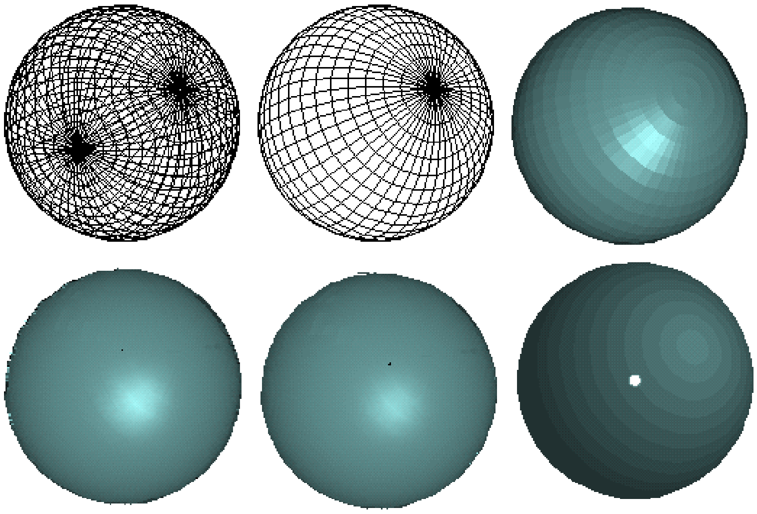

Table 1. CPU times required to render a thousand spheres

	Full Wire frame	Wire Frame Hidden lines removed	Shaded			
			Flat	Triangulated	Gouraud	Phong
Polyhedra	9.33	222	238	262	313	1388
IC model	5.08	5.13	8.07	-	-	-

moved, and a flat-shaded image. The bottom three spheres, from left to right, were rendered using Gouraud's method and Phong's method—both of which smooth-shaded patches from the polyhedra representation, and the IC model with specular reflection.

IC Model for Animated Visualization

Two approaches can be taken when animating data. In the first approach, the data points themselves are translated in three dimensions or rotated around one of the coordinate axes or about a line in three-dimensional space. In the second approach, the viewer moves around inside the data cloud and the data points remain static.

Figure 7 shows the three-dimensional visualization of the data points shown in Figure 1. These represent the evolution of mammals' brains in terms of changes in overall brain size. This data set was supplied courtesy of Professor Heinz Stephan, Max-Planck Institut fur Hirmforschung, Frankfurt. Exploratory univariate and multivariate analyses were applied by Mr. Willem De Winter and Professor Charles Oxnard (Department of Anatomy and Human Biology at The University of Western Australia) to the volumes of 11 non-overlapping brain parts from 921 specimens representing 363 species of various taxonomic groups consisting of primates, insectivores, bats, tree-shrews, and elephant shrews. This screen shot is from a visualization performed by software developed by Paul Merendah as an undergraduate, third-year Computer Graphics unit assignment (School of Computer Science and Software Engineering, The University of Western Australia). The assignment was specified and supervised by the author.

Uniform-sized spheres represent specimens, with the distances between the spheres representing the relative similarities in brain proportions (three dimensions). Perspective projection dictates the screen size of spheres. Species groups are color-coded (fourth dimension), and different levels of saturation and hue define individual relative significance within their animal group (fifth and sixth dimensions).

Figure 7. Visualization of the proportional sizes of the major brain divisions for a wide range of mammals

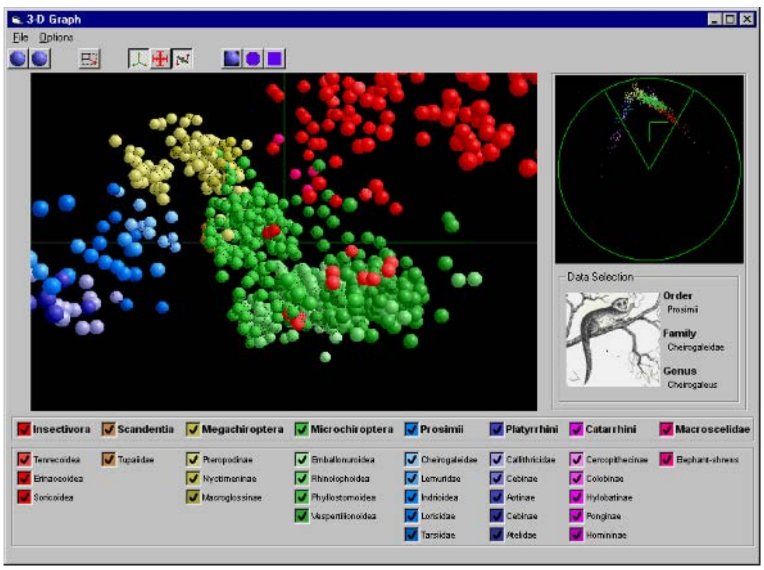

Figure 8. Visualization of the major brain divisions of mammals with different parameters in the illumination model

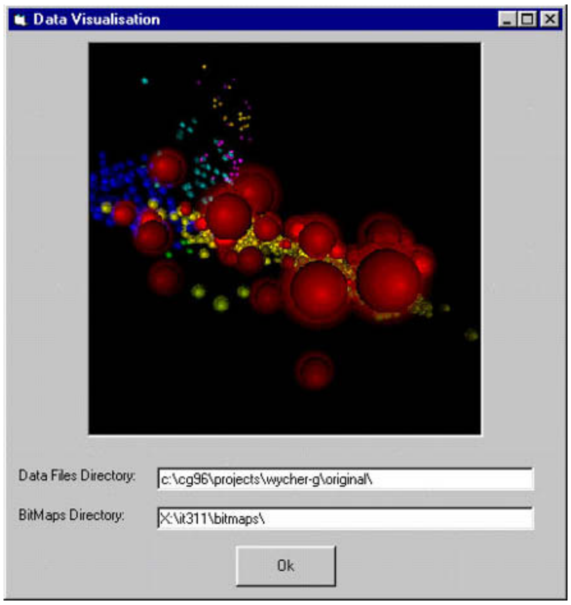


The data set contained 921 data points (spheres), and with the IC model it was possible to fly around the data cloud in real-time on a Pentium 166 PC. The relative position of the light source to the viewing position was assumed to be constant so that the contours of the spheres did not require reconstruction at any time during the simulation.

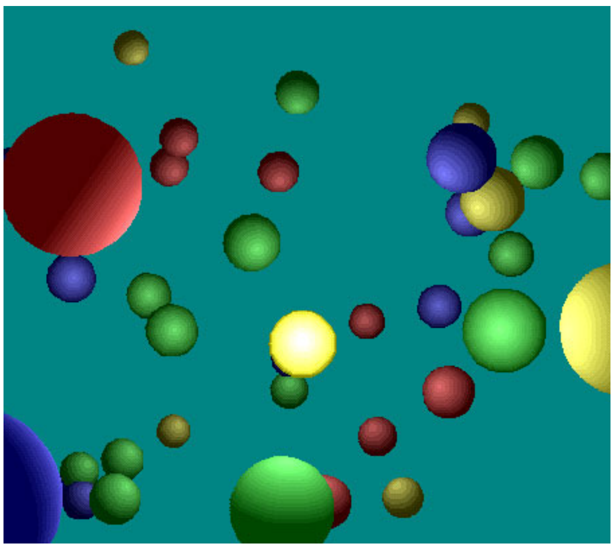
Figure 8 shows the same data set being visualized by software developed by Graham Wycherly in the same project; this software uses a different illumination model.

The ability to fly around the data clouds in real-time on such a slow PC was due to the adaptability of the IC model. The number of contours used for rendering any sphere was based on its screen size. The animation performed in these two student projects enabled even more relationships to be discovered, as before this dynamic visualization it was thought by biologists that the evolution of the brain in mammals was simply a matter of changes in the overall brain size (Finlay & Darlington, 1995). This visualization demonstrated the existence of different phylogenetic trends in the evolution of the mammalian brain and that where species shared a particular lifestyle the brain had evolved converging towards a similar proportional organization (Oxnard and de Winter 1997: 2 journals, de Winter).

Both these projects assumed that the light source was positioned infinitely far away so that all light rays were parallel and all spheres were shaded the same. However, it is possible to remove this assumption and still attain real-time animation if you have a sufficiently powerful PC.

Allowing the position of the light source and the viewing position to move independently means that the light direction vector is no longer constant throughout the scene, therefore, the spheres at different positions in space no longer have identical shading. This makes it necessary to create each sphere from scratch whenever the viewing position or the light source changes. This is still achievable in real-time on a Pentium 400 or faster PC.

Figure 9. Light source positioned in the data cloud in full view of the viewing position



This independence means that the light source itself may become visible. Figure 9 shows the light source (brightest sphere) positioned amongst the data cloud in full view of the viewing position.

You may be required to display a timed series of data points on the screen simultaneously. The visualization shown in Figure 10 displays "bid and ask" stock market data over a five-day period. Professor Philip Brown from the Department of Accounting and Finance at The University of Western Australia supplied the data. The software was developed by Ken Hooi for a third-year Computer Graphics unit assignment that was specified and supervised by the author.

"Asks" are shares for sale at a specified price and "bids" are offers to buy at a stated bidding price. The asking price is usually more than the bidding price. The bids are displayed as blue spheres and asks as red spheres. The software creates an x- and y-axes pair for each day requested by the user and displays the bids and asks not realized for that day. The x-axis depicts the volume of the bid or ask parcels of shares, and the y-axis depicts the bid or ask price per share. When an ask parcel and a bid parcel match in price and volume then a transaction takes place and the relevant spheres disappear off the screen. The dynamic view allows the user to watch while the bid and ask pairs are being processed, so that he/she can view the trades as they happen.

IC Model as an Adaptive Model for Real-Time Animation

Solids are created from templates to avoid having to recalculate the vertices for each one individually. To maintain the level of realism required, a template is defined by enough vertices to render the solid at its largest screen size. Since it would be inefficient to include all these vertices as the solid's screen size diminishes, the number of vertices copied from the sphere template is adapted to reflect the screen area. For example, suppose the viewing position starts close to a sphere solid and moves away, causing the sphere to zoom away into the distance. Initially, all the vertices must be rendered to maximize the smoothness of the sphere's surface. As the sphere moves away and its screen size grows smaller, every second vertex from every second contour can be used, then every third vertex from every third contour, and so on. For sphere solids, the screen size is calculated from the sphere's diameter, which is approximated by (maximum X – minimum X).

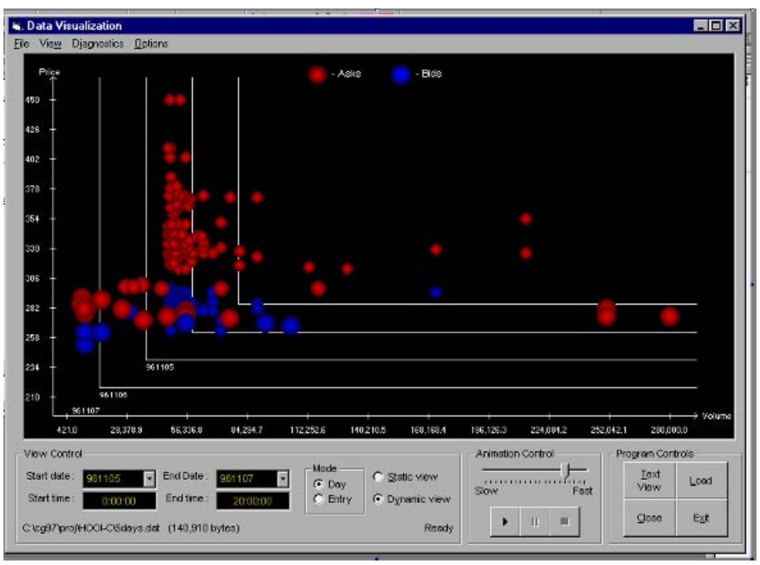
Additional information on the IC model is available from Cottingham (1989, 2004a, 2004b), Cottingham and Conway (1988), and Conway (1991, 1993).

FUTURE TRENDS

First, the Isoluminance Contour model could be generalized by introducing a pre-processing step that takes existing data sets and combines any adjoining patches that have similar normal direction vectors. This would require a more general data structure such as Baumgart's (1975)Winged-Edge Data Structure rather than the simpler CDS.

Second, because of the simplistic nature of the IC model, implementing it in hardware should be reasonably straightforward.

Figure 10. Displaying "bid and ask" stock market data one day per axis



CONCLUSION

The IC model is quick and simple to program as the topology of the solids is implied by the order of storage in a simple two-dimensional array. It eliminates the need for most of the steps required by traditional computer graphics techniques. It is extremely fast and does not require any quick-previewing methods to be developed. The realistic results that are indistinguishable from ray-tracing speak for themselves.

KEY TERMS

Data Cloud: Collection of data points in space.

Illumination Model: A mathematical formula for calculating the amount of diffuse light, ambient light, and specular reflection that contributes to the color value that will represent a particular surface point on the screen.

Isoluminance Contour: Planar polygon that has a single constant color at all points it encloses.

Real-Time Animation: Frames created at a minimum rate of 20 per second to avoid flicker.

Smooth-Shading Techniques: Interpolative techniques that restore the smoothness of solids whose surfaces are represented by planar polygons.

Viewing Position: The point in three-dimensional space where the user is positioned to view the data. There is also an associated direction where the user is looking.

Visualization: Viewing data in picture form in an attempt to gain a further understanding of the trends and relationships it contains.

Wire-Frame Drawing: Only the lines defining the edges of patches are drawn, which is useful as a quick previewing tool.

Issues and Challenges for IT in Small Business

Stephen Burgess
Victoria University, Australia

INTRODUCTION

This article examines the main issues and challenges facing small business owners and managers in the manner in which they use information technology and Internet technologies within their businesses. The first part of the article concentrates upon the issues. The "Challenges" section examines some of the areas that small business researchers are targeting in their recommendations for how the use of IT in small businesses can be improved. These are areas that small businesses often neglect or, even worse, know nothing about.

BACKGROUND

Issues

This section looks at some of the issues facing researchers as they attempt to investigate the use of IT in small businesses. It starts off by looking at some of the various definitions of small business that are being used. Then barriers to successful use of IT by small businesses are examined, leading into the factors that lead to its successful use.

What is Small?

When studying the use of IT in small business, the range of definitions used to describe "small business" is interesting to say the least. This range can make it extremely difficult for researchers to "match up" different small business studies. A 2003 study by worldwide members of the Information Resources Management Association Special Research Cluster on Small Business and Information Technology[1] found that:

- Definitions of "small business" ranged from less than 20 (Australasia), 50 (Europe) and 100 (North America) employees (with some definitions including requirements for annual turnover and asset levels).
- Definitions of "micro business" ranged from less than 5 to less than 10 employees.
- Definitions of "medium" business ranged up to 200, 250 and 500 employees!

A common acronym used to represent small and medium sized businesses is "SME". There was quite a deal of argument as to whether the term was of any use at all – given the vast differences between small and medium sized businesses. Still, half of the responding members felt there was still a use for the term.

Pollard and Hayne (1998) have identified a number of studies that set the upper limit of employees for a business to be classified as small as 50, 100, 200, 250 or 500!

Business Size is Important!

Why is it so important to consider the size of the business? A number of studies suggest that there is a relationship between the size of a business and its level of adoption of IT (McDonagh & Prothero, 2000). There is also a relationship between the size of a business and the different characteristics it will have that can lead to the successful use of IT (Igbaria et al., 1997; Pollard & Hayne, 1998). As such, research findings based upon traditional "MIS" in larger businesses are not necessarily directly applicable to small businesses.

Barriers and Success Factors

The literature around the area of small business and information technology is rife with what is now a fairly accepted list of "barriers" to the successful implementation of IT in small businesses. These barriers typically include (Igbaria et al., 1997; Management Services, 1997; McDonagh & Prothero, 2000; Pollard & Hayne, 1998):

The cost of IT
- Lack of time to devote to the implementation and maintenance of IT
- A lack of IT knowledge combined with difficulty in finding useful, impartial advice
- Lack of use of external consultants and vendors
- Short-range management perspectives
- A lack of understanding of the benefits that IT can provide, and how to measure those benefits
- A lack of formal planning or control procedures

One advantage that small businesses (especially innovative ones) have is that they are flexible. They are able to preserve labour relationships, bring a "personal touch" to operations, cater to niche markets and they have small capital requirements. The fact that they are under constant pressure can also spur them to be inventive and innovative in their business operations (International Trade Forum, 1999).

Having identified some of the barriers to the successful use of IT, there is also a fairly common list of factors that are listed in the literature that appear to indicate a greater chance of successful implementation of IT in small businesses.

Some of these factors are (Naylor & Williams, 1994; Swartz & Walsh, 1996; Yap & Thong, 1997; Zinatelli et al., 1996):

- The involvement of owner/managers in the implementation of IT
- The involvement of users (employees) in development and installation
- The training of users
- The selection of applications chosen for computerisation
- The use of disciplined planning methodologies in setting up applications
- The number of analytical/strategic (versus transactional) applications being run
- The level of IT expertise within the organisation
- The role of the external environment (especially consultants and vendors)

The idea behind introducing this list (and the barriers listed earlier) is that you will see these points raised again and again in the following sections as some of these and other issues are discussed.

Role of Owner/Managers

One of the key factors leading to successful use of IT in small businesses identified in the previous section was the involvement of small business owner/managers in the IT implementation.

There is some evidence to indicate that managers in small businesses are less likely to know how to use IT effectively or to keep up with the latest trends in IT than their counterparts in larger businesses (Pollard & Hayne, 1988). Igbaria et al. (1997) cite a number of references to support the view that management support can promote the acceptance of IT. They found that the support of management positively affected the perceived ease of use and the perceived usefulness of IT within the small business.

Applications

These days, the vast majority of small businesses in most countries have computers. Small businesses that use computers mainly use them for administrative and operational purposes (such as accounting, budgeting, payroll, inventory control and the like) (Bridge & Peel, 1999; El Louadi, 1998; Pollard & Hayne, 1998). Much of the software that is used by small businesses is purchased “off the shelf” (McDonagh & Prothero, 2000), although there is some evidence to suggest that small businesses with particular (specialised) needs are prepared to invest in customised software (Burgess, 1997).

The literature also suggests that some small businesses are beginning to realise that IT can be used to gain competitive advantage (Pollard & Hayne, 1998).

Location

Why is location important when considering the use of IT in small business? The major answer to this is a combination of resources and distance. The further you are away from resources, the longer it takes and the more it costs to get them. This can particularly be the case with hardware and software purchases, training and support.

Another reason for examining location is **culture.** Some countries, and even different regions within countries, have their own traditions and their own established ways of doing things. This can influence the behaviour of small businesses and the manner in which they use IT.

Developing Countries

Small businesses make up a major portion of businesses in developing countries (in some countries the percentage is higher than in developed countries). One of the major barriers faced by small businesses in developing countries is access to information, especially information used in decision making. Another problem is the lack of data sources from which to obtain the type of information required. Problems with the technological infrastructure of developing countries only exacerbate this (Sawyerr et al., 2000).

Today, the cost of installing a national telecommunications structure has fallen. When combined with reduced costs of international transport it is easier for small businesses in many developing countries to gain access to international markets (International Trade Forum, 1999). Uptake of the Internet in developing countries has been on the increase since 1996, the level of growth (again) being hindered by problems with the telecommunications infrastructure (Gallagher, 1999).

Rural Small Businesses

Some of the problems facing rural small businesses are similar to those facing small businesses in developing countries. One of the benefits that the Internet may provide is remote access to many desired IT resources, such as training (Gallagher, 1999). A year 2000 survey of Australian small businesses revealed that 29% of metropolitan small businesses had a Web site, compared to 20% of rural small businesses. The main reason given by rural small businesses for not having a Web site was that they did not have access to the skills needed to design, build and maintain a Web site (Telstra Corporation & NOIE, 2000).

Industry

There is some relationship between the industry that small businesses are involved in and the types of IT that they use. For instance, professionals and finance/property/business services small businesses are the ones that use the latest IT. The building/ construction industry is typically the least enthusiastic to use IT at all, let alone the latest IT (Burgess, 1997). There is also some evidence that different software is used by different industries. For instance, the building/construction industry uses scheduling, drafting/design and project management software. Manufacturing businesses use software for scheduling, operating machinery and monitoring operations. Wholesale/retail small businesses use point-of-sale software (as well as bar code scanners) (Burgess, 1997).

CHALLENGES

This section examines some of the areas that small business researchers are targeting in their recommendations for how the use of IT in small businesses can be improved. These are areas that small businesses often neglect or, even worse, know nothing about.

Planning

One of the barriers identified earlier that hinder the effective use of IT in small businesses is a lack of formal planning and control methodologies. This relates to a lack of knowledge of how to plan effectively, lack of time and money to seek this knowledge, lack of time to apply it even if they have the knowledge and a lack of understanding that they even need the knowledge! Small businesses are, however, concerned with issues relating to how they can operate more effectively and efficiently and/or how they can grow (El Louadi, 1998). One of the problems is that management practice in small businesses is often based on the short term and is informal and ad hoc. Much of the time is spent "surviving," so that little time can be devoted to examine IT projects (Pollard & Hayne, 1988).

Working Out the Benefits of IT

Another barrier to the successful use of IT in small businesses is a lack of understanding of the benefits that IT can provide, and how to measure those benefits. The most common way used to determine the level of IT success is to measure small business user satisfaction with information technology. Such measures of user satisfaction have one major problem – they are linked with user expectations (Naylor & Williams, 1994). For instance, an owner/manager understanding the strategic benefits that IT can provide may be less satisfied with a simple transactional system than an owner/manager who is unaware of these strategic benefits. This is despite the possibility that they may be reviewing systems that perform in a similar manner. Again, the problem falls back to a lack of proper knowledge about the advantages that IT can provide.

Training

Factors relating to a lack of knowledge of IT or lack of understanding of the benefits of IT have been mentioned a number of times already in this article. Appropriate training in IT has been mentioned earlier as one of the factors leading to successful use of IT in small businesses. Igbaria et al. (1997) found that the amount of training that users had received from other users or IT specialists within the firm had an effect on the perceived usefulness of the system. External training had a positive effect on the perceived ease of use of IT, which they theorise may enhance computer skills and reduce "negative attitude" barriers to the acceptance of IT. A lack of training was a cause of user frustration.

External Information

Small business managers perceive more uncertainty in their environment than their counterparts in larger businesses. Effective management of external information can help them to reduce the level of uncertainty that they feel (El Louadi, 1998).

Vendors and Consultants

In many instances, small businesses have to rely on the IT expertise of vendors and/or consultants because of a lack of internal IT expertise. Igbaria et al. (1997) have found that good external support provided by vendors and/or consultants, such as technical support, training and a harmonious working relationship can reduce the risk of IT failure in small businesses.

There is a view, however, that vendors and consultants do not understand the small and medium business market and that the level of support provided by them is only adequate or less than adequate (Management Services, 2000). Careful selection of vendors and/or consultants is vital.

Government Support

Governments worldwide are beginning to realise the importance of the small business community. The role of government in developing countries has already been touched upon in this article. IT is one of the areas that are the subject of increased government resources, through improved information programs, increased training opportunities and technology support grants and awards.

The Internet and Electronic Commerce

There is no doubt that a rapidly increasing number of small businesses are using the Internet (McDonagh & Prothero, 2000). Gallagher (1999) claims that the level of Internet use is growing faster than any other technology in history! The level of this growth is such that almost half of this book is devoted to chapters that address the use of the Internet or e-commerce in small businesses.

Many small businesses are establishing a presence on the Internet, be it through the development of a Web site or through the use of e-mail. Two primary uses of Internet technologies in small businesses are the use of e-mail for communication and the Internet to gather information (Dandridge & Levenburg, 2000; McDonagh & Prothero, 2000). "Proactive" small businesses were likely to have a Web site and saw it as (Telstra Corporation & NOIE, 2000):

- An essential part of their promotional and advertising mix,
- A means of providing business and product information to clients, and
- A basis for developing an order and payment facility

FUTURE TRENDS

As time goes on, governments are increasingly becoming aware of the importance of small businesses to their economies and are providing increased resources to their support. This has resulted in various support programs for small businesses that have directly or indirectly resulted in improvements in the use of IT by small businesses. It is anticipated that this trend will continue. There is also an increasing awareness of the importance of the efficient and effective use of IT by small businesses by the research community. There continues to be increased amounts of research being carried out in the field, which can only lead to greater understanding. Groups such as the Information Resources Management Association Special Research Cluster on the Use of Information Technology in Small Business reflect the increasing research being carried out.

CONCLUSION

This article has introduced a number of issues related to the use of IT in small businesses. When looking at small business research, it is important to determine what the researcher's view of "small" actually is. This is so that proper comparisons can be made across studies.

Barriers, opportunities, applications and success factors in relation to the use of IT were identified for small businesses as being common areas covered in the literature. The importance of owner/managers, the location of the business and industry involvement were other issues that were discussed.

A number of challenges facing small businesses were also identified. The need for planning, to be able to measure success, to provide effective training and have access to important external sources of information were discussed. Finally, the effect of e-commerce and the Internet on small businesses was introduced.

KEY TERMS

Medium Business: This term is used to describe businesses that are too large to be considered as being small and too small to be considered as being large. This somewhat vague description is matched by the varying definitions of medium sized business there are around. In relation to use of IT, medium sized businesses usually exhibit more of the characteristics of larger businesses than smaller ones.

Micro Business: This term is used to describe very small businesses. Many of these operate as family businesses. They form the majority of businesses.

Owner/Manager: In most small businesses the owner/manger is the driving force behind the business, and as such can be the catalyst for change in the business that occurs through or around IT. In some small businesses the positions of owner and manager are separated.

Small Business: Small business can be measured by number of employees, annual turnover and/or assets. It usually represents those businesses with up to 20, 50 or 100 employees (depending upon the region being investigated). This term encompasses micro businesses.

SME: This acronym is used to refer to small and medium sized enterprises as a collective group.

Issues in Delivering Course Material Via the Web

Karen S. Nantz
Eastern Illinois University, USA

INTRODUCTION

"Education over the Internet is going to be so big it is going to make e-mail usage look like a rounding error."
- John Chambers, Cisco Systems, New York Times, November 17, 1990

Web-based courses (Mesher, 1999) are defined as those where the entire course is taken on the Internet. In some courses, there may be an initial meeting for orientation. Proctored exams may also be given, either from the source of the Web-based course or off site at a testing facility. The Internet-based course becomes a virtual classroom with a syllabus, course materials, chat space, discussion list, and e-mail services (Resmer, 1999). Navarro (2000) provides a further definition: a fully interactive, multimedia approach. 2002 figures suggest that over two million students are taking at least one Web course (Thornton, 1999). According to *E-Learning* (2001), more than 3,000 universities will offer substantial Web courses by 2004.

The Web-enhanced course is a blend with the components of the traditional class, while making some course materials available on a Web site, such as course syllabi, assignments, data files, and test reviews. Additional elements of a Web-enhanced course can include online testing, a course listserver, instructor-student e-mail, and other activities on the Internet. Navarro (2000) defines this type of course as a "digitized text" approach.

Navarro (2000) suggests that faculty are far more likely to start by incorporating Internet components into a traditional course rather than directly offering Web-based courses. These Web-enhanced courses might be considered the transition phase to the new paradigm of Internet-based courses.

BACKGROUND

A 1999 research study showed that 27.3% of the faculty members think they use the Internet for the delivery of course materials, but only 15.6% actually did so. Of this group, the major use was simply the substitution of a Web page for the printed page. Most faculty members (73.8%) updated their sites so infrequently that the sites only served to replicate printed handouts. In a follow-up study at the same university, the number of faculty who used Web pages to enhance their courses showed a decrease from the previous year (Garrett, Lundgren & Nantz, 2000). In the same study, 22% of the faculty are not ever planning to use a Web site for delivery of any portion of their courses. Less than 5% are truly incorporating Web technology into their courses in a meaningful way.

Clearly, there are many positive reasons for using a Web site in a course including greater efficiency in the delivery of materials, providing up-to-the-minute content, enhanced status for the course and faculty, and of course the seemingly inevitable trend to use more technology in education.

Some of the issues inhibiting the use of Web sites include: lack of faculty knowledge of Web page design, HTLM, server sites, and file transfer protocols (Nantz & Lundgren, 1998); perceived need for Web glitz to provide entertainment along with content, such as high interactivity, animation, audio and video streaming; lack of accessibility to Web resources for both faculty and students (Rao & Rao, 1999); sufficient training for faculty (Rupp, 1999), and compensation for cyberprofs who typically spend twice as much time developing and teaching Web-based courses for no extra pay (Navarro, 2000).

A Course Web Site Classification

Web classes can be classified in six different levels. At the top levels are the Internet-based classes—those created and organized to be Web delivered. The middle levels involve a Web class that uses the Internet for delivery of content and communication among the course registrants, but also uses face-to-face meetings for some classes, orientation, and testing. At the lowest level, some course materials are simply presented in a hypertext format that replaces traditional printed handouts. Table 1 shows the classification levels of academic Web pages by typical content and maintenance levels.

The six levels presented above indicate progression from the most basic Web-enhanced course to a course delivered fully on the Internet. Faculty would likely proceed through the levels to reach Level 4 for traditional classes unless limited by resources, expertise, and admin-

Table 1. Classification of academic Web pages

Level	Description	Typical Content	Maintenance Level Required
1	Traditional Course Presentation, Basic-Level Course Materials on Web—Internal Links	Instructor data (name, phone, office hours, e-mail address) Course materials (syllabus, generic schedule, assignments); non-interactive	Low—static pages after initial upload. Low-volume e-mail correspondence.
2	Traditional Course Presentation—Intermediate-Level Course Materials on Web—External Links	All Level 1 Some external links, such as textbook and reference sites; non-interactive.	Low—mostly static pages with occasional updates and checking of external links. Low-volume e-mail correspondence.
3	Traditional Enhanced Course Presentation—Intermediate-Level Course Materials on Web and Web Content Delivery	All Level 2 All traditional course materials posted. Web access in class used for delivery of some course content. Some assignments/requirements involve interaction, e.g., e-mail submissions, listserv postings.	Weekly updates to schedule, FAQ, course materials, notes to students. Medium-volume e-mail correspondence.
4	Traditional Enhanced Course Presentation—Complete Web Content and Materials	All Level 3 Course presentations and lectures dynamically available on Web. Data files, links, programs on Web for students. Forms for student “reply” assignments, course evaluations, etc. Link to course grades.	2-3 times per week. Regular updating of grades. Medium-volume e-mail correspondence.
5	Web-Delivered Course with Orientation and Testing Meetings	All Level 4 plus any additional materials to allow for full Web delivery of course including audio and video augmentation; multimedia CDs. Few or no regular classes—orientation meeting may be necessary. Testing may be proctored off-site or unproctored on the Web.	Daily maintenance and access by instructor. High-level e-mail correspondence. Regular updating of grades and course materials.
6	Virtual Class	All Level 5 plus online testing and orientation. Discussion, chat groups, listserv, e-mail, and other interactive tools. Teleconferencing. No class meetings.	Substantial daily maintenance (average 1-3 hours) by instructor including all course aspects. High-level e-mail correspondence.

istrative factors. Levels 5 and 6 require significant changes in the academic structure and considerable support of the academic computing environment. The following table summarizes the resources that would be involved in the process of moving courses to the Web.

Although Table 2 shows a summary of the typical resources faculty need to develop Web course materials at varying levels, there are other elements that will be just as important in achieving a specific level of Web course expertise. The following list defines show of the issues. For a more comprehensive discussion, see Nantz and Lundgren (2003).

Issues Inhibiting Web-Enhanced Courses and Recommendations

- Be realistic about your own level of expertise and the instructional support you have available. Convert print-based materials to HTML using Word or some other familiar software. Once a comfort level is achieved, incorporate other HTML code using simple programs like Netscape Composer. Cut and paste code from sample Web pages. Extend knowledge to knowledge of common gateway interface

Table 2. Resources involved in moving to the Web

Level	Description	Resources Needed
1	Traditional Course Presentation, Basic-Level Course Materials on Web—Internal Links	Basic computer literacy, Web browsing experience. Course site can be created by the faculty member, professional designers, by use of Web course applications such as Blackboard (2001) or WebCT (2001).
2	Traditional Course Presentation—Intermediate-Level Course Materials on Web—External Links	Experience with preceding level. Web application packages can be extended or with additional training, a general Web development package like MS FrontPage or DreamWeaver can be used.
3	Traditional Enhanced Course Presentation—Intermediate-Level Course Materials on Web and Web Content Delivery	Experience with preceding level. Commitment to regular maintenance. Knowledge of e-mail attachments, listserv maintenance, or other interactive Web applications. Both Web application and general Web development packages can be extended for this level.
4	Traditional Enhanced Course Presentation—Complete Web Content and Materials	Experience with preceding level. Professional Web applications may not be able to accommodate this level without considerable difficulty. Usually requires considerable expertise with general Web development packages and some knowledge of HTML, and programming concepts include Javascript, ASP, and XML.
5	Web-Delivered Course with Orientation and Testing Meetings	All of the above. No additional faculty resources required; academic structural change to allow for registration and other student activities online.
6	Virtual Class	Use of a sophisticated commercial Web course package that allows for secure online testing; considerable administrative support and faculty expertise in the selected package.

(CGI) scripts, Java, or XML (Extensible Markup Language). Use university's instructional support personnel to help you set up simple Web pages that are at your comfort level for maintenance.

- Be realistic about the cost in time and money to maintain course Web sites. The development of a full Web-delivered course may be as high as $115,000 (Navarro, 2000). Marchese (1998) suggests a range of $12,000 to 90,000 per credit hour. Any Web platform provider will charge a licensing fee that may be based on the number of students. The equivalent of a one-hour lecture may require 24 hours for writing, recording, and editing, and up to 162 hours for full multi-media support.
- Be realistic about your access and the students' access to technology. Any administration who wants Web-delivered coursework must provide adequate technology to support it, either through on-campus servers or an off-campus Web host.
- Be realistic about converting paper-based content to Web content. A direct conversion usually doesn't work well. The visual indicators on printed materials (headers, footers, page numbering) don't convert well to HTML. Content and access must be re-evaluated. PowerPoint slides can be posted, but good slide design means key points only. Substantial notes must be provided to expand on the slides. Some students see the notes as ancillary and don't get the depth of content. Text-based sites are seen as boring. An academic course site that simply creates text on a Web page defeats the purpose of using Web pages—of having the ability to create links to interesting sites, to provide graphics, to provide sound and video. Providing hundreds of pages of text is the death knell for a Web class.
- Be realistic about your expectations of a Web-enhanced course. Our research shows that when course content is placed on the Web, student attendance will drop by as much as 50%. Students see printing Web pages as a substitute for class attendance (Lundgren & Lundgren, 1996).
- Be realistic about the stability of the technology. Over 90% of instructors report frequent problems (Navarro, 2000). You can't expect to use transparencies as a backup to an interactive lecture with dynamic linking. Especially with the vulnerability of the Internet and servers to virus and worm threats, there will be times when the Internet is down or so slow that interactivity isn't possible. Plan for technical problems and have a contingency plan that is communicated to students.

- Be realistic about the reward system for incorporating technology. If you are at an institution where research is valued more than teaching, then you may need to forego creating Web content. Navarro (2000) also notes that "cyberprofs" are reporting strong negative reactions from their colleagues. If you are sitting in your office answering student e-mail or creating course content, you don't appear to be teaching.
- Make sure intellectual property and royalty procedures are clearly spelled out. Many faculty do not consider the issue of copyright and intellectual property when course materials are developed (Rueter, 2001). Most faculty believe they own their own course materials. This is often not the case. The issue becomes even muddier when entire courses are delivered on the Web (Levels 5 and 6). A course that you developed could be offered by the university with someone else teaching it, without your consent or knowledge. Earnings from distance learning are viewed quite differently by faculty and administration (Guernsey & Young, 2001).
- Make sure you and your administration agree what "quality" teaching is. Age-old tenets of quality teaching include meaningful discussion, question-and-answer discourse, and significant teacher-student interaction. If faculty develops a Web-enhanced course following the myth of preserving student interaction, they will be quickly mired in Web activities that consume the majority of their time with no observable educational payoff. The less subtle problems that stem from a lack of administrative understanding include difficulties in obtaining resources, especially release time for the initial development of a Web class, lack of understanding about how many hours are needed to run the course when you aren't standing in front of a classroom, e-mail overhead, managing listservs, and problems in obtaining reasonable hardware and software to develop and maintain a Web course.

FUTURE TRENDS AND CONCLUSIONS

As younger, more computer-literate faculty emerges, there will be a slow and steady move toward the incorporation of Internet components into university courses. Many educational pundits believe that we are moving into a new learning paradigm with the integration of technology into our schools (Von Holzen, 2000). This new educational model envisions a complete shift in course delivery from the traditional lecture classroom to on-demand, flexible learning through the use of telecommunications technology or "Just-in-Time" learning. In this paradigm, the faculty will become the designers of interactive course materials. With this new paradigm, many of the issues discussed in this chapter may take care of themselves. In the meantime, faculty who are considering Web-enhanced or Web-delivered courses need to be aware of the issues. But, most of all, learning is more than just content delivery; we need to create learning environments whether they are in the classroom or in cyberspace.

ACKNOWLEDGMENT

KEY TERMS

Web-Based Course: A course that is delivered entirely by electronic methods, such as the Internet.

Web-Enhanced Course: A traditional course with some electronic enhancements, such as Web pages for course syllabi, data files, and test reviews.

Issues of E-Learning in Third World Countries

Shantha Fernando
University of Moratuwa, Sri Lanka

INTRODUCTION

Around the world, e-learning is becoming popular, especially among higher education institutes (universities). Many highly ranked universities have either already deployed an e-learning system and are fully operational, or they are in a process of deployment where e-learning-based and non e-learning-based educational environments co-exist. It is also possible to find a few virtual universities. The amount of money and effort that has to be spent on e-learning is high. In addition to the initial e-learning system installation costs, there are ongoing maintenance, management and content development costs. Due to the rapid growth in the field of e-learning and the role it plays in today's education systems, those working in the field have begun to introduce standards for different aspects of e-learning. The Open Knowledge Initiative (OKI) which is described as "a collaboration among leading universities and specification and standards organizations to support innovative learning technology in higher education" is an example (OKI, 2003).

Many highly ranked universities use commercial e-learning systems such as BlackBoard, WebCT, e-college, Netschool, etc. Several open source products are available though their usage is not wide spread, although it is expected that collaborative projects such as Sakai will enable large-scale open source products to be introduced to the market. This effort is described on the Sakai website as, "The University of Michigan, Indiana University, MIT, Stanford, the uPortal Consortium, and the Open Knowledge Initiative (OKI) are joining forces to integrate and synchronize their considerable educational software into a modular, pre-integrated collection of open source tools" (OKI, 2003).

BACKGROUND

Many third world countries have become "Transitional Countries". The term "transitional country" has been used in different ways in different times and different contexts. However, today's meaning of a "transitional country" is a country that lies between a developed and a developing country, and has an evolving market economy. Dung (2003) states:

Generally speaking, the expression 'transition' is used, mainly by political scientists, in the context of changes that have followed the fall of regimes, usually when dictatorial regimes have given way to more democratic ones, but this usage has been extended to contexts where previously rigid structures, such as those governing the economy, are giving way to more liberal, market-friendly structures and associated features of liberal democracy.

Third world or transitional countries require sustainable development. Sustainable development of a country is very much dependent on industry, higher education and research, hence university education is vital. The importance of the higher education is stressed in the United Nations Resolution on the Decade of Education For Sustainable Development January 2005 – December 2014 (UN Report, 2002). For a third world country, as De Rebello (2003) puts it, "The university system was seen as being uniquely equipped to lead the way by their special mission in teaching and training the leaders of tomorrow, their experience in transdisciplinary research and by their fundamental nature as engines of knowledge."

CURRENT TRENDS IN INFORMATION TECHNOLOGY IN THIRD WORLD COUNTRIES

IT is becoming a driving force of economy. Realizing its potential, many transitional countries have embarked on projects in collaboration with funding agencies to improve IT services, though their IT infrastructure facilities are not adequate. Many foreign investors start IT based companies in transitional countries. The products are aimed at the US or European market, where the parent companies are based. India, in particular, exemplifies this for the IT sector, and many major IT companies have branches in India. In Sri Lanka, due to the limited market, poor infrastructure and slightly higher labor costs, such foreign investments are limited. However, the level of IT expertise is at a competitive level. Many local IT companies carryout sub-contracts for foreign IT companies. A few companies directly interact with the global market. Realizing the potential, the Sri Lankan government embarked on "e-Sri Lanka move" project to introduce e-governance and to improve e-services within the country, and formed the ICT Agency using World Bank funds (Development Gateway, 2003). Motivated by these initiatives and realizing the importance of e-learning for today's form of higher education, some Sri Lankan universities have deployed e-learning systems as pilot projects and a few others have started exploring the possibility of using e-learning for their university education.

Due to the employment opportunities offered for IT professionals of transitional countries by developed countries, many professional IT programs have been initiated in transitional countries. In Sri Lanka, income generated by foreign employment has now become considerable compared to its other income sources such as garment, tea, rubber, minerals, spices, etc. Though most employment opportunities are labor-oriented, many professional opportunities are in the IT sector. However, this causes "brain drain".

IMPORTANCE OF E-LEARNING FOR HIGHER EDUCATION IN THIRD WORLD COUNTRIES

In order to understand the importance of e-learning, it is important to consider what we mean by e-learning. According to the definition of NCSA's e-learning group (Wentling, T.L. et al., 2000):

E-learning is the acquisition and use of knowledge distributed and facilitated primarily by electronic means. This form of learning currently depends on networks and computers but will likely evolve into systems consisting of a variety of channels (e.g., wireless, satellite), and technologies (e.g., cellular phones, PDA's) as they are developed and adopted. E-learning can take the form of courses as well as modules and smaller learning objects. E-learning may incorporate synchronous or asynchronous access and may be distributed geographically with varied limits of time.

In an abstract form, I would define it as "electronically facilitated, enhanced and managed learning". It can consist of many components or elements of a learning environment of a university system if they can be electronically facilitated, enhanced and managed. Some aspects that could be integrated into an e-learning system to make an impact in a university system, especially in the context of a third world country, are given below.

- Curriculum related aspects – courses and course contents, discussions, library catalogues, etc.
- Academic administration related aspects – registrations, student information, grading, etc.
- Technology infrastructure related aspects – alternative technologies, lab facilities, home use, etc.
- Societal context related aspects – cultural events, forums, activities, etc.
- Industrial collaboration related aspects – industrial expertise and contents, know-how dissemination, guidance to/from industry, etc.

These aspects, when incorporated in an e-learning system, will improve the quality of the higher education, if implemented using strategies and technologies suitable for constrained environments in third world countries. However, deployment of a suitable e-learning system requires a particular educational, administrative and technological environment, and the university educational system will also need to undergo changes. This is where the issues are faced in third world countries. One should not think that the deployment of e-learning is an adaptation to the required educational change. Contrarily, an ability to adapt is a must for the deployment of e-learning.

Bates (2000) states that higher education institutes consider technology-based learning for the following reasons:

- the need to do more with less
- the changing learning needs of society
- the impact of new technologies on teaching and learning (Bates, 2000, p. 8).

Although we observe that mainly the universities in developed countries tend to consider the above reasons, they are applicable to any university. It is in this context that e-learning is becoming attractive. However, when universities in third world countries embark on e-learning-based educational transformations, they face many barriers. In many cases, e-learning cannot be implemented in the way it is done at US or European universities. The approach has to be tailored to the environment, if it is to be a success.

COMMON ISSUES TO BE ADDRESSED

Administrative Issues

Most of the universities in third world countries are traditional universities. Gunn (2000) in his keynote paper states the following:

Perhaps the most critical challenge to traditional universities is develop capacity to change. This calls for major restructuring, removal of unnecessary processes and streamlined administration procedures. Motivation to progress, change and develop is hard found in the current insecure climate. . . The challenge this raises is being able to exploit the resources of commercial interests while maintaining quality and standards of service as a priority area. Ability to achieve the right balance between opposing forces of cost and quality without reducing education to the lowest common factor will be a powerful survival strategy.

In many third world countries university academic administration is stream-lined and rigid. Changes are usually not welcomed. Many fear loosing the value of their jobs if IT strategies are introduced. Many administrative officers have the mentality that the others should come to them to get the work done. While this shows an attitude problem or an inferiority complex, it affects many productive plans.

However, rigid administrative procedures are sometimes required to prevent exploitation and use of facilities for personal advantage.

Some administrative functions can be handled efficiently through e-learning. Typical examples would be student semester and exam registrations, yearly progress archiving, student information management, etc. However, administrative officers such as registrars, examination branch officers, etc, are not comfortable when it is handled entirely by the e-learning system. There is the fear they might loose their job. Another fear is whether they will have any value for the university. A valid concern that is raised is whether the e-learning system is secure enough to protect confidential data and prevent students tampering with data.

IT Infrastructure Issues

IT infrastructure facilities in third world countries are often primitive. While IT infrastructure needs improvement for better interconnectivity of academic institutes, a countryman's concern is food, water supply, clothing, roads and transportation, housing, primary schools, and other essential items for their living. Governments in these countries have to allocate the majority of their funds for the latter and a low priority is given for IT infrastructure. It is not justifiable to allocate huge funds for the improvement of IT infrastructure when the basic needs of the people are not met. The good news is that some form of infrastructure is already available. The solution we propose for the improvement of higher education using e-learning has to consider alternative techniques given this serious limitation. This is not to say that mobile communications and other new inventions are not penetrating the market.

Consider Sri Lanka as a case, every university is interconnected by a university network called LEARN (Lanka Academic and Research Network). Some universities have 2 Mbps E1 links, while the rest have only 128 or 64 kbps links. Very soon the latter will be upgraded, but the maximum would be 2 Mbps in the foreseeable future. The current international bandwidth allocated for the whole university network is below 2 Mbps. This will gradually increase on demand, but on-demand increase implies the presence of congestion. The universities also experience disruption of the telecom services, either due to faults or non-payment of bills. However, within these infrastructure constraints, the majority of universities are able to have an acceptable level of communication for the current IT operations within the country. Web servers are acceptably fast and e-mail is heavily used for communication and collaboration among academics. A few e-learning systems are also operational.

Any e-learning-based solution has to work within these IT infrastructure constraints. Within a university it will work acceptably since many universities have local area networks with either gigabit fibre optics, or fast Ethernet or at least 10 Mbps links. Between universities it will work as long as it does not have heavy content delivery, congesting the links. However, international collaborations through e-learning will not be at the levels required by many e-learning systems in the near future.

Limitation of Equipment

In third world countries, equipment such as servers, routers, cabling, laboratory computers, etc. are usually procured under special university budgets, or grants and loans from funding agencies. It is not possible to expect frequent upgrades to equipment. It is very unlikely that high-end servers with redundant power supplies and disk arrays will be always available for the deployment of an e-learning system and redundancy and backup systems are not a priority. Sometimes valuable information stored in the system may be at stake. However alternative approaches such as weekly or critical time-based backups may be carried out.

Thus, any approach to introducing e-learning has to start with a low-end solution. Once the importance is recognized by the authorities, some form of ongoing support is feasible. Strategic planning is required to get the funds for improving the performance and reliability of the systems gradually.

It is not possible to assume that students will always have access to computers. While a few have their own computers, the majority of the students in transitional countries use common lab facilities to access computers. Labs are open only during working hours and usually scheduled for different groups of students based on assignments and workloads. In most cases, e-learning-based learning activities also need to be planned accordingly. For an example, if an assignment is given with a deadline for the submission through the e-learning system, this deadline has to be flexible in situations such as insufficient computers, labs being not open on demand, workers' strikes which are frequent in many third world countries, long electricity power cuts, etc.

Cost Factors of E-Learning Systems

Most of the commercially developed e-learning systems such as BlackBoard, WebCT, etc, used by US and European universities are extremely expensive for the third world countries to purchase. A monetary grant may be a possibility, but then the question would be maintenance costs, purchase of additional modules to suite the changes as time passes, costs of customizations, etc., if these costs have to be born by the university, which are very high given the limited budgets. Therefore, any grant must include these costs. Otherwise, it will be a waste of funds.

An alternative is to select an open source solution. However, currently it is difficult to find the exact match of an open source solution, or to customize it to a particular university's environment. Projects such as Sakai may help solve this situation in the future, but we have to wait until their collaborative environment is functional. However, there is the concern whether it also will assume state-of-the-art technology infrastructure.

Another alternative is in-house development, however, for this to be a success, continuous employment of developers and good software development approaches with research input from an e-learning perspective is required. Finding developers is not a difficulty in most transitional countries, and the costs for this will be far below the purchase of a commercial e-learning system. To succeed, however, a vision to continue the project, and institutionalized incentives to the people involved, should be in place. While the result of this approach may not be as sophisticated as, or as reliable as, available commercial systems, it is possible to come up with an acceptable solution at a very low cost. In the author's environment, it was possible to get a group of students to start on the development of an e-learning system using research findings. Later, an expert was used to further improve it to be used as a production system. It needs further development, but the advantage is, while the required institutional changes for an e-learning-based education are conveyed to the rest of the faculty, the changes can also be synchronized with the development cycle, as illustrated by Collis and Moonen (2001). Even if a fully fledged e-learning system had been purchased, it would have been a failure due to the faculty being not ready to adapt immediately.

Reliability Issues

Reliability issues have already been mentioned under IT infrastructure issues and limitation of equipment. The following summary is provided to emphasize the issue of reliability.

- Frequent electricity power failures.
- Data communication connectivity failures or disruptions due to non payment of bills.
- Congested links.
- Less emphasis on backup and redundant systems.

Socio-Cultural Issues

In most of the third world countries, especially in South Asian and African continents, socio-cultural setting is very prominent. It affects how people engage in learning activities. Verbal and physical interactions are important and hence total virtual learning environments may not produce good results. This situation may change in the years to come, especially among the urban population. However, socio-cultural aspects cannot be neglected when dealing with education, and it is true also for technology-based education, as described by Gunawardena (1998).

Most of the e-learning systems and available contents are based on popular languages. However, this is not to say that they do not support other languages, but it will require an additional effort to prepare contents in native languages. In many third world countries primary education is done in native languages, although at university level popular languages like English or Spanish may be the medium. This situation can create communication barriers in e-learning-based learning processes.

Many people in third world countries believe that developments in IT will cause many people to lose their jobs. This is a serious social issue. However, there are situations where it is thought to be the other way round. For an example, in e-Sri Lanka move, the government expects that there will be an increase in job opportunities if IT is promoted. For an example, to deploy e-learning in a university environment, additional support staff is required for facilitation, content creation, maintenance, etc.

FUTURE TRENDS AND CONCLUSION

E-learning can play a major role in higher education in third world and transitional countries. It will help improve the higher education, thereby contributing to sustainable development. Using e-learning it is possible to improve curriculum, academic administration, industry collaboration, etc.

Emerging related standards such as Sharable Content Object Reference Model (SCORM, 2003), IEEE Learning Technology Standards Committee (LTSC, 2002) and collaborative work currently being carried out such as OKI (OKI, 2003) will make e-learning more widespread.

However it may not be possible to deploy it in third world countries in the way it is done in the highly ranked universities in the US and European countries. First, the related issues have to be addressed and alternative solutions should be explored. Given suitable alternative solutions, or desirable approaches, e-learning can be a success in many third world and transitional countries.

KEY TERMS

Academic Administration: Administration procedures or formalities linked with university education, such as registrations for semesters or examinations, progress reviews and monitoring, eligibility formalities, student history records or progress archiving, promotions to levels or years, academic timetables, etc.

E-learning: Electronically facilitated, enhanced and managed learning.

IT Infrastructure: Technological infrastructure that enables the transfer of information.

Learning Environment: Overall university setting in which many educational and administrative processes interact.

Open Source E-learning Systems: E-learning systems developed by the Open Source Community and freely distributed with their own license or a GPL (General Purpose License) to use, modify and distribute together with the source code.

Third World Countries: Countries that are not yet developed.

Transitional Countries: A third world country that is in a transition process based on more liberal, market-friendly structures and associated features of liberal democracy.

Virtual Universities: All the learning and administration activities are done through e-learning and very minimum physical interactions, or no physical interactions at all.

IT Implementation in Small Business

Elaine R. Winston
Hofstra University, USA

Dorothy G. Dologite
Baruch College, City University of New York, USA

INTRODUCTION

The small business owner's dominating role in any information technology (IT) implementation is well documented (Cragg & King, 1993; Doukidis, Smithson, & Lybereas, 1994; Thong & Yap, 1995). A survey of the IT implementation process in small businesses indicates that both the owner's attitude towards IT and management style influence the implementation process and have a direct impact on outcomes (Winston & Dologite, 1999). These characteristics, attitude and style play a key role in directing the small business owner's decisions regarding the technology to implement, the personnel that will manage the implementation, and the supporting managerial polices (Winston & Dologite, 2003).

A more practical and pressing reason for concern with the small business owner's attitude towards IT and management style comes from the Internet. Innovative owners, who are early IT adopters, seize new opportunities that the Internet offers by reaching and selling to new markets (Pratt, 2002). More cautious managers will wait for the pioneers to reorganize as e-businesses and then attempt to learn from them (Pratt, 2002; Winston & Dologite, 2002). Other small business owners will completely avoid investing in Internet technologies (Winston & Dologite, 2002). It is advantageous for the IT practitioner to recognize how the small business owner's attitude and management style affect the adoption of IT and quality of the implementation.

BACKGROUND

Quality of IT Implementation

At an operational level, the results of a high-quality IT implementation process include increased internal organizational performance and efficiency, better customer service, and a higher quality working life within the organization (Doukidis et al., 1994; Julien, 1995). Studies of IT implementations have identified specific outcomes of success and find such indicators as increased profits, greater market share, or improved return on investment (ROI) performance (Byrd, Sambamurthy, & Zmud, 1995; Iivari & Ervasti, 1994). For small organizations, it is the added considerations of a high quality IT implementation that lead to increased profits, greater market share, or improved ROI performance.

Attitude Towards IT

Generally, small business owners with positive attitudes towards IT often have a deep knowledge about IT and find it easy to commit to an IT implementation (Cragg & King, 1993; Nickell & Seado, 1986; Ray, Thomas, & Dye, 1994; Winston & Dologite, 1999). More specifically, a positive attitude will likely help the owner endure the frustration and effort of overcoming the technical and organizational obstacles that frequently confront innovative initiatives (Harrison, Mykytyn, & Riememschneider, 1997; Winston & Dologite, 2002).

Conversely, small business owners with negative attitudes towards IT implementation generally avoid investing in IT because they fail to understand the strategic impact of IT on their business (Cragg & King, 1993; DeYoung & Spence, 2004). Only when faced with the threat of closing do these entrepreneurs seek the short-term solution of implementing IT for survival (Agarwal & Prasad, 1997). Some small business owners who perceive IT implementation as risky become immobilized by indecision and hesitation (Beckers & Schmidt, 2001). Even after approving an investment, owners with a negative or uncertain attitude towards IT often have difficulty sustaining commitment through an implementation. This results in reducing resources allocated to a project, inhibiting organizational changes required to achieve benefits, and preventing the use of IT to its fullest potential.

Management Style

Management style influences various aspects of the implementation process, such as IT strategy, owner involvement, and timing (Winston & Dologite, 2002). Yet, IT studies often do not explore the owner's management style. Perhaps this is because of the confusion that style is connected to personality, and therefore not likely to change. Management style, however, is demonstrated by work role and by patterns of actions (Waterman, Peters, & Phillips, 1995). A small business owner's management style, then, is essentially manageable. Management style may be generally classified as either entrepreneurial or traditional (Jelinek & Litterer, 1995; Senge, 1990; Waterman et al., 1995).

An entrepreneurial policy enhances the capacity of a business to address and reduce any risk and uncertainty connected with a new IT implementation (Jelinek & Litterer, 1995). Employees tend to rely on one another to make the IT implementation successful and to keep others informed of its progress (Cragg & King, 1993; Winston & Dologite, 2003). Procedures that allow employees to have their views considered greatly affect the support and commitment a work force has to an IT implementation (Senge, 1990; Way, 2002). In other words, in organizations with a shared management style, employees accept responsibility for guiding the affairs of the organization.

The small business owner who practices a traditional style typically attempts to reduce the uncertainty surrounding the use of IT by maintaining policies that support bureaucracy, identifying clear boundaries of responsibility, and retaining control of the problem as well as its solution (Herbert & Bradley, 1993; Thong & Yap, 1995). The basis of the traditional management style is to establish order, exercise control and achieve efficiency in the work force. Policies may not exist or be clearly defined for hearing end-users' opinions (Jelinek & Litterer, 1995).

The entrepreneurial and traditional management styles provide small business owners with an approach to actively deal with the complexity of an IT implementation. Furthermore, the management style that is employed may support or moderate an owner's attitude towards IT (Winston & Dologite, 2002).

ATTITUDE/STYLE PROFILES

This section discusses the emergence of distinct attitude/style profiles, which are Positive Entrepreneur (PE), Negative Entrepreneur (NE) and Uncertain-Traditionalist (UT). In a study conducted by the authors, support for classifying small business owners into these three profiles was provided by a consistent pattern of data that describes attitude towards IT and management style (Winston & Dologite, 2002). Alternative attitude/style profiles, such as positive-traditionalist, negative-traditionalist, or uncertain-entrepreneur, were not identified in this study.

Table 1 lists the data clusters and sample supporting statements for the three identified attitude/style profiles. To further demonstrate the profiles, more detailed descriptions and quotes from business owners follow.

Positive-Entrepreneur (PE)

A small business owner classified as a positive-entrepreneur (PE) has a positive attitude towards IT and actively seeks applications of IT to enhance his or her business.

Table 1. Attitude/style profiles of small business owners towards IT implementation

	Positive-Entrepreneur (PE)	**Negative-Entrepreneur (NE)**	**Uncertain-Traditionalist (UT)**
Attitude	**Positive:** Expresses a positive perception about IT, identifies opportunities for innovative use of new IT.	**Negative:** Expresses a negative perception about IT, hesitates to invest in IT, implements IT out of necessity.	**Uncertain:** Expresses indecision about IT, hesitates to invest in IT, is anxious about using IT.
Management Style	**Entrepreneurial:** Identifies the use of policies that encourage collaboration and shared management.	**Entrepreneurial:** Identifies the use of policies that encourage collaboration and shared management.	**Traditional:** Uses policies that support power, authority, and status; demonstrates an inability to adopt tactics to decipher overwhelming data and IT alternatives, as well as conflicting suggestions about them.

The following statements exemplify the proactive strategies of PE owners (study participant numbers appear in parenthesis):

I'm fascinated at how things change because of IT and often investigate how change can impact my business. (PE1)

We put in the latest IT to remain competitive. We know the technology because we develop software for it. (PE3)

It gives me the image that I've got a huge organization behind me. I learned about the IT that was available and I knew exactly what I wanted from it in terms of my business. (PE4)

In addition, PE owners exhibit an entrepreneurial management style by encouraging their employees to become involved in areas well beyond their normal scope of responsibility. They encourage employees to consider such fundamental IT implementation issues as hardware and software purchases and training.

Employees tell us how to do things more effectively. (PE3)

We provide lots of employee training and even let the employees decide when they could use a computer specialist for additional help. (PE1)

I have employees I can trust to make decisions in my business. Even though I am stuck with a key person who limits the amount of technology I can use, what I do have I used—and it made me in the hundred thousands. (PE4)

Negative Entrepreneur (NE)

Small business owners classified as negative entrepreneurs (NE) reflect negative attitudes towards IT and invest in IT primarily to remain in business. As a group, they indicate that a barrier to investing in IT is their lack of knowledge. Eventually, they become like PE owners, when they take actions about IT that characterize an entrepreneurial style; however, they consistently report reactive rather than proactive strategies:

We are purchasing a major IT system that's costing over $100,000, and by the time we pay it off, we will need a new system. The cost of the IT [in relation to its] longevity is ludicrous—what we are buying now will be obsolete in five years, but we have no other choice. No one knew anything about enterprise software, only that we had to purchase a package just to remain competitive in business. (NE2)

Interestingly, all NE owners have developed practices that might assist them to overcome their negative attitudes towards IT. Displaying an entrepreneurial management style and the desire to remain competitive in the marketplace, NE owners rely on young, IT-current employees for IT recommendations. The following statements made by small business owners provide supporting evidence:

We use young employees right out of college to show us how to use some of the new IT required by law. They tell me what we need. (NE1)

Employee suggestions are tremendously important. We asked the employees what they wanted, and their suggestions were taken seriously. (NE2)

Uncertain Traditionalist (UT)

Small business owners classified as uncertain traditionalist (UT) have uncertain attitudes towards IT. They take actions about IT that characterize a traditional style of management. These owners state that they actively learn about IT, but they do not have the capability to interpret all of the information. Consequently, they rely on traditional practices, as evidenced in the following statements:

For us to put in a voice mail system would cost over $5,000 and it's not necessary. We like the personal touch that comes from a person actually picking up the telephone. (UT4)

UT owners are technologically aware; however, information overload appears to aggravate their uncertainty towards IT:

I spent a lot of time and got a lot of information on systems, but I still don't know much about any of them. (UT1)

A different perspective on the uncertain attitudes of small business owners towards IT emerged from case UT3, perhaps because it involved telephony technology implementation. It illustrates how conflict arising in the outside environment creates ambiguity, as illustrated by both incentive and deterrent:

Incentive: We are looking into telephony where we can track telephone calls in the system. When I get a call a list of the last five conversations ... will come up. I can get an idea of the last conversation the customer had with our company and say, "Yes, I know so and so, whom you spoke with on this date is doing this." (UT3)

Deterrent: The technology moves people beyond wanting information in one minute. Now they want it this second. They assume everything is online and that we have instant access to it. (UT3)

In the case of UT3, the customers and their satisfaction drive the business and supply both the incentive and the deterrent for IT implementation. The implementation that resulted, in this case, was of a low quality.

ATTITUDE AND MANAGEMENT STYLE ISSUES

The key issues focus on the interaction between different types of attitudes and management styles. The biggest surprise concerns the negative-entrepreneur type of small business owner. Although an NE owner invested in new IT primarily as a reactive strategy to avoid going out of business, he or she still experienced a high quality IT implementation. This is a revelation because previous literature suggests that owners with negative attitudes towards IT would most likely achieve poor quality IT implementations (Agarwal & Prasad, 1997).

Owners with negative attitudes towards IT may reduce the risk associated with new technology initiatives by using collaborative and shared management policies and practices in their organizations (Winston & Dologite, 2002). They not only depend on employee input, but they also acted on recommendations of employees. This practice was reported to be a significant influence when contending with changes that occurred as a result of an IT implementation.

Conversely, it appears that the uncertain traditionalist type of small business owner is unable to initiate a forward looking approach for guidance through an IT implementation process (Winston & Dologite, 2002). Based on previous research, we would expect that the uncertain owner would seek advice and information from employees, or other more technical sources, about which type of IT is an appropriate investment. It is more likely that uncertain-traditionalist owners became immobilized from an information overload in their pursuit of IT knowledge.

The uncertain-traditionalist owners' preference for a high level of control and bureaucracy inhibits innovation and theoretically reduces the chance for a quality IT implementation. Often, UT owners evaluate IT primarily on a financial basis. They easily calculate the cost of the IT as well as the additional employee time required to maintain it. However, it is difficult for a UT owner to calculate productivity increases that arise from more accurate reports or faster processing time. Such operational benefits of IT are elusive to them. Further, as a result of an overload of IT information, they do not wish to become heavily involved in the IT adoption and implementation process.

Generally, small business owners with a positive attitude toward IT, have a high-quality IT implementation. An interesting aspect surfaces: Positive attitude is coupled with an entrepreneurial management style. This type of owner reports a collection of proactive strategies, such as:

- Engaging the support and input of employees;
- Making a concerted effort to learn about IT;
- Becoming involved in the IT implementation process;
- Using IT to attain competitive advantage for the business; and
- Finding benefits from an IT implementation in operational areas much before they appear in financial areas.

Unlike the uncertain owner, the positive entrepreneur takes advantage of a deep knowledge of the business as well as knowledge of IT to resolve ambiguous issues that might otherwise impede the successful and creative use of IT in the organization (Winston & Dologite, 1999).

FUTURE TRENDS

Future trends concerning the implementation of IT in small business will likely incorporate knowledge management. Owners adapt IT information to their small business with the help of both internal and external collaborators. As the e-commerce environment becomes more complex, the different backgrounds of collaborator and owner may hinder their ability to transfer implicit knowledge of IT among themselves. Therefore, organizations will rely on knowledge management to identify the quality of the sources and type of IT information obtained by an owner. This information will help to reduce the uncertainty surrounding the use of IT in small business.

CONCLUSION

Early in an implementation process, an IT practitioner should recognize a small business owner's attitude/style profile and be aware of how the profile can influence implementation quality. The following suggestions may help IT practitioners improve the likelihood of achieving a high quality IT implementation.

- Consider that a small business owner with a negative attitude toward IT might improve the likelihood of achieving a high quality IT implementation by

Table 2. Summary

Small Business Owner		Quality of IT Implementation	Contributors of IT Implementation Quality
Attitude Towards IT	**Management Style**		
Positive	Entrepreneurial (open, collaborative)	High	Attitude and style
Negative	Entrepreneurial (open, collaborative)	High	Reliance on employees
Uncertain	Traditional (closed, hierarchical)	Low	Bureaucracy and feeling of being overwhelmed

practicing entrepreneurial management policies.

- Work to help change a small business owners' traditional management style, rather than try to change an owners' negative attitude towards IT, which is potentially a more complex issue to deal with.
- Encourage owners with traditional management styles to employ policies that require employee participation and collaboration in IT decisions.
- Help uncertain-traditional small business owners solicit support from employees in their business who understand the IT and how it can be applied to the business.

Table 2 displays an interesting relationship between attitude and management style when considering the achievement of a high or low quality IT implementation. Main contributors to IT implementation quality were also identified, and business owners were classified, as Positive-Entrepreneur, Negative-Entrepreneur, and Uncertain-Traditionalist. Only the Uncertain-Traditionalist experienced a low quality IT implementation.

The results concerning how attitudes towards IT and management style affect the quality of an IT implementation can guide the small business owner and information expert concerned with the design and plan of the implementation process. This also suggests that IS work should increasingly address combined managerial and technical issues. In a small business, the owner's feelings and organizational policies, rather than the technology, may be most important in determining an IT initiative's success.

KEY TERMS

Entrepreneurial Management Style: An approach that supports interaction and shared decision making with employees and the early adoption of IT. Employees are encouraged to embrace ambiguity as a source of opportunity, present new ideas, and initiate action in new directions.

Implementation Quality: The outcome of an IT installation in an organization, where operational success can be indicated by increased internal organizational performance and efficiency, better customer service, and higher quality working life within the organization, although other traditional indicators are increased profits, greater market share, and improved return on investment performance.

IT Implementation Process: All the activities involved in initiating IT in an organization, from the original inception of an idea to innovate or install IT, to evaluating the success or failure of the IT in an organization.

Management Style: Refers to the way the small business owner delegates authority and responds to new technologies and innovative practices. This is demonstrated by work role and by patterns of actions that influence various aspects of the IT implementation process.

Negative Attitude: A perception about IT that results in behavior that displays discomfort around IT, hesitation to invest in IT, and the implementation of IT out of necessity.

Positive Attitude: A perception about IT that results in behavior that identifies opportunities for innovative uses of new IT.

Traditional Management Style: An approach that maintains dominance and control over employees and relies on a "wait and see" policy for new technology adoption. Employees are encouraged to ignore data that do not fit existing frames of reference, focus only on the job at hand, and comply with established reporting relationships and rules.

Uncertain Attitude: A perception about IT that results in behavior that shows indecision about IT, hesitation to invest in IT, and anxiety about using IT.

IT Industry Success in Finland and New Zealand

Rebecca Watson
Deloitte, Australia

INTRODUCTION

At the beginning of the 21st century, information and communication technologies are creating global markets for goods and services. These technologies are impacting on every aspect of our lives, including how people work, communicate, and entertain themselves. Many economists have started to suggest that we may be entering a new era of greater productivity (without inflation) in the "knowledge economy" of the future.

Given the importance of the IT industry in today's global economy, much recent research has focused on the relative success of small countries in fostering IT industries. This research is important because those countries that can adapt and develop new information based industries will thrive and become significant players in the global economy. Those countries that cannot adapt will suffer and may find themselves as producers of low value products for wealthier nations. This article summarizes the factors of IT industry success in small developed countries, focusing on two such countries, Finland and New Zealand.

BACKGROUND

Most of the previous research in this area has compared a reasonably large number of countries. For example, Blanning et al. (1997) examined the information infrastructure of 12 Asia Pacific nations; Dedrick et al. (1995) examined reasons for the success of IT industries in nine small countries from around the world; and Kraemer, Gurbaxani, and King (1992) discussed the diffusion of computing use in nine Asia Pacific nations. Generally, these studies have examined a small range of factors that impact on either the success of a nation's IT industry or its extent of IT usage.

In contrast, Ein-dor et al. (1997) examined only three small countries – Israel, New Zealand, and Singapore. These three countries were of similar size and economic development; however, they were experiencing differing levels of IT industry success. Ein-dor et al.'s (1997) study has been one of the few pieces of research that has examined only a small number of countries in an in-depth manner.

Ein-dor et al.'s (1997) model was largely based on Grossman and Helpman's (1991) macro-economic theory concerning the relationship between technology development, trade, and growth as applied to small open economies. The latter suggested that growth stemmed from endogenous technological progress, as entrepreneurs introduced innovative (intermediate) products whenever the present value of the stream of operating profits covered the cost of product development. Grossman and Helpman (1991) postulated that the best growth path can be attained with subsidies to both R&D and the production of "intermediates" (those products that are used to produce consumer goods). The second-best growth path can be achieved with subsidies to R&D alone.

In order to study IT industry success in accordance with this theory, Ein-dor et al. (1997) considered four groups of variables. These variables are all frequently quoted in the context of industrial success. The variables they considered were as follows:

1. Controlled variables: country size and economic development.
2. Dependent variables - those that define IT industry success.
3. Exogenous mediating factors.
4. Endogenous mediating factors:
    - Domestic IT use.
    - Firm strategies.
    - Government IT policies.
    - Government education policies.

Watson and Myers (2001) adopted the model used by Ein-dor et al. (1997) to compare just two countries, New Zealand and Finland. In that study, the authors considered the same four groups of variables; however, they replaced "firm strategies" with "level of research and development," because the latter appeared to have more explanatory power. The major factors that were considered in the study by Watson and Myers (2001) are represented graphically in Figure 1.

This model was then used to compare and explain IT industry success in Finland and New Zealand. As will be summarized next, three major factors that impact on the development of a successful IT industry were identified: the extent of government IT promotion, the level of re-

Figure 1. Factors affecting IT industry success (Watson & Myers, 2001)

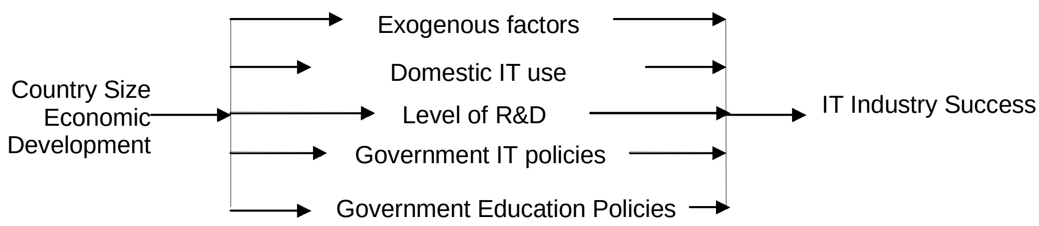

Table 1. IT industry success (1998)

	Finland	New Zealand
IT Industry Development		
IT Industry Sales (US$ billions)	11,087	2,155
IT Sales/GDP	9.0%	4.1%
Number of Firms in IT	4,200	2,500
IT Firms/Largest Firms	4/50	1/50
IT Industry Employment	5.5% (1997)	2.6% (1996)
IT Industry Success		
IT Exports:		
Hardware (US$ millions)	7,255	175
Software (US$ millions)	488	123
Total (US$ millions)	7,743	298
High Technology Exports (US$ millions) –1997	8,797	428
High Technology Exports/Manufactured Exports -1997	26%	11%
Stock Market Listings:		
Domestically listed IT firms	27	3
Internationally listed IT firms	1	0

search and development, and the existence of an education system that produces IT literate graduates.

COUNTRY SIMILARITIES

Dedrick, Goodman, and Kraemer (1995) define a small country as one that has fewer than ten million people. Finland and New Zealand, with populations of 5.2 million and 4.0 million respectively, are thus considered small countries. The physical size of the two countries is also similar, meaning that their population densities are almost identical.

Finland and New Zealand are remarkably alike in terms of economic development. Both countries entered the 20th century with a heavy dependence on commodity products. Forestry has played the same role in Finland's development as agriculture has played in New Zealand's development. The only real difference between the two countries is that Finland has moved away from its dependence on forestry and has embraced new technologies, whereas agriculture is still a major part of New Zealand's economy (Watson & Myers, 2001).

IT INDUSTRY SUCCESS

Finland's IT industry is far more successful than New Zealand's, as can be seen from Table 1.

Table 2. A summary of government IT policies in Finland and New Zealand

	Finland	**New Zealand**
National IT Strategies	• "Finland Towards the Information Society - a National Strategy" developed in the 1990s • Government promotion of information networks and the Internet • Extensive government grants available to the IT industry • Government assisted in the development of Technopolis, a leading science park	• No formal IT strategy • "Growing an Innovative New Zealand (GIF)" framework only released in 2002 • Preference to let the free market reign • All industries supported through wider economic strategies • No special tax incentives and few government grants for the IT industry • Government does not insist on purchasing local IT products where possible • Breaking its free market stance, the government assisted in the development of the Canterbury Technology park
IT Priority	• Development and use of IT receives very high priority • IT strategy work prolific in other areas, including the industrial, educational, cultural and health and welfare sectors	• Historically lower priority than Finland • Only since 2002 has IT become a priority with the release of the GIF framework and the development of an Information and Communication Technology (ICT) Taskforce
Government IT Organizations	• The Technology Department develops IT strategies and policies • Three additional government departments provide advice and stimulate discussion on IT issues (Science and Technology Policy Council, National Information Society Forum and Government Committee for Information Society Issues)	• No New Zealand government IT organization is responsible for setting IT related policies • Government does receive advice from ITAG and the ICT taskforce

KEY IT INDUSTRY SUCCESS FACTORS

There are three major factors that have been identified to explain the differing IT industry success between Finland and New Zealand. These include – extent of government IT promotion, level of private sector research and development investment, and existence of an education system that produces IT literate graduates.

Government IT Policies

The majority of recent research has concluded that direct government promotion seems necessary for the development of a successful IT industry (Dedrick et al., 1995; Ein-Dor et al., 1997; Kraemer & Dedrick, 1992; Kraemer et al., 1992). Therefore, as summarized in Table 2, the existence of national IT strategies, the priorities attached to IT, and the role of government IT organizations are considered

Table 3. A summary of R&D in Finland and New Zealand

	Finland	New Zealand
Extent of R&D	• Priority area for the last 20 years • Growth in research spending among the highest of the OECD countries • Proportion of GDP spent on R&D has been steadily rising for the last two decade • Research activity in IT has been growing over the last decade, initially encouraged by increases in government funding • Majority of today's IT R&D funded by the private sector • As a percentage of sales, Finnish companies spend double the amount on R&D than other OECD countries • Nokia alone spends more on R&D than the whole of New Zealand	• New Zealand is more than halfway down the OECD country list of R&D expenditure • Government is the most significant contributor to R&D • Government funded R&D is less than half the OECD average and disproportionately skewed toward the agriculture sector • IT R&D spending is an insignificant percentage of total R&D spend • IT R&D largely funded by the private sector though government funding has increased since 2000
Performance of R&D	• Majority of R&D activities performed by the private sector • Research directed towards commercially viable areas • The Technology Development Center of Finland (TEKES) has been fostering industry oriented R&D since 1983 • TEKES encourages close industry-university interaction • TEKES has encouraged R&D growth in many industries, including IT	• Most R&D performed by the government's Crown Research Institutes (CRI) • CRI focus is on basic research from which commercial applications can be derived • Concentrates on primary production industries • Recent developments are encouraging as CRI funding has been opened up to companies and private researchers
R&D Tax Incentives	• Tax incentives provided to stimulate investment, which have now been discarded • Current tax situation still favorable to R&D investment as companies can deduct current business expenditures on R&D in the year incurred	• R&D tax situation is one of the least favorable of the OECD countries • No tax incentives or subsidies offered • Recent tax improvements for R&D still do not allow all R&D expenditure to be deducted in the year incurred • The requirement to capitalize R&D may lead to an under-reporting of R&D and/or act as a disincentive to such investments

Source: ICT Taskforce 2003; Watson & Myers, 2001 important to the development of a successful IT industry.

Finland and New Zealand are clearly different in terms of government IT promotion. Finland has a high priority national IT strategy that promotes both IT use and industry development. As a result, Finland is both a heavy user of IT and a significant player in the international IT industry. New Zealand has no IT strategy and IT has only recently become a high priority industry for the current labour government (ICT Taskforce, 2003). Whilst this historic lack of government support has not hindered New Zealand's adoption of IT, it has hindered its IT industry success. Government promotion of IT is thus one factor that impacts on the development of a successful IT industry (Watson & Myers, 2001).

Level of Research & Development

Investment in research and development (R&D) fuels innovation and raises the technological sophistication of manufacturing processes. The amount of R&D undertaken in an industry is often an indication of potential growth, productivity gains, and competitive advantage (Dobbeck & Woods, 1994). Total R&D expenditures, sources of R&D funding, and R&D tax incentives are summarized next, as these factors are believed to be associated with success in IT production (Kraemer & Dedrick, 1992).

Finland and New Zealand have vastly different levels of R&D investment. Finland spends an increasingly

Table 4. A summary of education in Finland and New Zealand

	Finland	**New Zealand**
Total Education Expenditure	• One of the highest education expenditures as a percentage of GDP within OECD countries • Finland spends slightly more of its GDP on education than New Zealand	• One of the highest education expenditures as a percentage of GDP within OECD countries
School Education	• Actively promotes IT skills at school level • Extensive IT usage throughout schools • Primary and secondary schools have offered computing since the mid 1980s • Computer literacy is part of today's national curriculum • Every student has access to a computer and every school has fast Web access	• Smaller investment in IT infrastructure than other OECD countries • Limited computer access in primary and secondary schools • Only 55% of primary and 60% of secondary schools have Web access from at least one classroom • IT expenditure in schools increasing and it is expected that all schools will have adequate computer and Web access within the next few years
Tertiary Education	• Around 20 universities and institutes of higher education • Computing established in the higher education sector in 1965 • IT topics taught in over 15 universities which annually graduate over 600 5-year degrees and 40 doctorates • Polytechnic network produces over 2,000 degrees a year in computing and engineering • Five times as many science and technology graduates as law graduates	• Currently nine universities • Most universities and the 25 polytechnics offer IT related degrees or diplomas • Student enrolments in IT related degrees have rapidly increased over the past decade • IT graduates still a fraction of the total number of graduates • The IT industry has complained of a mismatch between IT graduate skills and those required

Source: Watson & Myers, 2001

significant proportion of its GDP on R&D. Most of this R&D is funded and performed by the private sector, ensuring that it is concentrated in growth industries such as IT. Further, R&D continues to be stimulated through favorable tax conditions and grants from TEKES. In New Zealand, R&D spending is extremely low. The government funds and performs most of the research, which tends to be concentrated in agricultural industries. As a result, R&D in the IT industry is minimal. Even with recent improvements, New Zealand's R&D tax situation could be further enhanced to increase private sector R&D. Therefore, a country's level of R&D appears to affect the development of a successful IT industry. Moreover, a high level of private sector R&D investment seems to be important for IT industry success.

Government Education Policies

It is believed that a top quality education system is essential to being successful in the information age. Both Finland and New Zealand consider education important and have well developed education systems. Total education expenditure, quality of school education and the quality of tertiary education is used to compare the education systems of Finland and New Zealand.

Both Finland and New Zealand consider education important and have well-developed education systems, indicating that a reasonable level of education is required for IT industry success. However, the Finnish and New Zealand education systems differ in two main ways. Firstly, Finland has implemented IT and promoted IT use in schools to a greater extent than New Zealand. Secondly, Finland is producing a greater number of IT related graduates. These two findings may even be correlated. Students that are exposed to IT in schools may be more inclined to pursue IT related courses at tertiary level. In any case it appears that educational policies have an impact on IT industry success and suggests that a high degree of IT competence at school and tertiary level is associated with a successful IT industry (Watson & Myers, 2001).

FUTURE TRENDS

These findings have many implications for policy makers in small countries. The findings suggest that governments need to take a proactive role in fostering their IT industry if they are to have any chance of developing information-based industries of their own. Those governments that do support their IT industries are likely to experience strong growth and significant success. Governments that do not support their IT industries may still become sophisticated users of IT; however, it is not expected that they will develop IT industries that are as successful as countries providing government support through policy, education and R&D support. The extent of support required is still a matter for debate, but it is clear that more support is better than none at all.

Further, after witnessing the success of countries that have supported their IT industries, other countries may begin to increase their levels of support in order to compete in the information-based economy. This trend has already been seen in New Zealand. Traditionally, New Zealand governments have preferred to let the free market reign. However, since 2002 a number of initiatives have been implemented to boost the development of New Zealand's IT industry. If these initiatives are successful, it is expected that further initiatives will be developed.

CONCLUSION

Finland and New Zealand have been identified as being similar in terms of country size and economic development. Despite this similarity, the two countries are experiencing differing levels of IT industry development. Finland's IT industry is far more successful than New Zealand's, particularly in terms of the hardware sector.

Though there may be other factors that have contributed to Finland's success, research has suggested three major factors – government IT promotion, high levels of private sector R&D investment, and an education system that produces IT literate graduates - as being important for IT industry success. These findings are consistent with those of Ein-Dor et al. (1997) and support the macroeconomic theory of Grossman and Helpman (1991). It appears that there is an optimal level of government support for IT industries in small, open economies, and that government support for the IT industry (as in Finland) is substantially better than no support at all (as in New Zealand).

Of course, one of the main limitations of these findings is that only two small, developed countries were studied. Whether these findings hold for other small, developed countries requires further research. Despite this limitation, the findings are consistent with earlier work in this area.

KEY TERMS

High Technology: Includes space and aviation, computers and office machinery, electronics and telecommunication equipment, pharmaceuticals, scientific instruments, electrical machines and equipment, chemicals, non- electrical machines, and weapons.

IT Hardware: Includes telecommunications equipment, computing hardware, and computing parts. Excludes embedded hardware in other products.

IT Industry: Includes the IT hardware and IT software industries. Excludes embedded hardware and software in other products (e.g., washing machines).

IT Industry Development: In this context is measured by gross IT sales, IT sales relative to GDP, firms in IT and their relative size, and IT industry employment relative to total employment.

IT Industry Success: In this context is measured by IT software and hardware exports, high technology exports, and IT stock market listings.

IT Software: Includes software applications, computer services, and training. Excludes embedded software in other products.

IT Productivity Impacts in Manufacturing Contexts

Arlyn J. Melcher
Southern Illinois University at Carbondale, USA

INTRODUCTION

The fundamental questions of whether and how information technology (IT) contributes to firm performance have been answered in different ways. IT value research findings have been equivocal, with some studies finding negative performance impacts (Berndt & Morrison, 1995; Johansen, Karmarkar, Nanda & Seidmann, 1996), some finding no overall effect (Barua, Kriebel & Mukhopadhyay, 1995; Dos Santos, Peffers & Mauer, 1993; Loveman, 1994; Strassman, 1985, 1990), and some finding positive impacts (Brynjolfsson & Hitt, 1996; Brynjolfsson & Yang, 1997; Hitt & Brynjolfsson, 1996; Mukhopadhyay, Kekre & Kalathur, 1995).

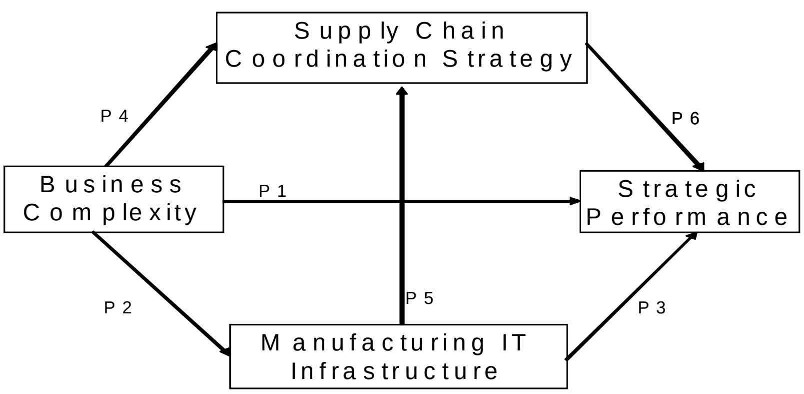
To reconcile these findings, several studies suggest that contextual factors associated with the firm and/or its environment mediate IT's performance effects (c.f., Banker, Kauffman & Morey, 1990; Brynjolfsson & Yang, 1997; Scott-Morton, 1991; Venkatraman, 1991; Weill, 1992). Brynjolfsson and Hitt find that "firm effects" accounted for roughly half the productivity benefits attributed to IT. Firm capabilities leverage investments in IT. They suggest:

"…an interesting extension would be to identify common characteristics of the highly productive firms and thereby examine some of the conventional wisdom regarding management best-practice" (1995, p. 12).

BACKGROUND

This project explores how business complexity, supply chain coordination strategy, and manufacturing IT infrastructure interact to impact inventory productivity. The research model is represented in Figure 1, where theoretical constructs are represented by rectangles, and proposed associations between them are represented by numbers.

Figure 1. Research model



Business complexity describes the degree of coordination difficulty associated with a firm's supplier- and customer-facing processes due to volatility and diversity of its product-market (Holland, 1995). This reflects the transactions cost perspective in which uncertainty results from imperfect foresight and difficulty in solving problems containing multiple variables.

Business complexity has become a crucial consideration, as global competition has pressured firms to diversify their product offerings into markets with which they have little experience, and at the same time, to compete on cost, quality, reliability, and responsiveness. They are attempting to maximize performance on all dimensions, while struggling to cope with product proliferation and heightened customer expectations in unfamiliar product markets.

Manufacturing IT infrastructure describes the extent of IT deployment for manufacturing planning and control (MPC) functions. It is defined as the enabling base of shared IT capabilities which "provides common services to a range of applications" (Broadbent, Weill, O'Brien & Neo, 1997, p. 175), including "…information to efficiently manage the flow of materials…coordinate internal activities with those of suppliers, and communicate with customers about market requirements" (Vollmann, Berry & Whybark, 1992, p. 2). It is hypothesized to mediate business complexity's impact on inventory turnover.

As companies struggle to expand margins and improve operational excellence within their own organizational boundaries, their efforts often earn diminishing marginal returns. Accordingly, organizations have begun to focus on performance optimization across organizational boundaries in the supply chain. IT presents opportunities to streamline and integrate key operations and processes by coordinating distributed activities within and across a firm's boundaries. Consequently, as firms within a supply chain coordinate product designs, demand forecasts, and production among themselves, schedules become more stable and coordination simpler.

Schedule stability improves output efficiency by reducing inventory buffers and their attendant physical costs throughout the supply chain. This confers competitive advantage, in that capital invested in inventory becomes available for other differentiating opportunities. Market mediation costs are also reduced. These include costs associated with lost sales and customer dissatisfaction due to stock outs, as well as lower profits due to product markdowns on unsold goods. In volatile industries, these costs can exceed the manufacturing cost (Fisher, 1997).

Brynjolfsson and Yang (1997) found that firms investing in complementary intangibles such as business process adjustments, training, and interorganizational relationships reap four times the return from their investment in IT as those not making these investments. To the extent that firms leverage IT to improve interorganizational relationships, and to coordinate and integrate their marketing, planning, and production decisions, their inventory productivity and other measures of performance should improve.

The *supply chain coordination strategy* describes the firm's approach to process coordination across firm boundaries. The goal is to improve performance across the entire supply chain. It measures the extent to which the firm has integrated its activities with those in the larger business network so that efficiencies are maximized across the whole business network—not just the individual function or firm (Venkatraman, 1991). This construct is measured on a continuum anchored by transaction on one end and partnership on the other (c.f., Henderson, 1990; Malone, Yates & Benjamin, 1987).

Inventory productivity is the dependent variable, calculated as annual sales revenue/value of average total inventory (Vollmann et al., 1992). This is consistent with Brynjolfsson and Yang's (1997) calculation of productivity, and is regarded as a useful measure of the physical efficiency of a firm's supply chain (Fisher, 1997). This key measure addresses the physical movement of goods and the efficiency of this process. Inventory productivity also reflects firms' effectiveness in responding to market context. Whether the market dictates responsiveness, or low-cost strategies, or both, annual sales revenue reflects success in meeting market demands.

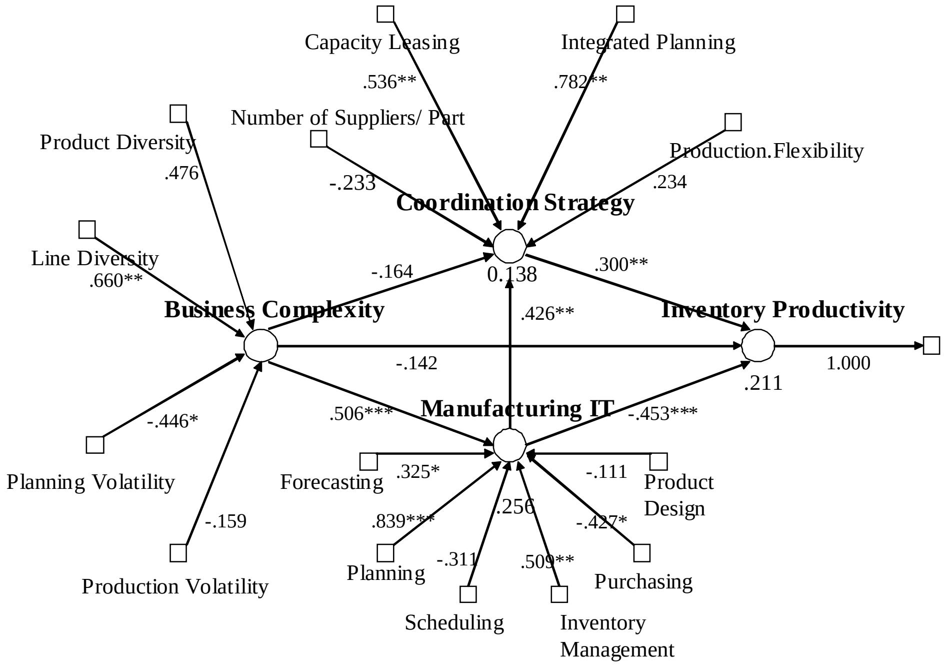
The reduction of physical costs associated with production, transportation, and inventory, and of market mediation costs associated with stock-outs and markdowns, has become a strategic necessity. To the extent that IT can be used to accurately forecast demand; efficiently plan, schedule, and accomplish production; and purchase and manage inventory in the supply chain, it can support improved performance.

MEDIATION EFFECTS OF SUPPLY CHAIN COORDINATION STRATEGY AND MANUFACTURING IT

Our research question asks, "How do manufacturing IT infrastructure and supply chain coordination strategy mediate the relationship between business complexity and inventory productivity?"

Previous empirical studies have generally attempted to measure generic IT dollar investments and their relationships to productivity, profitability, or firm valuation. These rely on aggregated data regarding multiple applications from a variety of industries. We're aware of none that include both complexity and supply chain coordina-

Figure 2. PLS model results



tion strategy in the study of manufacturing IT infrastructure and its effect on inventory turnover.

A few theoretical studies (Das, Zahra & Warkentin, 1991; Holland & Lockett, 1997) have suggested that these variables' fit is important for firm performance. Few of the relationships have been tested empirically. Also, since our study controls for confounding factors, and our partial least squares (PLS) method of analysis is more precise than first-generation multivariate methods, we are able to distinguish these mediation effects, where previous studies have not.

This research was able to empirically test theoretical frameworks (c.f., Das et al., 1991; Holland & Lockett, 1997), suggesting that the degree of fit between an organization's complexity level, its supply chain coordination strategy, and its manufacturing IT infrastructure influences its performance. Figure 2 shows the PLS model results. Firms with longer planning horizons and more product lines deployed more IT for forecasting, planning, and inventory management. This deployment alone was associated with lower levels of inventory productivity; however, it was associated with higher levels of integrated planning and capacity leasing, which were associated with higher inventory productivity.

This result empirically supports theorists who postulate that IT alone is insufficient for success. Complementary factors, especially those that are tacit—that is, intangible and inimitable—also need to be adjusted in order to reap IT's promised payoff (c.f., Brynjolfsson & Yang, 1997; Clemons & Row, 1992; Davidow & Malone, 1992; Milgrom & Roberts, 1990; Rockart & Short, 1989; Short & Venkatraman, 1992; Venkatraman, 1991). This complementarity between integrated planning, capacity leasing, and elements of manufacturing IT infrastructure probably enhances inter-organizational "sense-and-respond capabilities" to improve performance, as evidenced by coordination strategy's positive and significant relationship with inventory turnover. Our results also support Bhaskaran's (1998) suggestion that supply chain cooperation and coordination improve forecast accuracy and schedule stability, which improves productivity.

Our study adds an additional theoretical dimension, as previous empirical IT value studies have measured highly aggregated IT dollar investments and their relationships to financial performance measures. We have instead measured IT deployment (which necessarily includes some investment and adoption decisions related to complementary intangibles such as training, change management, and process reengineering) for a particular use in a single industry over a two-year period. This focus has allowed us to control for many confounding factors. Further, our PLS method of analysis allowed us to distinguish the mediation effects of coordination strategy and manufacturing IT infrastructure, where previous studies may not have. Thus, our deployment measures have included some intangible elements and excluded some extraneous factors.

FUTURE TRENDS

To increase our understanding, IT value studies should consider more contextual variables and model them more realistically. The PLS method is a good analysis tool for this type of work (Chin, 1998).

We plan to extend the study to measure competitive advantage as indicated unit cost of manufacturing, product quality, throughput speed, delivery speed and reliability, flexibility, and design time. This would be especially important in contexts where inventory efficiency is secondary to market responsiveness. Additionally, we plan to extend the study of these constructs to a more modern IT paradigm, that of B2B e-commerce such as in the auto industry, where supply chain coordination strategy and business complexity are paramount concerns.

CONCLUSION

In this age of e-business, managers must beware of generalizing theoretical prescriptions too broadly. Managers must analyze IT deployment in terms of desired, sometimes conflicting, performance impacts; using relevant, sometimes non-financial, measures; and in terms of complementary investments, some of which are intangible. We found that firms with more product lines deployed more forecasting, planning, and inventory management IT; but without complementary deployment of integrated planning and capacity leasing, they experienced significantly lower inventory productivity. However, with these complementary investments, they reaped significantly better inventory productivity.

Where inventory productivity is critical, deployment of these technologies must be coupled with cooperative supply chain coordination strategies. Managers must consider complementary investments and strategic adjustments for tangible IT investments to confer advantage.

KEY TERMS

Business Complexity: Degree of difficulty associated with supplier- and customer-facing processes. Incorporates diversity and volatility aspects.

Electronic Hierarchies: Markets that entail few suppliers, as an intermediate step from hierarchical, ownership strategies toward electronic markets.

Electronic Markets: Markets characterized by infinite numbers of competing suppliers, selling completely specifiable products.

Manufacturing IT Infrastructure: Enabling base of shared IT capabilities which "provides common services to a range of applications" (Broadbent et al., 1997, p. 175), including "…information to efficiently manage the flow of materials…coordinate internal activities with those of suppliers, and communicate with customers about market requirements" (Vollmann et al., 1992, p. 2).

Market Mediation Costs: Costs associated with lost sales and customer dissatisfaction due to stock-outs, as well as lower profits due to product markdowns on unsold goods.

Physical Costs: Costs associated with production, transportation, and inventory.

Productivity Paradox: Term coined to describe the decline in productivity growth that began in the 1970s, just as IT investment began to dramatically increase. Labor productivity growth slowed from 2.5% per year from 1953 to 1968, to 0.7% per year from 1973 to 1979. Multifactor productivity growth also fell from 1.75% a year to 0.32% over this timeframe. Concurrent with these declines, office computers and machines capital rose from 0.5% of all producers' durable equipment in the 1960s to 12% in 1993 (Brynjolfsson & Yang, 1996).

Supply Chain Coordination Strategy: Extent to which the firm has integrated its activities with those in the larger business network. "Choices made for coordinating economic activity with trading partners and includes…degree to which the relationship with trading partner…reflects a long-term commitment, a sense of mutual cooperation, shared risk and benefits, and other qualities consistent with concepts and theories of participatory decision making" (Henderson, 1990, p. 8). Measured on continuum anchored by partnership and transaction coordination strategies.

APPENDIX I: STUDY VARIABLES

Business Complexity

Business Complexity—Firm's response to the scale and difficulty of supplier and customer facing processes in the marketplace (Holland & Lockett, 1997).
(Less Complex ↔ More Complex)

A) Product diversity: Number of products (Less Complex ↔ More Complex)
   1. Number of products for which sales forecasts are developed (Few ↔ Many)
   2. Number of products for which production plans are developed (Few↔Many)

B) Product line diversity: Number of product lines (Less Complex ↔ More Complex)
   1. Number of product lines produced (Few ↔ Many)
   2. Number of product lines forecast (Few ↔Many)
   3. Number of product lines in production plan (Few↔Many)

C) Planning volatility: (Less Complex↔More Complex)
   1. Reverse of months into future company's sales forecast extends (Few↔Many)
   2. Reverse of months into future company's production plan extends (Few↔Many)

D) Production volatility: (Less Complex ↔More Complex)
   1. % orders for which customer schedule changes occur after the start of production (Low↔High)
   2. % orders for which engineering or design changes occur after the start of production (Low↔High)
   3. % incoming material rejected (Low↔High)

IT Infrastructure

Manufacturing IT Infrastructure—The enabling base of shared IT capabilities which "provides common services to a range of applications" (Broadbent et al., 1997, p. 175), including "…information to efficiently manage the flow of materials…coordinate internal activities with those of suppliers, and communicate with customers about market requirements" (Vollmann et al., 1992, p. 2). (Less Extensive↔More Extensive)

Extent of IT deployment for:

A. sales forecasting (Low↔High)
B. production planning (Low↔High)
C. production scheduling (Low↔High)
D. inventory management (Low↔High)
E. purchasing (Low↔High)
F. product design (Low↔High)

Supply Chain Coordination Strategy

Supply Chain Coordination Strategy: "Choices made for coordinating economic activity with trading partners and includes…degree to which the relationship with trading partner…reflects a long-term commitment, a sense of mutual cooperation, shared risk and benefits, and other qualities consistent with concepts and theories of participatory decision making" (Henderson, 1990, p. 8). (Transaction ↔ Partnership)

A. Integrated planning: (Low↔High)
   1. Extent to which firm invests in JIT, MRP, TQM, and supplier partnership programs (Low↔High)
   2. Extent to which sales forecast is used for subcontracting decisions (Low↔High)
   3. Extent to which customers' future plans are considered in the development of the company's production plan (Low↔High)

B. Capacity leasing: (Low↔High)
   How often company responds to capacity imbalance by
   1. leasing temporary capacity from others (Low↔High) or by
   2. leasing excess capacity to others (Low↔High)

C. Reverse of number of suppliers/part: (Low↔High)

D. Production flexibility: (Low↔High)
   Extent to which the firm considers
   1. set-up time (Low↔High) and
   2. set-up cost (Low↔High)
   in determining the size of its production lots

Inventory Productivity

Annual Sales Revenue/Average Inventory Investment

IT Supporting Strategy Formulation

Jan Achterbergh
Radboud University of Nijmegen, The Netherlands

INTRODUCTION

This overview approaches information and communication technology (ICT) for competitive intelligence from the perspective of strategy formulation. It provides an ICT architecture for supporting the knowledge processes producing relevant knowledge for strategy formulation.

To determine what this architecture looks like, we first examine the process of strategy formulation and determine the knowledge required in the process of strategy formulation. To this purpose, we use Beer's viable system model (VSM). Second, we model the knowledge processes in which the intelligence relevant for the process of strategy formulation is produced and processed. Given these two elements, we describe an ICT architecture supporting the knowledge processes producing the knowledge needed for the strategic process.

BACKGROUND: STRATEGY FORMULATION, A VIABLE SYSTEM PERSPECTIVE

Strategy formulation aims at developing and selecting goals and plans securing the adaptation of the organization to its environment. These goals and plans may refer to specific product-market-technology combinations (PMCs) for which the organization hypothesizes that they ensure a stable relation with its environment. The process of strategy formulation needs to generate such goals and plans, needs to reflect upon their appropriateness, and needs to select certain goals and plans to guide the behavior of the organization. This is a continuous process. Goals and plans can be seen as hypotheses about what will work as a means to adapt and survive. Therefore, they should be monitored constantly and revised if necessary. In short, strategy formulation is a continuous contribution to maintaining organizational viability.

Although many authors deal with the process of strategy formulation, we choose the viable system model of Beer (1979, 1981, 1985) to define this process more closely. We select the VSM because Beer explicitly unfolds the functions required for the viable realization and adaptation of an organization's strategy.

To explain what these functions entail, it is useful to divide them into two groups: functions contributing to the *realization* of the organization's strategy and functions contributing to its *adaptation*.

The first group deals with the realization of the organization's strategy. It consists of three functions. Function 1 comprises the organization's primary activities constituting its "raison d'être" (Espejo, Schumann, Schwaninger, & Billello, 1996, p. 110). Function 2 (coordination) coordinates interdependencies between these primary activities. The third function is called the control function. It ensures the synergy of and cohesion between the primary activities by specifying their goals and controlling their performance.

To illustrate these functions, consider Energeco, a company servicing its environment with eco-energy. Function 1 of Energeco consists of three primary activities: supplying solar, tidal, and wind energy. To give an example of the coordination function, suppose that specialists in high-voltage energy are a shared resource between Energeco's business units. Also suppose that there is no coordination between these business units. In this case, the allocation of high-voltage specialists to a project in the business unit Solar Energy may require a revision of the allocation of these same specialists to a project in the business unit Wind Energy. Without a function supporting the coordination of these interdependencies, the business units Solar Energy and Wind Energy may become entangled in a process that oscillates between allocating and revising the allocation of these specialists to projects. It is the task of Function 2 to coordinate these interdependencies. The control function's task is to translate the identity and mission of the viable system (for Energeco, supplying eco-energy) into goals for the primary activities (in this example, supplying wind, solar, and tidal energy) and to control the realization of these goals.

The second group deals with the adaptation of the organization's strategy. It consists of control (Function 3), intelligence (Function 4), and policy (Function 5). Intelligence scans the organization's relevant environment and generates and proposes plans for adaptation. In the example of Energeco, developments in production technology may introduce the possibility of cost-effective, large-scale production of eco-energy from biomass. Intelligence should pick up these developments, assess them, and if relevant, translate them into proposals for innovation. Because of its knowledge of the potentials for change of the primary activities, control (Function 3) reviews the feasibility of the plans proposed by intelligence. For instance, it may object to the plans proposed by intelligence because they require a change posing a risk to the performance of the primary activities.

Discussion about the relevance and feasibility of the proposals for adaptation between intelligence and control should produce finalized plans for adaptation. It is the task of the policy function to balance the discussion between intelligence and control and to consolidate the finalized proposal in the organization's strategy. For instance, in the discussion between intelligence and control about the feasibility of the adoption of large-scale production of eco-energy from biomass, the policy function should ensure that control and intelligence are equally represented in the discussion. By opting for the production of energy from biomass, the policy function consolidates producing eco-energy from biomass as a new goal for Energeco. Figure 1 depicts the process of strategy formulation in terms of the VSM functions and activities.

To contribute to the strategy-formulation process, control, intelligence, and policy require knowledge about particular domains. Table 1 provides an overview of the knowledge required by each function to contribute to the process of strategy formulation.

Given the overview of functions involved in the strategy-formulation process, their relations, and the knowledge required by these functions to contribute to the process of strategy formulation, it is now possible to look into the knowledge processes needed to produce this knowledge and the ICT architecture supporting these knowledge processes.

KNOWLEDGE PROCESSES CONTRIBUTING TO STRATEGY FORMULATION

The question for this section is by means of what processes knowledge in the knowledge domains should be produced and processed so that the process of strategy formulation can take place. To answer this question, we first need to specify what these knowledge processes are. Then we need to link these processes to the knowledge required by control, intelligence, and policy to contribute to the strategy-formulation process.

We distinguish four relevant processes for producing and processing knowledge: generating (G), sharing (S), retaining (R), and applying (A) knowledge (cf. Achterbergh & Vriens, 2002; Bukowitz & Williams, 1999; Davenport & Prusak, 1998).

These four knowledge processes can now be linked to the process of strategy formulation, as formulated according to the VSM. According to the VSM, the functions intelligence, control, and policy contribute to strategy formulation. This contribution involves the *application* of knowledge in the knowledge domains to arrive at the four core products of strategy formulation: proposals for innovation, their reviews, the finalized plans for innovation, and their consolidation. The knowledge applied by each function is *generated* either by that function or by one of the other functions of the VSM. In the latter case, knowledge must be *shared* between functions. Applying, generating, and sharing knowledge requires the *retention* or *storage* of knowledge.

Figure 1. The process of strategy formulation according to the VSM

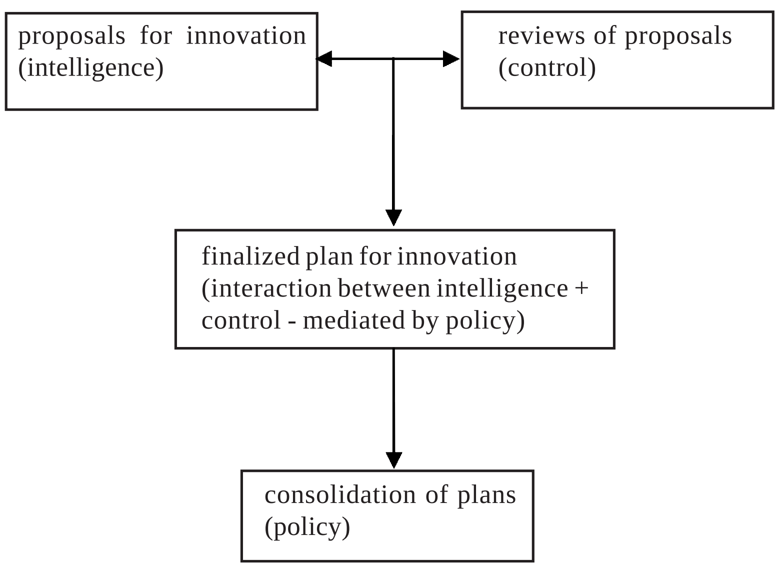

Table 1. Knowledge required by each function to contribute to the strategy formulation process

Function	Related domains of knowledge
F3: Function 3 (control)	For reviewing F4 proposals Organizational goals Proposals for innovation made by F4 Desired goals for F1 based on proposals for innovation Expected performance of the primary activities (goals for F1 activities) Gap between desired and current goals for F1 Required capacity for reorganization of F1 activities Modus operandi of F1 activities Actual capacity for reorganization of F1 activities Gap between required and actual capacity for reorganization Review of proposals for innovation Finalized plans for adaptation of organizational goals (a joint F3 and F4 product) Regulatory measures to counter the imbalance between F3 and F4 (see Function 5)
F4: Function 4 (intelligence)	Organizational goals Goals set by performance and modus operandi of F1 activities Developments in the relevant environment of the organization Reviews by F3 of proposals for innovation Regulatory measures to counter the imbalance between F3 and F4 (see Function 5) Finalized plans for adaptation of organizational goals (a joint F3 and F4 product)
F5: Function 5 (policy)	For balancing purposes Norms for balance between F3 and F4 Proposals by F4 and their reviews by F3 (relative contribution of F3 and F4 to the discussion on adaptation) Actual (im)balance between F3 and F4 Causes of imbalance between F3 and F4 Experiences with regulatory measures to counter the imbalance between F3 and F4 Regulatory measures to counter the imbalance between F3 and F4 For consolidation purposes Finalized plans for adaptation of organizational goals (a joint F3 and F4 product) Organizational goals

Table 2 provides an overview of the relation between the five functions in the VSM, the knowledge domains, and the application and generation of knowledge in these domains. Based on this table, it is possible to draw conclusions about sharing and retaining knowledge. In the table we only included the relevant knowledge for strategy formulation. However, some of this knowledge is generated by Function 1; this is the reason of its inclusion in the table.

The first column of Table 2 summarizes the knowledge domains listed in Table 1. In this column, we eliminated all redundant entries. Columns 2 to 5 indicate whether knowledge in a specific knowledge domain is generated and/or applied by a specific function.

Given the link between the knowledge processes, the functions contributing to the strategy-formulation process, and the knowledge required by them, it is now possible to outline an ICT architecture that can support the generating, retaining, sharing, and applying of this knowledge by these functions.

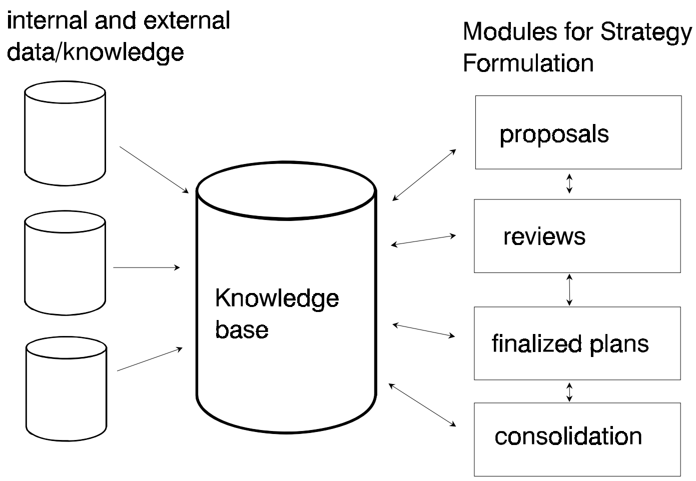
AN ICT ARCHITECTURE SUPPORTING KNOWLEDGE PROCESSES NEEDED FOR STRATEGY FORMULATION

Knowledge from several knowledge domains specified in Table 2 should be generated, stored, shared, and applied to take the steps in the process of strategy formulation: formulating proposals for innovation, reviewing them, making finalized plans for innovation, and consolidating them. We use these steps in the process of strategy formulation as a point of departure for outlining an ICT architecture (cf. Laudon & Laudon, 1997; Tan, 2003; Turban, McLean, & Wetherbe, 2002) for an information system supporting this process. In the literature, ICT architectures are presented as conceptual models, specifying (at a general level) the parts of an ICT infrastructure (applications, databases, technological ICT elements) and their relations. In this chapter we focus on

Table 2. Functions, knowledge domains, and knowledge processes for strategy formulation

Knowledge domains	F1	F3	F4	F5
Goals set by performance and modus operandi of the primary activities in F1	G,A	A	A	
Organizational goals	A	A	A	G,A
Proposals for innovation made by F4		A	G,A	A
Desired goals for F1 based on proposals for innovation		G,A		
Gap between desired and current goals of F1		G,A		
Required capacity for reorganization of F1 activities		G,A		
Actual capacity for reorganization of F1 activities		G,A		
Gap between required and actual capacity for reorganization of F1 activities		G,A		
Reviews by F3 of proposals for innovation		G,A	A	A
Finalized plans for adaptation of organizational goals (a joint F3 and F4 product)		G,A	G,A	A
Regulatory measures to counter the imbalance between F3 and F4		A	A	G,A
Developments in the relevant environment of the organization			G,A	
Norms for balance between F3 and F4				G,A
Actual imbalance between F3 and F4				G,A
Causes of imbalance between F3 and F4				G,A
Experiences with regulatory measures to counter the imbalance between F3 and F4				G,A

Figure 2. Outline of an architecture of an information system supporting strategy formulation



the application and databases parts. An outline of the architecture is presented in Figure 2.

This architecture consists, ideally, of five modules and knowledge and/or databases. The modules (at the right in Figure 2) are applications helping to generate the products of the process of strategy formulation. With the help of these modules, the knowledge from the knowledge domains is applied to produce the proposals, reviews, and (consolidated) plans. The architecture further consists of a central knowledge base in which the knowledge in the knowledge domains necessary for strategy formulation (see Table 2) is stored. This central knowledge base in turn may receive knowledge from other internal and external knowledge and/or databases. Below, we discuss the modules and knowledge bases and their relation to relevant knowledge processes in the course of strategy formulation in more detail.

1. The proposal module
   The main product of this module is a list of innovation proposals and their justification. To produce this list, one should have access to the knowledge in the relevant knowledge domains. To generate this knowledge, the module should have access to external and internal information. For instance, it may have access to a data warehouse by means of a front-end tool, or it may have access to external online databases. Furthermore, the module may have access to a database consisting of previously re-

jected or accepted proposals. The proposals for innovation produced with this module are stored in the central knowledge base.

2. The review module
The input for this module consists of the proposals for innovation. The output is a list of accepted and rejected proposals and the reasons for their acceptance or rejection. To make this list, the module should apply the knowledge in the central knowledge base. This knowledge may be available or may have to be generated. To generate the knowledge, access to several internal and external databases may be required. Also, (external) data on the results of the current PMCs may be input for rejecting or accepting innovations. The review module may benefit from a database with (a classification of) reasons for acceptance or rejection.

3. The finalized-plans module
This module is mainly a means for sharing proposals for innovation (and their reviews) in order to arrive at a finalized plan. It overarches the proposal and review module. By means of this module, results of the review module are shared and applied to revise the proposals (with the aid of the proposal module). The revised proposals are, in turn, used to produce new reviews (with the aid of the review module) and so forth. This module should (a) facilitate sharing proposals and (b) ensure the finalization of an innovation plan. To these ends, this module should support sharing knowledge about

   • the rules for interaction (such as discussion format and deadlines),
   • criteria for imbalance in the discussion,
   • a monitoring function regarding the imbalance,
   • rules and incentives for countering this imbalance, and
   • an overview of the history of the discussion (as well as an overview of previous discussion).

   Implementation could be by means of intranet applications (e.g., an internal discussion site).

4. The consolidation module
This module has as its output the consolidation of (a specific selection of) the innovations on the finalized list of innovations. To make this selection, the arguments used in the previous modules should be scanned and valued. Its main goal is to share the results of the strategy-formulation process with relevant parties in the organization. It should enable sharing knowledge about (a) the selected innovations, (b) the reasons for their selection, and (c) their consequences for the current way of doing business. The process of sharing may benefit from a database with (previously successful) communication formats that can be a part of the consolidation module.

5. The central knowledge base
The central knowledge base consists of all the knowledge in the knowledge domains relevant for strategy formulation. The knowledge base stores the knowledge produced in the modules and supports these modules by servicing them with knowledge relevant to their processes.

Above, an ICT architecture is outlined for an information system supporting strategy formulation. It shows how support should be focused on the products of strategy formulation. Moreover, the focus of the support is on the four knowledge processes involved in the production of proposals, reviews, plans, and consolidations. That is, the application of knowledge leads to proposals for innovation, reviews of these proposals, finalized plans, and consolidation of selected finalized plans. For these products, knowledge from the knowledge domains should be generated, stored, and/or shared. This knowledge is (partly) stored in the knowledge base. The knowledge may be generated by using the four modules and/or by using internal or external databases. Furthermore, knowledge from the knowledge domains may be shared by using connections between the modules.

The description of the architecture specifies the functionality of the different modules in it and how they should be connected. These specifications can be used to select or build the ICT tools to realize the architecture and the knowledge processes it supports.

FUTURE TRENDS

Given the particular outline of the proposed ICT architecture supporting the strategy formulation process, it is possible to link up with current trends that may enhance its performance.

- Developments in the technology for integrating databases (e.g., data warehouse technology) may support the intelligence function in the proposal phase by facilitating the integration and analysis of internal and external knowledge required for strategy formulation.
- Currently, data warehouses are often organized to fit the format of the Balanced Business Scorecard (Kaplan & Norton, 2001). This scorecard is primarily

geared to strategy implementation. The format of the VSM, its related knowledge domains, and steps for formulating strategy may be used to organize data warehouses to fit the requirements for strategy adaptation (Achterbergh, Beeres, & Vriens, 2003).

- Proposing and reviewing proposals for adaptation may be enhanced by the application of computer-aided techniques such as gaming, system dynamics, scenario analysis, and group model building.
- By systematically linking strategy formulation to knowledge management, it becomes possible to enhance the quality of the knowledge processes related to strategy formulation by using acquired insights on improving infrastructures for knowledge management.

CONCLUSION

In this overview, we design an ICT architecture supporting strategy formulation on the basis of the viable system model. By applying the viable system model to the strategy-formulation process, it becomes possible to identify the functions required for strategy formulation, the relations between these functions, and the knowledge required by them.

By identifying the knowledge processes producing and processing this knowledge, and by linking these processes to the functions and the knowledge they require to contribute to the strategy-formulation process, it becomes possible to outline an ICT architecture supporting the processes of generating, retaining, sharing, and applying the knowledge needed for strategy formulation. This architecture consists of five modules dedicated to proposing, reviewing, finalizing, and consolidating strategy changes and related knowledge databases containing knowledge in the knowledge domains required for strategy formulation.

KEY TERMS

ICT: Information and communication technology. ICT can be used to indicate the organization’s technological infrastructure (comprising of all hardware, software, and telecommunications technology) and to indicate one or more specific collections of hardware, software, and telecommunications technology (i.e., one or more ICT applications).

ICT Architecture: The ICT architecture provides a conceptual model, specifying (at a general level) the parts of an ICT infrastructure (applications, databases, technological ICT elements) and their relations. In this chapter we concentrate on the application and databases parts.

Knowledge Domain: the knowledge related to defining, recognizing, and solving a specific problem.

Knowledge Processes: In the literature, one often finds four knowledge processes: (a) generating knowledge, (b) sharing knowledge, (c) storing knowledge, and (d) applying knowledge.

Strategy: In the literature, many definitions are given. A possible definition is the desired portfolio of product-market-technology combinations of an organization.

Strategy Formulation: The process by means of which the desired portfolio of product-market-technology combinations is defined and updated. This process can be modeled using the viable system model consisting of four steps: defining proposals for innovation, reviewing these proposals, finalizing proposals, and consolidating finalized proposals.

Viable System Model: This model is developed by Beer (1979, 1981) and specifies the necessary and sufficient functions organizations should possess to maintain a separate existence in their environment.

Viability: Viability is the ability of a system "to maintain a separate existence." Most organizations are continuously trying to maintain their viability.

Java 2 Micro Edition for Wireless Enterprise

Kin Choong Yow
Nanyang Technological University, Singapore

Nadia N. Moertiyoso
Hewlett-Packard Singapore, Singapore

INTRODUCTION

For the last couple of years, the wireless industry has been experiencing tremendous growth. Wireless devices have become more intelligent and are providing a new notion of communication. It is now possible to conduct business using the wireless network that will greatly improve the speed and quality of the business. Examples of business decisions across the wireless Internet include:

- A sales manager will be able to browse and download the latest price and stock availability of products during the journey to a client meeting.
- Support engineers, couriers, and delivery services will be able to manage their schedules better by organizing their orders on their cell phones. The headquarters will also be able to monitor their workers in the field.

This article will discuss the issues concerning the development of wireless applications using Java 2 Micro Edition (J2ME). This article will also explain what J2ME is and discuss the guidelines and technical aspects to implement wireless enterprise applications using J2ME.

BACKGROUND

Introduction to Java 2 Micro Edition

Java 2 Micro Edition (J2ME), from Sun Microsystems, is designed to run on consumer devices and electronic appliances, including wireless devices such as cell phones and Palm PDAs (Raju, 2000). J2ME provides a way to exploit the processing power on the mobile device better by running the code on the device itself. Therefore, it provides better network implementation, better graphical user interface, and local database management.

The Java virtual machine for consumer devices is known as the Kilo Virtual Machine (KVM), which is a complete Java runtime environment for small devices. KVM was designed to be small, with a static memory footprint of 40 – 80 kilobytes. KVM is derived from a research system called Spotless at Sun Microsystems Laboratories.

J2ME Profiles and Configurations

J2ME is divided into *configurations* and *profiles* (Ashri et.al., 2001). Configurations are specifications that detail a virtual machine and a base set of APIs that can be used with a certain class of device. A profile builds on a configuration but adds more specific APIs to make a complete environment for building applications. While a configuration describes a JVM and a basic set of APIs, it does not by itself specify enough detail to build complete applications.

Configurations

Mobile devices such as cell phones, pagers, organizers, etc., are diverse in form, functionality, and features. For these reasons, the J2ME supports minimal configurations of the Java Virtual Machine and APIs that capture the essential capabilities of each kind of device (Feng & Zhu, 2001). J2ME configuration defines a set of horizontal APIs for a family of products that have similar requirements.

Profiles

A profile is a set of vertical APIs that reside on top of the configuration to provide domain specific capabilities. Currently, there is one profile defined and implemented, the Mobile Information Device Profile (MIDP) (Sun Microsystems, 2001). Other profiles, which are in the works, include the PDA profile and the RMI profile.

Table 1 shows the current and anticipated configurations, profiles, and APIs.

Comparison of J2ME versus WAP in Enterprise Application

Phone.com (now Open Wave), a merged venture with Software.com, first introduced the Wireless Application Protocol (WAP) in 1995. WAP is an open standard that

Configurations		
JSR 30	CLDC 1.0	Connected, Limited Device Configuration
JSR 139	CLDC 1.1	Connected, Limited Device Configuration 1.1
JSR 36	CDC	Connected Device Configuration
Profiles		
JSR 37	MIDP 1.0	Mobile Information Device Profile
JSR 118	MIDP 2.0	Mobile Information Device Profile 2.0
JSR 75	PDAP	PDA Profile
JSR 46	FP	Foundation Profile
JSR 129	PBP	Personal Basis Profile
JSR 62	PP	Personal Profile
JSR 134		Game Profile
APIs		
JSR 66		RMI Optional Package
JSR 80		Java USB API
JSR 82		Java APIs for Bluetooth
JSR 120		Wireless Messaging API
JSR 135	MMAPI	Mobile Media API
JSR 169		JDBC Optional Package for CDC/FP
JSR 179		Location API for J2ME
JSR 180		SIP API for J2ME
JSR 184		Mobile 3D Graphics API for J2ME

enables easy delivery of information and services to mobile users. WAP is intended to address the need to access the Internet from handheld devices such as cell phones and PDAs. It defines a set of standard components that enables communication between mobile terminals and network servers, including the WAP programming model. WAP has received wide support in the wireless industry.

J2ME and WAP are complementary technologies. J2ME is not going to replace WAP. WAP is comparable to HTML and Web browsers on desktop computers, while J2ME is comparable to desktop Java applications. However, in the enterprise application situation, J2ME is found to be superior to WAP.

Limitations of WAP

WAP is limited in some ways, including:

- Network disconnections: Mobile device communication over wireless networks tend to suffer from greater occurrences of disconnections due to a variety of problems, such as limited cell coverage, loss of signal, limited battery life, etc. Current frameworks only provide partial support for disconnected operations.
- Constant airtime: WAP requires constant airtime in order to operate. When combined with the previous point, this may cause disruptions in the application's usage. This constant airtime requirement is also economically inefficient.
- Lack of security: The infrastructure of WAP forces the information to be passed into a WAP Gateway before it is presented to a cell phone. Therefore, there is a security loophole in the architecture, since the WAP Gateway is usually controlled by a third party (network carrier). In addition, security issues may arise during the translation of pages from the server to the WAP Gateway.
- Primitive user interface: The user interface for WAP-enabled sites is primitive when compared to traditional Web sites. Devices that might be capable of displaying a richer graphical user interface (GUI) through higher screen resolution are not being exploited.

Benefits of J2ME

J2ME has the following benefits:

- Local Computing Power: Browser-based applications can often be an adequate solution for constructing software for devices, allowing Web access with minimal configuration. However, it is more valuable to be able to exploit the device's resources more by executing code on the device's processor and using the device's memory to run the application locally.
- Multithreading: J2ME allows an application to use multithreading. This provides a mean for application developers to create a more complex logic.
- User personalization: Browser-based applications often lack sophistication in user interface compared to applications that take greater advantage of local operating systems. This sophistication can be leveraged by J2ME with better manipulation of device-side services.
- Offline operation: J2ME provides a solution that can run on or off the network, something that a browser solution can do only in a very unsophisticated way with local browser page caching.
- Lower network usage and server load: In a WAP-based solution, the server is responsible for generating display markup. This requires a round-trip every time the interface changes. In contrast, a MIDP client's interface is contained within the device, so it can operate even when disconnected.
- Security: J2ME offers an enhanced security model. It provides connection end-to-end from client device to company servers and does not require gateways such as in WAP.
- Connectivity with distributed system: J2ME provides a better way to talk to the back-end system. Applications written in J2ME are able to talk in XML, a language that is suitable for cross-platform and distributed system applications (Castro, 2001).

WIRELESS ENTERPRISE APPLICATION DESIGN USING J2ME

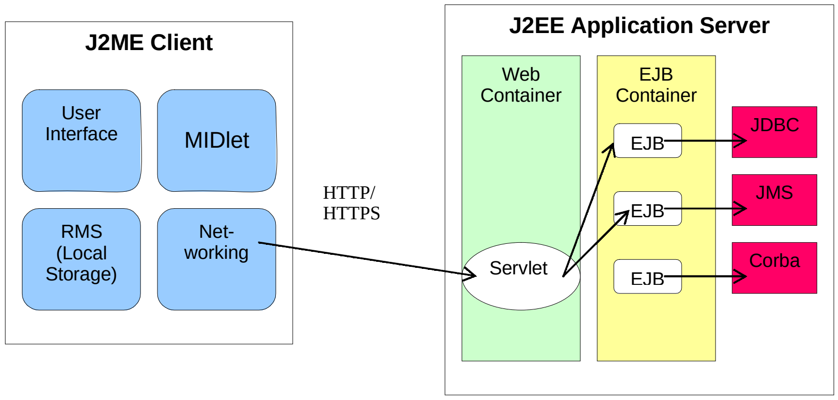
Overall Enterprise Application Architecture

An enterprise application usually does not consist of the wireless module alone. A wireless application usually acts as an interface module that connects to an existing or running system. This section examines the overall enterprise architecture, including the wireless component.

Figure 2 shows the overall logical architecture of a typical Java wireless enterprise application, spanning a J2ME device and a J2EE application server. The use of J2EE for the back-end system is, of course, optional. The J2ME MIDP is flexible enough to talk to any back-end system that supports HTTP transport.

The logical architecture of an enterprise application

Figure 2. High-level architecture of a Java wireless enterprise application



serving wireless clients is similar to that of a canonical J2EE application (Girdley et al., 2002):

- An application client implemented using MIDP, or a *MIDlet* client, provides the user interface on the mobile device. This MIDlet communicates with a Java servlet, usually via HTTP, and over a secure channel (HTTPS) when necessary.
- The servlet interprets requests from the MIDlet, and in turn, dispatches client requests to EJB components (Adatia et al., 2001). When the requests are fulfilled, the servlet generates a response for the MIDlet.
- The EJB components, or *enterprise java beans*, encapsulate the application's business logic. An EJB container provides standard services such as transactions, security, and resource management so that developers can concentrate on the business logic.
- The servlet and EJB components may use additional APIs to access enterprise information and services. For example, they may use the JDBC API to access a relational database, or the JavaMail API to send e-mails to a user.

Developers can write networked application clients that connect to wireless services using standard networking protocols. MIDP requires all devices to support HTTP, the same protocol that Web browsers use (Mahmoud, 2000).

The physical architecture of an entire enterprise application (e.g., Customer Support System) is shown in Figure 3. Client entities (e.g., Support Engineers) access the system through the wireless modules while Helpdesk, System Administrators, and Managers access the system through the Web modules. The back-end system uses Web servers, application servers, and database servers.

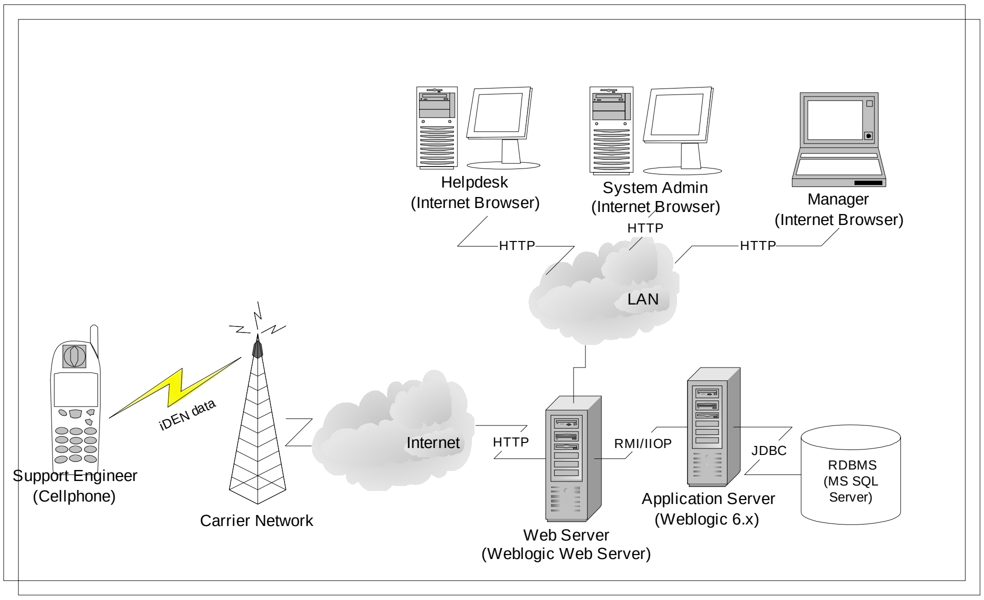
The wireless module (J2ME) runs in a J2ME-enabled cell phone on GPRS or other similar packet data network. It accesses the back-end system using HTTP (Hypertext Transfer Protocol).

Considerations in Designing the J2ME Wireless Module

Enterprise applications usually impose a requirement on the client devices to communicate with the servers to query and manipulate data. In a wireless scenario, the wireless application presents new problems to database query management due to the mobility of the users, power and resource restrictions, and the limited bandwidth of the wireless connection (Bukhres et al., 2002). These challenges are the major issues in designing the architecture of the application and are summarized below:

1. Limited bandwidth: the wireless network operates at a much lower rate than a wired network.
2. Network disconnection: the wireless network is also more susceptible to network disconnections compared to a wired network. The framework must therefore provide a way to ensure that data in the mobile devices will not be lost due to this.
3. Limited computing power and memory resources: mobile devices have much lower computing power than a standalone PC. Therefore, operations that require a lot of computing power must be distributed to other nodes in the system.
4. Working online and off-line: There are many reasons that require the application to be able to work off-line. Some of these reasons include network

Figure 3. Architecture of enterprise applications



interruptions and weak signals. One of the more economical reasons is to save airtime charging.

5. Synchronization and data consistency: The framework must also provide a way to maintain the consistency of the data in the mobile device and the server.

M-Commerce Considerations in the J2ME Application

The J2ME module can easily be extended to transfer financial transaction information on the move (m-commerce). Bank account information and the instruction to transfer funds, etc., are all treated as data to be sent over the wireless network.

However, as in the case of electronic commerce (e-commerce), the security of the transaction is the primary concern (Claessens et al., 2002). The following general security requirements apply to m-commerce applications:

- Confidentiality: Need to ensure that only authorized entities have access to the content of the exchanged information, e.g., an eavesdropper should not be able to find out what transactions a particular user is executing.
- Entity authentication: Client entities should be sure that they are communicating with the real back-end entity, before sending sensitive information to it while the back-end entity should also know the identity of the client entity before processing its transactions.
- Data authentication: This involves data origin authentication and data integrity. The back-end (at least) should be able to detect manipulations (e.g., insertion, deletion, and substitution) and replay of data by unauthorized parties.
- Non-repudiation: This is to prevent an entity from denying previous commitments or actions, e.g., the back-end entity should be able to prove to a third party that a client entity performed a certain transaction, in case the client entity denies having performed it.

To achieve the above requirements, cryptography techniques (Jon, 2001) should be used. Cryptography allows information to be sent in a secure form such that only the intended recipient is able to retrieve the information. Practically all modern cryptographic systems make use of a key to encrypt the information. There are two key-based cryptography: symmetric key encryption and public key encryption:

1. Symmetric key encryption: Symmetric algorithms use the same key to both encrypt and decrypt the plaintext. Hence, both the sender and the receiver need to have a copy of the same key. The key is often called a secret key, as it can only be known by the communicating parties in order for the ciphertext to be secure.

2. Public key encryption: Public key cryptography, also known as asymmetric cryptography, involves a pair of keys called the public key and private key (Benantar, 2002). The encryption key (public key) is used to encode a message, but this message can only be decoded by using the corresponding decryption key (private key). Conversely, a message encrypted using the private key can only be decrypted by the public key. This system allows the recipient to make the public key widely available, so that anyone can send an encrypted message to the recipient.

In J2ME, crypto-APIs such as the Rivest-Shamir-Adleman (RSA) algorithm (RSA Security, 2002) is already available. This greatly reduces the time for developing secure m-commerce applications.

FUTURE TRENDS

The trend is moving increasingly to allow developers to enhance the look and feel of the mobile device. In the future, new APIs may be added such as:

- Phone-centric APIs
  - External Display Access (Caller ID Display)
  - RF Enabling
  - Call Receiving (Answer an incoming phone call with Caller ID)
  - Call Initiation (Place outgoing calls)
- Data Manipulation APIs
  - Gzip/ZIP compression and decompression
  - Secure File
- Graphics APIs
  - MIDP 2.0 Gaming
  - 3D API
  - Additional Image Formats
- JPEG
- WBMP
- PNG w/Alpha Transparency

CONCLUSION

In this article, we have described the use of Java 2 Micro Edition for developing wireless applications. We have given a brief description of the features of J2ME and a comparison with WAP on the suitability of developing Enterprise Applications. We have also outlined the various considerations in developing wireless enterprise using J2ME and their associated m-commerce considerations.

A complete enterprise model consisting of wireless modules, back-end modules, and Web-site modules can easily be developed using J2ME. Cryptographic APIs are already available in J2ME to build secure m-commerce applications. J2ME is an obvious choice because it is portable and designed to run on consumer devices.

KEY TERMS

Enterprise Applications: Enterprise Applications provides computer application support for the full life cycle of business application development and system support. Involves in-depth understanding of business processes and workflow.

Interoperability: The property of software applications that will enable diverse applications to interact and share data seamlessly.

Virtual Machine: A software system that enables a collection of heterogeneous computers to be used as a coherent and flexible concurrent computational resource.

Application Programming Interfaces (APIs): Programming tools that provide developers with a simple, consistent mechanism for extending the functionality of an application and for accessing existing computing systems.

Memory Footprint: The memory usage during the execution of an application. It depends on what kind of processor you intend to use and what components of the system you include.

Multithreading: Programs written to execute in a parallel manner, rather than a serial or purely sequential one, in order to take advantage of multiple processors.

Distributed System: A system made up of components that may be obtained from a number of different sources, which together work as a single distributed system providing the run-time infrastructure supporting today's networked computer applications.

Journalism Online in Peru

Antonio Díaz-Andrade
Escuela de Administración de Negocios para Graduados - ESAN, Peru

INTRODUCTION

Online journalism dates back to the end of the 1970s, when Knight-Ridder launched an initiative to develop a video-text service in the United States, which it later dropped, in 1986, after realizing enormous losses. In 1988, Knight-Ridder bought *Dialog Information Services, Inc*.; only a year later, the first signs of success appeared. By the end of the 1980s, Gannet launched a daily news piece in text format. In 1992, *The Chicago Tribune* became the world's first daily to launch an electronic version of its newspaper. In 1993, Knight-Ridder started publishing what would eventually become one of the paradigms of electronic journalism, the *San Jose Mercury Center*. By 1994, the major newspapers in the United States offered readers an online version (Díaz & Meso, 1998). Now, Internet users can read newspapers, listen to the radio, and watch TV from anywhere, anytime (McClung, 2001).

BACKGROUND

Electronic journalism stands out for four features: it uses multimedia resources; it breaks down the sequence of information through hypertext and hypermedia; it breaks down periodicity, because it allows for information to be accessed at any time; and it is interactive (Díaz & Meso, 1998; Cohen, 2002). Interactivity gives an opportunity for readers to disagree with the publishers or contribute to the writers' work by incorporating readers' opinions (Giles, 2000; Cohen, 2002).

Many sites relating to printed media have evolved from pages that initially were simply reproductions of the printed version into a dynamic environment that is constantly updated (Pack, 2001). In this sense, Internet journalism principles should not be different from those governing traditional channels. Digital-era journalists must find the way to reach a global audience without compromising the values of truthfulness, of reliable sources, and of independence (Pavlik, 2000).

Nowadays, the Internet opens the door to new, purely virtual media, although they must still walk a long way before they gain enough credibility. Additionally, they must rise to the challenge of a huge infrastructure that has already been put in place by consolidated newsgroups and overcome limited access to capital (Giles, 2000; Uy, 2001). Purely virtual media must carefully analyze their projects' feasibility. The collapse of Taiwan's virtual *Tomorrow Times* information medium—despite 1.8 million daily page visits—poses a question about the viability of sustaining the high cost of generating news (Ling & Guyot, 2001), when no journalistic infrastructure has been developed in the physical world. So, online journalists must reconcile money-making and news interests (Cohen, 2002).

Although the cost of preparing a news feature has remained almost unaltered, and although presenting news in a multimedia format (Fulton, 2000) may slightly increase costs, it is clearly cheaper to prepare a page and make it available to millions of people around the world over the Internet than to distribute it on a printed format (Small, 2000 and Singer, 2001).

Finally, given the phenomenon of ethnocentricity (Priess, 2000), publishers may find it convenient to specialize on reporting about a reality that is best known to them (Singer, 2001).

PERUVIAN ONLINE JOURNALISM

To evaluate Web journalism in Peru, the most important print, broadcast, and purely virtual media were analyzed. The criteria to select the media were their readership or rating in the physical world and their number of visits in the virtual world.

The following printed media were chosen:

- *El Comercio* is Lima's best recalled and most widely read daily (Apoyo Opinión y Mercado, 2003). It has a reputation for being the most truthful, entertaining, and the best at covering local political news events (Apoyo.com, 2001). It is read by an average 574,700 people in Lima (Instituto Cuánto, 2001).
- *Gestión* was Peru's first written medium to produce an online version. Its printed edition, targeting the business community, reaches an average 27,500 readers in Lima (Instituto Cuánto, 2001).
- *La República* was Peru's second printed medium to publish an electronic version. It is regarded as the second most truthful and is also mentioned as the second most reliable daily in providing local political news coverage (Apoyo.com, 2001). It is read by

an average 171,300 readers in Lima (Instituto Cuánto, 2001). At this time, it is regarded as the second most widely read online Peruvian daily (Apoyo Opinión y Mercado, 2003).

Radio broadcasters in this study comprise those that broadcast over the Web but focus on news programming:

- *Radioprogramas del Perú*, *RPP Noticias*, enjoys a spontaneous recall rate of 27% among all radio broadcasters and 62% among news radio broadcasters. Its annual average half-hour audience in Lima reaches 95,100 listeners (Insituto Cuánto, 2001). It is one of the most widely heard radio broadcasts (Apoyo Opinión y Mercado, 2003).
- *CPN Radio*, *Radio Cadena Peruana de Noticias*, has an annual average half-hour audience of 22,900 listeners in Lima (Insituto Cuánto, 2001). It is the second most widely heard news radio broadcast in Peru (Apoyo Opinión y Mercado, 2003).

Rather than displaying full and updated information, Peruvian television networks on the Web underscore programming information. Their Web sites are closer to an institutional page than to an information page, so they were not included in this study.

Of the three Peruvian information media lacking a print, radio, or television matching part, only www.peru.com and www.primerapagina.com.pe participated in this study; the latter plummeted shortly after this research; the third did not answer.

A preliminary evaluation of the selected media Web sites was conducted preceding in-depth interviews with their managers; a subsequent examination on the media Web sites complemented the analyses.

In the following pages, a brief explanation is provided about the origins, main goals, content, audience, and income sources of the studied Peruvian Internet media.

El Comercio

Founded in Lima in 1839, it published the company's institutional page on the Internet in 1996 and in 1997 started publishing the www.elcomercioperu.com.pe electronic daily; in May 2001, it organized an independent area charged with the Web publication. News is updated on the Web using information provided by the daily's reporters and input from news agencies. Its Web site gets an average 11 million monthly hits, mostly from Peruvian expatriates. Information sections in the daily's electronic version include national and world affairs, business, entertainment, politics, and sports; its most widely read pages are the front page and local soccer news.

The revenues of www.elcomercioperu.com.pe come from advertising by some announcers, sale of news to the telephone operators who distribute the news to their cellular telephone customers, as well as preparation of private circulation newsletters for other companies. The daily's electronic version has created a portal providing, among other services, the www.ec-store.com.pe virtual shop as an additional source of revenue. At the same time, an Internet public kiosks network was put in place around the country. Additionally, *El Comercio* offers free e-mail and a PDA news service.

El Comercio's management has made a decision to make the newspaper a Latin American leader. Comprised in their strategy to reach their goal is the effort to provide Internet-based news services.

Gestión

Gestión was Peru's first written medium to produce an online version when it launched its electronic site www.gestion.com.pe in September 1996. An economics, finance, and business newspaper, *Gestión* first circulated in 1990. Its specialized reports go hand in hand with information about political events and world affairs.

From the daily's Web site, it is possible to access other media run by the corporation: *CPN Radio* (www.cpnradio.com.pe) information broadcast station and its *Gestión Médica* (www.gestion.com.pe/GM) weekly health publication. Most of its visitors are businessmen from abroad who have business and interests in Peru. Articles on political issues are the most frequently visited, followed by economic reports. *Gestión*'s contents are prepared with materials gathered by its reporters, together with news from news agencies. Information in www.gestión.com.pe is posted on the Web and updated by *CPN Radio* personnel. *Gestión* also offers a free e-mail news service twice a day.

La República

Founded in Lima in 1981, it has as its objective to inform and become an opinion maker for the Peruvian public. Since 1995, it uses satellites to publish local editions in other cities around Peru. In October 1996, *La República* launched its electronic version (www.larepublica.com.pe).

Since its Web site launching, the number of opinion letters it gets through e-mails from readers outside Peru has grown steadily. Some visitors at www.larepublica.com.pe have become the newspaper's foreign correspondents who "add a Peruvian flavor" to international reports. Foreign readers account for 70% of the electronic edition's readership. All of *La República*, including its supplements, is published on its Web site;

the most visited pages cover current political affairs and sports. News is not updated during the day.

Radioprogramas del Perú

Initially conceived in 1963 as an entertainment radio broadcaster, in 1979 it became a round-the-clock news broadcaster. At the end of 1999, the www.rpp.com.pe site was added to the original product. At this time, *RPP Internet* gets an average 12 million monthly visits; about 40% of them originate in Peru. At its Web site, visitors find the latest news in the "news by the minute" section, as well as local affairs, political, sports, world affairs, finance, cultural, and entertainment sections. There is also the option to participate in opinion surveys and a discussion forum concerning current affairs as well as to access the audio-on-demand option. Likewise, the direct *RPP Noticias* audio broadcast can be heard on www.rpp.com.pe. Additionally, wireless application protocol (WAP) technology enables telephone operators' clients to access news.

It is widely held that launching this service has had a positive influence on RPP Group's image building by creating among both listeners and announcers a perception of leadership, while strengthening the Group's competitive standing in terms of its capacity to reach a wider target audience that comprises both radio listeners and Web users.

CPN Radio

This news radio chain has been owned by Corporación Gestión since 1998. Motivated by positioning itself and creating an image before the public vis-à-vis *Radioprogramas del Perú*, *CPN Radio*, through an agreement with Terra Networks, launched the www.terra.com.pe/cpn site in June 2000. In September 2001, a new page was launched at www.cpnradio.com.pe. *CPN Radio* and *Gestión* newspaper share their general information sources; so, to launch the Internet project, professional journalists within the organization were reassigned. Most visitors to www.cpnradio.com.pe originate in Peru, and these visitors can also listen to radio programming in real time. In its publication, www.cpnradio.com.pe includes headlines and the political, economic, financial, business, world affairs, show business, sports, and culture sections; political features are most often followed. It also has a "last minute news" flash section, complete radio programming, and links to articles written by the broadcaster's columnists.

www.peru.com

Interlatin Corporation—a Peruvian company holding similar domains (www.colombia.com, www.bolivia.com, and www.futbolargentino.com)—owns this site that seeks to develop portals that provide information and specific services adapted to individual countries. The site www.peru.com has been operational since 1998; its name became the company's main tool in luring traffic toward its site. The site gets around 16 million visits monthly, mostly of Peruvian expatriates, to its different news sections dedicated to delivering information about Peru and offering other services that include a browser, chat rooms, free e-mail addresses, job searches, a communication media directory, messaging to cellular telephones, access to music radio broadcasts, and electronic postcards.

Interlatin Corporation has two main sources of revenue: its www.iquiero.com virtual shop and its travel agency www.peru.com/travel. Additionally, www.peru.com accepts advertising and provides Web page design services; likewise, through agreements with telephone operators, it sells news to be distributed among their users.

Becoming an Internet news leader is the goal of www.peru.com. Its journalists recognize that they do not have the entire journalistic infrastructure available to traditional media and, therefore, resort to their own inventiveness in finding and publishing the most recent information.

FUTURE TRENDS

Some of the Peruvian media moved onto the Internet seem more clearly determined to explore new options to increase their revenues and earnings, while others simply wish to expand their readership or number of listeners by drawing international audiences. However, they all seem persuaded that there is no turning back, and they have entered the Web never to escape from it. In contrast, those media that do not have a traditional media foundation have no choice but to yield satisfactory economic results that will allow them to survive. News pieces and reports prepared for traditional media are the raw material for the articles published by conventional media on the Web. Exclusively virtual media had to draw a press team out of the blue and have made them responsible for searching news and then publishing their reports.

Initial plans had to be modified, as Internet media identified difficulties and opportunities along the way. Purely virtual Peruvian media are hard put to make any short-term inroads into traditional channels. Instead, they must try and develop business lines that can sustain the work of their news teams. Using Internet resources to offer a varied and interesting range of content options as well as to create virtual communities that may be served with alternative products is an option deserving consideration.

Likewise, increasing participation of Peruvian information groups on the Web opens the possibility for them to reach a larger number of users and thus develop new businesses in the field of information. Notwithstanding, the Peruvian media must acknowledge the restrictions that apply to the Internet in Peru.

Finally, when easy-to-use, flexible, and portable devices are sufficiently developed and widespread, all featuring multimedia capabilities, newspeople will have to be ready to meet the ever faster pace of information needs in modern societies. In the meantime, the number of Peruvians that go to the Internet to stay abreast of events increases constantly.

CONCLUSION

A common feature among all aforementioned media is that the most visited sections are the Peruvian political current affairs and sports pages. In almost all media, most visits come from abroad, likely because of the strong familial, cultural, and social ties of the Peruvian expatriates, which constitute an expression of ethnocentricity, as was explained previously. Nonofficial figures show that Peruvian expatriates may reach 2.5 million. In the same way, it should be noticed that those living overseas are likely to have better conditions for accessing the Web than those in Peru, where the information and communication infrastructure is still poor, although it shows one of the highest rates of public access to the Internet in Latin America, thanks to the phenomenon of the "cabinas públicas" (OSIPTEL, 2003; Salvador, Sherry, & Urrutia)

Using multimedia resources is another characteristic of online journalism. All of the studied news media use text and photographs; www.peru.com, *CPN Radio*, and *Radioprogramas del Perú* broadcast directly over the Web, while the latter is the only one that offers audio on demand. *El Comercio's* Web site and www.peru.com present some news through video.

Except for the Internet media owned by Corporación Gestión, *Gestión* daily, and *CPN Radio*, all the analyzed media make available advertisement space for commercial announcers on their Web sites. However, it is clear that advertising, no matter how high the traffic through the site, does not constitute, in itself, a sufficiently sound source of revenue to cover operating costs.

KEY TERMS

Direct Audio Broadcasting: The possibility of listening to the transmission of radio broadcast programming directly from the Web.

Electronic Journalism: The use of every Internet resource to disseminate information on an ongoing, updating basis.

Ethnocentric Content: Pieces of information provided by local journalists of particular interest for locals who find sufficient elements for understanding it. On the contrary, local and specific content could be strange to overseas readers.

Information and Communication Technology Indicators (ICTs): Indicators that show the extent of the development of a information and communication infrastructure. They include fixed telephone density, mobile telephone density, personal computer density, Internet access, and host density, usually expressed as a ratio of inhabitants.

Internet Public Kiosk: A booth that provides Internet access in return for a payment on a time basis.

Journalism: The job of compiling and disseminating information.

Multimedia: Combined use of several media, such as text, audio, and images. The Internet provides the ability to use one, some, or all of them to deliver content.

Purely Virtual Media: Those media that do not have any presence in the physical world, neither printed nor broadcasted.

K

Knowledge Discovery Solutions for Intelligent Enterprises

Nilmini Wickramasinghe
Cleveland State University, USA

Sushil K. Sharma
Ball State University, USA

INTRODUCTION

The exponential increase in information—primarily due to the electronic capture of data and its storage in vast data warehouses—has created a demand for analyzing the vast amount of data generated by today's organizations so that enterprises can respond quickly to fast changing markets. These applications not only involve the analysis of the data but also require sophisticated tools for analysis. Knowledge discovery technologies are the new technologies that help to analyze data and find relationships from data to finding reasons behind observable patterns. Such new discoveries can have profound impact on designing business strategies. With the massive increase in data being collected and the demands of a new breed of intelligent applications like customer relationship management, demand planning and predictive forecasting, the knowledge discovery technologies have become necessities to providing high performance and feature rich intelligent application servers for intelligent enterprises. The new knowledge based economy entirely depends upon information technology, knowledge sharing, as well as intellectual capital and knowledge management.

Knowledge management (KM) tools and technologies are the systems that integrate various legacy systems, databases, ERP systems, and data warehouse to help facilitate an organization's knowledge discovery process. Integrating all of these with advanced decision support and online real-time events would enable an organization to understand customers better and devise business strategies accordingly. Creating a competitive edge is the goal of all organizations employing knowledge discovery for decision support. They need to constantly seek information that will enable better decisions that in turn generate greater revenues, or reduce costs, or increase product quality and customer service. Knowledge discovery provides unique benefits over alternative decision support techniques, as it uncovers relationships and rules, not just data. These hidden relationships and rules exist empirically in the data because they have been derived from the way the business and its market work.

The following is a brief synopsis of the major tools and major considerations required to enable an organization to go through the key processes of knowledge sharing, knowledge distribution, knowledge creation, knowledge capture and codification as well as embracing effective knowledge management (KM).

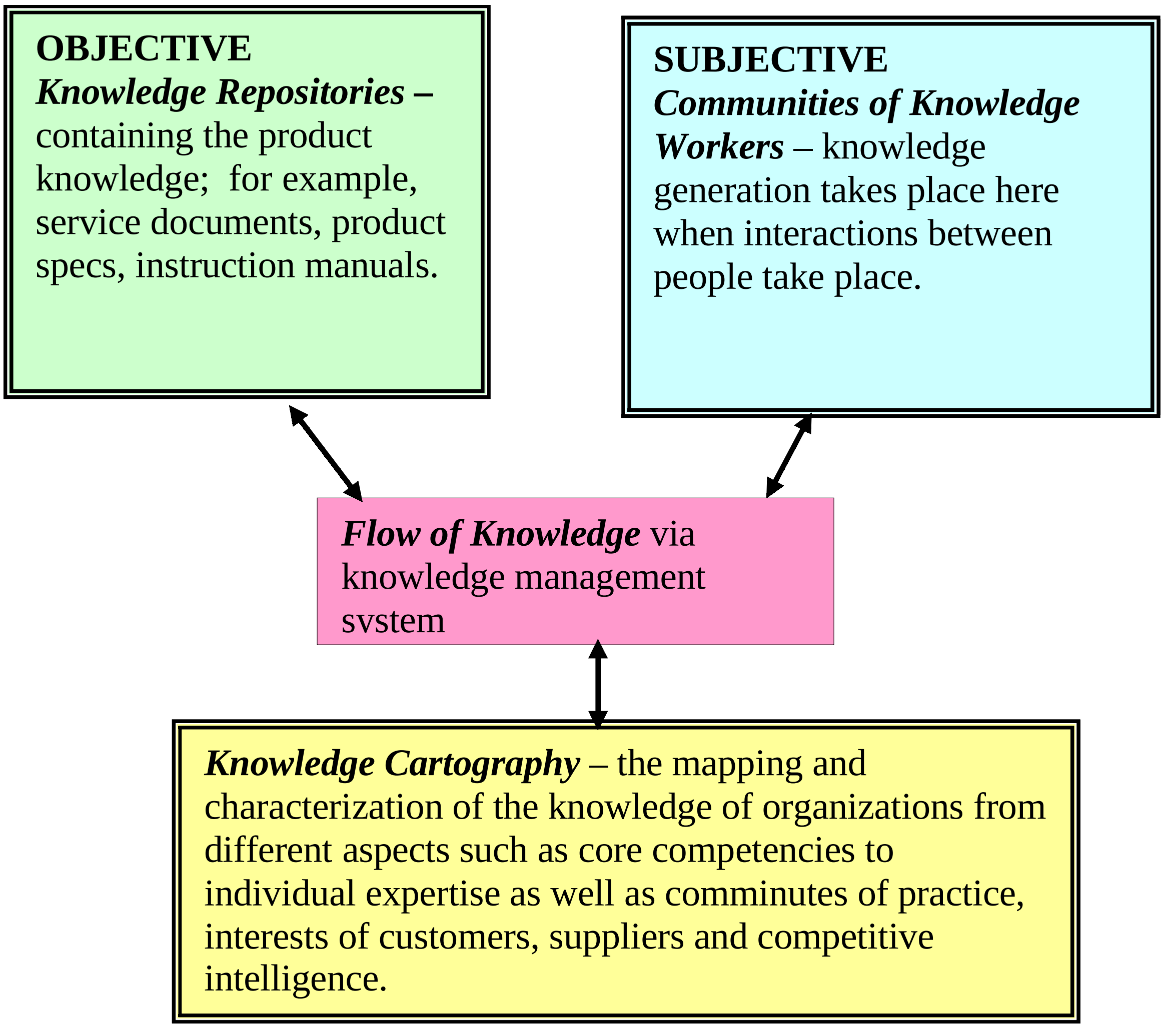
ESTABLISHMENT OF KM INFRASTRUCTURE

The KM infrastructure, in terms of tools and technologies (hardware as well as software) should be established so that knowledge can be created from any new events or activity on a continual basis. This is the most important component of a learning organization. The entire new know-how or new knowledge can only be created for exchange if the KM infrastructure is established effectively. The KM infrastructure will have a repository of knowledge, and distribution systems to distribute the knowledge to the members of organization and a facilitator system for the creation of new knowledge. A knowledge-based infrastructure will foster the creation of knowledge, and provide an integrated system to share and diffuse the knowledge in the organization (Srikantaiah & Koenig, 2000).

KNOWLEDGE ARCHITECTURE

Architecture, specifically the information technology architecture, is an integrated set of technical choices used to guide an organization in satisfying its business needs

Figure 1. The knowledge architecture (Wickramasinghe & Mills, 2001)



(Weil & Broadbent, 1998). Underlying the knowledge architecture (refer to Figure 1) is the recognition of the binary nature of knowledge; namely its objective and subjective components. What we realize when we analyze the knowledge architecture closely is that knowledge is not a clearly defined, easily identifiable phenomenon; rather it has many forms, which makes managing it even more challenging.

The knowledge architecture then recognizes these two different yet key aspects of knowledge; namely, knowledge as an object and a subject, and provides the blueprints for an all-encompassing knowledge management system (KMS). The pivotal function underlined by the knowledge architecture is the flow of knowledge. The flow of knowledge is fundamentally enabled (or not) by the knowledge management system.

KNOWLEDGE MANAGEMENT SYSTEMS

Given the importance of knowledge, systems are being developed and implemented in organizations that aim to facilitate the sharing and integration of knowledge; that is, support and facilitate the flow of knowledge. Such systems are called knowledge management systems (KMS) as distinct from transaction processing systems (TPS), management information systems (MIS), decision support systems (DSS) and executive information systems (EIS) (Alavi, 1999). For example, Cap Gemini Ernst & Young, KPMG and Acenture all have implemented KMS (Wickramsinghe, 1999). In fact, the large consulting companies were some of the first organizations to realize the benefits of knowledge management and plunge into the knowledge management abyss. These companies treat knowledge management with the same high priority as they do strategy formulation, an illustration of how important knowledge management is viewed in practice (Wickramasinghe, 1999). Essentially, these knowledge management systems use combinations of the following technologies: the Internet, intranets, extranets, browsers, data warehouses, data filters, data mining, client server, multimedia, groupware and software agents to systematically facilitate and enable the capturing, storing, and dissemination of knowledge across the organization (Alavi, 1999; Davenport & Prusak, 1998; Kanter, 1999). Unlike other types of information systems, knowledge management systems can vary dramatically across organizations. This is appropriate if we consider that each organization's intellectual assets, intangibles and knowledge should be to a large extent unique and thus systems enabling their management should in fact differ.

KNOWLEDGE MANAGEMENT TOOLS AND TECHNIQUES

KM tools and techniques are defined by their social and community role in the organization in 1) the facilitation of knowledge sharing and socialization of knowledge (production of organizational knowledge); 2) the conversion of information into knowledge through easy access, opportunities of internalization and learning (supported by the right work environment and culture); and 3) the conversion of tacit knowledge into "explicit knowledge" or information, for purposes of efficient and systematic storage, retrieval, wider sharing and application. The most useful KM tools and techniques can be grouped as those that capture and codify knowledge and those that share and distribute knowledge.

a) **Capture and codify knowledge**
   There are various tools that can be used to capture and codify knowledge (Sharma et al., 2004). These include databases, various types of artificial intelligence systems including expert systems, neural networks, fuzzy logic, genetic algorithms and intelligent or software agents.
   i) *Databases*. Databases store structured information and assist in the storing and sharing of knowledge. Knowledge can be acquired from the relationships that exist among different tables in a database. For example, the relationship that might exist between a customer table and a product table could show those products that are producing adequate margins, providing decision-makers with strategic marketing knowledge. Many different relations can exist and are only limited by the human imagination. These relational databases help users to make knowledgeable decisions, which is a goal of knowledge management. Discrete, structured information still is managed best by a database management system. However, the quest for a universal user interface has led to the requirement for access to existing database information through a Web browser.
   ii) *Case-Based Reasoning Applications.* Case-based reasoning (CBR) applications combine narratives and knowledge codification to assist in problem solving. Descriptions and facts about processes and solutions to problems are recorded and categorized. When a problem is encountered, queries or searches point to the solution. CBR applications store limited knowledge from individuals who have encountered a problem and found the solution and are useful in transferring this knowledge to others.
   iii) *Expert Systems.* Expert systems represent the knowledge of experts and typically query and guide users during a decision making process.

They focus on specific processes and typically lead the user, step by step, toward a solution. The level of knowledge required to operate these applications is usually not as high as for CBR applications. Expert systems have not been as successful as CBR in commercial applications but can still be used to teach knowledge management.

iv) *Using I-net Agents - Creating Individual Views from Unstructured Content.* The world of human communication and information has long been too voluminous and complex for any one individual to monitor and track. Agents and I-net standards are the building blocks that make individual customization of information possible in the unstructured environment of I-nets. Agents will begin to specialize and become much more than today's general purpose search engines and "push" technologies.

Two complimentary technologies have emerged that allow us to coordinate, communicate and even organize information, without rigid, one-size-fits-all structures. The first is the Internet/Web technologies that are referred as I-net technology and the second is the evolution of software agents. Together, these technologies are the new-age building blocks for robust information architectures, designed to help information consumers find what they are looking for in the way that they want to find it. The Web and software agents make it possible to build sophisticated, well performing information brokers designed to deliver content from multiple sources to each individual, in the individual's specific context and under the individual's own control. The software agents supported with I-net infrastructure can be highly effective tools for individualizing the organization and management of distributed information.

b) **Systems to share and distribute knowledge**

Computer networks provide an effective medium for the communication and development of knowledge management. The Internet and organizational intranets are used as a basic infrastructure for knowledge management. Intranets are rapidly becoming the primary information infrastructure for enterprises. An intranet is basically a platform based on Internet principles accessible only to members of an organization/community. The intranet can provide the platform for a safe and secured information management system within the organization, help people to collaborate as virtual teams, crossing boundaries of geography and time. While the Internet is an open-access platform, the intranet, however, is restricted to members of a community/organization through multi-layered security controls. The same platform can be extended to an outer ring (e.g., dealer networks, registered customers, online members, etc.), with limited accessibility, as an extranet. The extranet can be a meaningful platform for knowledge generation and sharing, in building relationships, and in enhancing the quality and effectiveness of service/support. The systems that are used for share and distribute knowledge could be: group collaboration systems; groupware, intranets, extranets and Internet, office systems; word processing, desktop publishing, Web publishing and so forth.

HOW TO BECOME A KNOWLEDGE-BASED ENTERPRISE

Just implementing a knowledge management system does not make an organization a knowledge based business. For an organization to become a knowledge-based business several aspects must be considered. An organization that values knowledge must integrate knowledge into its business strategy and sell it as a key part of its products and services. To do this requires a strong commitment to knowledge management directed from the top of the organization. Furthermore, the knowledge architecture should be designed that is appropriate to the specific organization given its industry and the activities, products or services it may provide. From the knowledge architecture it is important to consider the organization's structure as well as its culture. Do the structure and culture support a knowledge-sharing environment or perhaps a more team focussed, sharing culture needs to be fostered (Newell et al., 2002). Then it is necessary to consider the processes of generating, representing, accessing and transferring knowledge throughout the organization and the technology that is required to enable this. Finally, a knowledge based business should also enable organizational learning to take place so that the knowledge that is captured is always updated and current and the organization is continually improving and refining its product or service.

K

CONCLUSION

This discussion has attempted to provide a synopsis of the major technologies for knowledge management. We did this by firstly discussing the knowledge management infrastructure. Then we analyzed the knowledge architecture, highlighting the subjective and objective aspects of KM. From this we discussed knowledge management systems. Finally we discussed how to become a knowledge-based business and that by adopting these techniques and strategies organizations will be able to truly embrace knowledge discovery solutions and thereby maximize their knowledge assets.

KEY TERMS

KM Infrastructure: The tools and technologies (the specific tools required to capture and codify organizational knowledge, specific tools required to share and distribute organizational knowledge) that are required to support and facilitate KM in the organization. KM tools and technologies are the systems that integrate various legacy systems, databases, ERP systems, and data warehouse to help organizations to create and use KM systems in the organization.

Knowledge: Knowledge is more comprehensive than data or information. It is a mix of experience, values, contextual information, expert insights, and grounded intuition that actively enables performance, problem solving, decision-making, learning, and teaching.

Knowledge Architecture: The blueprints of subjective and objective knowledge, its flows and cartography of knowledge within the organization.

Knowledge Assets: The knowledge regarding markets, products, technologies, processes and organizations that a business owns or needs to own and which enable its business processes to generate profits, add value, and so forth.

Knowledge-Based Enterprises: Knowledge-based enterprises are those enterprises that derive the most value — from intellectual rather than physical assets. Knowledge-based enterprise is a firm that is fully embracing knowledge management and committed to fostering continuous learning.

Knowledge Management (KM): KM is the process through which organizations generate value from their intellectual and knowledge-based assets. Most often, generating value from such assets involves sharing them among employees, departments and even with other companies in an effort to devise best practices. KM is a newly emerging interdisciplinary business approach that involves utilizing people, processes and technologies to create, store and transfer knowledge.

Knowledge Discovery Using Heuristics

Alina Lazar
Youngstown State University, USA

INTRODUCTION

Uninformed or blind search, which processes and evaluates all nodes of a search space in the worst case, is not realistic for extracting knowledge from large data sets because of time constraints that are closely related to the dimension of the data. Generally, the search space increases exponentially with problem size, thereby limiting the size of problems that can realistically be solved using exact techniques such as exhaustive search. An alternative solution is represented by heuristic techniques, which can provide much help in areas where classical search methods failed.

The word "heuristic" comes from Greek and means "to know," "to find," "to discover" or "to guide an investigation". Specifically, "Heuristics are techniques which seek good (near-optimal) solutions at a reasonable computational cost without being able to guarantee either feasibility or optimality, or even in many cases to state how close to optimality a particular feasible solution is" (Russell & Norvig, 1995).

Heuristic refers to any techniques that improve the average-case performance on a problem-solving task but do not necessarily improve the worst-case performance. Heuristic techniques search the problem space "intelligently" using knowledge of previously tried solutions to guide the search into fruitful areas of the search space. Often, search spaces are so large that only heuristic search can produce a solution in reasonable time. These techniques improve the efficiency of a search process, sometimes by sacrificing the completeness or the optimality of the solution. Heuristics are estimates of the distance remaining to the goal, estimates computed based on the domain knowledge.

The domain knowledge provides help to heuristics in guiding the search and can be represented in a variety of knowledge formats. These formats include patterns, networks, trees, graphs, version spaces, rule sets, equations, and contingency tables. With regard to heuristics, there are a number of generic approaches such as greedy, A* search, tabu search, simulating annealing, and population-based heuristics. The heuristic methods can be applied to a wide class of problems in optimization, classification, statistics, recognition, planning and design.

Of special interest is the integration of heuristic search principles with the dynamic processes in which data become available in successive stages, or where data and inputs are subject to uncertainties or with large-scale data sets. The integration is a vehicle to generate data driven hypotheses.

The kind of knowledge produced, and the heuristic search algorithm selected, will reflect the nature of the data analysis task. The hypotheses are being represented as sets of decision rules and the extracted rules will be represented in terms of rough sets. Rough sets were selected because of the nature of our data sets.

From a mathematical point of view, the problems can be formulated in terms of the well-known, minimal set cover problem, which is a combinatorial optimization problem.

Traditional methods for combinatorial optimization problems are not appropriate here for several reasons. These methods are NP-hard in the worst case and would be costly to use given the size of the data sets. Also, since large data sets are dynamical in nature, adding new data would require running the traditional combinatorial approach again.

The techniques used to solve these difficult optimization problems have slowly evolved from constructive methods, like uniformed search, to local search techniques and to population-based algorithms. Our research goal was to use blend population-based algorithms with methods dealing with uncertainty in order to induce rules from large data sets.

BACKGROUND

Population-based heuristic methods are iterative solution techniques that handle a population of individuals who are evolving according to a given search strategy. At each iteration, periods of self-adaptation (mutations) alternate with periods of cooperation (crossover), and periods of competition (selection). The population-based heuristic search (Conrad, 1978) is dependent on the following components: the knowledge representation for the specific problem to solve and the search strategy or the evolution process. The adaptability of an individual represents its ability to survive in an uncertain environment. Artificial intelligence researchers have explored different ways to represent uncertainty (Russell & Norvig, 1995): belief networks, default reasoning, Dempster-Shafer theory, fuzzy sets theory, rough sets theory.

The learning task will require a representation that explicitly deals with uncertainty. The evolutionary learning methods that are employed must be able to work with such a representation. In this article we look first at basic ways to represent uncertainty in developing rules. And, then we will investigate how that uncertain knowledge can be used to direct evolutionary search and learning.

Uncertainty, as well as evolution, is a part of nature. When humans describe complex environments, they use linguistic descriptors of real-world circumstances, which are often not precise, but rather “fuzzy”. The theory of fuzzy sets (Zadeh, 1965) provides an effective method of describing the behavior of a system that is too complex to be handled with the classical precise mathematical analysis.

The theory of rough sets (Pawlak, 1991) emerged as another mathematical approach for dealing with uncertainty that arises from inexact, noisy or incomplete information. Fuzzy sets theory assumes that the membership of the objects in some set is defined as a degree ranging over the interval [0,1]. Rough sets theory focuses on the ambiguity caused by the limited distinction between objects in a given domain.

Fuzzy sets have been employed to represent rules generated by evolutionary learning systems. Using fuzzy concepts, Hu and Tzeng (2003) tried to overcome the limitations of the conventional rule-based classifier system (Holland, 1975) when representing continuous variables.

Likewise, fuzzy functions have been used to describe and update knowledge in cultural algorithms. First, Reynolds (1994) employed a fuzzy acceptance and influence function in the solution of real-valued constrained optimization problems. Following the same idea, Zhu designed a fully fuzzy cultural algorithm (Reynolds & Zhu, 2001) that included a fuzzy knowledge representation scheme in order to deal with the continuous variables in the belief space, as well as a fuzzy acceptance and influence function. All these approaches were tested on real-values function optimization problems. Jin (2000) used a fuzzy knowledge representation for normative knowledge in the belief space of cultural algorithms to solve the real-valued constrained function optimization.

The design of a fuzzy representation system is not an easy job, because the membership functions should be carefully chosen, and the procedures that use these functions should be specified precisely. The problem is to optimize the fuzzy membership functions for a problem and to find optimum plans related to the fuzzy performance measures. It is a natural approach to use heuristics (i.e., evolutionary algorithms) to solve this task.

Another approach to represent uncertainty is with rough sets. Rough sets are based on equivalence relations and set approximations, and the algorithms for computing rough set properties are combinatorial in nature. Wroblewski (1995) implemented a genetic algorithm for computing reducts, based on permutation code as well as a “greedy” algorithm. Another approach for building reducts is described by Vinterbo (2000) and it is based on the set cover problem, in particular on finding minimal hitting sets using a classical genetic algorithm. Finding a minimal set of decision rules or a satisfactory set is an NP-complete problem. Agotnes (1999) used a genetic algorithm to build an optimal set of decision rules, where the fitness function was based on the quality of each rule. Decision rules extracted via rough set theory could be used to represent hard coded information from neural networks (Lazar & Sethi, 1999).

Evolution can be defined in one word, “adaptation” in an uncertain environment. Nature has a robust way of dealing with the adaptation of organisms to all kinds of changes and to evolve successful organisms. According to the principles of natural selection, the organisms that have a good performance in a given environment survive and reproduce, whereas the others die off. After reproduction, a new generation of offspring derived from the members of the previous generation is formed. The selection of parents from these offspring is often based upon fitness. Changes in the environment will affect the population of organisms through the random mutations. Mayr said, “Evolution is a dynamic, two-step process of random variation and selection” (Fogel, 1995). Using examples from natural systems and theories of adaptive behavior, researchers have been trying to build heuristic evolutionary learning systems.

Evolutionary algorithms are heuristic optimization methods inspired from natural evolution processes. Currently there are three basic population-only mechanisms that model evolution: genetic algorithms, evolution strategies and evolutionary programming. Each of the methods models the evolution of a population of individuals at a different scale and applies election and reproduction operators to find an individual that is fit with regard of the fitness function. The genetic algorithm models evolution at the gene scale, but evolutionary strategies and evolutionary programming model evolution at the species level.

The cultural algorithms (Reynolds, 1994) approach adds another level to the evolutionary process inspired from the human societies and cultural evolution. It adds to the population space, belief space. The belief space will be a collection of symbolic knowledge that will be used to guide the evolution of the population.

Besides the rule-based methods, decision trees (Ziarko, 2003) are well known for their inductive learning capabilities. Any decision tree can be reformulated as a set of rules. One of the problems related to the decision trees is finding the smallest decision tree. Simple heuristics can solve the problem. Researchers have tried to integrate genetic algorithms with decision tree learning in order to solve complex classification problems. Bala (1997) applied this methodology for difficult visual recognition problems involving satellite and facial image data. Other researchers combined the genetic algorithms or evolutionary strategies with neural networks.

Reynolds (2000) investigated the use of cultural algorithms to guide decision tree learning. The data were taken from a real-world archeological database, with a collection of sites found in Valley of Oaxaca, Mexico. The problem was to localize the sites that present evidence of warfare as opposed to those that did not. Evolution-based techniques were used to mine a large-scale spatial data set describing the interactions of agents over several occupational periods in the ancient valley of Oaxaca, Mexico. Specifically, we wanted to extract from the data set spatial constraints on the interaction of agents in each temporal period.

One of the major questions was how to represent the constraint knowledge. Popular data mining methods such as decision trees work well with data collected in a quantitative manner. However, the conditions under which the surface survey data were collected here introduced some uncertainty into the data. Would a representation that explicitly incorporated uncertainty into its structure produce a more efficient representation of the constraints here than one that did not? This is important since the complexity of the constraint set will impact the complexity of the simulation that uses those rules.

We use genetic algorithms to guide the search for a collection of rough set rules to describe constraints on the location of particular types of warfare in the Valley. Since warfare was a major factor in the social evolution in the Valley, the constraints reflecting its spatial and temporal patterning are important ingredients in the model. The rules generated are compared with those produced by a decision tree (Reynolds, 2000) algorithm. In each of the phases examined, the best rule set that used the rough set representation always had fewer conditions in it, and the average rule length was less than that for the decision tree approach in every case but one. In that case they were equal. The differences were most marked in those periods where the warfare patterns were most complex. It was suggested that the differences reflect the inclusion of noise factors as explicit terms in the decision tree representation and their exclusion in the rough sets approach.

Table 1. Comparison between decision trees and rough set rule induction

	Decision Trees	**Rough Set Rules**
Advantages	Easy to understand	Very expressive Modular knowledge Good with missing data They handle imprecise data
Disadvantages	May be difficult to use with continuous data They look at simple combinations of attributes They need to break numeric fields into fixed ranges Not very good with inexact data Not flexible No way to handle missing data Cannot easily approach large data sets May have over fitting Less accurate predictions	Can be memory intensive Can be computationally intensive

A comparison (Table 1) of two decision systems demonstrates that the rough set approach has fewer disadvantages than for the decision tree approach.

In addition, the rough set approach needs to evaluate fewer conditions relative to the inconclusive ones than the decision tree approach. These differences, it is argued, result from the explicit consideration of uncertainty into a period that is more complex and more prone to the introduction of such uncertainty than previous periods.

FUTURE TRENDS

The focus of the comparisons here was on the syntactic or structural differences in the decision systems produced. In future work a comparison of the semantic differences will be accomplished by using the approaches to produce alternative ontologies in the agent-based simulation and assess the differences that are produced. In other words, do the syntactic differences reflect semantic differences in simulation model performance? And, what impact does the use of uncertainty to represent ontological knowledge of the agents have on the basic simulation results?

CONCLUSION

Genetic algorithms, as population-based algorithms, are good vehicles in which to build meta-level heuristics to guide the search more efficiently. That knowledge, rough sets concepts, or rules, can be employed to direct the evolutionary search. The rules can reflect spatial and temporal patterns that will guide the generation of new candidate search objects by the evolutionary engine. The spatial and temporal continuity of the data will facilitate this process.

KEY TERMS

Cultural Algorithms: Another kind of evolutionary algorithm that adds a belief space to the usual population space from the genetic algorithms in order to improve the search. It is inspired from human societies and cultural evolution.

Evolutionary Computation: Computer-based problem solving systems that use computational models of evolutionary processes as the key elements in design and implementation.

Evolutionary Strategies: Evolutionary algorithms, devoted to the parametric optimization.

Fuzzy Set Theory: Fuzzy set theory replaces the two-valued set-membership function with a real-valued function; that is, membership is treated as a probability, or as a degree of truthfulness.

Genetic Algorithms: An evolutionary algorithm that generates each individual from some encoded form known as a “chromosome” or “genome”. Chromosomes are combined or mutated to breed new individuals. “Crossover,” the kind of recombination of chromosomes found in sexual reproduction in nature, is often also used in GAs. Here, an offspring’s chromosome is created by joining segments chosen alternately from each of two parents’ chromosomes, which are of fixed length.

Heuristics: A rule of thumb, simplification, or educated guess that reduces or limits the search for solutions in domains that are difficult and poorly understood. Unlike algorithms, heuristics do not guarantee optimal, or even feasible, solutions and are often used with no theoretical guarantee.

Knowledge Discovery: In data sets, is the process of identifying valid, novel, potentially useful, and ultimately understandable patterns/models in data.

Rough Set Theory: Rough set theory is a new mathematical tool to deal with vagueness and uncertainty. Any vague concept is replaced by a pair of precise concepts - called the lower and the upper approximation of the vague concept. The lower approximation consists of all objects that surely belong to the concept and the upper approximation contains all objects that possibly belong to the concept.

K

Knowledge Exchange in Electronic Networks of Practice

Robin Teigland
Stockholm School of Economics, Sweden

Molly Wasko
Florida State University, USA

INTRODUCTION

Communities of practice (CoPs) are regarded as essential building blocks of the knowledge economy, and organizations are promoting them as sources of competitive advantage and facilitators of organizational learning. Within organizations, CoPs have traditionally emerged through the mutual engagement in work by individuals who are either physically co-located or who frequently meet face-to-face (Orr, 1996; Wenger, 1998). In an effort to replicate traditional CoPs online and in response to hypercompetitive conditions and increasing complexity, numerous organizations have implemented online networks to facilitate knowledge sharing. We refer to these online social structures focused on knowledge exchange as "electronic networks of practice" (ENoPs).

Although prior researchers have used the term "community" to describe these structures (i.e., electronic community of practice, electronic community, or virtual community), following Brown & Duguid (2000) we use the term "network of practice" to distinguish these social structures from "communities of practice." Networks of practice refer to social structures that link similar individuals engaged in a shared practice, but who may never get to know one another or meet face-to-face. These networks typically consist of weak ties where individuals coordinate through third parties such as professional associations or indirect ties such as newsletters, Web sites, bulletin boards, and listservs (Brown & Duguid, 2000). Thus, we adopt the term network rather than community to distinguish between collectives characterized by sparsely connected weak, indirect ties and collectives where members are connected through frequent face-to-face interactions and direct personal ties. We add the term "electronic" to highlight that communication and coordination within this type of network of practice occurs through asynchronous computer-mediated communication, such as bulletin boards, listservs, etc., and that the focal network structure exists solely in electronic space. The purpose of the network is to facilitate knowledge exchange around a specific practice, and the network structure consists of the aggregation of ties between individuals that are created when individuals post and respond to messages. More precisely, we define an electronic network of practice as *a self-organizing, open activity system focused on a shared practice that exists through computer-mediated communication*. These four defining characteristics are essential for understanding how individuals communicate, coordinate, and interact in these networks.

While traditional, face-to-face CoPs within organizations have received considerable attention, we know much less about ENoPs and knowledge exchange supported by them. Initial research suggests that ENoP participation provides access to useful sources of technical advice for organizational members (Constant, Sproull & Kiesler, 1996). However, there is ample evidence that simply investing in information technologies does not directly enhance knowledge sharing. In fact, researchers estimate that 50-70% of knowledge management projects fail to meet expectations, and they attribute these failure rates to an over-reliance on information technology (Ambrosio, 2000). Thus, a key question for researchers and managers is how to turn an empty electronic space into a vital, active forum devoted to knowledge exchange.

The goal of this chapter is to provide a discussion of ENoPs for researchers and managers interested in studying and supporting these networks. We begin by presenting the characteristics that define ENoPs before discussing two questions related to individual ENoP participation: (1) why do people participate and help others in ENoPs and (2) does participation result in positive knowledge outcomes? Finally, we present and discuss findings from a recent study in a global consulting organization that investigated these questions.

BACKGROUND: DEFINING ELECTRONIC NETWORKS OF PRACTICE

While ENoPs are similar to CoPs in that they are collectives where individuals working on similar problems self-organize to help each other and share perspectives about their practice, they differ in terms of the primary means of communication. In CoPs, mutual engagement typically occurs through physically co-located, face-to-face interactions. However, in ENoPs, individuals mutually engage through asynchronous, text-based computer-mediated communication, such as bulletin boards, listservs, and newsgroups. By posting messages to the ENoP, individuals requiring help may quickly reach out to other participants who then provide valuable knowledge and insight in response. Participants may also share personal experiences and discuss relevant practice issues (Wasko & Faraj, 2000). This posting and responding to messages is recorded like a conversation between participants, representing active mutual engagement in problem solving. However, unlike face-to-face interactions in CoPs where participants perceive various social and visual cues and have access to immediate feedback, in electronic communication these cues are filtered out. As a result, ENoPs represent a lean medium of exchange and the technology impacts how knowledge is actually exchanged between participants (Daft & Lengel, 1986). This mutual engagement also distinguishes ENoPs from more static forms of electronic knowledge exchange, such as document repositories and other databases.

A second characteristic of ENoPs is that the technology creates a weak structural link between an ubiquitous, unlimited number of like-minded "strangers." Participation is open to anyone with a connection anywhere in the world, and as a result, constraints due to size are eliminated. Thus, knowledge exchange occurs between people regardless of personal acquaintance, familiarity, and location. Knowledge seekers are not limited to asking only others whom they personally know or are able to identify, thus increasing the likelihood of connecting with someone willing and able to help. Additionally, membership is fluid, making it difficult to create and enforce boundaries. This sharply contrasts with the tightly knit relationships between specific members that typify CoP structures. Also, this characteristic separates ENoPs from virtual teams, where members are designated and assigned.

Third, ENoP participation is voluntary. Individuals choose whether or not they want to participate, as well as how often - ranging from simply lurking to becoming an active participant. Additionally, individuals have choices about how they participate, deciding whether or not to post questions, replies, or both. Finally, individuals voluntarily determine what they want to contribute and what knowledge they are willing to disclose as well as the length of the messages they contribute, thus influencing the quality and helpfulness of the knowledge exchanged. Because participation is voluntary, a knowledge seeker has no control over who responds to their questions or who uses their responses. This sharply contrasts with CoPs where people typically know one another and interact over time, creating expectations of obligation and reciprocity that are enforceable through social sanctions. This voluntary participation further distinguishes ENoPs from virtual teams, where participants are expected to coordinate efforts to deliver a specific outcome.

Finally, mutual engagement in ENoPs is typically archived and available to all participants in the network. This creates an online repository of knowledge that can be accessed later by any interested individual, regardless of his or her ENoP tenure or participation in the original engagement. This contrasts with CoPs where access to advice is limited to whom you know, and knowledge is exchanged between seeker and provider without necessarily being made available to other members of the CoP.

CURRENT ENOP RESEARCH THEMES

ENoP research to date tends to be limited to an investigation of individual motives behind participation and knowledge sharing in these networks (e.g., Lakhani and von Hippel, 2000; Wasko and Faraj, 2000). Studies have revealed that individuals share knowledge with "strangers" due to expectations of returns for themselves (e.g., increased reputation, enjoyment, etc.) as well as for the network (e.g., advancing the community). Furthermore, research by Lakhani & von Hippel indicates that individuals make discretionary choices regarding their willingness to share knowledge and help others in ENoPs. However, while ENoP research is increasing, there is little research other than Constant et al.'s 1996 study specifically focusing on *intra-organizational* ENoPs. Thus, one question to ask is, why do individuals participate and help others in intra-organizational EnoPs?

Secondly, numerous organizations are attempting to support or even construct various forms of ENoPs within and between their organizations (e.g., Wenger et al., 2002). Similar to other knowledge management initiatives implemented to enhance organizational performance, management's hope is that these efforts will positively affect individual behavior in the workplace and thus ultimately drive increases in firm performance (Davenport & Prusak, 1998; Wenger et al., 2002). However, there is a dearth of solid academic empirical support for this positive relationship, with researchers paying little systematic attention to the relationship to performance at any level (Teigland, 2003). Thus, a second question is, does participation in intra-organizational ENoPs result in positive knowledge outcomes?

Below we further develop these two questions. Additionally, we provide some preliminary findings to these questions based on a study conducted in the Nordic operations (Denmark, Finland, Norway, and Sweden) of Cap Gemini (performed prior to the merger of Cap Gemini and Ernst & Young Consulting). Cap Gemini had numerous ENoPs to enhance the company's knowledge management activities. We chose one ENoP, referred to as the NCN MS Community. This ENoP had 345 members throughout the Nordic countries and was designed for individuals who worked with applying Microsoft products in their Cap Gemini responsibilities. It was based on listserv (mailing list) technology, with members using the listserv when they needed help performing their work tasks.

Why Do People Participate and Help Others in Intra-Organizational ENoPs?

Researchers have proposed that one theoretical lens with which to investigate ENoPs is the theory of collective action and public goods (Fulk, Flanagin, Kalman, Monge & Ryan, 1996; Monge, Fulk, Kalman, Flanagin, Parnassa & Rumsey, 1998). A public good, for example a public park, is a resource that is created only if a collective, or a group of individuals, contributes to its production. However, a public good cannot be withheld from any member of the collective, even if he or she does not participate in the production or maintenance of the good (Olson, 1965; Samuelson, 1954). With public goods, the optimal individual decision is to enjoy the public good without contributing anything to its creation or maintenance and to simply free-ride on the efforts of others. However, if everyone were to act rationally and decide not to contribute, then the good would never be created and everyone would be worse off.

ENoPs are a type of collective in which the knowledge exchanged and created is the collective's public good. As discussed above, mutual engagement in ENoPs is open and voluntary. Participation typically results in the creation of a knowledge repository of archived messages that is available to all individuals regardless of their original participation. This begs the question then – why would individuals invest their valuable time and effort helping strangers in an ENoP if it is in their best interest not to do so?

Our Cap Gemini findings suggest that people who help others in this ENoP are not acting irrationally. Rather, our findings suggest that through ENoP participation, individuals are able to improve their own level of technical competence, helping them to remain competitive in relation to their technical skills. For example, through the ENoP, individuals were able to access help and advice not available locally and individuals learned by receiving help and information related to their work tasks. Additionally, they felt that participation enabled them to keep up-to-date with technical developments and to know who was actively working in different areas. Second, a key dynamic underlying knowledge exchange in this ENoP was a strong norm of reciprocity between the members, or a strong sense of paying back. In other words, to receive help from the ENoP, individuals felt obligated to help others in return. Finally, another key motive underlying why people participated was related to organizational identification or a strong sense of organizational citizenship. Respondents felt that helping others in the ENoP was part of their job at Cap Gemini. Through their participation, they were able to improve the level of technical competence of the ENoP as a whole and ultimately Cap Gemini's competitiveness.

Does Intra-Organizational ENoP Participation Affect Knowledge Outcomes?

The second question deals with the relationship between intra-organizational ENoP participation and knowledge outcomes and, in particular, whether ENoPs exhibit the same degree of continuous incremental innovation as CoPs. As mentioned above, CoPs are generally characterized by rich, face-to-face exchange through person-to-person interactions. Mutual engagement between individuals in CoPs creates boundaries around the shared practice within which the community's knowledge is embedded, and tacit knowledge is shared relatively easily between individuals within the community, often without ever being made explicit. These tightly knit social structures facilitate the creation of a shared identity through the development of a common language, social capital (such as norms, trust, and obligations), boundaries, and social controls, resulting in strong social ties between individuals. These characteristics have been argued as essential for the continuous incremental improvements in the community's practice and the reason why CoPs are centers for learning and innovation within organizations (Brown & Duguid, 1991, 1998; Wenger, 1998).

In contrast, the ability of ENoP members to develop a shared identity and common language through narration, collaboration, and social construction is hampered due to the communication occurring through text-based, asynchronous, computer-mediated communication. However, ENoPs have a greater reach than CoPs, supporting the creation of weak electronic "bridging ties" between an unlimited number of like-minded others. Due to this extensive reach, individuals benefit from ENoPs, gaining access to new information, expertise, and ideas that are often not available locally. As such, the weak tie relationships in ENoPs potentially increase an individual's access to greater resources and advice than those locally available. Thus, one question to ask is whether this extended reach results in positive knowledge outcomes. In other words, are weak electronic links, like their strong tie counterparts, also useful for supporting knowledge sharing and innovation?

Our Cap Gemini research provided some interesting results. First, respondents indicated that ENoP participation had indeed helped them. Participation greatly improved the speed with which respondents were able to solve their problems, and individuals were able to learn and receive new insights from the ENoP. Statistical analysis of the survey responses also suggested that the level of ENoP participation was more important for supporting positive knowledge outcomes in terms of knowledge acquisition and contribution than the length of time an individual had participated. This implies that ENoP newcomers can reap the same benefits of participation as long standing participants. Additionally, both knowledge acquisition from and knowledge contribution to the ENoP were positively related to individual performance. However, tenure in the ENoP was not associated with higher rates of participation nor with individual performance. Finally, and of considerable interest, the results suggested that individuals who relied more on their co-located colleagues and less on the ENoP for help or advice with their work tasks reported no associations with knowledge acquisition or knowledge contribution. In fact, the survey results indicated that *reliance on co-located colleagues is associated with lower levels of self-reported individual performance*.

FUTURE TRENDS AND CONCLUSION

In conclusion, this discussion of ENoPs for researchers and managers began by presenting ENoP characteristics before developing two questions related to intra-organizational ENoP participation and discussing these based on a study of a successful ENoP at Cap Gemini. Our results suggest that ENoPs may support the complex interactions necessary for the sharing of knowledge between individuals, thus facilitating continuous incremental innovation and positive knowledge outcomes. It appears that individuals value accessing new insights and ideas through weak electronic links that transcend their strong tie networks.

Additionally, while research on CoPs and face-to-face interactions with colleagues has provided evidence of knowledge exchange, learning, and innovation, it has also been suggested that tightly knit CoPs may lead to the "not invented here" syndrome or the resistance to new ideas not locally developed. Our finding that individuals who participate in ENoPs outperform colleagues who primarily rely on co-located colleagues for knowledge and advice supports the latter argument. This suggests that knowledge in tightly knit CoPs may be largely redundant, thus providing little additional information over what an individual may already know and impeding the development of new and creative ideas (Granovetter, 1983). Therefore, managers concerned with improving knowledge exchange should note that the highly efficient structures that support knowledge integration in CoPs may evolve into core rigidities and competency traps – inappropriate knowledge sets that preserve the status quo and limit new insights (Leonard-Barton, 1992; Levitt & March, 1988). Our findings suggest that one way to alleviate this concern is to use ENoPs to create electronic bridging links between strong tie communities to enhance the development of new ideas and innovations.

In terms of limitations, our research provided little explanation of how ENoP social contexts develop over time, what factors influence development, and how motives and social context interact and change over time.

Thus, future research could examine ENoP dynamics as well as how individual participation in various ENoPs changes over time. Future research could also compare the dynamics of intra-organizational and inter-organizational ENoPs. Finally, the relationship between ENoP participation and the characteristics of the communication technology supporting the ENoP, e.g., bulletin board, listserv, etc., should be investigated.

KEY TERMS

Bulletin Board: A discussion forum, similar to that of Usenet newsgroups, in which questions and responses are connected in a “thread,” resembling a conversation.

Collective Action: The voluntary cooperation of a group of individuals that typically involves the production of a public or semi-public good.

Community of Practice: An emergent group of a limited number of individuals (generally in the same location) informally and contextually bound through close face-to-face interactions in the pursuit of a common enterprise.

Electronic Network of Practice: An emergent group of an unlimited number of dispersed individuals working on similar tasks using a similar competence whose communication channel is purely electronic.

Free-riding: The act of enjoying the public good without contributing anything to its creation or maintenance.

Listserv: Mailing lists that forward e-mail messages to everyone who has subscribed to the list. Members seldom know each other due to the large size of these lists.

Lurking: The act of reading interactions between electronic network of practice participants but seldom if ever publicly contributing anything.

Public Good: Resources from which all individuals in the collective may benefit regardless of whether they have contributed to providing the good.

Knowledge Management and Social Learning

INTRODUCTION

There are probably as many variations of knowledge management definitions as there are practitioners and researchers in the discipline. Complete consensus in such a group would be a surprising finding. This is because the two words are loaded with pre-existing meanings that do not always sit comfortably in juxtaposition, so what it means to "manage knowledge" is difficult to ascertain, and hence comes to mean different things to different people.

We do know, however, that knowledge exists in the minds of individuals and is generated and shaped through interaction with others. In an organizational setting, knowledge management must, *at the very least*, be about how knowledge is acquired, constructed, transferred, and otherwise shared with other members of the organization, in a way that seeks to achieve the organization's objectives. Put another way, knowledge management seeks to harness the power of individuals by supporting them with information technologies and other tools, with the broad aim of enhancing the *learning capability* of individuals, groups, and, in turn, organizations.

BACKGROUND

In this article, we examine both theoretical and practical socio-cultural aspects of knowledge management based on years of research by the authors in a large and diverse organization. The study involved numerous functional settings of the organization and the researchers used qualitative and quantitative methodology to gather data. Elements required to build an organizational culture that supports knowledge management are discussed. Unless otherwise specified, words in double quotes in the text are direct quotes from personnel in research settings.

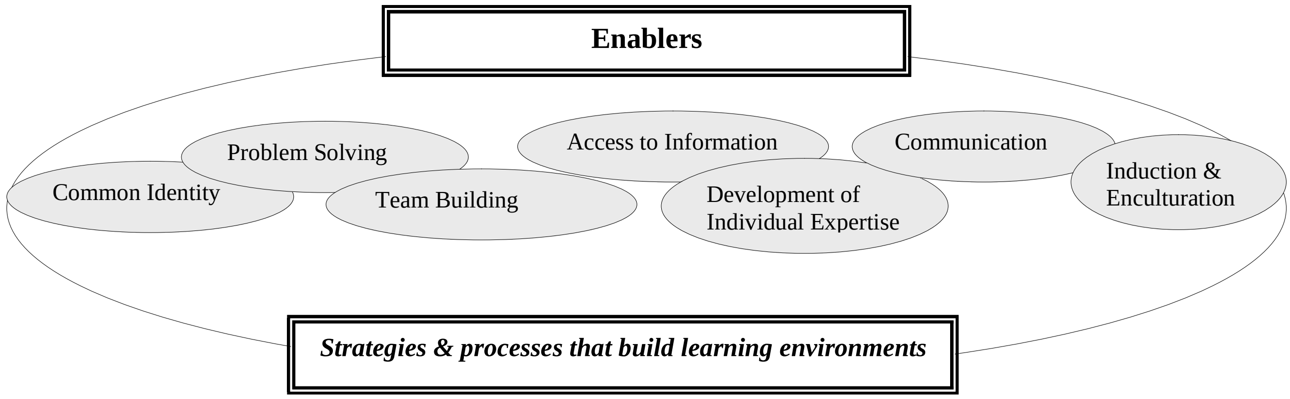
MAIN THRUST OF THE ARTICLE

The research team identified seven basic categories that constitute enabling processes and strategies to facilitate social learning: common identity; problem solving; team building; access to information; development of individual expertise; communication; and induction and enculturation (see Figure 1).

Common identity: a common ground/understanding to which many people/groups can subscribe, and requires a shift from seeing oneself as separate to seeing oneself as connected to and part of an organization unit. Based on our research, motivators impacting on *common identity* are: goal alignment, cultural identity, gendered identity, language, morale, and workplace design (spatial and physical design).

- Doney, Cannon et al. (1998) discuss the relationship between goal alignment and group cohesiveness, claiming that the extent of group cohesiveness relies on the extent to which a team's goals are clear and accepted and also on the degree to which all members adopt team behaviors.
- The term cultural identity refers to a member's sense of self in relation to the specific "tribe" and "tradition" to which they belong and how this distinctiveness applies in their workplace. Cultural identity is another important motivator for social learning because, like common identity, it impacts on the extent to which staff feels that they are part of the system or alienated from it.
- Gendered identity relates specifically to one's sense of self, which is imbued with the social, cultural and historical constructions surrounding femininity and masculinity. Gender identity, because of its relationship with common identity, was also seen to impact on social learning.
- Language is another important factor fundamental to the overall social learning processes. By reflect-

Figure 1: Constructs enabling social learning



ing the social and political relationship between various members, language can impact on common identity. Language is also important in terms of creating a shared understanding among workers and their relationship to the wider organization. "Words are bullets. Never, never use imprecise language." Thus learning the specific work-related language is of central importance to broader social learning development, and is an important outcome of the enculturation process.

- Morale has been a significant focus in the overall study because the research team found evidence of low morale being coupled with higher levels of alienation towards senior management. Such alienation has obvious implications for the broader understanding of a common identity and thus for social learning.
- Workplace design and proximity also threatens common identity when staff are not working in the same location. "[Building X] and us. We don't see them. There is not any spirit that we are belonging to one branch. I have more to do with [a specific area] than anything else and I've made some good contacts in there,... who I sit around with."

Problem solving: a core activity. It fosters social learning, because each problem represents an opportunity to generate knowledge. Motivators associated with this enabler are: networking, perceptions of the organization, systemic understanding, and time for inquiry and reflection.

- An individual's personal and social networks are an important means of acquiring, propagating, and sharing knowledge. As Davenport and Prusack (1998) claim, when those who are in a position of "know-how" share their expertise they contribute to problem solving. Personal networks were seen to function as channels supporting both "information pull" and "information push".
- Individual and shared perceptions of the organization, and how they operate, provide an essential backdrop to problem solving within an organizational context. These perceptions may consist of deeply ingrained assumptions, generalizations, or even pictures or images that influence how people understand their organizational world and how they should act within it (Senge, 1992). The importance of these perceptions cannot be stressed enough, because they directly influence the construction of individuals' knowledge and understandings that they draw upon in their day-to-day-activities.
- Effective problem solving often requires a systemic understanding of organizational and inter-organizational issues. Systemic understanding requires a holistic view of an organization and its interrelationships, an understanding of the fabric of relationships and the likely effect of interrelated actions (Senge, 1992).
- Inquiry and reflection together are a powerful means of enhancing social learning and knowledge creation. Inquiries, or questions, are triggered by problems that require solutions or explanation. Reflec-

tion allows time for examination, contemplation and, often, resolution of the inquiries. To use a common metaphor, it is perhaps the best means for distinguishing between the forests and the trees of everyday working life.

Team building: working together and understanding what each member is trying to do. Team building was seen to be essential for effective social learning and problem solving. Motivators associated are: leadership, team-based morale, performance management, public recognition and reward systems, use of humour, and workplace design.

- In general, the caliber of leadership within the settings studied was to be admired. The leaders and managers were innovative and they motivated and developed their staff, mainly by demonstrating that staff are highly valued and by acknowledging expertise and knowledge regardless of their pay or position. Another team building issue that emerged was that people were appreciative of informal "drop-ins" by senior managers inquiring how they were doing. This "roving management" was said to contribute to better cohesion of teams, to promote system thinking, to help focus on overall goals, and to facilitate communication and feedback.
- "Team spirit" and "team cohesiveness" are both important values within the work culture and work ethic; nonetheless, there was nothing uniform about this in the settings studied. Some teams did not see the significance of their particular tasks to the overall goals of the organization. However, good examples of teamwork and team spirit were also evident. There were instances where teamwork was well integrated into daily work and where people worked collaboratively. Such teams were goal-oriented and were not only teams in structure but in spirit and were led by a leader who saw his/her role as serving team members rather than just having the position of a leader.
- For many employees, the performance cycle is annual and the outcome of a performance report often determines the prospects of one's career progression. Some felt somewhat uneasy as their performance evaluation was due relatively early into their posting cycle. A well-planned performance appraisal system should help to make equitable and unbiased decisions regarding staff selection, placement, development and training (Wood, 1989). Researchers were told that there was often a lack of clear communication about performance expectations. Also, an annual performance appraisal appears to be too long to wait for recognition of good work and too late to correct a performance problem. Morgan (1989) and Wood (1989) explain that to maximize positive results, the appraisal process should be two ways: it should facilitate and coach staff in doing their jobs effectively; and it should be frequent and informal.
- It was observed that humor was used for smoothing discussions that were becoming heated and to stop the conflict from escalating while also enabling the conflicting subordinates to save face. At meetings, humor was used to assist in uniting people around common themes and to make criticism palatable.
- One way of increasing team and individual morale is to publicly acknowledge outstanding work. Making employees feel appreciated, and saying, "Thank you, we know that you are a good employee, we value you and your work", is a big factor in motivation (Mitchell, 2000). Key informants stated that public recognition of good work was scarce and that a written or verbal word of praise, a pat on the back often means more, for example, than a pay raise – "praise is better than money" and praise is needed at all levels.
- Workplace design was seen to have impact on social learning. Staff located at small isolated outposts were at risk of feeling isolated and did not identify strongly with the parent organization. As stated earlier, out-posted staff identified more with the workplace with which they were based than their branch where they affiliated. This was further exacerbated by the fact that they often felt excluded by their colleagues.

Access to information: the easy availability of corporate information in whatever format was observed to effect knowledge acquisition and generation of new knowledge and social learning. Motivators associated are: record keeping, networking, meetings, and information technology (IT) infrastructure.

- The researchers observed that general familiarity with records keeping procedures was quite poor. Some people have developed their own personal records keeping systems but there was little uniformity in these and no adherence to file naming conventions and standards. As some informants stated: "I believe that physical files in the … are no longer managed well because their management has been farmed out to outside bodies." Or "I think we have problems with passing on information in the organization as a whole. We just don't do it very well." The issue of electronic records, particularly e-mail messages containing evidence of business transactions, posed problems not only in the setting studied but also in the whole of organization.

- Personal networks from previous postings as well as newly acquired contacts in the new environment play a vital role in knowledge construction and acquisition. New knowledge often begins with the individual and through conversations people discover what they know, what others know and in the process of sharing, new knowledge is created. Knowledge sharing depends on the quality of conversations, formal or informal, that people have. Webber (1993) aptly describes it: "Conversations – not rank, title, or the trappings of power – determine who is literally and figuratively 'in the loop' and who is not."
- Meetings are another means of accessing information and those that were observed varied significantly in format and the protocols in place. At the tactical headquarters, meetings that were mission-related provided excellent opportunities for learning. Strict protocols were observed at these briefings, for example, allowing participants to discuss errors or problems encountered during missions without assigning blame or shame to individuals. There were few equivalent meetings at the strategic headquarters, other than some induction sessions and briefings, and it appeared that learning how to do one's job was not given quite the same priority.
- The researchers observed that information access due to failings in the IT infrastructure inhibited access to information within the strategic settings. Another issue that caused problems was the difficulty in finding information on the shared drive. Since there was no specific person responsible for maintaining the shared drive and for naming folders, it was left to the discretion of the document originator where information would be stored.

Development of individual expertise: the acquisition and development of expertise was seen as an integral part of social learning. Motivators associated with this enabler are: career trajectories, professional currency, professional training, postings and promotion, and mentoring.

- A career trajectory describes the positions, roles and experience that individuals have accumulated, up to and including the position they currently hold. While not excluding personal experiences outside of a work or training context, a well-designed career trajectory generally equips an individual with the skills, experience, maturity and personal networks needed to successfully fill a particular posting.
- The term professional currency has a somewhat different meaning within different environments. However, professional currency promotes social learning in the same way that appropriate career trajectories do so " by providing a foundation for the generation of new knowledge.
- Appropriate professional training is a significant component of the development of individual expertise and, therefore, a fundamental for generating new knowledge. Training courses are important for furthering individuals' expertise, as well as for forming the personal networks that subsequently develop. However, in times of budgetary constraints, training money is often the first to go, with damaging consequences for the organization's ability to learn and manage their knowledge.
- Mentoring is regarded as an effective method of assisting the development of individual expertise; especially for junior staff, a degree of informal mentoring was seen to be built into elements of the training program in some of the settings studied. In terms of developing a career trajectory, the knowledge acquired through mentoring may also be important when individuals want to prepare themselves for specific roles in the future.

Communication: essential to effective learning within an organization and to effective social learning. Motivators associated with this enabler are: overall communication climate, formal and informal information flows, time for inquiry and reflection, use of humor, language, and workplace design.

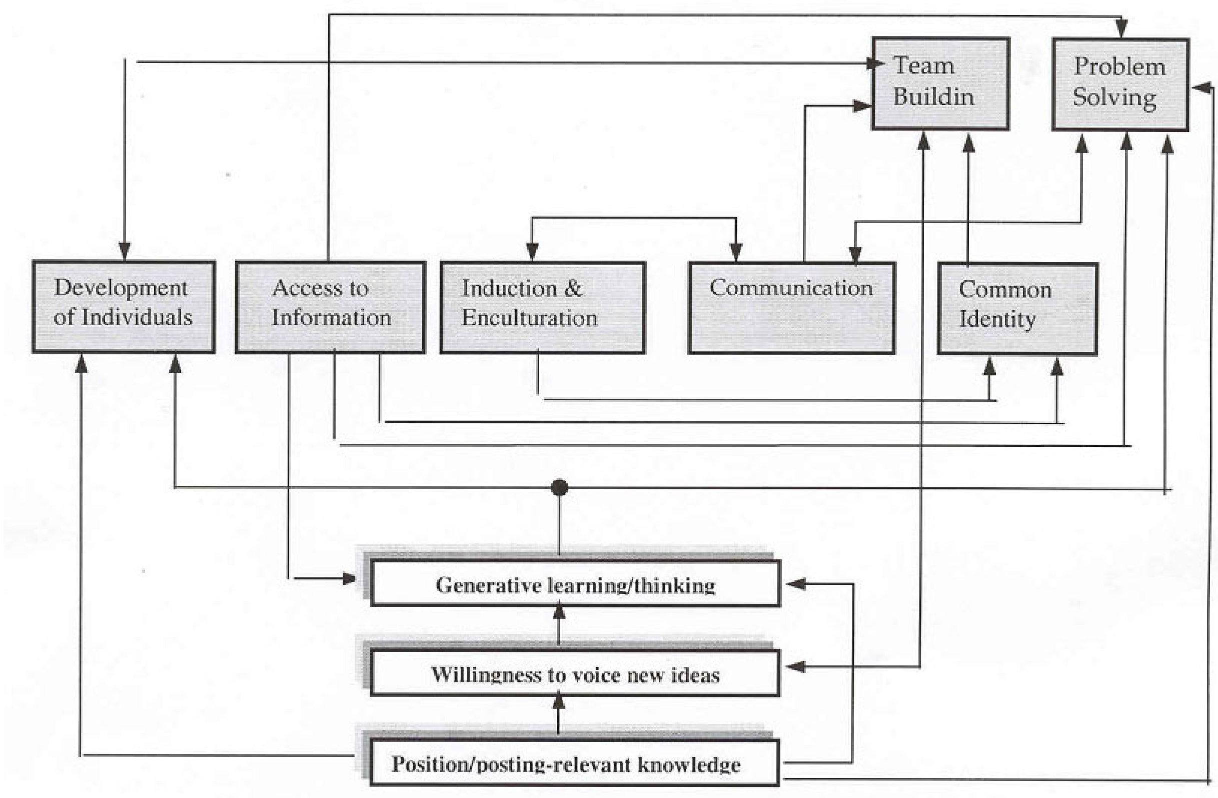
- Supportive communication climates are being positively linked to open and free exchange of information and constructive conflict management. Characteristics of a supportive communication climate include a culture of sharing knowledge, treating each other with respect, and generally behaving in a cooperative manner. Research has established the link between supportive organizational communication climates and generative learning (Bokeno, 2000; Ruppel, 2000) and with higher levels of organizational commitment (Guzley, 1992).
- An important element of generative learning is for organizational members to be able to engage in dialogue which is open and is based on inquiry and reflection. A supportive communication climate is a prerequisite for such dialogue, and it requires learning how to recognize defensive patterns of interaction that undermine learning (Senge, 1992).

- The issue of workplace design and its impact on teams, network building, and on accessing information arose repeatedly during the study. Physical location and proximity to each other had the potential to promote the transfer of pertinent knowledge. The point was made that in addition to more quickly obtaining answers to questions about particular tasks, an open plan workplace enabled one to tap into pertinent knowledge by overhearing others' conversations. Hutchins (1996) uses the term "horizon of observation" to describe the area of the task environment which can be seen, and is therefore available as a context for learning by team members.

Induction and enculturation: facilitates social learning by providing a foundation upon which an individual can become fully productive. Issues associated with this enabler are: timeliness and comprehensiveness of the process, buddy/mentoring system, handovers and information packages, and training.

- Good induction is more than just an introduction to a new job and workmates; it is a way of helping people find their feet. Attitudes and expectations are shaped during the early days of new employment, and work satisfaction is linked to well-timed and conducted work orientation (Dunford, 1992; George & Cole, 1992). The interviews clearly indicated a relationship between meaningful and timely induction and subsequent job satisfaction. An interesting finding was that those who were not properly inducted or enculturated into the organization saw no need and responsibility to actually prepare any form of handover for anyone who may take over their position in the future.
- Although highly desirable, it was not always feasible to conduct an induction program at the beginning of a new posting cycle. In the interim, a "buddy" or "mentoring" system could fill in the gap. A "buddy" would be an experienced workmate who could be available to answer questions and assist the orientation of new members during the initial few weeks. Some interviewees said that having a buddy when they started was invaluable to settling into a new job and to effective learning.

Figure 2. Enabling processes and their impact on social learning



- The researchers were repeatedly told that early training is an important part of effective induction and enculturation. It is an opportunity to learn the explicit knowledge that is taught as part of formal training. It is also an opportunity to be exposed to the attitude and cultural perceptions of colleagues and peers.

These factors enabling social learning identified from our data are by no means exhaustive, however, based on the available data, the research team could see a relationship between these enablers and social and generative learning. Figure 2 depicts these relationships and their impact on social learning.

CONCLUSION

Therefore, organizations seeking to improve information sharing and knowledge generation need to develop a greater awareness of the processes and strategies of organizational learning. Organizational knowledge is distributed across functional groups, and its generation and continual existence is dependant on the overall communication climate which is embedded in the organizational culture. This study indicates that information sharing and subsequent knowledge generation would be successful when interactive environments are cultivated before other, for example, technology-based solutions are implemented.

KEY TERMS

Career Trajectory: Describes the positions, roles and experience that individuals have accumulated, up to and including the position they currently hold.

Common Identity: A common ground/understanding to which many people/groups can subscribe, and requires a shift from seeing oneself as separate to seeing oneself as connected to and part of an organizational unit.

Communication Climate: Extend to which there is an open and free exchange of information, transparency of decision-making, and how constructively conflict is managed.

Knowledge: An understanding gained through experience or learning: The sum, or a subset, of what has been perceived and discovered by an individual. Knowledge exists in the minds of individuals and is generated and shaped through interaction with others.

Knowledge Management: In an organizational setting, it must, *at the very least*, be about how knowledge is acquired, constructed, transferred, and otherwise shared with other members of the organization, in a way that seeks to achieve the organization's objectives.

Social Learning: Learning occurring in or by a cultural cluster and includes procedures for transmitting knowledge and practices across different work situations/settings and time.

Systemic Understanding: A holistic view of an organization and its inter-relationships, an understanding of the fabric of relationships and the likely effect of interrelated actions.

Knowledge Management on the Web

Ruidong Zhang
University of Wisconsin-Eau Claire, USA

INTRODUCTION

The importance of knowledge management has been recognized both in academia and in practice. In recent years, corporations have started talking about knowledge management, organizational learning, organizational memory, and computerized support. A few years ago, Microsoft®'s awareness of knowledge management and corporate memory was demonstrated by Bill Gates through his keynote speeches in the second and third Microsoft's CEO summits that attracted quite a few CEOs and other corporate executives from Fortune 1000 companies. Gates (1998) outlined his vision through a term he coined "digital nervous system," which is an integrated electronic network that can give people the information they need to solve business and customer problems. An effective digital nervous system should include access to the Internet, reliable e-mail, a powerful database, and excellent line-of-business applications, and should transform three major elements of any business: the relationships to customers and business partners—the e-commerce element; the information flow and relationships among workers within a company—the knowledge management element; and the internal business processes—the business operations element. The recent release of Windows® Tablet PC® edition is an example of a Microsoft tool that supports the concept of digital nervous system.

Even though knowledge management as a conscious practice is still young (Hansen et al., 1999), using information technology to support knowledge management is being explored and is well under way in many organizations. The Web technologies are not only changing the landscape of competition and the ways of doing business but also the ways of organizing, distributing, and retrieving information. Web-based technology is making effective knowledge management a reality, and Web-based knowledge management systems have been developed and deployed.

Currently, Web-based technology is enabling the management of knowledge at the document management level, in contrast to the traditional record-level data management. The record-level data management is basically the focus of traditional database management systems. The document level is higher than the record level. For example, we generally handle daily problems through communicating with each other by using documents and exchanging ideas or perspectives about an issue, rather than dealing with database fields or records. Document-level information management is generally viewed as a lower level of knowledge management.

In this chapter, Web-based knowledge management is explored. Four representative types of Web-based knowledge management models are identified and studied. The study of these models would shed light on the effective management of organizational knowledge, what should be contained in a knowledge management system, the levels of knowledge management support, and how knowledge management support systems can be technically implemented. This chapter is organized as follows. In the next section, some theoretical issues about knowledge management are reviewed. Then, it is justified why Web technology is an enabling technology to the effective knowledge management and why Web-based knowledge management is desirable. Then, the four types of Web-based knowledge management models are discussed and compared. Finally, the conclusion section summarizes the results of this chapter and discusses future directions of Web-based knowledge management.

BACKGROUND

Traditional Information Systems versus Knowledge Management Systems

Traditional information systems were developed to capture data about daily business transactions (transaction-processing systems), and to access, process, and analyze those internal and external data to generate meaningful information to support management [management information system (MIS), decision support system (DSS), or enterprise integration system (EIS)]. These traditional systems help make an organization operate smoothly. However, they were developed at a time when the importance of knowledge management was not recognized.

They all emphasize quantitative data processing and analysis. But an effective organization does not rely on quantitative analysis alone to deal with its problems. The nonquantitative side, such as knowledge creation and management, mental models, document sharing, human communications, information exchange, and meaning making, play a great role in an organization's growth and development. Thus, the nonquantitative areas also need to be supported. Knowledge management systems are supposed to fulfill this role. In other words, knowledge management systems should complement traditional systems in providing nonquantitative side support. A difficult task is to define what needs to be contained in the knowledge management system. A lot of existing studies provide only theoretic suggestions. A study described and discussed 10 knowledge management frameworks (Holsapple & Joshi, 1999). These frameworks are generally concentrated on conceptual knowledge creation or knowledge-building activities. They may be useful in deciding what functions a knowledge management system should eventually provide, but they fall short in suggesting what should be contained in a knowledge management system and how such a system may be implemented. In this chapter, the study of four types of Web-based knowledge management models should provide some practical advice about the content of a knowledge management system.

Knowledge versus Information versus Data and Knowledge Management

Commonly agreed, data is often defined as the raw facts, and information as the processed data. Davenport and Prusak (1998) defined knowledge as "a combination of experience, values, contextual information, and expert insight; and knowledge provides a framework for evaluating and incorporating new experiences and information." On the other hand, Applehans and coresearchers (1999) defined knowledge as the ability to turn information and data into effective action, which brings desirable outcomes for an organization. In this chapter, we follow a compromised approach to define knowledge: it is about the application of data and information for a given task so that the given task can be effectively performed.

The traditional view about the relationship between knowledge, information, and data is that knowledge is above data and information; data is a prerequisite for information; and information is a prerequisite for knowledge. This theory can be simply illustrated by the following diagram:

Data $\rightarrow$ Information $\rightarrow$ Knowledge

The second view, also a different view, is called a reversed knowledge hierarchy, which suggests that we first need to have the knowledge about what information we want, and then we will know what data to look for (Tuomi, 1999). In other words, data emerge only after we have information, and that information emerges only after we already have knowledge. This view can be simply illustrated by the following diagram:

Knowledge $\rightarrow$ Information $\rightarrow$ Data

The third view is also possible. We have a large amount of data collected but fail to make use of the data to create information because of our lack of relevant knowledge. An historical example is at point, which is about the making of the everyday weather map. For a long time in history, weather data were collected, and there were rich data available. But the usefulness was limited when these data are not combined with a map (Monmonier, 1999). Once we have the relevant knowledge about how to process data, how to visualize data, the boring data start making sense and generating meanings. In this situation, the knowledge is the catalyst that transforms data into information. This process can be simply illustrated by the following diagram:

Data $\rightarrow$ Knowledge $\rightarrow$ Information

These differing logics and understandings about the relationships and the sequences between data, information, and knowledge are meaningful, depending on the context. The development of the traditional information systems (TPS, MIS, DSS) basically follows the traditional view of data, information, and knowledge, while scientific research and inference statistics generally follow the second view (the reverse hierarchy) on data, information, and knowledge. In terms of knowledge management, the third view bears more impacts and implications. This third view suggests a fundamental fact in many organizations—there are a lot of documents (data) accumulated over years, and we need to know what to do to turn them into information to support a given task. All knowledge is tacit in nature and largely resides in the human mind, and to articulate knowledge is to create information about knowledge (Stenmark, 2002). The document is one place where information about knowledge can be found. Another place is the human mind, and the identification of the right human mind (expert) for a given task must be a responsibility of knowledge management. This help explains why the awareness of corporations to identify and utilize inside expertise for a given task has increased in recent years.

To summarize, knowledge management is concerned about how documents (data) may be organized, associated, and retrieved so that meaningful information can be produced for a certain task. This also includes identifying experts whose expertise can immediately help a given task. In other words, the following understanding about knowledge management is used in this chapter: Knowledge management is about meaningful organization of data (documents) and people who have expertise about a task, so that for a given task, meaningful information can be uncovered, associated, and retrieved, and experts with matching expertise can be identified.

THE WEB TECHNOLOGY

The content of a knowledge management system is not created by one individual. The content collection and the access of the content is a collective behavior. Therefore, the technological infrastructure installed must be able to facilitate the collective behavior of knowledge management. In a study where 31 knowledge management projects in 24 companies were examined, eight factors were identified to characterize a successful project (Davenport et al., 1998). One of these factors was the use of a technology infrastructure that includes common technologies for desktop computing and communications. Web technology has provided a common technological infrastructure to support the collective knowledge management, which is justified by the following observations in a separate study conducted by Zhang and Chen (1997):

- Web-based technology uses standard transmission-control protocol/Internet protocol (TCP/IP), which is mature and is supported by almost every vendor (Panko, 1997; Telleen, 1996; Strom, 1995).
- Information can be collected, retrieved, and shared through popular browsers like Netscape Navigator and Internet Explorer.
- A home page can be quickly developed, deployed, and shared.
- There are languages specially developed for Web-based applications, such as Java or VB script. Java applets can be embedded in Web home pages. The applets are executed on the client's PC and make it possible to develop interactive home pages with instant user responses and with multimedia features.
- With Web technologies, an organization enjoys platform independence or cross-platform operation. JAVA applets do not have to be rewritten to work with PC browsers, Macintosh browsers, and UNIX browsers (Panko, 1997).

In addition to the common technical infrastructure feature offered by Web technology, there are several major reasons why Web-based knowledge management is desirable:

1. The basic unit of knowledge is at the document level, which is equivalent to the level at which human beings normally communicate. Documents are usually created to deal with particular issues, and we live our everyday lives by dealing with issues. Different from an expert system, a document-based knowledge management system cannot automatically derive solutions. Instead, its usefulness lies in its large repository of classified documents, its multi-indexed powerful searching capabilities, the links between documents, the links within a document, and the potential of including other advanced features (e.g., animation). The interpretation of the documents provided by a knowledge management system largely lies with the users. The function of a document-based knowledge management system is largely to support relevant information for a task.
2. The intranet, which is based on Web technology, is the driver for new business applications. As one study has found, corporate intranets and the Internet have made the process of finding the right expert for a given task more feasible than ever before (Yiman & Kobsa, 2000). Another study has shown that intranets can provide useful and people-inclusive knowledge management environments (Stenmark, 2002).
3. The association between documents and tasks can be easily established by creating hypertext links. Hypertext links can be created between documents and within a document. Hypertext links make explicit the meaningful documents relevant for a given task.
4. The collective behavior of knowledge management can be supported. A Web site can be easily configured to allow multiple users or contributors to edit existing documents or add new documents. When talking about the knowledge management architecture, Morey (1999) suggested that successful knowledge management architecture must have the following characteristics: be available, be accurate, be effective, and be accessible. Web-based technology has made it possible to have effective knowledge management architecture.

THE WEB-BASED KNOWLEDGE MANAGEMENT MODELS

Four Web-based knowledge management models are identified in this section. These models represent the current level of Web-based knowledge management. Nonetheless, these four types of models may not represent all of the Web-based knowledge management models. These four representative models are as follows:

- Library model
- Attachment/association model
- Directory model
- Press center model

Library Model

This model enables content-based document searches. Under this model, a large collection of documents is established. Both the attributes and the content of a document are indexed, in contrast to the traditional method where only the attributes of a document are indexed. The attributes of documents may include title, subject, author name(s), publication (creation) date, number of pages, and so on. Under this model, powerful search functions are provided, where not only these attributes (title, subject, etc.) are searched, but also the contents of documents are searched.

An example was provided by the ITKnowledge.com Web site, which is a large repository of information technology (IT)-related books. The contents of the books are fully available. The chapters in a book are hypertext-linked, and a book is essentially a set of hypertext documents. Not only the attributes of the books are classified and indexed and can be searched easily, but also the chapter titles (the content) are indexed by keywords and can be searched. This makes it possible to find a document with attributes (title, subject) that do not meet a search criterion but that may contain chapters that are relevant to the search criterion. In Figure 1, the ITKnowledge.com search screen is displayed. In Figure 2, a search result is returned. As can be seen in Figure 2, a chapter in the book *Handbook of Data Management* that is relevant to the search criterion "knowledge management" has been returned. If the book is only indexed by its title, this search result should not have been possible.

Attachment/Association Model

Under this model, information is organized around topics. If we search for a particular topic, all information associated with the topic will be returned. New information can be attached to a topic once it becomes available. In fact, anyone at any time can attach new information to a topic. The attachment creation is an ongoing process.

An example of this model is Amazon.com, which is also an example of successful e-commerce. Bookselling is its major business. Amazon.com maintains a large database of book titles. To help sell a book faster and to make users understand a book better, all information relevant to a book title is stored and organized around a book title. Therefore, essentially, the book database is more than just a collection of book attributes. Amazon.com provides users more than book titles. Suppose we want to find books that are relevant to "knowledge management."

After a title that matches the search criterion is returned, other relevant titles, and what other customers often purchase together with the current title, are returned

Figure 1. IT Knowledge.com expert search screen

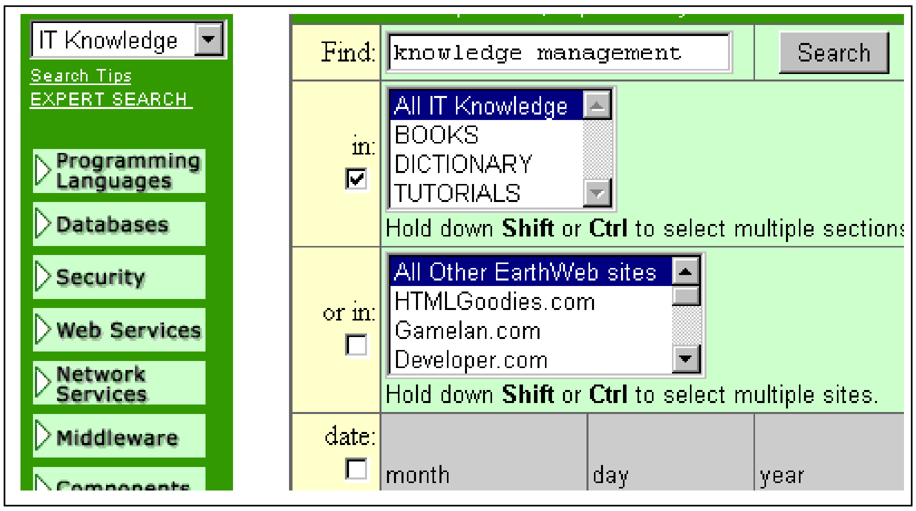

Figure 2. Search results returned

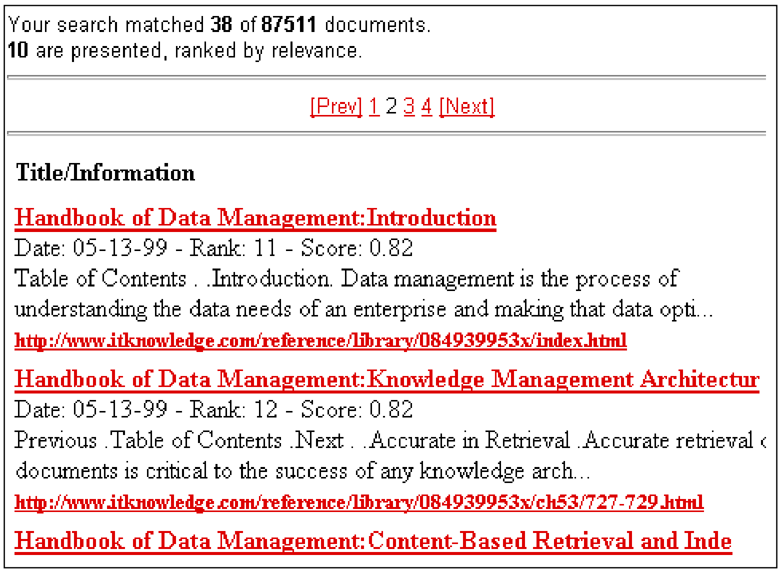

Your search matched **38** of **87511** documents.
10 are presented, ranked by relevance.

and displayed. In addition, one can learn more about a book by reading the reviews attached to or associated with the book and other customers' comments attached to the book. If a reader wants, he or she can write comments about a book and easily attach his or her comments to the existing pool of information about this book.

Directory Model

Under this model, the experts in different areas are identified, and a directory of experts is created. The areas of expertise of these experts are classified and organized. A directory of experts, together with their areas of expertise, is provided.

A representative example of this model is the Round Table Group (round.table.com). Round Table Group (RTG) was founded in 1994 with a vision of being a virtual consulting firm where business leaders, management consultants, and litigation attorneys could shop for answers to critical questions from world-class thinkers, anywhere in the world, in Internet time (STVP, 1999). According to an STVP case study, RTG has formed a worldwide network of over 3,000 Round Table scholars—professors, researchers in well-known think tanks, and other experts. Essentially, RTG's most valuable competitive asset is its directory of professors from around the world who were available to consult with clients on demand. RTG provides answers-on-demand services to its clients. In Figure 3 below, the classified area of expertise by topic is displayed.

Press Center Model

Under this model, any information that can possibly be collected, including news, relevant articles, solution providers, publications, and discussions about a task is collected. A representative model is Kmworld.com, where a rich collection of relevant information about knowledge management can be found. If one is interested in knowledge management, a good starting point would be to visit a site like Kmworld.com. One could be overwhelmed by the information available, such as discussions, news, and solution providers. But, by spending some time and effort, one could figure out what is going on with a task, the current status, the issues, and history information on some issues.

A Comparison of the Models

The four types of Web-based knowledge management models as discussed above reflect the current level of Web-based knowledge management, which can be summarized as the content-based information retrieval and topic-oriented information organization.

These four models share the following common characteristics:

- Are basically document-based and content-indexed
- Have powerful searching capabilities
- Focus on a specific application area (task-specific: IT knowledge, bookselling)
- Offer anytime, anywhere access
- Have potential to have more advanced features (e.g., multimedia, animation)
- All have an external orientation and are customer focused

On the other hand, the four models discussed above also have unique characteristics, which are indicated in Table 1.

FUTURE TRENDS AND CONCLUSIONS

Current Web-based knowledge management is essentially at the document management level—a lower level of knowledge management, but indeed beyond pure document management (pure classified collection of documents in a central file cabinet) to allow content-based retrieval, distributed access, and topic-oriented information organization and association. In this chapter, four different Web sites that represent four different models of Web-based knowledge management are discussed. But it is believed that a Web site could employ multiple models at the same time. For example, a Web site can be constructed based on the library model while supporting the association and attachment model. As a matter of fact, ITKnowledge.com is planning to include the association and attachment model in its site. It is expected that a sophisticated Web site will provide a menu of knowledge models for its users to choose from so that the potential of a Web site can be fully utilized.

A study, conducted by Hansen, Nohria, and Tierney (1999), discussed two strategies of knowledge management, based on the authors' studies on the practice of knowledge management in consulting firms, with computer vendors, and with health care providers. One strategy is called the personalization strategy, where knowledge is closely tied to the person who developed it and is shared mainly through direct person-to-person contacts. The computer information systems are used mainly to help people communicate knowledge, not to store it. Other examples like the use of groupware products to support the knowledge management process also fall into this category. This may be called the communication-based knowledge management level.

Table 1. Key characteristics of Web-based knowledge management models

Model	Key Characteristic
Library	Content-based document retrieval
Association/attachment	Topic-oriented information organization/attachment
Directory	A well-organized directory of experts that can be searched for a given task
Press Center	A clearinghouse with rich organized information

Another strategy, from the same study conducted by Hansen, Nohria and Tierney (1999), is called codification strategy, where knowledge (actually, a variety of documents) is codified and stored in databases to be used by anyone in the company. The knowledge is extracted from documents and may take the forms of interview guides, work schedules, benchmark data, or market segmentation analysis. These knowledge forms are codified and stored into a database with search capabilities. This is may be called the document-based knowledge management level.

The existing Web-based knowledge management, as evidenced by the four types of models identified and discussed in this chapter, basically corresponds to the knowledge management levels (especially the second). However, these levels are considered as lower levels of knowledge management, because they do not consider the support of meaning interpretation or sense making, they are generally text based, and they do not challenge whether the knowledge inherent in the document is accurately transmitted (knowledge transfer). But, after all, good steps on the right track have been made.

As future research directions about Web-based knowledge management, the higher levels of knowledge management may need to be addressed. Other functional areas should get involved, such as sales and marketing, customer support, and research and development. Other models about Web-based knowledge management may also need to be identified. Automatic and intelligent knowledge extraction and retrieval (knowledge agents) should also be studied for Web-based knowledge management.

KEY TERMS

Data, Information, Knowledge: Data is often defined as the raw facts, and information as the processed data. Knowledge is about the application of data and information for a given task so that the given task can be effectively performed.

Knowledge management: This is concerned about how documents (data) may be organized, associated, and retrieved so that meaningful information can be produced for a certain task. This also includes identifying experts whose expertise may help a given task.

Web-based knowledge management: This is about using Web technologies to support knowledge management processes.

Web-based knowledge management model: This is about how knowledge may be collected, accessed, and presented on the Web platform. This chapter identifies four Web-based knowledge management models.

Web-technology: This refers to the combination of the Internet communication protocols (TCP/IP), networks, Web server (e.g., IIS), and client (e.g., Opera) software, and the languages that can be used to develop Web applications.

Knowledge Management Systems Acceptance

INTRODUCTION

Knowledge management is a set of systematic actions that organizations can take to obtain the greatest value from the knowledge available to it (Davenport & Prusak, 1998). Systematic means that knowledge management is made up of intentional actions in an organizational context. Value means that knowledge management is measured according to how knowledge management projects contribute to increased organizational ability (see for example Prieto & Gutiérrez, 2001; see Goldkuhl & Braf, 2002, on the subject of organizational ability). The motivation for knowledge management is that the key to competitive advantage for organizations in today's business world is organizations' ability to manage knowledge (Nonaka & Takeuchi, 1995; Davenport & Prusak, 1998). Knowledge management as an intentional and value-adding action is not easy to accomplish in practice (Scarbrough & Swan, 1999). Scarbrough and Swan (1999) present several case studies in knowledge management, successful and unsuccessful in their respective knowledge management projects. A major point and lessons learned from the case studies is that prevalent approaches in knowledge management overstate technology and understate how technology is implemented and applied.

To succeed with knowledge management, encompassing development of information technology-based information system, some requirements have to be fulfilled. An important aspect in the development process is system acceptance. Implementation is at large a process of acceptance. Implementation is the process where the system becomes an integrated part of the users' or workers' work practice. Therefore implementation is essential to make a knowledge management project successful in order attain an increased organizational ability and to succeed with knowledge management.

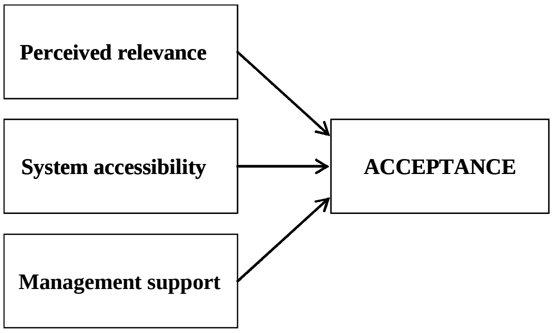
ISSUES OF KNOWLEDGE MANAGEMENT—SYSTEMS AND ACCEPTANCE

In this section we provide broad definitions and discussion of the topics to support our positions on the topics of knowledge management and systems acceptance.

MANAGING KNOWLEDGE

Work in knowledge management has a tendency to omit social or technological aspects by taking on one of two perspectives on knowledge management, the anthropocentric or the technocratic view (Sveiby, 2001; Swan, 1999). The anthropocentric and the technocratic views represent two contradictory views on knowledge management and can be summarized as technology can or technology cannot. The gap between the anthropocentric and technocratic view depends on a difference of opinions concerning the notion of knowledge. The technocratic view conceives knowledge to be some organized collection of data and information, and the anthropocentric view conceives knowledge to reside in humans, not in the collection (Churchman, 1971; Meredith & Burstein, 2000). Our conception of knowledge is that of the anthropocentric view. Taking on an anthropocentric view on knowledge management does not mean that we discard knowledge management technologies; we rather take on a balanced view on the subject. Information technology can support knowledge management in an organization through a number of different technological components, for example intranets, extranets, data warehouses, and database management systems (Borghoff & Pareschi, 1998; Tiwana, 2000; Ericsson & Avdic, 2002). The point in taking on an anthropocentric view of knowledge management is not to lose sight of the knower who gives meaning to the information and data found in IT-based knowledge management systems.

Figure 1. Requirements of Acceptance Model (Ericsson & Avdic, 2003)



KNOWLEDGE MANAGEMENT SYSTEMS

Information systems can include either operative or directive and decision support information (Langefors, 1966; Yourdon, 1989). Operative systems provide system users with information necessary in workers' daily work, while directive and decision support systems provide system users with information that improves the quality of decisions workers make in daily work. Knowledge managements systems are systems developed to manage knowledge directly or indirectly to give support for an improved quality of a decision made in workers daily work, and as an extension, an increased organizational ability. A knowledge management system typically includes directive information, for example in guiding a user's choice in a specific work situation. Such systems are often optional in the sense that users can deliberately refrain from using the system and/or refrain from taking the directed action. Accordingly, user acceptance is crucial for the degree of usage of knowledge management systems.

ACCEPTANCE OF TECHNOLOGICAL SYSTEMS

Technology acceptance has been subject of research by, for example, Davis, Bagozzi, and Warshav (1989), who developed the well-known Technology Acceptance Model (TAM) and later a revised version of the original model, TAM2 (Venkatesh & Davis, 2000). TAM is an explanative model explaining user behavior of computer technologies by focusing on perceived ease of use, perceived usefulness, attitude towards use, and behavioral intentions as determinants of user behavior. TAM2 is an extension of the original model including external factors related to perceived usefulness.

The framework for system acceptance, Requirements of Acceptance Model (RAM) have some resemblances with TAM and the later TAM2. RAM is in comparison with TAM descriptive in nature. Workers' work practice is treated as an integrated element of RAM, compared with not being treated as a determinant of system use in the original TAM and as an external factor in TAM2. Further, RAM covers acceptance of knowledge management systems, and TAM/TAM2 cover a broad range of computer technologies. RAM systematically acknowledges factors important in implementation of knowledge management systems to gain acceptance of such systems.

REQUIREMENTS OF THE ACCEPTANCE MODEL

We perceive acceptance to be a function of perceived relevance, systems accessibility, and management support. Together these elements constitute our framework RAM. In this section we present the requirements of acceptance in RAM. The Requirements of Acceptance Model is illustrated in Figure 1.

PERCEIVED RELEVANCE

The workers, who are to use the system, must perceive the knowledge management system as relevant. Since it is possible for workers to work without using the system, it has to be obvious that usage of the system implies adding value to the work result. An additional aspect of relevance related to perceived relevance is how the system should be integrated in running work, that is, to make the system an integrated part of the workers' work practice.

In summary, perceived relevance is about workers, who are to use the system, perceiving the system as (Ericsson & Avdic, 2003)

- adding value to the work results; and
- being integrated in running work.

ACCESSIBILITY

To obtain acceptance of knowledge management systems, accessibility has to be satisfactory. It must be accessible to the workers who are to use the system. Accessibility is a question of who is to be the user (type of workers concerning organizational position), what action and work the system is to support (daily work, product development, innovation, etc.), where users get access to the system (the physical access), when the system is ready to use, and how the system's interface fulfills the goal of the system.

In summary, systems accessibility is about (Ericsson & Avdic, 2003):

- knowing who the user is;
- systematizing the actions workers perform in the work practice the system is to support;
- deciding the system's physical access;
- securing a certain degree of usage before the system is put into operation; and
- ensuring the system's design meets the goals of the system.

MANAGEMENT SUPPORT

Management support is vital according to many models on information systems development, especially when the system is a directive/decision support system (Yourdon, 1989). Knowledge management systems are typically directive systems, and workers have a choice in deciding whether to use the system or not. Management support is important to stress the value for workers to use the system and to make conditions for workers to do so.

DEVELOPMENT IS A PROCESS OF ACCEPTANCE

There must be a fit between workers' work practice and technology to get acceptance of knowledge management systems. The technology used to create a knowledge management system must fit the actions workers perform in their work practice. On an overall level there must be a fit between technology and actions performed by individual workers, and between individual workers and the organization as a whole, thus forming a coherent whole. It is in the development of knowledge management systems that the requirements of acceptance are fulfilled. A common conception concerning information systems development is that it constitutes analysis, design, construction, and implementation of information systems (Hirschheim, Klein & Lyytinen, 1996).

The groundwork for acceptance is made during the design, but foremost when implementing the system. Workers who are to use the system should be engaged at an early stage of the development process. The point of including workers at an early stage is to acquaint users with the system and the purpose of the system. Further, this is an opportunity for workers to influence the system's design and content. The most prominent aspect addressed when involving workers at an early stage is that of choosing and determining the meaning of crucial concepts managed by the system. Crucial concepts managed by the system are the knowledge represented in the system, and by determining concepts, knowledge represented in the system takes on a systematized character. Further, by involving the workers in the process of choosing and determining the meaning of crucial concepts managed by the system, the knowledge represented in the system does not lose its origin or meaning. The point is to keep the knowledge represented in the system within a frame of understanding or meaning, as perceived by workers. A knowledge management systems should be seen as a tool developed to support workers in learning and acquiring knowledge about actions taking place at work. This requires closeness between how concepts are perceived by

Table 1. Summary of RAM (Ericsson & Avdic, 2003)

Perceived relevance—Workers, who are to use the system, have to perceive the system as:
- Adding value to work results
- Being integrated in running work

Systems accessibility—System accessibility is about:
- Knowing who the user is
- Systematizing actions workers perform in the work practice the system is to support
- Deciding the physical location where users get physical access to the system
- Securing usage of the system before it is put into operation
- The systems' design must meet up to the goals of the system

Management support—Fundamental because management authorizes development of systems workers and how such concepts are represented in a system.

FUTURE TRENDS

Research on technology acceptance (i.e., Davis et al., 1989; Venkatesh & Davis, 2000) has focused on user behavior of computer technologies. RAM is developed for and is used to assess acceptance of knowledge management systems. Acceptance has not been a crucial issue within the knowledge management area. A problem with knowledge management systems is that they work in theory, but seldom in practice (Wickramasinghe, 2003). A contributing factor to that picture may very well be that of having overlooked usage-related problems connected to knowledge management systems. In that sense, knowledge management systems acceptance can be expected to be an area for further research in the future.

CONCLUSION

Acceptance of knowledge management systems is a function of perceived relevance, systems accessibility, and management support. Together these elements constitute our framework RAM. RAM is summarized in Table 1.

The Requirements of Acceptance Model point towards several important aspects concerning relevance, accessibility, and support. The groundwork for system acceptance is the development process. Development is very much a process of acceptance as a process of developing the system itself. Through requirements of acceptance, knowledge management systems can remain and continue to be a contributing factor for the organization's ability to do business.

KEY TERMS

Anthropocentric View of Knowledge: Knowledge resides in humans.

Information Systems Development: Constitutes analysis, design, construction, and implementation of information systems.

Knowledge: Knowledge is personal and talked about and may thus be public and shared among a group of people who have a common frame of reference, providing means for people to make sense of and apply knowledge in practice.

Knowledge Management: The name given to the set of systematic actions that an organization can take to obtain the greatest value from the knowledge available to it.

Knowledge Management Systems: Typically, directive systems developed to manage knowledge directly or indirectly to give support for an improved quality of a decision made in workers' daily work, and as an extension, an increased organizational ability.

Perceived Relevance: Workers who are to use the system perceive the system as adding value to the work results and being integrated in running work.

Systems Acceptance: A function of perceived relevance, systems accessibility, and management support.

Systems Accessibility/Development: Knowing who the user is, systematizing the actions workers perform in their work practice the system is to support, deciding the system's physical location, securing a certain degree of usage before the system is put into operation, and ensuring the system's design meets the goals of the system.

Technocratic View of Knowledge: Knowledge is an organized collection of data and information.

Knowledge, IT, and the Firm

Petros A. M. Gelepithis
Kingston University, UK

INTRODUCTION

No company has ever existed or will ever exist without knowledge. Still, it was only recently that knowledge started being heralded as the way forward (Drucker, 1993; Itami, 1987; Toffler, 1990). This may explain why in the business world, knowledge management (KM) is still perceived in two substantially different senses: (a) as synonymous to information management (e.g., Dempsey, 1999; Vernon, 1999) and (b) as a distinct area of study and practice dealing with the management of knowledge (e.g., Newing, 1999; Zack, 2003). In contrast, the academic world sees knowledge and information as related but fundamentally distinct. Furthermore, the vast majority of both of these communities has focused on the managerial or social aspect of KM (see, for example, Birkinshaw & Sheehan, 2002; Davenport & Glaser, 2002; Davenport, Thomas, & Cantrell, 2002; Gupta & Govindarjan, 2000). The *nature* of knowledge and its implications for management have been largely ignored. The limited work considering knowledge issues falls into the four categories below.

1. Knowledge is self-explainable and, therefore, in need of no further consideration (e.g., Newing, 1999).
2. Knowledge is self-explainable and classifiable into several commonsense categories (see, e.g., Quinn, Baruch, & Zien, 1997; Savage as cited in Skyrme, 1999).
3. Knowledge is attempted to be explained or defined without taking into account the vast relevant work done in epistemology and cognitive science. Primary examples are Borghoff and Pareschi (1998) and Davenport and Prusak (1998).
4. Organisational knowledge creation is a social interaction between tacit knowledge and explicit knowledge (Nonaka, 1991; Nonaka & Takeuchi, 1995).

The first three attempt to deal with the nature of knowledge and give the impression that there are no problems in an area beset with significant issues, whereas the fourth pays serious attention to the fundamental issue of knowledge creation.

Nonaka and Takeuchi's (1995) theory consists of two interacting knowledge spirals. The epistemological one is based on the distinction between tacit and explicit knowledge; the ontological one is based on the widely accepted distinction between the individual and the organisation. Their important contribution is an excellently written expansion of their working hypothesis called "knowledge conversion," namely, "human knowledge is created and expanded through social interaction between tacit knowledge and explicit knowledge" (p. 61). This important "dichotomy" is one of seven that form the basis of their theory, specifically, (a) tacit/explicit, (b) body/mind, (c) individual/organisation, (d) top-down/bottom-up, (e) bureaucracy/task force, (f) relay/rugby, and (g) East/West. Knowledge conversion comprises four modes: socialization (from tacit to tacit), externalisation (from tacit to explicit), combination (from explicit to explicit), and internalisation (from explicit to tacit). These four modes "constitute the 'engine' of the entire knowledge-creation process" (p. 57).

There are four weaknesses in their approach. First, their working hypothesis is characterised by a coarse grain size: Tacit and explicit knowledge are left unanalysed. As a consequence, no actual mechanisms for knowledge creation are proposed. Second, despite an impressively long index on knowledge, the issue of the *nature* of knowledge is ignored. Third, their synthesis of the seven dichotomies, although a highly welcome attempt in bridging unnecessary gaps, it is still biased since their underlying "model of knowledge creation favors the Japanese view" (Nonaka & Takeuchi, 1995, p. 237). Finally, their wide-ranging literature review fails to take into account—or refute—the most widely accepted metaphysical position, namely, physicalism.

The next section presents the results of a unified theory of mind (Gelepithis, 1984, 1989, 1991, 1997, 2002, 2004, in press) that are relevant to the issues of knowledge creation and the nature of knowledge, and form the background to the future-trends section.

BACKGROUND

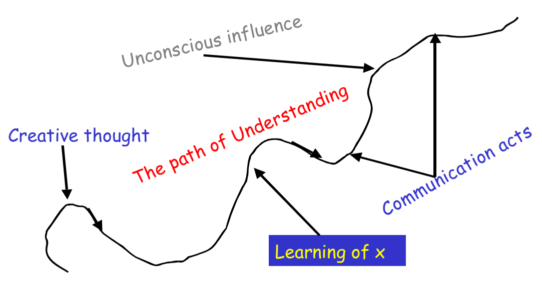
In accordance with contemporary physicalism (a position accepted by the majority of scientists and philosophers), individual human knowledge should, primarily, be seen as neurally realisable. When externalised, in the form of written language, individual human knowledge becomes fossilised. It becomes a snapshot and loses its capacity to initiate near-immediate action. Furthermore, and most crucially, it may be entirely meaningless to virtually all other humans. As a matter of fact, after the passage of some time, it may become unintelligible even to the very human who first externalised it. In other words, externally represented human knowledge becomes information.

It follows that organisational knowledge (sometimes known as organisational memory) may refer to either knowledge or information. Specifically, it may refer to employed people and their individual knowledge, or it may refer to an organisation's information. The latter needs to be interpreted by a human to be useful in any way. Interpreted information becomes internalised, possibly assimilated, and subsequently may trigger, or be involved in, knowledge creation. The central mechanism responsible for human knowledge creation is the process of understanding. It is an invariant neurophysiological process with many significant contributors to its cause as the Figure 1 illustrates. This complex system of interacting processes I call the knowledge nexus.

Through successive instantiations of the process of understanding over a period of time—quite often on the same topic—humans accumulate knowledge. The end result of understanding embodies aspects of individual human knowledge. The knowledge of human H at time t is the *system of understandings* that H has reached by that time. Eventually, an overall complex system of premises and primitives is developed comprising the axiomatic base of H's knowledge-based action. To move away from the subjectivity of individual human knowledge, communication is required. It contributes the component of breadth and intersubjective agreement characterising collective human knowledge.

Because the knowledge nexus is neurally realisable, it is opaque and most likely never fully presentable. Nevertheless, through language, the axiomatic base is externally representable and potentially formalisable. This interdependence and foregoing analysis should have made clear the inseparable link between biology and human language, that is, the inseparability of the subjective and the objective.

Figure 1. Aspects of the proces of understanding



The next section draws upon the background already presented to outline two major directions concerning (a) information and communication technologies (ICT) and (b) the economy.

FUTURE TRENDS

Before embarking on a sketch of the two major future trends, it is worth emphasising that it is the development of the appropriate environment that would nurture employees' knowledge nexus, which is important for business innovation. Successful management will be that which can realise both the near-unlimited scope and the fundamental limits of that nexus. It is in this respect the management of a company that is significant rather than futile attempts to manage knowledge.

ICT and, increasingly, artificial intelligence (AI) are at the forefront of developments providing aids for addressing problems associated with the knowledge nexus. The majority of such problems include the identification, acquisition, and sharing of information, as well as the creation of knowledge. Books and edited collections addressing aspects of information-related or knowledge nexus problems abound (e.g., Borghoff & Pareschi, 1998; Hlupic, 2003; Quinn et al., 1997; Skyrme, 1999). What is much less widely available is discussion of the scope and limits of technology.

The scope of AI and ICT technology is enormous. The following three types of problems cover an extremely large space with far-reaching potential consequences for our society.

- Overall integration of information sources and tools.
- Identification of appropriately specified information through the use of search engines.
- Formalisation of certain aspects of human knowledge through R&D in knowledge representation and reasoning.

In all these cases, advanced technology can be a very significant help. It has to be realised, though, that AI and ICT systems cannot, on their own, either create or share knowledge. This is a point that is very often overlooked with serious negative consequences. Several people have noted that despite the increasing use of artificial aids, the human remains in the loop (see, for instance, Cross & Baird, 2000; Senge & Carstedt, 2001). Actually, no future technology can possibly take the human(s) out of the loop of human knowledge creation. Let us briefly see the reason for this intrinsic limit.

AI and ICT systems may be distinguished into two possible categories: human based and machine based primitives (Gelepithis, 2001). The latter is not yet available. The former type of AI and ICT systems, whether creative or not, are automated axiomatic systems with inbuilt procedures for drawing consequences from their human premises. At worst, they are ad hoc systems capable of providing a cost-effective and, quite often, enhanced solution with respect to their human counterparts. A better solution, nevertheless, does not constitute creation of new knowledge. In the best-case scenario, they are capable of producing all possible consequences, some of which are bound to be new. In other words, "creative" AI systems can produce *new consequences* of existing knowledge. They are incapable, though, of producing *novel* human knowledge. Such knowledge involves *evaluation* of human premises and that, in turn, requires the full spectrum of human primitives, a task shown to be technologically impossible (Gelepithis, 1991). Finally, the highly desirable and potentially fruitful capability of current AI and ICT systems to produce new consequences of existing knowledge has to be ultimately evaluated by humans.

It should be noted that although humans are the only creators of novel human knowledge, ICT and, in particular, AI can facilitate the creation of such knowledge through the development of tools enabling (a) increased connectivity within the semantic system of humans and (b) increased and enhanced human-human communication. The latter should be what Skyrme (1999) calls knowledge networking. It is along these lines that a brighter future for business innovation lies.

As with technology, the intrinsic limit of economy is derived from the nature of knowledge and its associated mechanisms of creation, as sketched in the previous section. In the case of the economy, the limit concerns the scope of the notion of market. Specifically, the notion of a knowledge market is not realisable.

Claims for or against the possibility of a knowledge market are few and far between. They also vary in how convincing they are. At one extreme, reasoning is reduced to blind faith: "Given time, market forces will undoubtedly take care of the situation" (Burton-Jones, 1999, p. 221). At another extreme, Gamble and Blackwell (2001, p. 185) remark, "It is almost axiomatic in management that what you cannot measure you cannot manage." Unfortunately, the next step they go to is to create a metric for a "knowledge management initiative." It is unclear whether a "shifting the goalposts" approach is being practiced or whether an implicit belief against the possibility of a knowledge market is being held.

A more substantial argument is put forward by Davenport and Prusak (1998). Their starting point is that knowledge markets exist not as "pure" markets (i.e., markets that operate solely in economic terms). They claim that a price system for a knowledge market revolves around the notions of money, reciprocity, reputation, altruism, and trust. In a nutshell, they recognise that money is far from adequate and believe that reciprocity, reputation, and altruism (these three in diminishing degree), as well as their combinations, constitute the substitute for money. Since transactions involving reciprocity, reputation, and altruism do not constitute payment in the traditional, monetary sense of the term, they are forced to introduce the notion of trust as the necessary factor for the workings of such a market. But trust is one of the goods (the other two are loyalty and truth telling), which "cannot, in principle, be taken as commodities in the market sense" (Arrow, 1974, p. 22).

One may take Arrow's principle as a basis for an argument against the possibility of a knowledge market. It is nevertheless an argument based on extrapolation and henceforth not fully convincing. Our knowledge-based argument for the impossibility of a knowledge market is summarised below.

Markets require two elements for their existence: (a) an object to be transacted among their players and (b) a price system as its mechanism for the transactions.

Some may argue that knowledge markets have existed at least since humans started exchanging goods they produced themselves. For, any good produced—or procedure for making goods—was bound to involve the use or description of some knowledge. Nevertheless, what was traded was the good or procedure, not the knowledge involved.

What about information such as a piece of advice, a report, or an academic paper? Could such information not be transacted? No; since the meaning of some information depends on the receiver, its price cannot be fixed. Put differently, since the interpretation of information depends on the individual, its value depends on the potential client. Therefore, no common price can be assigned, no metric can be designed. The following two examples should clarify our point. First, what should be the value of the 21st-century equivalent of Newton's laws? Second, how much should one pay for that imperceptible, yet consciously made, grimace that reveals a no-purchase of company X?

True, for thousands of years now, people have been able to sell information to someone able to use it. Nevertheless, the circle of potential buyers and sellers was and will continue to be extremely limited because information is only subjectively evaluative. Expert advice is valuable only to a small number of people, quite often to a single individual only. A knowledge market is not viable because individual human knowledge is neurally realisable, and collective human knowledge is only individually interpretable and assessable (see the background section). It follows that our resources will be better spent in creating a knowledge environment rather than the chimera of a knowledge market. Sustainable business innovation requires near-continuous knowledge creation, and that requires in turn a knowledge environment. This is a difficult but necessary objective. It is difficult because knowledge has no airtight compartments.

CONCLUSIONS

Knowledge management is both mistaken and indispensable. It is mistaken because no one can manage something that takes place inside another one's mind. It is indispensable because it brought to managers' consciousness what they always relied upon: human knowledge.

Innovations (both minor and major) will come with improvements of search engines and further formalisation of the formalisable part of collective human knowledge. Breakthroughs are more likely to come from innovative hybrid designs (i.e., novel human-AI systems interactions). Both require humans in an environment that can nurture their knowledge nexus. Managers should act accordingly.

Finally, because of the strong push for economic, political, and cultural globalisation, one issue becomes of paramount importance. How could the particular cultures of all the peoples be synthesised into an Earthian culture rather than be obliterated and replaced by the monolithic pursuit of profit? Companies should understand the key cybernetic principle: variety requires variety. Innovation requires variety, too.

KEY TERMS

Artificial Intelligence: The study of the principles of intelligence (scientific objective), and the design and build of intelligent machines like robots (engineering objective).

Cognitive Science: The multidisciplinary study of intelligent systems (natural, artificial, and hybrid). The disciplines that currently comprise cognitive science are (in alphabetical order) anthropology, artificial intelligence, education, linguistics, neuroscience, philosophy, and psychology.

Collective Human Knowledge: Shared human knowledge that has been linguistically represented.

Communication: H1 communicates with H2 on a topic T if, and only if, (a) H1 understands T (symbol: U(H1 T)), (b) H2 understands T (symbol: U(H2 T)), (c) U(H1 T) is presentable to and understood by H2, and (d) U(H2 T) is presentable to and understood by H1.

Epistemology: The study of knowledge. It is a vast area that has been studied for more than 2,500 years by the greatest minds in philosophy and, increasingly, by scientists in disciplines like psychology, neuroscience, and cognitive science.

End Result of Understanding: An entity E has understood something, S, if, and only if, E can present S in terms of a system of its own primitives (i.e., self-explainable notions).

Information: Potentially meaningful (material) patterns. For a summary presentation of the major views on information along with a rudimentary theory of information and some of its consequences (see Gelepithis, 1997).

Physicalism: The thesis that everything in the universe is physical. Applied to the mind, physicalism asserts that (a) all entities in the universe are physical entities and their combinations (ontological physicalism) and (b) all properties of any entity in the universe are physical properties (property physicalism).

Shared Human Knowledge on a Topic T at a Particular Time t: The end result of all communication processes among the members of a community on the topic T by the time t.

Knowledge-Based Support Environment

INTRODUCTION

Organizations and universities alike depend on the collection of the data pertaining to the purpose (Curtis, 1999) of the domain in which they operate. Internally, each functional part of the organization works with data collected from the different types of systems used (Laudon & Laudon, 2000). Organizations, therefore, use technology to collect and store data (Whitten, Bentley, & Barlow, 1994) to be processed by the rules formulated to produce valuable information (Connelly, Begg & Strachan, 1996) and eventually knowledge. Universities, too, collect data, processes them, and endow them with relevance and importance (Drucker, 1993). Most organizations use knowledge, for example, regarding their target audience, to gain a competitive advantage. Knowledge and knowledge workers are theoretically the "products" produced by universities. However, they face the same dilemma as the majority of firms, that is, too much data and information but not enough knowledge. Information can be described as explicit knowledge, the significance of which is that information has meaning and it is clearly understood. Knowledge is regarded as volumes of relevant information but, importantly, in addition to experience (tacit knowledge) in the form of an expert (Avison & Fitzgerald, 1995). An expert, to be effective, must use extensively both formal (quantitative) and informal (qualitative) information in decision making. Knowledge is regarded as a strategic asset and therefore the creation of which is often an enterprise-wide goal. Alavi and Leidner (1999) argued that the importance of knowledge is based on the hypothesis that the barriers to the transfer and duplication of knowledge award it with enormous strategic importance. Universities, with the technological capability necessary, are developing systems that can collect and manage knowledge. The combination or integration along with the capability to combine an expert's experience in the form of a system is regarded as a strategic tool. Systems capable of combining both explicit and tacit knowledge are referred to as knowledge management systems (KMSs). Research in this area is not very detailed due to the fact that organizations, not universities, have only been implementing the systems in the last few years. These systems are used to acquire and manage knowledge and distribute it among the different functional units as well as with any external collaborating groups. The idea of disseminating knowledge is not a new concept, be it in education or in industry. Like the classroom, the traditional approach, such as paper-based knowledge sharing, and the virtual are used, depending on factors such as the number of students or the type of decisions to be made. An organization creates a knowledge base to reduce the level of experience needed by managers and to improve the effectiveness of their decisions (Peterson & Davie, 1996). Industry invests an enormous amount of capital in the training of its employees and therefore in the creation of so called "experts in the field"; a "true" knowledge base will allow the acquisition of the experience of experts to reduce the loss of investment should the employee leave (Curtis, 1999).

BACKGROUND

Nonaka (1995) define knowledge as "just true belief." Knowledge is regarded, in this information-driven economy (Drucker, 1993), as power or a source of competitive advantage (Barua, 1996; Drucker, 1993; Grant, 1996; Laudon & Laudon, 2000). Powell et al. (2001) and Casey (1995) describe knowledge as a combination of both information and expertise. Knowledge is acquired or created when an individual, with expertise in a field, uses relevant information productively (Hertog & Huizenga, 2000). The training and the experience that academics amass over the years (knowledge) allow them to both teach and collaborate to produce additional knowledge. Therefore, a knowledge base support environment (KBSE) in this case can be described as a dynamic repository of existing learning and processing systems such as discussion forums, virtual libraries, and research to allow academics and students to retrieve knowledge (either tacit or explicit) based on individual profiles. The possibilities of such a system are limited only by constraints imposed by the university in question, such as technological or managerial support (Neville, 2000). Innovative universities could use this implementation for a number of reasons, specifically to keep staff and students abreast of research and emerging technologies in their fields (Khan, 1997). Designing the system requires a thorough investigation into the use of the Web as a medium for delivery (Driscoll, 1998; McCormack & Jones, 1997; Ritchie & Hoffman, 1996). The designer must be aware of the attributes of the

WWW (World Wide Web) and the principles of instructional design to create a meaningful learning environment (Gagne, Briggs, & Wagner, 1988; Driscoll, 1998). The Web-based classroom is viewed, as already stated, as an innovative approach to teaching (Relan & Gillani, 1997). It, like the traditional method, requires careful planning to be both effective and beneficial (Dick & Reiser, 1989). A Web-based classroom must do more than just distribute information, it should include resources such as discussion forums to support collaboration between learners and ultimately it should also support the needs of both the novice and advanced learner (McCormack et al., 1997; Sherry, 1996; Willis, 1995). A KBSE is composed of a number of components that are integral to the success of the environment (Banathy, 1994): (a) a student mentoring system to support both full- and part-time learners, (b) an exam domain to test both practical and cognitive abilities, (c) a virtual library to allow easy access to conference papers and journals, and (d) the knowledge base facilitated by an agent to integrate all of the components and automate the retrieval of information for the end users.

THE SYSTEM

The KBSE can be developed to support a (generic) university environment. As well as providing a support system for both students (postgraduate or undergraduate) and staff, the system produces a large amount of reports for managing and expanding research within the test department. The environment tests students' problem-solving skills with "real-world" simulations and Multiple Choice Questions (MCQs) providing feedback to both lecturers and students. The environment will grow and change as both staff and students collaborate to add and extract material from the system. Duplication of work by staff can be dramatically reduced, freeing staff to concentrate on other tasks. The environment itself can be used by the university in training and in the management and creation of knowledge. The system will enable or automate four of the many components that constitute a university, and therefore support virtual learning and research. The four components of the system are as follows.

STUDENT MENTORING SYSTEM

Web-based mentoring systems (WBMSs) can be described as learning-delivery environments in which the WWW is its medium of delivery (Crossman, 1997; Driscoll, 1998). Due to the increase in student numbers, there is a need for greater student support, which can be provided through the Web. The mentoring component of the system allows students to log in and view lecture and tutorial material. In addition, a discussion forum will enable both the mentors (lecturers and tutors) and students to exchange ideas and add to the environment, eliminating constraints such as time and location, making the knowledge base available to each type of student. The mentoring component of the system will do the following.

- allow lecturers and tutors to update the content segments of the Web site (for example, course homepages or online reading lists) through a Web browser on or off campus
- provide 24-hour online support to students
- facilitate group collaboration, for example, in discussion forums
- allow students to have positive input into courses
- provide students with the ability to add to the environment through discussion forums, link, and papers enable anonymous feedback and questioning, for example, with feedback forms

EXAM DOMAIN

Students attend tutorials and demonstrations for practical subjects, for example, programming languages and computer networking. However, due to security systems in place to protect network resources (for example, workstations and servers), students' access rights are restricted. Therefore, written exams are used in universities to test practical skills when industry itself tests the student's practical ability rather than the student's ability to memorise material. A domain (server) with user accounts allocated to test material will enable lecturers to fully evaluate the skills gained through practical work. The exam domain will do the following.

- give students and lecturers the opportunity to both test and evaluate skills in a simulated environment where they can assume roles such as a network or database administrator without risk to departmental resources
- house written exam material for IT and other courses
- reduce the duplication of course materials (MCQs and research) on the part of teaching staff
- enable students to assess their understanding of course material and prepare for summer assessment
- supply lecturers and instructors with case examples to expand students understanding of a particular topic

VIRTUAL LIBRARY

Every college department and individual lecturers archive material in the form of journals and books related to specific topics. However, few use systems to track departmental and individual repositories to facilitate research and budgeting. This component will do the following.

- track research material within departments
- automate the lending of research material to staff and students
- enable inventory and budget reporting
- assist lecturers in managing their personal resources (journals, books, and proceedings)
- eliminate duplicate purchases of material
- reduce the workload of administrative and academic staff

THE KNOWLEDGE BASE

The knowledge base (KB; see Figure 1) is the integrating component of the environment, which acts both as a repository and as the channel enabling the ongoing process of knowledge creation. It is intended to extend and compliment the other parts of the system as well as add the ability for users to automate the task of retrieving research and technical papers relevant to their areas of interest. The KB will generate profiles of users relating to their areas of interest. The KB will intermittently build indexes based on the content collected from the different components, and the system will notify the users when items of interest are added based on the different profiles. The KB has the following functionalities.

- searches out users' particular areas of interest on the Web
- automatically provides users with links and updates of online material
- profiles users areas of research from which the agent can learn more about what information the users would find helpful in the pursuit of their specific research interests
- builds a knowledge base of research, as defined by the individual users, to support research acquisition and collaboration

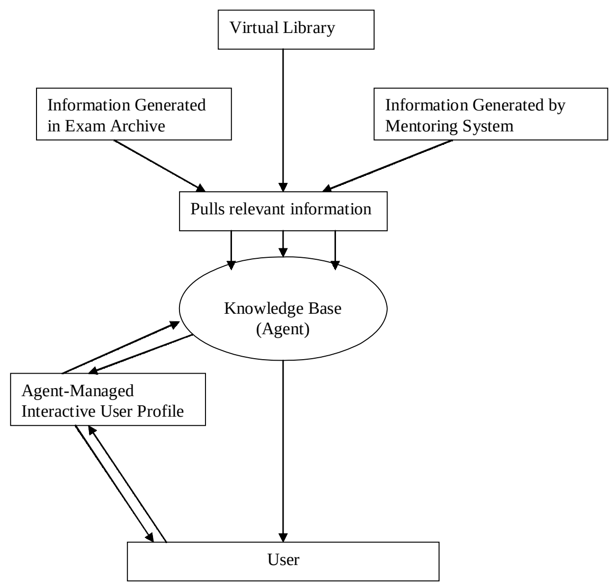
FUTURE TRENDS

Evaluation is the final stage in the development of a KBSE. However, it is an important component of the process. Evaluation is defined as "the value or merit of something" (Driscoll, 1998; McCormack & Jones, 1997). KBSE is a relatively new phenomenon, therefore the evaluation stage of the development life cycle will provide valuable insight into the success and failures of both the development of the system and the value of the system as a knowledge-management tool (Driscoll; McCormack & Jones). The data gathered during this phase will aid in the development of future environments. Evaluation should not be viewed simply as a process of measurement and estimation but a method of learning about the end product, the learner's acceptance of the system, and the effectiveness in creating knowledge. Rowntree (1990) states the following.

1. Evaluation is not an assessment.
2. The unexpected should not be ignored.
3. Evaluation is a planned, systematic, and open endeavour.

Evaluation and assessment are often confused; however, the processes refer to different levels of the investigation into the success of the environment. Evaluation involves all of the factors that influence the acceptance of the system. However, assessment measures the level of understanding of a learner. The developer can perform a number of different evaluations, each of which seeks to elicit specific information. The developer can evaluate the platform used to deliver the system to determine if it provided adequate support. The second type merely involves determining if the system addressed the goals and objectives of the research. Evaluating the impact of the environment on academics and students alike provides the developer or researcher with valuable data regarding its use. Questionnaires are the easiest method used in the evaluation process. The researcher can design a questionnaire to elicit the desired information regarding the system. The questionnaire provides a number of advantages, such as anonymity, which usually provides genuine responses. It enables the researcher

Figure 1. A knowledge base support environment (KBSE)



to collect a large amount of data in a simple format. It is easy to administer to the target group under review, usually by post, and it is relatively easy to analyse. However, the technique cannot be utilised as the only method of evaluation; follow-up interviews are necessary. Semistructured interviews allow the researcher to obtain an elaboration of issues identified as a result of the questionnaires. However, interviews tend to collect large quantities of data that is difficult to analyse. Evaluation provides rich data if designed properly. It is an ongoing process that should be an integral component of the methodology used to develop the system. The use of knowledge-based environments is increasing in importance. Therefore, a suitable method of evaluation is necessary to collect information regarding both the effectiveness and the ineffectiveness of the different components and the system as a whole to continue to add to the value of this knowledge approach. The virtual support environment will initially be offered to a sample of end users (both staff and students) who will manage and use the system for a period of time before the environment is made available to all potential users.

CONCLUSION

Pressures of the information age are forcing organizations and universities to turn to knowledge environments to provide a strategic advantage in this global economy. Effective support environments help create and maintain the knowledge base of a university or organization. There are numerous technologies available to support educational needs. Technologies such as distributed desktop training and computer-based training offer a number of advantages to both universities and organizations. However, these methods can be expensive to maintain as they become out of date relatively quickly. Therefore, more and more universities are turning to KBs to support their knowledge workers. Academics and students alike can share information and access resources over the World Wide Web without restrictions such as geographic location, time, or the platform used. The utilisation of the Web as an educational tool is not an innovative approach to the needs of the learners, however, the use of the Web and software agents as facilitating technologies in the creation of knowledge is.

Educators have discovered that through the use of learning networks and environments, students can interact with their peers to create and improve group work in distance education and it provides the learners with access to online resources and relevant information. Education is built around the use of textbooks, classrooms, and assignments. A KBSE makes the interactive textbook a reality. A network, itself, is defined as a shared space. Telephone and satellite signals form a vast Web or network of computers to enable communication to anywhere in the world. KBs can, therefore, be used by trainers to create a learning environment. Educators and students from any location can share their knowledge and collaborate with each other. Learning in a traditional classroom can be intellectually engaging, as it produces a competitive and collaborative environment. Web-based learning allows "educators and students alike to perform learning related tasks" (McCormack & Jones, 1997). The development of KBSEs requires careful investigation into the requirements of the problem case. The developer must consider factors such as the method employed by the student to learn, incentives to ensure use, the identification of goals and objectives, and the different roles that are needed to support this new approach in training and ease of use. However, the advantages far outweigh the limitations, which through careful planning can be reduced.

KEY TERMS

Agent: Automates a task of, for example, retrieving research and technical papers relevant to end-user areas of interest.

CBT (Computer-Based Training): Is training delivered to employees or students on a computer, providing training on something like word processing or on a programming language such as Java.

DDT (Distributed Desktop Training): Allows the student (employee) to avail of both audio and video applications to enhance training by providing interactive communication between the student and the trainer without being limited by distance.

Explicit Knowledge: Information that has specific meaning and that can be easily and clearly understood.

KBSE (Knowledge-Based Support Environment): A dynamic repository of existing learning and processing systems such as discussion forums, virtual libraries, and research to allow academics and students to retrieve knowledge (either tacit or explicit) based on individual profiles.

Knowledge Web: The use of electronic linkages among different teaching and learning communities to facilitate information acquisition and knowledge building.

Mentoring: A method of teaching that has been used for hundreds of years; this design is incorporated into learning networks to develop more effective learning practices and provide additional support to the learner.

Learning Networks: Computer networks that are used for both educational and training purposes. They consist of groups of people working together, online, to educate both themselves and others. The hardware and software that forms the network system is the only limitation to these groups.

Tacit Knowledge: That which refers to knowledge gained through an individual's own experiences.

Web-Based Classroom: The application of a selection of intellectually stimulating lessons implemented within a creative and collaborative learning environment that utilises the resources of the World Wide Web.

Leader–Facilitated Relationship Building in Virtual Teams

David J. Pauleen
Victoria University of Wellington, New Zealand

INTRODUCTION

How do virtual team leaders assess and respond to boundary crossing issues when building relationships with virtual team members? Virtual teams are a new phenomenon, defined as groups of people working on a common task or project from distributed locations using information and communications technology (ICT). With rapid advances in ICT allowing alternatives to face-to-face communication, virtual teams are playing an increasingly important role in organizations. Due to their global coverage, virtual teams are often assigned critical organizational tasks such as multi-national product launches, negotiating global mergers and acquisitions, and managing strategic alliances (Maznevski & Chudoba, 2000). Their use, however, has outpaced the understanding of their unique dynamics and characteristics (Cramton & Webber, 2000).

Virtual team leadership remains one of the least understood and most poorly supported elements in virtual teams. Virtual team leaders are often the nexus of a virtual team, facilitating communications, establishing team processes, and taking responsibility for task completion (Duarte & Tennant-Snyder, 1999), and doing so across multiple boundaries. Recent research (Kayworth & Leidner, 2001-2002) has begun to look at virtual leadership issues and suggests that the trend toward virtual work groups necessitates further inquiry into the role and nature of virtual team leadership.

This article begins by briefly looking at the key concepts of virtual team leadership, relationship building and boundary crossing. Then, drawing upon the author's research, it examines the complexity inherent in building relationship across boundaries, and concludes with suggestions on how virtual team leaders can mediate this complexity.

BACKGROUND

Virtual Team Leadership

There has been extensive research on leadership in collocated teams and groups. Typically, leadership can be viewed in a number of ways, from a structured authoritative role to the ability of individuals to intrinsically or extrinsically motivate followers. It is generally agreed that leadership involves social influence and the use of communication activities in motivating teams to achieve goals. Barge proposes leadership as mediation in order to overcome the variety of task and relational problems that may be encountered by a group and explains that leadership "entails devising a system of helping the group get its work done, that is simultaneously stable and flexible and assists in managing the information shared among members and between the group and its external audience" (Barge, 1996, p. 319).

A key leadership skill in Barge's concept of leadership as mediation is that of relational management, which refers to the ability of leaders to "coordinate and construct interpersonal relations that allow an appropriate balance of cohesion, unity, and task motivation with a group" (Barge, 1996, p. 325). Cohesive teams tend to perform better and are more motivated to complete tasks. Of concern here is how team leaders can coordinate and construct interpersonal relations in a virtual environment to overcome the difficulty of multiple boundaries that do not exist in traditional collocated teams.

The Importance of Relationship Building in Virtual Teams

The link between team effectiveness and team member relationships is an important but underdeveloped area of study in virtual teams. Usually defined implicitly rather than explicitly, relationships develop over time through a negotiation process between those involved (Catell, 1948). While face-to-face meetings are the preferred way to build relationships and to deal with sensitive and complex situations, it is possible with the skillful and thoughtful application of virtual communication channels to effectively lead a completely virtual team. Research has found that computer-mediated teams do share relational information and are likely to develop relational links over time (Chidambaram, 1966; Warkentin, Sayeed & Hightower, 1997).

The role of the team leader is to move the team towards its objectives by encouraging collaboration. This is done through a sustained process of relationship building, idea generation, prioritisation and selection. The particular challenge to virtual team leaders is to manage this process through ICT. In virtual team research stronger relational links have been associated with higher task performance, more effective information exchange, enhanced creativity and motivation, increased morale, and better decisions (Warkentin & Beranek, 1999; Warkentin et al., 1997). The building of relationships with virtual team members has been shown to be a fundamental concern of virtual team leaders (Pauleen, 2003-04).

Boundary Crossing in Virtual Teams

Boundary crossing is a defining characteristic of virtual teams. Contemporary organizations have highly permeable boundaries allowing substantial communication across boundaries (Manev & Sorenson, 2001). Boundary crossing is an important organizational activity that enhances the flow of information from the external environment. The role and activities of virtual teams leaders make them natural and strategic boundary crossers.

While traditional co-located teams may have members from different functions and cultures, sophisticated new synchronous and asynchronous ICT make it ever easier to form teams consisting of members from different functions, offices, organizations, countries and cultures. Furthermore, virtual teams must function across time and distance, often with team members having never met. These conditions present significant challenges to team leaders and members, team processes and ultimately team outcomes. Because virtual teams are still relatively new, outdated organizational HR and IT policies, which do not support virtual team performance, may be compounding the challenges (Jackson, 1999; Vickery, Clark & Carlson, 1999).

Boundary crossing in virtual teams can affect relationship-building efforts. Maznevski and Chudoba (2000) showed that deliberately addressing relationship building to develop shared views and trust across all types of boundaries could help virtual team performance. The more boundaries between leaders and team members at the start of a virtual team, the more likely higher levels of relationship with team members as well as more intensive relationship-building strategies will be needed.

MAIN THRUST OF THE CHAPTER

The Effects of Boundary Crossing on Relationship Building

The practical effect of working across distance means that teams can and do comprise members from different departments, head and branch offices, and organizations, as well as different countries and cultures. Indeed, access to different organizational, functional and cultural perspectives is a key reason for using virtual teams. These differences represent important conditions that team leaders will probably need to assess and accommodate before commencing a virtual team. According to team leaders, the development of personal relationships between themselves and team members is an important prerequisite in establishing and maintaining virtual working relationships across three conceptual boundary-crossing categories: (1) Organizational Boundary Crossing, (2) Cultural/Language Boundary Crossing and (3) Time/Distance Boundary Crossing (Pauleen, 2003-04). While organizational and cultural/language barriers exist in co-located teams, they are more likely to be found in virtual teams and to a have a more significant impact. Time and distance boundaries are unique to virtual teams.

Organizational Boundary Crossing

Organizational boundary crossing includes intra- and inter-organizational boundaries. Different functions, departments, and organizations may have diverse work cultures as manifested by deeply held core beliefs and assumptions (Kayworth & Leidner, 2000). Wiesenfeld, Raghuram and Garud (1998) suggested that organizational identification would be the psychological tie that binds virtual workers together into an organization, preventing workers from thinking of themselves as independent contractors, operating autonomously.

A strong organizational culture might influence the level of relationship building necessary in a team composed of members from within the same organization, even if they are located in different countries. Strong organizational cultures are exemplified by institution-based trust relationships (Nandhakumar, 1999; van der Smagt, 2000) and an anticipation of future association (Pauleen, 2003-04). The degree of relationship building necessary and the strategy for going about it are likely to be quite different when a team starts with a strong intra-organizational culture. Conversely, virtual teams with members from different organizations will need to be aware of and navigate the different organizational cultures.

Another aspect of organizational boundary crossing is the particular preferences of certain organizations for certain technologies, for example, communication channels such as e-mail or voice mail when leaving messages. Team leaders may experience difficulties trying to agree on common communication platforms with team members outside of the organization.

Cultural/Language Boundary Crossing

Cultural/language boundary crossing is another critical area. Cultural/language boundary crossing will most likely take place in global virtual teams, though it may also be a factor in national or even local virtual teams (Pauleen, 2003-04). The key point is whether a team leader is working with a team member from another nationality or ethnic culture. The effects of culture in team settings can be profound, and include, among other important issues, how individuals relate to each other (Kayworth & Leidner, 2000). Misinterpretations or distortions may occur as team members and team leaders interpret communications through their own cultural programming (Lewis, 1996), a challenge that is greatly complicated when attempted through ICT. In all cases, team leaders need to assess the impact of cultural differences.

In some cases, there may be a strong cultural preference for the use of face-to-face communication to build relationships. Only after a certain level of comfort is attained can ICT be used with any effectiveness. This strategy supports Hall's (1976) theory of high and low context cultures, which states that for some cultures communication is more about context then the actual verbal message. In high-context cultures, messages have little meaning without an understanding of the surrounding context, which may include the backgrounds of the people involved, previous decisions, and the history of the relationship. People from low-context cultures prefer more objective and fact-based information. The message itself is sufficient.

Team leaders will need to consider the degree of personal relationship necessary to get the working relationship underway, as well as the use of appropriate communication channels along with appropriate messages delivered in an appropriate manner (Pauleen, 2003-04).

Time and Distance Boundary Crossing

Time and distance boundaries most obviously distinguish virtual teams from co-located teams. The effect of distance on relationship building strategies is proportional to how far the team leader and team members are from each other. The further away, the more difficult the use of face-to-face communication, which could be problematic in situations where face-to-face communication is the best or maybe only option.

The effect of time on relationship building strategies concerns the challenge of working across time zones. This may have little impact on the degree of relationship building that may be necessary, but a large effect on creating strategies to build relationships, as the time differences can restrict the kinds of ICT, particularly synchronous channels such as telephone and videoconferencing, available to the team leader. Probably not an issue that will make or break a virtual team of professionals, it is one of the conditions that must be carefully and fairly assessed by the team leader before creating relationship-building strategies.

If asynchronous communication channels are used, such as e-mail, the problem of pacing communication exchanges can become a serious consideration. Response times between team leaders and team members may differ, constraining communications, causing uncertainty and negatively impacting trust (Jarvenpaa & Leidner, 1999;Warkentin & Beranek, 1999). Time lags due to technical infrastructure and technological breakdowns, if not understood by the people involved, can cause the team leader or team member to attribute non-communication to lack of manners or conscientiousness, which can then seriously affect relationships (Cramton & Webber, 2000).

Problems associated with crossing time and distance have the potential to greatly disrupt relationship building in a virtual team, particularly with inexperienced team members. It is necessary for the team leader to carefully assess these potential obstacles before creating relationship-building strategies, as well as anticipate the problems that may be caused by time and distance.

Challenges and Solutions for Team Leaders and Organizations

This discussion points to significant differences in co-located and virtual teams in leadership-led relationship building across boundaries. The greater number and variety of boundaries and their deeper impact pose special challenges that virtual team leaders will need to mediate. Table 1 summarizes the key communication challenges faced by virtual team leaders. Two of these challenges are discussed. First the need for virtual team leaders to expand and hone their repertoire of skills in handling virtual communication channels and second, what organizations can do to improve their teams' virtual communication skills.

The strategic use of communication channels is one critical skill that virtual team leaders will need to hone. Table 2 illustrates ways in which virtual teams leaders need to mediate cultural/language boundaries by consciously selecting the most appropriate communication channels. Higher context cultures will tend to require media rich channels such as phone and video conferencing to build relationships, at least until the development of a sufficient level of trust. In contrast, lower context cultures, which are more task-oriented, will tend to be more tolerant of a wider range of communication channels. Indeed, being task-oriented, building relationships might be secondary to getting started on the task. Knowing the

Table 1. Mediating complexity - Communication challenges when building relationships with virtual team members across boundaries (Pauleen & Rajasingham, 2004)

	Types of Boundaries Crossed		
	Organizational	**Cultural/Language**	**Time & Space**
Co-located Teams	Shared organizational culture supports relationship building, although functional culture can pose challenges.	Nonverbal cues can be understood by experienced leaders. Non-native speakers	The ability to regularly meet face-to-face supports relationship building across cultures of all types.
Virtual Teams	Differing organizational policies inhibit communication, as do organizational preferences for the use of different communication channels and ICT infrastructure. Lack of situational knowledge of team members can cause misunderstandings and mis-attribution, leading to potential difficulties.	Lack of nonverbal cues is difficult to overcome with most available communication channels. Cultural preferences for certain communication channels, often face-to-face (see Table 2 for more detailed analysis of the use of channels across cultures)	Building relationships across time and space requires concerted efforts and more time than in co-located contexts. Arranging synchronous meetings or even phone calls across time zones is often problematic. Asynchronous channels face the problem of pacing communications. Dealing with "silence" is a particularly difficult challenge.

Table 2. Mediating complexity - Guidelines for using communication channels to build relationships in virtual teams across cultural/language barriers (Pauleen & Rajasingham, 2004)

Preferred Communication Channels			
		Native Speakers	Non-native Speakers
High Context Cultures (relationship-oriented) (tend toward formality)	Media rich, Synchronous, Face-to-face, phone, video/audio	Media rich, Synchronous, asynchronous	Face-to-face with interpreter, Asynchronous written with editor
Low Context Cultures (task-oriented) (Tend toward informality with notable exceptions, e.g., Germans)	Flexible, as above, plus e-mail, fax, computer conferencing (online synchronous written chat, asynchronous discussion boards)	All channels – synchronous and asynchronous	All channels with translator, interpreter or editor as required

cultural composition of the team and team members' prior experiences working virtually and across boundaries in general are part of the complex web of factors that leaders need to determine and then mediate if they are to successfully build relationships with team members and ultimately complete team tasks.

The second challenge concerns organizational support structures to improve both virtual team leader and member skills. Organizations need to be willing to provide training and support to develop effective boundary crossing behaviors among virtual team members. Virtual team processes and dynamics are different from those of co-located teams and require special skills focusing on networking and establishing links across boundaries (Duarte & Tennant-Snyder, 1999). Team members, and particularly team leaders, will often need to play multiple roles as negotiators (with customers), network and coalition builders (with other teams), lobbyists (with top management), and motivators (of team members). To be effective, team leaders will need training in boundary crossing, networking and relationship building skills (Yan & Louis, 1999).

FUTURE TRENDS

There has been a pressing need for rigorous conceptual and empirical work to examine factors that influence virtual teams (Pare & Dube, 1999), and it is only in the most recent literature that there have been systematic attempts to look at how virtual team leadership can support virtual team success. This article has briefly looked at issues related to team leader-facilitated relationship building across boundaries. Its results suggest directions for future research and practice, including the development of virtual leadership mediation and communication skills.

Realizing effective leadership in group, team and multicultural interorganizational communications across diverse perspectives and global virtual environments presents new, real and compelling challenges to team leaders, but these challenges also present unparalleled opportunities for teams to explore new perspectives, approaches and ideas (Adler, 2002). Understanding these challenges and developing effective leadership and organizational processes to meet them presents opportunities for both practitioners and researchers.

CONCLUSION

Crossing organizational, cultural and time and distance boundaries requires training, experience and organizational support. These can help team leaders determine how to work across boundaries that may be present in their team. In addition to its effects on building relationships, boundary-crossing differences can affect team processes and performance in many ways. Ignoring them is an invitation to team failure. Leaders must learn to mediate the increased complexity inherent in virtual teams. A starting point for leaders is to approach the complexity introduced by boundary crossing by asking these two questions:

1) What are the boundary crossing influences of this situation?
2) How can they be understood and worked with so that a good people-oriented environment of assurance and trust can be maintained and productivity enhanced?

Perhaps the ultimate challenge for team leaders, particularly in long-term or on-going virtual teams, is to work to merge the individual cultures – functional, organizational, national, and so forth - of the team members into a team culture.

KEY TERMS

Asynchronous Communication Channels: Communication channels that support communication that usually requires a period of time to pass between communicative transactions. These channels include e-mail, discussion boards, fax, and so forth.

Boundary Crossing: Virtual teams are often characterized by their boundary spanning attributes; that is, they usually cross time and distance, and often include different national (ethnic), organizational and functional cultures.

Personal Relationships: The kind of relationship between people exemplified by shared understanding, mutual trust and social bonding. Communication in personal relationships is initially directed toward the exchange of personal information and later toward the sharing of mutual experiences.

Synchronous Communication Channels: Communication channels that allow real-time interaction. These include telephone, video conferencing, chat, and of course, face-to-face communication.

Virtual Team: A given number of people at distributed locations communicating and working to some degree via information and communication technologies on a set project or task, which may be of a limited or unlimited duration. Face-to-face meetings at the start-up of the team or at regular intervals are possible in a virtual team.

Virtual Team Leader: This is the person who functions as the hub of the team, holding it together. In the literature, this person may be termed a team facilitator, (virtual) project manager, coordinator or coach depending on the nuances of the role, the perspective of the researcher and organizational terminology. The team leader responsibilities may include all or some of the following: selecting team members; setting team tasks and team member roles; ensuring project or task completion; liaising with stakeholders and clients; establishing communication and team protocols, facilitating interpersonal and team communication, handling conflict, and managing technology and in general ensuring effective participation of all the team members.

Working Relationships: The kind of relationship exemplified by people who work together toward the completion of work-based tasks. It involves communication related to sharing information, coordinating tasks, meeting timelines, and so forth.

Leapfrogging an IT Sector

Eileen M. Trauth
The Pennsylvania State University, USA

INTRODUCTION

Accompanying the global spread of the post-industrial society (Bell, 1973) are nations who see economic opportunity deriving from the development of an information economy to support it (Porat, 1977). But while advanced industrialized nations moved gradually from industrial to post-industrial work over a period of decades, newly industrializing countries are "leapfrogging" directly from agrarian to information-intensive work in a matter of years. Given this rapid labor force transformation, a critical consideration in the development of a global information sector is the development and management of information technology (IT) workers.

Ireland is an appropriate country for examination of this leapfrog phenomenon because it was one of the earliest examples of this phenomenon, having developed its information sector rapidly and successfully through inward investment by multinational firms during the 1970s to the 1990s. Thus, this case offers the point of view of both an advanced industrialized or "first wave" country and of a "second wave" country that is taking an alternate path into the information economy by rapidly moving directly from an agrarian or partially-developed industrial economy into an information economy. Since Ireland was one of the earliest examples of "leapfrogging", the Irish case has lessons applicable to other contexts (Trauth, 2000).

BACKGROUND

Ireland's rapid transformation from a poor, agrarian society to a robust information society fueled by its information economy was the result of policy initiatives, cultural compatibility with IT work and adaptive responses to opportunities and crises. Ireland's policy of economic development through inward investment was a direct reversal of the preceding policy of cultural and political sovereignty achieved largely through economic isolationism. But a combination of high emigration and high unemployment signaled the need for change (Trauth, 2001).

The multinational firms brought direct benefits through the jobs that kept people in Ireland and away from unemployment, and indirect benefit through the foreign investment that would provide both jobs and a new business climate. These outside influences were expected to help Ireland more quickly develop an indigenous entrepreneurial capacity. The long-term benefits would be the spillover effects from the development of technical and business expertise.

Ireland provided attractive economic incentives in the forms of tax relief and grants for equipping their factories, and training the work forces. These were the necessary conditions for establishing the multinational IT sector in Ireland. But the sufficient conditions were a societal infrastructure supportive of IT work and a qualified labor force to do it. Today, Ireland's software industry has emerged as a strong contender for multinational sites, along with Israel, India (Heeks, 1996) and Eastern Europe (Heavin, Fitzgerald, & Trauth, 2003). Ireland's software sector employs 30,000 people in both indigenous and multinational operations and creates revenues in excess of Euro 10 billion (Flood et al., 2002).

The Irish case offers two important sets of human resource issues. The first set relates to ensuring a supply of appropriately qualified IT workers. The second set relates to managing IT workers in a cross-cultural environment. To the extent that Ireland's experiences are typical of other second wave countries, the lessons learned apply to indigenous and multinational managers as well as government policy makers in other counties.

ENSURING A SUPPLY OF QUALIFIED IT WORKERS

(Re)Designing Societal Structures to Support IT Work

Among the societal infrastructures that were adapted to support the emerging IT sector, the most important was the educational infrastructure (Clancy, 1988). Irish policy makers recognized that the well-educated Irish population was a powerful resource that could be leveraged to support the emerging information sector. But there were two serious issues to overcome. The first was establishing equality of access to education. This was accomplished in 1968 when secondary education became state-funded. The other issue was enabling potential IT workers to acquire the specialized skills and knowledge for work in this sector. In the 1960's, the traditional university was not oriented toward vocational education much less vocational education of a technical nature. Consequently, in the 1970's and 1980's, two new universities were established and the existing universities were adapted to incorporate business and IT skills into their curricula. Technical colleges were also established. Evening, adult-oriented programs were established for workers to develop their skills and employment prospects. Finally, the government-sponsored IT training programs for those with university degrees or who had been made redundant in other fields (Trauth, 1993).

It was also necessary to maintain alignment between the particular skill sets being developed in the schools and training programs, and the available types of jobs. An unintended consequence of Ireland's educational success was that Irish IT workers became a desired human resource in other countries. In response, industrial policy assessments recommended a closer match between the educational plans of the universities and the employment opportunities available in the country (Industrial Policy Review Group, 1992).

Addressing Barriers to a Wider Participation in IT work

There were barriers to full participation in Ireland's IT sector with respect to age, gender and social class. The perception of IT as a young person's field was reinforced by the extremely young population of the country. This age divide was exacerbated by the prior educational policy limiting access to secondary and, therefore, higher education. Thus, in the early 1990's, those over the age of thirty-five, those who had not had access to free secondary education, were fewer in number in the IT labor force.

Another type of barrier relates to gender. While women found the IT sector better for women than traditional industries, banking and the civil service, there was still a tension between opportunity and restriction. IT was a new industry without established patterns of gendered work. However, there was also an acknowledged stereotype of IT work as a male activity and recognition by both men and women that women were not full participants in the IT sector. The reasons have been typically linked to a culture of large families in which child rearing was a woman's responsibility (Kvasny & Trauth, 2002; Trauth, 1995).

The final type of barrier relates to social class. Despite Ireland's historic disdain for rigid social class categories, there is evidence of social class barriers in the information sector. The absence of free secondary education was a barrier to poor and working class individuals. Further, in family settings without a history of or value placed upon education, there can be pressure on young people to enter the work force as soon as possible in order to add to the family income. Other evidence of attitudinal barriers, coming from members of the middle class, was the importance of having the "correct" accent and address in order to secure employment in indigenous IT firms.

Managing IT Workers in a Cross-Cultural Work Environment

The second set of issues relates to managing IT workers in a cross-cultural work environment in which the "first wave" nation's culture is embedded in the corporate culture of the multinational firm (Trauth, 1996). A firm's corporate culture " its values, management style, method of operations and work environment" reflects the national culture in which it developed. Thus, the multinational IT workplace was a cross-cultural mix of American and Irish cultures, the IT culture, and the particular corporate culture of the firm. While the Irish workers welcomed the American management style and corporate culture, there was also tension over how far – and in what direction – the cultural influence should go. Not surprisingly, the American managers favored the American culture, believing that the multinational firms ought to have a significant cultural impact. On the other hand, Irish human resource managers argued for tailoring the corporate culture to the particular national context. The viewpoint was that while the multinationals were bringing certain values and attitudes to the workplace, there was also a significant contribution to be made by the Irish culture. But along with resistance to the multinational influence was the recognition that importing another work culture was part of the plan. By bringing in multinational firms Ireland would be able to import a well-established work ethic that would have taken considerably longer to develop if done indigenously.

FUTURE TRENDS

Managing IT workers in a cross-cultural environment requires the acknowledgment that two different national cultures are involved when a multinational IT firm sets up operations in a country. Both of these cultures have positive contributions to offer the workplace. Multinational managers should strive to understand work patterns and attitudes of the host country culture that, while different, may nevertheless be productive. They should also understand that introducing a corporate culture means introducing a different national culture. At the same time, the host country must recognize that when the intent is to import expertise in order to quickly introduce an IT sector, one side effect will be the changes in national culture.

This has been referred to in the literature as *situating culture* (Weisinger & Salipante, 2000; Weisinger & Trauth, 2002, 2003). According to this theoretical framework, culture is a socially negotiated, dynamic, practical, and locally situated process. Hence, it is a view of culture as "doing" (which places emphasis on the actual behaviors of people) rather than "thinking" (which places emphasis on shared cognitive schemas). This view sees the interaction among the group members' different cultures as being situated in a particular context. Thus, by situating culture in a particular context, a manager may be better able to comprehend the emergence of unique local cultural processes that reflect distinct socially negotiated realities and workplace practices.

By recognizing that there is more than one way to achieve a management goal, multinational managers can develop procedures and management approaches that exploit the best features of the host country. In the presence of two distinct cultures, it is also necessary to acknowledge that cultural influence goes in both directions. It is natural that the home culture of the multinational IT firm will influence the society it enters. But it is also natural that the workers will influence the corporate culture to make it compatible with their own. By building a permeable wall, by the open exchange of values and norms, both cultures can be enriched.

For example, American managers in Ireland learned that a human relations problem could be diffused by utilizing an Irish cultural institution: the pub. By meeting in a setting that, according to cultural norms, conveys equal standing, a manager could more easily work out the problem with the employee. Clearly, this management approach fits well with Irish culture but may not suit another cultural context. Likewise, what works best in Japan or in America may not be what works best in Ireland. Another example is the approach taken to knowledge management. Knowledge management refers to the capturing and recording of the tacit organizational knowledge that has built up over time and that resides within the employees of a firm. One of the main objectives of engaging in knowledge management is to improve the flow of organizational knowledge to facilitate organizational learning of new employees and cross-training. In Ireland, managers can address some aspects of this goal by leveraging certain cultural characteristics instead of investing in expensive equipment. The cultural characteristic of interest in others and sociability leads naturally to employees knowing more about their colleague's work than might be the case in another culture that places less emphasis on sociability (Trauth, 2000). Hence, cross-training is a natural outcome of this interaction. Simply, by recognizing that this is occurring, management can reap knowledge transfer benefits.

CONCLUSION

The case of Ireland represents an early example of the issues associated with what is currently recognized as a trend toward global outsourcing. Because it was a leader in positioning itself as a destination for global outsourcing, Ireland's experiences offer insights for both nations and multinational companies interested in outsourcing. One insight is that a qualified labor force must be available. Because of the specialized skills required for employment in the information sector, education is the key to attracting outsourcing. But in order to ensure that all citizens are able to participate in this employment sector, there must be equal educational opportunity. In Ireland, and elsewhere, members of certain groups experience barriers that inhibit full and equal participation in the information economy. In order to ensure that the society can sustain its IT sector, the educational infrastructure needs to be aligned with the skills and knowledge required for IT work, and the educational plans of the universities should be coordinated with the employment objectives of the firms. Finally, management consideration needs to be given to the mix of cultures that is present when a multinational firm from one country sets up operations in another. In this new cultural context, both cultures come together to produce a new, *situated* culture. The public policy, human resource and management issues that are raised in this case reveal some of the issues that must be addressed as more and more countries "leapfrog" an IT sector in order to reap the benefits of global outsourcing. These issues must be considered from two perspectives: that of the firms engaged in outsourcing, and that of countries inviting firms to its shores.

KEY TERMS

Cross Cultural IT Management: Managing the IT function and its personnel in a globally distributed setting.

Global Outsourcing: The trend towards directing outsourcing—contracting with other firms to perform non-critical functions for a business—toward countries with low workforce costs.

Information Economy: That portion of the national economy that is based upon information processing and related activities (Porat, 1977).

Information Sector: A component of the information economy. The *primary information sector* includes those who develop hardware, software and information systems. The *secondary information sector* includes those engaged in information processing activities in the course of doing work related to some other primary activity such as insurance claims processing.

Information Society: A societal transformation in which information is the key resource.

Information Technology (IT) Worker: One who works in the primary or secondary information sector.

Post-industrial Society: A society in which knowledge replaces capital as the key economic resource and the predominant type of work is in the service sector (Bell, 1973).

Learnability

Philip Duchastel
Information Design Atelier, Canada

INTRODUCTION

Learnability is not exactly a new concept in information technology, nor in cognitive science. Learnability has been a key concept of usability (Folmer & Bosch, 2004) in the area of software system design, where it relates to such issues as consistency, familiarity and simplicity. It has also been a traditional concept in linguistics in relation to the ease of language learning (McCarthy, 2001) and in machine learning (Valiant, 2000).

The concept of learnability has recently been repurposed within the field of instructional technology (Duchastel, 2003), building on the concept of usability in Web site design (Nielsen, 2000), and it is that learnability that is considered here. Learnability in this new sense concerns how learnable some piece of instruction is. It deals with a facet of educational resources.

The basic question is this: What makes the content of an instructional site (or of some resource) learnable? Take any one of the many thousands of online learning courses currently available on the Web and ask yourself: Does this course seem difficult to learn (assuming you have the proper background for it)? What would improve it? What would the ideal online course in this area look like? These questions all underlie the learnability of the course.

What then is learnability? Could we say that it is defined by successful learning? That would mean that students who study the course thoroughly learn its content, as evidenced on a good test for instance. Or could we say that a main criterion is ease of learning? Meaning that students experience good intellectual flow and enjoy the course.

Both of these factors, success in learning and enjoyment of learning, can be considered criteria of learnability. Are there others? That is the issue of learnability.

The skeptic will immediately insist that learning takes place within a learner and that it is that locus that mainly determines learnability – that is, the curiosity, intelligence, motivation and persistence of the learner. These are what make or break learning. The teaching materials can only go so far, the learner has to make a go of it, make it succeed.

While there is some truth to that view, it is certainly not the full picture, nor the most useful picture. Consider traditional usability in Web sites or software products. There too, the user plays a role. If he is dull-witted, or perhaps too pressed for time (showing a lack of interest), or just resistant to learning the basics (jumping in and thrashing around – as often happens), there is little scope for success no matter how usable the site or program may have been made. But we do not give up on usability in Web site creation because of that.

The point is designers do not blame the user for incompetence, for ill-will or for the lack of success of their site or program. They maximize usability, realizing well enough that usability is certainly contextual. The same applies, as it should, to learnability: success in learning can be maximized through the product, over and beyond context issues, or in spite of them.

The product view of instruction is an important one, one that is emphasized here. An alternate view, much more widespread, is a process one: learning is a process, and so is instruction in the sense of manipulating the situation so as to facilitate learning. This is why the immense amount of research on learning and education over the past century has not dealt explicitly with learnability.

The process view is not to be denigrated, but a product view can incorporate processes and has definite design advantages. Learnability is best considered in this light.

LEADING QUESTIONS

The challenge before us is to identify those features of excellent learning materials. What makes something learnable? Very learnable, most learnable?

But first, why is it so difficult to pinpoint these features? What are the deep issues underlying learnability? There are three of them we need to consider. They are learning, design, and curriculum. Each is difficult in its own right and learnability involves considering them jointly – hence the magnitude of the challenge.

The first deep question is what is learning? The field of learning has long been a core issue in psychology and numerous theories of learning have been put forth in answer (Kearsley, 2004). The issue is far from settled, as practitioners such as educators well know. There is acknowledgment of different kinds of learning, with different factors at play, but no large agreement on these or on the overall picture.

The second deep question concerns teaching. How do you design for learning? There are general principles that have evolved over time, codified broadly in what is known as the field of instructional design (Reigeluth, 1999). But here too, there is hardly agreement. All design theorists will subscribe to general systems principles like those found in software design or in HCI. All subscribe to the value of usability testing, the trying out of the materials designed with sample students in order to verify the strength of the design and capture any ways of improvement. But given divergences in views of learning, it is natural that hard disagreements will occur here too, in how to design for learning.

The third deep question concerns what to teach - the content. That was what led educators to determine and discuss taxonomies of learning objectives half a century ago (Bloom, 1956) and why this issue remains at the heart of much debate in education (Egan, 1997).

At first thought, you might think that this is an outside issue. That first, we decide what to teach, then only after that, how to teach it, how to design it. Or we might think that teachers and curriculum specialists, or professors and institutions, determine the content "to be covered". That learnability applies to any content, whatever it is determined it should be. But that overlooks the crucial notion that the *what* and the *how* of learning are inextricably linked (Carroll, 1990), just as in communication more generally. An instructional designer must fashion the content as much as the process, in the same way an information designer fashions information well beyond the graphic design aspect. Both are information architects, but that is not yet widely recognized, which creates difficulties for the acceptance of learnability.

In the next sections, I will address these leading questions by introducing some simple models that synthesize them in a nutshell. This remains a very cursory look at the issues, but nevertheless shows the direction in which they can be further explored, as is done in Duchastel (2003).

LEARNING - THE CIM MODEL

At its most general, learning is the process of internalizing information in memory, making that information available later on when needed. But learning the names of the bones in the body and learning the principles of acoustics are rather different forms of learning. We learn them in different ways. What are the commonalties? What are the differences?

There are three types of learning, conveniently contrasted in what we can call the CIM model. CIM stands for Comprehension, Interest, Memorizing, these being the three factors involved in the learning process.

Comprehension is based on our ability to reason, to fit things together, to see how they all work together. Comprehension is the process of generating internal models of the world in all its workings, large and small. We comprehend when we see how things fit together, how it all makes sense. Understanding is a process of rational model building.

Interest, the second element in CIM, is the attentional factor in learning. If something stands out from its context, it will be more easily remembered, as will things that are extremely vivid or of great personal importance. More often, we try to learn things that are only of mild interest and then, if attention wanders, learning suffers. Interest has the function of keeping us on task.

The third element, memorizing, handles things that do not fit well together, that have no basis in rationality. For instance, the name "cochlea" to represent one of the components of the ear is quite arbitrary to us – there is no reason for it [no reason that we know]. It is [to us] purely arbitrary and no amount of reasoning will assist in "understanding" it. We just have to associate the name and the component.

DESIGN - THE MOCAF MODEL

Based on the CIM model, we can see that there will be three types of elements that are needed within an instructional product: models, cases and facts. Combining these (and any product would have all three) leads to the acronym MoCaF for the design model appropriate for the creation of highly learnable instructional products.

Models are the tools of understanding; they are what lead to comprehension. Cases are the illustrative materials that instantiate the models in particular settings. They are the main means of grabbing and holding attention. As for facts, they are just the basics that need to be brutely memorized.

Models are what drive comprehension. The aim of design in this area is to create models that embody the disparate elements of content while synthesizing them in an artifact [the model] that clearly communicates and is easily learned. Models show how elements relate to one another; they capture relationships and interactions.

The craft of developing models is one of establishing the underlying structures in a field [content expertise is essential here] and of then representing those structures in synthetic form that facilitate communication and understanding (Wurman, 2000).

Cases are the illustrative material in instructional content. They embody the living problems and the living application of the models. They range from simple examples to complex case studies. Of particular interest are those relatively complex cases that mirror difficult real-life settings, such as those used in problem-based medical education or in business education.

Cases are multi-functional in an instructional application. At least three functions can be served:

1. To illustrate the content of a model, instantiating it and situating it in real life.
2. To provide practice to the student in applying knowledge.
3. To test the student's knowledge (either self-testing for monitoring purposes or formal testing for assessment and validation purposes).

Facts are those ill-fitting elements of knowledge that are considered important to know and that hang out there on their own, only incidentally attached to some model or other.

Facts are simple to state, for instance in a textbook or in a presentation. But that does not ensure they will be learned. While simple to state, facts are hard to enrobe in a context that will make them easily learnable. Practice or an eventful context is needed. There are means to accomplish this in instructional terms, such as through games, problems, contests, high-impact media, and so forth. Often, though, when these are not developed, the student is left pretty much to his or her own devices for rehearsing the facts to be learned. This is not an optimal situation.

Learning involves interacting with information. And so it is the design of that information that is crucial to learnability. We are dealing here with the content of the instructional product, that content being modeled through design into a certain form that makes it understandable, interesting and memorizable.

Models, cases, facts are all basically information content of particular sorts, information with which the learner will interact during learning. To a very large extent, then, instructional design is mostly a matter of information design, a notion that needs to become widely recognized. Even the more recent notion of interaction design [often applied to Web site design or to exhibition design] is largely a matter of information design involving models (structures), cases (events), and facts (impressions). In sum, learnability must focus primarily on the content to be included in an instructional product, that is, on information design. That is the key contribution of the learnability approach to design and its central usefulness in the practical design of knowledge artifacts.

FUTURE TRENDS

Perhaps the greatest trend emerging in the future with respect to learnability will be the continuing merging of instructional design into information design. As access to information becomes more ready, we will likely see a reduction of our need to memorize arbitrary information beyond the frequently used or crucial to know kind. Our external memory supports will fill the need for the less needed information.

This merging of the two traditionally distinct design worlds (information and instruction) is particularly informative for the learner-control issue in education. Adult learners like to have more control (or like to think they do) over what they learn, how they learn it and when they learn. They operate more in an access mode than in a traditionally receptive educational mode.

Well-designed information/instruction products will facilitate this approach, being used at times for informational purposes and at other times for instructional purposes. Informal learning (outside of academic structures) and formal instruction both involve learning, both involve interacting with information, both profit from good information design.

The design of e-learning materials also might offer more means of controlling interaction than does for instance the design of textbook or other printed materials. This may or may not be an advantage, depending on a whole host of factors, such as maturity of the learners, prior knowledge of the learners and other context factors. But it does raise once again the general issue of content vs. process.

This philosophical issue remains a challenging one, as well as a thorn in any attempt to devise an overarching theory of learning and instruction. One facet of this issue, and I will conclude with it, is why we speak of the learnability of instructional products. After all, we learn also a great deal from interacting with the world at large, not just with artifacts.

The way to come to grips with this issue is to adopt a wide conception of information, as does the field of semiotics. Information goes far beyond the written word, and beyond the world of illustration too. Information is structure that lies within the world around us, both in its structural elements and its processes (Duchastel, 2002). Some of these are found elements, others are designed artifacts, ones the design of which we can control. This is where we can affect the learnability of a product or of a structured process.

KEY TERMS

Information Design: A similar soft technology applied to information more broadly for the purpose of successful access to information.

Instructional Design: The soft technology of organizing learning materials and events so that instruction will be most successful.

Interaction Design: A similar soft technology focusing on the processes of interacting with information, particularly in high-impact or strongly emotive contexts.

Learning: The processes used by organisms, including humans, to augment their knowledge base or their skill set for the purposes of better adaptation to their milieu.

Machine Learning: The processes used to fine-tune a program's performance or to augment its knowledge and functionality.

Online Course: A Web-based instructional program that organizes the learning of a student in a particular subject. Not all learning materials need be online and much of an online course involves dynamic interactions with other participants.

Usability: The ease with which a user can accomplish a desired task within a Web site. One also talks of a site being user-friendly.

Learning 3D Face-Animation Model

INTRODUCTION

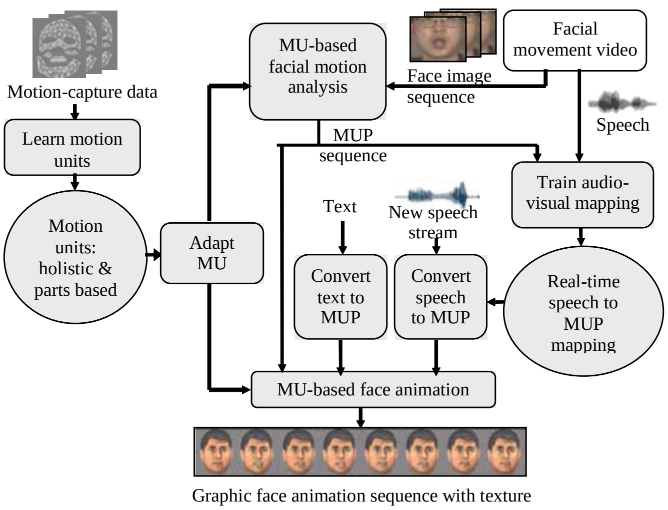
A synthetic human face is useful for visualizing information related to the human face. The applications include visual telecommunication (Aizawa & Huang, 1995), virtual environments and synthetic agents (Pandzic, Ostermann, & Millen, 1999), and computer-aided education.

One of the key issues of 3D face analysis (tracking) and synthesis (animation) is to model facial deformation. The facial deformation is complex, which often includes subtle expressional variations to which people are very sensitive. Therefore, traditional models usually require extensive manual adjustment. Recently, the advance of motion-capture techniques sparked data-driven methods (e.g., Guenter et al., 1998). They achieve realistic animation by using real face-motion data to drive 3D face animation. However, the basic data-driven methods are inherently cumbersome because they require a large amount of data.

More recently, machine learning techniques have been used to learn *compact* and *flexible* face-deformation models from motion-capture data. The learned models have been shown to be useful for realistic face-motion synthesis and efficient face-motion analysis. A unified framework on facial deformation analysis and synthesis is demanded to address in a systematic way the following problems: (a) how to learn a compact 3D face-deformation model from data, and (b) how to use the model for robust facial-motion analysis and flexible animation.

In this article, we present a unified machine-learning-based framework on facial deformation modeling, and facial motion analysis and synthesis. The framework is illustrated in Figure 1. In this framework, we first learn from

Figure 1. Machine-learning-based framework for facial deformation modeling, and facial motion analysis and synthesis



extensive 3D facial motion-capture data a compact set of *Motion units* (MUs), which are chosen as the quantitative visual representation of facial deformation. Then, arbitrary facial deformation can be approximated by a linear combination of MUs, weighted by coefficients called *motion unit parameters* (MUPs). Based on interpolation, the MUs can be adapted to the face model with new geometry topology. MU representation is used in both robust facial motion analysis and efficient synthesis. We also utilize MUs to learn the correlation between speech and facial motion. A real-time audio-to-visual mapping is learned using an artificial neural network (ANN). Experimental results show that our framework achieved natural face animation and robust nonrigid tracking.

BACKGROUND

Facial Deformation Modeling

Representative 3D spatial facial deformation models include free-form interpolation models (e.g., affine functions, splines, radial basis functions), parameterized models (Parke, 1974), physics-based models (Waters, 1987), and more recently, machine-learning-based models. Because of the high complexity of natural motion, these models usually need extensive manual adjustments to achieve plausible results. To approximate the space of facial deformation using simpler units, people (Tao, 1998) proposed to describe arbitrary facial deformation as a combination of action units (AUs) based on the facial action coding system (FACS; Ekman & Friesen, 1977). Because AUs are only defined qualitatively, they are usually manually customized for computation. Recently, people turned to apply machine learning techniques to learn models from data (Hong, Wen, & Huang, 2002; Kshirsagar, Molet, & Thalmann, 2001; Reveret & Essa, 2001).

Facial Motion Analysis

Human facial motion analysis is the key component for many applications, such as model-based very-low-bit-rate video coding, audiovisual speech recognition, and expression recognition. High-level knowledge of facial deformation must be used to constrain the possible deformed facial shapes. For 3D facial motion tracking, people have used various 3D deformable model spaces, such as the 3D parametric model (DeCarlo, 1998), B-spline surface (Eisert, Wiegand, & Girod, 2000), and FACS-based models (Tao, 1998). These models, however, are usually manually defined, thus may not capture characteristics of the real facial motion well. Therefore, people have recently proposed to use subspace models trained from real motion data (Reveret & Essa, 2001}.

Facial Motion Synthesis

In this article, we focus on real-time-speech face animation. The core issue is the audio-to-visual mapping. HMM-based methods (Brand, 1999) utilize long-term contextual information to generate smooth motion trajectory, but they can only be used in off-line scenarios. For real-time mapping, people proposed various methods such as vector quantization (VQ; Morishima & Harashima, 1991), the Gaussian mixture model (GMM), and ANN (Morishima & Harashima). To use short-time contextual information, people used the concatenated audio feature over a short time window (Massaro et al., 1999) or a time-delay neural network (TDNN; Lavagetto, 1995).

LEARNING 3D FACE-DEFORMATION MODEL

In this section, we introduce our facial deformation models. We use iFACE (Hong et al., 2002) for MU-based animation; iFACE is illustrated in Figure 2.

The Motion-Capture Database

We use motion-capture data from Guenter et al. (1998). 3D facial motion is captured at the positions of the 153 markers on the participant's face. Figure 3 shows an example of the markers. For better visualization, a mesh is built on those markers (Figure 3b and c).

Learning Holistic Linear Subspace

We try to learn the optimal linear bases, MUs, whose linear combination can approximate any facial deformation. Using MUs, a facial shape $\vec{s}$ can be represented by

$$\vec{s} = \vec{s}_0 + \left(\sum_{i=1}^{M} c_i \vec{e}_i + \vec{e}_0\right) , \qquad (1)$$

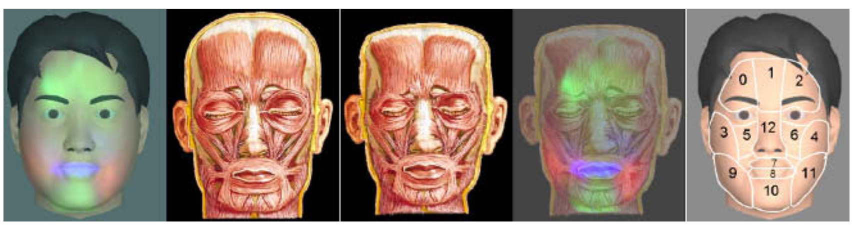
where $\vec{s}_0$ denotes the facial shape without deformation, $\vec{e}_0$ is the mean facial deformation, $\{\vec{e}_0, \vec{e}_1, \ldots, \vec{e}_M\}$ is the MU set, and $\{c_o, c_1, \ldots, c_M\}$ is the MU parameter set.

Principal component analysis (PCA) is applied to learning MUs from the facial deformation of the database. The mean facial deformation and the first seven eigenvectors are selected as the MUs, which capture 93.2% of the facial deformation variance. The first four MUs are visualized by an animated face model in Figure 4.

Learning Parts-Based Linear Subspace

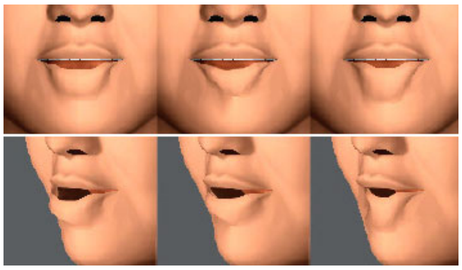
Because the facial motion is localized, it is possible to decompose the complex facial motion into parts. The

Figure 5. (a) NMF learned parts overlaid on the generic face model; (b) the facial muscle distribution; (c) the aligned facial muscle distribution; (d) the parts overlaid on muscle distribution; (e) the final parts decomposition.



(a) (b) (c) (d) (e)

Figure 6. Three lower lip shapes deformed by three of the lower lip parts-based MUs respectively. The top row is the frontal view and the bottom row is the side view.



decomposition helps reduce the complexity in deformation modeling, and improve the analysis robustness and the synthesis flexibility. The decomposition can be done manually using prior knowledge of facial muscle (Tao, 1998). However, it may not be optimal for the linear model used because of the high nonlinearity of facial motion. Parts-based learning techniques, such as nonnegative matrix factorization (NMF; Lee & Seung, 1999), provide a way to help design *parts-based facial deformation models*. We present a parts-based face-deformation model. In the model, each part corresponds to a facial region where facial motion is mostly generated by local muscles. The part decomposition is done using NMF. Next, the motion of each part is modeled by PCA. Then, the overall facial deformation is approximated by summing up the deformation in each part. Figure 5 shows the parts-decomposition results.

The learned parts-based MUs give more flexibility in local facial deformation analysis and synthesis. Figure 6 shows some local deformation in lower lips, induced by one of the learned parts-based MUs. These locally deformed shapes are difficult to approximate using holistic MUs. For each local deformation shown in Figure 6, more than 100 holistic MUs are needed to achieve 90% reconstruction accuracy. Therefore, we can have more flexibility in using parts-based MUs. In face animation, people often want to animate a local region separately, which can be easily achieved by adjusting MUPs of parts-based MUs separately. In face tracking, people may use parts-based MUs to track only regions of interest.

MU Adaptation

The learned MUs are based on the motion-capture data of particular subjects. They need to be adapted to the face model with new geometry and topology. We call this process *MU adaptation*, whose first step fits MUs to a face model with different geometry. It is done by moving the markers of the learned MUs to their corresponding positions on the new face. We interactively build the correspondence of facial feature points shown in Figure 2c via a GUI (graphical user interface). Then, warping is used to interpolate the remaining correspondence. The second step is to derive movements of facial surface points that are not sampled by markers in MUs. It could be done using the radial basis function (RBF) in a similar way to Marschner, Guenter, & Raghupathy (2000).

MODEL-BASED FACIAL MOTION ANALYSIS

In existing 3D nonrigid face-tracking algorithms using the 3D facial deformation model, the subspace spanned by the AUs is used as constraints of low-level image motion. However, the AUs are usually manually designed. For these approaches, our automatically learned MUs can be used in place of the manually designed AUs. We choose to use the learned MUs in the 3D nonrigid face-tracking system in Tao (1998) because it has been shown to be robust and in real time. Details of facial motion estimation can be found in Tao. In the original system, AU is manu-

ally designed using Bezier volume and represented by the displacements of vertices of a face-surface mesh. We derive AUs from the learned holistic MUs using the MU adaptation process. The system is implemented to run on a 2.2-GHz Pentium 4 processor. It works at 14 Hz for nonrigid tracking for image size 640×480. The estimated motion can be directly used to animated face models. Figure 7 shows some typical frames that it tracked, along with the animated face model to visualize the results.

The tracking algorithm can be used in model-based face video coding (Tu et al., 2003). We track and encode the face area using model-based coding, and encode the residual in the face area and the background using traditional waveform-based coding method H.26L. This hybrid approach improves the robustness of the model-based method at the expense of increased bit rate. Eisert et al. (2000) proposed a similar hybrid coding technique using different model-based tracking. We capture and code videos of 352×240 at 30 Hz. At the same low bit rate (18 kbits/s), we compare this hybrid coding with the H.26L JM 4.2 reference software. Figure 8 shows three snapshots of a video. Our hybrid coding has 2 dB higher PSNR around the facial area and has much higher visual quality. Our tracking system could also be used in audiovisual speech recognition, emotion recognition, and medical applications related to facial motion disorders such as facial paralysis.

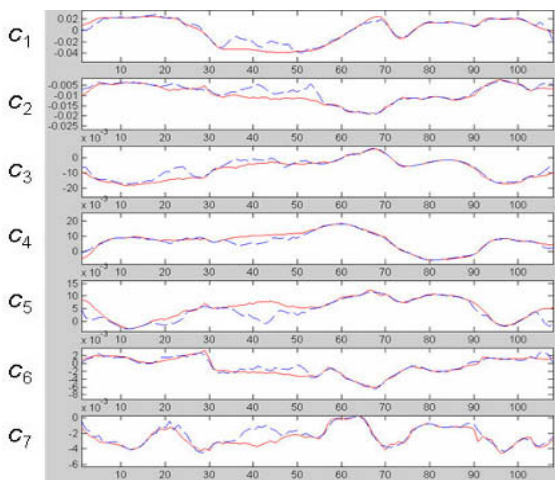
REAL-TIME SPEECH-DRIVEN 3D FACE ANIMATION

We use the facial motion-capture database used for learning MUs along with its audio track for learning audio-to-visual mapping. For each 33-ms window, we calculate the holistic MUPs as the visual features, and 12 Mel-frequency cepstrum coefficients (MFCCs; Rabiner & Juang, 1993) as the audio features. To include contextual information, the audio feature vectors of frames *t*-3, *t*-2, *t*-1, *t*, *t*+1, *t*+2, and *t*+3, are concatenated as the final audio feature vector of frame *t*.

The training audiovisual data is divided into 21 groups, where one is for silence and the remaining groups are generated using the *k*-means algorithm. Then, the audio features of each group are modeled by a Gaussian model. After that, a three-layer perceptron is trained for each group to map the audio features to the visual features. For estimation, we first classify an audio vector into one of the audio feature groups using GMM. We then select the corresponding neural network to map the audio feature to MUPs, which can be used in Equation (1) to synthesize the facial shape. For each group, 80% of the data is randomly selected for training and 20% for testing. A typical estimation result is shown in Figure 9. The horizontal axes represent time. The vertical axes represent the magnitude of the MUPs. The solid red trajectory is the original MUPs, and the dashed blue trajectory is the estimation results.

We reconstruct the facial deformation using the estimated MUPs. For both the ground truth and the estimated results, we divide the deformation of each marker by its maximum absolute displacement in the ground-truth data. To evaluate the performance, we calculate the Pearson

Figure 9. Compare the estimated MUPs with the original MUPs. The content of the corresponding speech track is, "A bird flew on lighthearted wing."



product-moment correlation coefficients (R) and the mean square error (MSE) using the normalized deformations. The Pearson product-moment correlation ($0.0 \le R \le 1.0$) measures how good the global match is between two signal sequences. The coefficient R between the ground truth $\{\vec{d}_n\}$ and the estimated data $\{\vec{d}_n'\}$ is calculated by

$$R = \frac{tr(E[(\vec{d}_n - \vec{\mu}_1)(\vec{d}_n' - \vec{\mu}_2)^T])}{\sqrt{tr(E[(\vec{d}_n - \vec{\mu}_1)(\vec{d}_n - \vec{\mu}_1)^T])tr(E[(\vec{d}_n' - \vec{\mu}_2)(\vec{d}_n' - \vec{\mu}_2)^T])}}, \quad (2)$$

where $\vec{\mu}_1 = E[\vec{d}_n]$ and $\vec{\mu}_2 = E[\vec{d}_n']$. In our experiment, $R = 0.952$ and MSE = 0.0069 for training data, and $R = 0.946$ and MSE = 0.0075 for testing data. Figure 10 shows a typical animation sequence.

Our real-time speech-driven animation can be used in real-time two-way communication scenarios such as videophone. On the other hand, existing off-line speech-driven animation can be used in one-way communication scenarios, such as broadcasting. Our approach deals with the mapping of both vowels and consonants, thus it is more accurate than real-time approaches with only vowel mapping. Compared to real-time approaches using only one neural network for all audio features, our local ANN mapping (i.e., one neural network for each audio feature group) is more efficient because each ANN is much simpler.

Human Emotion Perception Study

The synthetic talking face can be evaluated by comparing the influence of the synthetic face and real face on human emotion perception. We choose three facial expressions, (a) neutral, (b) smile, and (c) sad, and three audio tracks, (a) "It is normal," (b) "It is good," and (c) "It is bad." The information associated with the sentences is (a) neutral, (b) positive, and (c) negative. We capture video and generate animation for all nine combinations of expressions and sentences. Sixteen untrained people participated in the experiments.

The first experiment investigates human emotion perception based on visual-only stimuli. The subjects are asked to infer the emotional states based on the animation sequences without audio. The emotion inference results in terms of the number of the subjects are shown in Table 1. As shown, the effectiveness of the synthetic talking face is comparable with that of the real face.

The second and third experiments are designed to compare the influence of the synthetic face on bimodal human emotion perception and that of the real face. In the second experiment, the participants are asked to infer the emotion from the synthetic talking face animation with audio. The third experiment is the same except that the participants observe the real face instead. In each of the experiments, the audiovisual stimuli are presented in two groups. In the first group, audio content and visual information represent the same kind of information (e.g., positive text with smile expression). In the second group, the relationship is the opposite. The results are combined in Table 2. If the audio content and the facial expressions represent the same kind of information, the human perception is enhanced. Otherwise, it confuses human participants. An example is shown in the fifth and sixth columns

Table 1. Emotion inference based on visual-only stimuli. The S column is the synthetic face, the R column the real face.

		Facial Expression					
		Neutral		Smile		Sad	
		S	R	S	R	S	R
Emotion	Neutral	16	16	4	3	2	0
	Happy	0	0	12	13	0	0
	Sad	0	0	0	0	14	16

Table 2. Emotion inference results agreed with facial expressions. The inference is based on both audio and visual stimuli. The S column is the synthetic face, the R column the real face.

		Facial Expression			
		Smile		Sad	
		S	R	S	R
Audiovisual Relation	Same	15	16	16	16
	Opposite	2	3	10	12

Figure 10. Typical animation frames. Temporal order is from left to right, top to bottom.

of Table 2. The audio content is positive while the facial expression is sad. Ten participants report "sad" for the synthetic face with sad expression. The number increases to 12 if the real face is used. Overall, the experiments show that the effectiveness of the synthetic face is comparable with that of the real face, though it is slightly weaker.

FUTURE TRENDS

Future research directions include investigating systematic ways of adapting learned models for new people, and capturing appearance variations in motion-capture data for subtle yet perceptually important facial deformation.

CONCLUSION

This article presents a unified framework for learning compact facial deformation models from data, and applying the models to facial motion analysis and synthesis. This framework uses a 3D facial motion-capture database to learn compact holistic and parts-based facial deformation models called MUs. The MUs are used to approximate arbitrary facial deformation. The learned models are used in 3D facial motion analysis and real-time speech-driven face animation. The experiments demonstrate that robust nonrigid face tracking and flexible, natural face animation can be achieved based on the learned models.

ACKNOWLEDGMENT

This work was supported in part by NSF Grant CDA 96-24386 and IIS-00-85980. We thank Dr. Brian Guenter, Heung-Yeung Shum, and Yong Rui of Microsoft Research for the face-motion data.

KEY TERMS

Artificial Neural Networks: Type of machine learning paradigm. They simulate the densely interconnected, parallel structure of the mammalian brain. They have been shown to be powerful tools for function approximation.

Facial Deformation Model: Model that explains the nonrigid motions of human faces. The nonrigid motions are usually caused by speech and facial expressions.

Facial Motion Analysis: Procedure of estimating facial motion parameters. It can also be called "face tracing." It can be used to extract human face motion information from video, which is useful input for intelligent video surveillance and human-computer interaction.

Facial Motion Synthesis: Procedure of creating synthetic face animations. Examples include text-driven face animation and speech-driven face animation. It can be used as an avatar-based visual interface for human-computer interaction.

Machine Learning Techniques: Techniques that can automatically improve computational models based on experiences

Motion Capture: Techniques that measure complex motions. One type of motion-capture techniques places markers on the target object and tracks the motions of these markers.

Motion Unit Model: Facial deformation model we propose. It is based on measurement of real facial motions. Motion units (MUs) are a set of vectors whose linear combinations can be used to approximate arbitrary facial shapes.

Learning Portals as New Academic Spaces[1]

Katy Campbell
University of Alberta, Canada

INTRODUCTION

Many functional definitions emphasize a portal as an integrated system providing a gateway to organized data (c.f., Batson, 2000; Copeland, 2001; Eisler, 2001; Looney & Lyman, 2000). However, a learning portal may go beyond the information management function to provide important mechanisms for reaching out to new populations of learners and engaging them in new ways to facilitate learning and development. Beyond serving as a gateway and an organizer, a portal can provide access to a broader range of contemporary information and learning resources (experts, teachers, researchers, mentors), encourage enriched interaction with those resources and with other learners anywhere in the world, and support new models of teaching, learning and research. Ultimately, a collaborative, community-based process of designing and implementing a portal may support institutions in reorienting towards a user-centered learning community.

BACKGROUND

Portals and a Transformed Learning Environment

Universities are seeking ways to manage emerging areas of research and discipline specialization, learner profiles, and partnerships with learning providers that challenge the autonomy of the single-source institution. The public has expressed strong interest in alternative methods for delivering, supporting, and facilitating learning — any time, any place, any pace — required in new knowledge-intensive environments and enabled by converging information and communication technologies. Therefore, the decision to implement a campus portal for enhanced learning opportunities must address issues of equity and access, flexibility, innovation, personalization, credibility, quality, transparency, and transferability within the framework of evolving institutional goals and strategies.

Both Campbell (2001) and Batson (2000) contend that *commercial portals* are built on different values and assumptions than those of the academic community, and pursue different goals and purposes. Erhmann (2000) identifies service provision, flexibility and responsiveness of instruction, the enrichment and extension of academic communities, attracting and retaining students and staff, fostering universal, frequent use of computing communications, and sustainability.

A learning portal expands on traditional academic space, which has traditionally been defined as physical infrastructure with related resource structures that shapes the nature of the interactions that occur within it (Batson, 2000). This space has an important socialization function: Members of the community know how to speak and act within these spaces, understand power relationships by the way these spaces organize interactions (e.g., rows of desks with a lectern at the front of the room) and, once acculturated, can subvert the purposes of these spaces. The nature of teaching and learning has been entirely defined by a familiar landscape, the physical classroom, where learning events were structured by place and time and format.

This landscape has fundamentally changed. Faculty have old maps and must redefine their relationships with learners, with new ways of representing knowledge, with research colleagues, and with external communities such as the corporate world. Learners demand customized learning experiences that are flexible, authentic, and relevant, have no brand-loyalty and expect program mobility. This is a challenge to administrators whose management strategy focuses on internal factors like time-definite program completion (e.g., the 4-year undergraduate degree).

FUTURE TRENDS

Although institutions have ranged themselves along an academic space continuum from primarily face-to-face to primarily virtual, most have settled on a technology-enhanced, or blended approach to learning and access. Employing alternative forms of instructional and delivery models, this approach includes: synchronous tools and environments such as classroom lectures, audio and videoconferencing, and data conferencing; and asynchronous tools such as computer-mediated conferencing and other communications systems, learning management systems, and print and digital media. Much of the learning content and interactions can be stored as learning objects and extended and reused in digital repositories. This approach fundamentally realigns and redefines institutional infrastructure to be more learner-centric and open in design and support and include extended information services. It also has a significant social effect on the academic community, raising questions about academic freedom, intellectual property rights management, and the nature of knowledge discovery, representation, and stewardship.

Learning portals can provide the functionality of consumer systems, and at the same time, support the social, cultural, and political goals of HE. While more or less resisting the culture of the corporation, universities nevertheless have begun to adopt the concept of portals as learning storefronts (Galant, 2000). Yet, in order to respect HE values of knowledge creation and dissemination for the greater social good, these portals must go beyond the functional requirements and gateway view of commercial portals.

Gilbert (2000) and Eisler (2000) identify major categories into which a variety of portal features and functions can be organized: gateways to information, points of access for constituent groups, and community/learning hubs. A synthesis of public reports identifies the range of stakeholders that should be involved in this task, and their values and functional requirements. Principles for the new portal-as-learning-environment include:

- Inclusiveness: the portal design must support diverse communities including learners who are: older professionals, at a distance, challenged, at different life cycles, learning outside of formal structures, and those with alternative languages, cultural, and perceptual needs; both present and virtual faculty; multidisciplinary teams of researchers; local and international academic, business, and political partners, and others.
- Integration: learning management systems such as Blackboardä and WebCTä have begun to develop and refine enterprise systems that integrate instructional, delivery, and administrative systems. These portals have evolved from a teaching/learning orientation and reflect institutional movement towards a seamless, multi-purpose, integrated learning environment.
- Learner-centeredness: portal design is based on the interrelated concepts of customization and personalization, reflecting learning environments in which learners can build learning portfolios based on their circumstances, experiences, and current needs. Traditionally, institutional Web sites have been owner-centric.
- Accessibility: the new economy implies that the intellectual resources of the university should be packaged and made available to a global community. Portals identify, organize, and represent these resources in ways that make them easy to retrieve, use, and reuse (see, for example, MIT's Open Knowledge Initiative, or OKI).
- Flexibility: for many reasons, including changes in professional accreditation, a globally mobile workforce, new and emerging professions, and life events, individuals will search for opportunities to time-shift, place-shift, and construct individual programs from many providers. A well-designed learning portal will be scalable and act as a gateway to these opportunities.
- Transparency: a learning portal makes the institution's strategic directions visible to the community. Learners, external research communities, the private sector, and others construct their own "footprint". They can search for all of the services they need, and deal directly with the systems that facilitate their interactions with the environment. Portals can help the community discover and promulgate best practices.
- Accountability: as the learning and support environment becomes more transparent, and as learning opportunities become more available and flexible, community members will expect to be able to evaluate the services and resources to which they have access. As rich information hubs, learning portals can make the institution's quality framework apparent and available for querying.
- Expanded and blended learning communities: a learning portal manages transparent and reliable communication tools, which increase access to resources and social learning communities. These tools are easily accessible from the portal and can therefore include and support group members from different institutions, organizations, regions, and cultures. These communities broaden and enrich the learning environment and enhance inclusiveness. Looney and Lyman (2000) believe that the value of a learning portal is that "it can be used to engage constituent groups, *empower* them with access to information resources and communication tools, and ultimately *retain* them by providing a more encompassing sense of membership in an academic community" (p.33).
- Flattened structures: virtual academic spaces do not support status clues to the same extent as traditional spaces. For example, a physical campus contains buildings with classrooms, labs, information resources, and administrative offices. Very of-

ten administrative offices are grouped around department chairs and the dean's office – there is an inner sanctum access to which is constrained by furniture, walls, workstations, and staff. Appointments must be made. Classrooms sometimes have permanently fixed seating arrangements (e.g., tiers) facing a lectern. Resources are under lock and key. There are barriers. These physical constraints disappear with online access. Implications include democratizing interactions within, and external to, the institution.

- Collaboration: a campus learning portal will fundamentally change the way universities treat its intellectual capital, increasing opportunities for collaborative work on campus, nationally, and internationally. It is critical to involve the owners of this capital in the design of the portal environment. As faculty members, support staff, librarians, learners, administrators, alumni, the public, and partner institutions engage each other a deeper, transformed understanding of the whole knowledge management enterprise will emerge (Beller & Or, 1999).

CONCLUSION

The learning portal can be designed to include a wide range of information, communication, and development tools (Alharti, Bourne, Dawant, & Mayadas, 2000; Eisler, 2000; Erhmann, 2000; Gold, 2001; Moore, 2002; Paadre,

Figure 1. Resources and services for instructors, students, and the public

Resources and Services for Instructors, Students and the Public	
Tools	**Example**
• an array of interactive multi-media tools • extended elements of traditional library services • increasingly rich interlinked libraries of both traditional and electronic resources • access to extra-curricular virtual events • a broadband-enhanced learning object repository • online advising • uniformity of single campus-wide interface linking all courses	A School of Business develops a portal that includes a large database of digital resources for courses in economics, organizational behavior, accounting and finance, human resources management and management and information systems. Resources include case studies (text and video), simulations (video), interactive demonstrations (e.g. graphs in which variables can be changed), exemplars of student projects, historical artifacts, etc. Faculty and students can search for and download these resources using a custom search engine, and can also share or "deposit" new resources, extend existing materials with quizzes; commentary, additional activities. The database (or repository) links directly to other repositories like MERLOT. Users are invited to review resources, similar to Amazon.com's system. The repository also links to the University's library system which is increasing its full-text journal holdings online and is also acquiring digital resources such as archived speeches. Users can customize their portals by choosing among options when they first logon. For example, there are several student-led clubs that hold regular meetings, sponsor guest speakers and events, and offer scholarships. A user may select which of these clubs to include on their portal so that they receive only those announcements on the homepage. The School's IT department has created a library of templates that faculty may use/customize for their own courses. The templates include case-based, collaborative projects, role-plays and other methods – faculty upload text or media files into the templates in categories including "course objectives", "course readings", etc. The templates can be used with a campus-wide LMS. The IT team has created a library of graphics, banners, assessment activities, etc.

Figure 2. Learning environments and tools

Learning Environments and Tools	
Tools	**Example**
• intelligent agents, such as "tutors" • course space • access to learning support systems • interactive discussion spaces, open to the world • an integrated suite of tools for instructional designers, content authors, instructors and learners • flexible delivery platforms	One university is developing a learning portal for faculty called the Faculty Toolkit. Designed to support faculty professional development, the portal is based on a dynamic content management system and includes tools and resources for faculty interested in redesigning their courses or learning activities. The management system will contain examples of course designs; access to peer mentors and their stories and observations; links to research on teaching and learning in HE; templates, checklists, guides, and information resources; scheduled conferences, workshops and institutes, both virtual and campus-based; moderated discussion forums; team-based activities; access to online consultations with instructional designers; evaluation tools, and more. Faculties will be able to design their own interfaces to sit on top of the database. For example, the Faculty of Education is creating a building metaphor with offices, libraries, and classrooms.

Heiki, & King, 2000). These tools could be divided into categories such as those included in Figures 1-3.

Figure 3. Research and administrative support

Research and Administrative Support	
Tools	**Example**
• publishing tools • links to the student information system • a capacity for individual users to customize and organize personal resources external to the campus • horizontal links among departments on campus and vertical links to national academic fields	One Faculty of Adult and Continuing Education has implemented a portal for internal and external communities – including the professional associations with which their programs are aligned. For example, the Association of Professional Engineers can select only those activities, program announcements, course changes etc that relate directly to their professional development needs, and include the link on their own site. When their members logon to the APE site, they link directly only to relevant information. For Faculty staff, access is provided to online research tools such as qualitative analysis software, style guides, and tutorials on proposal writing. The Faculty maintains its own student registration system but the portal allows it to tie in to the campus' administrative system for record-coordination, financial services, etc.

KEY TERMS

Accessibility: Refers to problems encountered by Internet users with perceptual and cognitive challenges, physical conditions or other factors such as geographical location, sociocultural, political and economic issues, language, and so forth, which influence their use of the Web.

Blended Learning: Defined broadly, blended learning is the integration of classroom face-to-face learning with online or technology-supported learning, including a range of pedagogical approaches and delivery systems. Strategic applications of blended learning have shown achievement of learning gains while tackling other problems faced by our universities, most notably the pressures of increasing class sizes, and limitations in funding, classroom space, and learning support.

Inclusiveness: In this context, inclusiveness is a both a value and a design process. Inclusive environments are purposefully designed to address accessibility challenges and to make resources and services available to the broadest (and most diverse) possible audience. An approach based on inclusiveness is also known as Universal Instructional Design (UID), and User-Centered Design (UCD).

Learning Portals: Integrate information, administrative, communication, research, teaching, and learning support systems with global networks of resources and services. Learning portals are typically designed to increase flexibility and accessibility to institutional resources and to encourage interaction and engagement with diverse communities of users.

User-centered Design (UCD): A client or user-centered philosophy in which the individual is at the center of an iterative design process encompassing multiple factors in an interaction between user and information product. UCD considers cognitive, sociocultural, political, and technological factors involved in defining user tasks and goals that drive the design and development of software, Web sites, information systems and processes – anything with which people interact. UCD is concerned with the usefulness, usability, desirability, legibility, learnability, accessibility and meaningfulness of an information product.

Learning Systems Engineering

Valentina Plekhanova
University of Sunderland, UK

BACKGROUND

Traditionally multi-agent learning is considered as the intersection of two subfields of artificial intelligence: multi-agent systems and machine learning. Conventional machine learning involves a single agent that is trying to maximise some utility function without any awareness of existence of other agents in the environment (Mitchell, 1997). Meanwhile, multi-agent systems consider mechanisms for the interaction of autonomous agents. Learning system is defined as a system where an agent learns to interact with other agents (e.g., Clouse, 1996; Crites & Barto, 1998; Parsons, Wooldridge & Amgoud, 2003). There are two problems that agents need to overcome in order to interact with each other to reach their individual or shared goals: since agents can be available/unavailable (i.e., they might appear and/or disappear at any time), they must be able to find each other, and they must be able to interact (Jennings, Sycara & Wooldridge, 1998).

Contemporary approaches to the modelling of learning systems in a multi-agent setting do not analyse nature of learning/cognitive tasks and quality of agents' resources that have impact on the formation of multi-agent system and its learning performance.

It is recognised that in most cognitively driven tasks, consideration of agents' resource quality and their management may provide considerable improvement of performance process. However, most existing process models and conventional resource management approaches do not consider cognitive processes and agents' resource quality (e.g., Norman et al., 2003). Instead they overemphasise the technical components, resource existence/availability problems. For this reason, their practical utilisation is restricted to those applications where agents' resources are not a critical variable. Formal representation and incorporation of cognitive processes in modelling frameworks is seen as very challenging for systems engineering research.

Therefore, future work in engineering the learning processes in cognitive system is considered with an emphasis on cognitive processes and knowledge/skills of cognitive agents as a resource in performance processes. There are many issues that need new and further research in engineering cognitive processes in learning system. New/novel directions in the fields of systems engineering, machine learning, knowledge engineering, and mathematical theories should be outlined to lead to the development of formal methods for the modelling and engineering of learning systems. This article describes a framework for formalisation and engineering the cognitive processes, which is based on applications of computational methods. The proposed work studies cognitive processes, and considers a cognitive system as a multi-agents system.

This project brings together work in systems engineering, knowledge engineering and machine learning for modelling cognitive systems and cognitive processes. A synthesis of formal methods and heuristic approaches to engineering tasks is used for the evaluation, comparison, analysis, evolution and improvement of cognitive processes.

In order to define learning processes, cognitive processes are engineered via a study of knowledge capabilities of cognitive systems. We are not interested in chaotic activities and interactions between cognitive agents (since cognitive tasks require self-managing activities/work), nor interested in detailed tasks descriptions, detailed steps of tasks performance and internal pathways of thoughts. Rather, we are interested in how available knowledge/skills of cognitive agents satisfy required knowledge/skills for the performance of the cognitive tasks.

The proposed research addresses the problem of cognitive system formation with respect to the given cognitive tasks and considers the cognitive agent's capabilities and compatibilities factors as critical variables, because these factors have an impact on the formation of cognitive systems, the quality of performance processes and applications of different learning methods.

It is recognised that different initial knowledge capabilities of the cognitive system define different performance and require different hybrid learning methods. This work studies how cognitive agents utilise their knowledge for learning the cognitive tasks. Learning methods lead the cognitive agent to the solution of cognitive tasks. The proposed research considers a learning method as a guide to the successful performance. That is, initial knowledge capabilities of cognitive agents are correlated with learning methods that define cognitive processes. An analysis of impact of different cognitive processes on the performance of cognitive agents is provided.

This work ensures support for a solution to resource-based problems in knowledge integration and scheduling of cognitive processes to form a capable cognitive system for learning the required tasks.

AIMS AND OBJECTIVES

The aims of the project are to develop a formal method for the modelling and engineering of cognitive processes. Capability and compatibility factors have an impact on the formation of cognitive systems, the performance processes and define different learning methods. Therefore this work studies cognitive processes and knowledge capabilities of cognitive systems to ensure the required level of the learning and performance of the cognitive systems. In order to support the formation of a cognitive system that will be capable of learning the required tasks within the given constrains, this work addresses problems of the knowledge integration and scheduling for cognitive system modelling, taking into account critical capability and compatibility factors. Study of learning conditions in cognitive systems defines an important task of the proposed project.

The individual measurable objectives are:

- Evaluation of knowledge integration and scheduling approaches in cognitive systems.
- Evaluation of existing machine learning approaches in cognitive systems.
- Determination of the impact of capability and compatibility factors on the formation of cognitive systems.
- Development of knowledge integration metrics.
- Development of knowledge integration models for the formation of the cognitive systems.
- Development of scheduling models for learning of cognitive systems.

METHODOLOGY AND JUSTIFICATION

In order to identify the best learning processes we analyse the cognitive processes. A scenario for engineering the cognitive processes is based on the following steps (Figure 1).

The methodology of the proposed project is based on the following new theoretical basis (Plekhanova, 2003).

- Profile Theory and Machine Learning: For formal modelling of complex systems we utilise the profile theory (Plekhanova, 1999a). A profile is considered as a method for describing and registering multifaceted properties of objects. There are important practical applications of the profile theory (Plekhanova, 2000a, 2000b). For instance, internal properties of the system elements such as capability and compatibility factors are critical variables in modelling, design, integration, development and management of most modern complex systems and their structure. Table 1 provides a comparison of capability and compatibility problems of technical and soft systems.

Figure 1. A scenario for engineering the cognitive processes

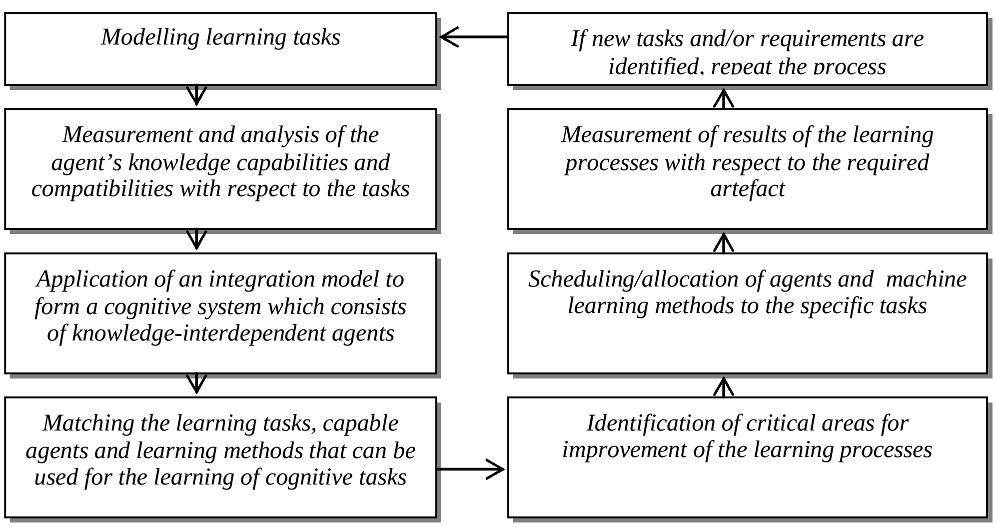

Table 1. A comparison of capability and compatibility problems

Technical Systems	Soft Systems
In *technical systems* the internal characteristics of technical elements are described in specifications, standards and formal documents (i.e., are known a priori) from which it is not difficult to conclude whether combinations of elements are capable and compatible or not and whether they can be used for technical system design, development and construction. Each capability and compatibility factor can be represented by one characteristic.	There are a number of real-world examples when an object factor cannot be described by just one characteristic. For example, systems such as human resources, software, information systems, and cognitive agents, where the internal multifaceted properties can be changed with time, and capability and compatibility factors cannot be defined by one characteristic alone, and cannot be explicitly measured. These systems are termed *soft systems*. At the present time there are problems in the formal definition of specifications/standards and metrics that allow one to determine the capability and compatibility of such complex systems. For this reason, heuristic approaches are used for soft complex system modelling.

Profile theory is used for formal modelling of cognitive agents/systems since existing mathematical theories are limited. In particular, contemporary mathematical theories describe objects, where each internal factor is represented by one meaningful piece (e.g., set theory - an element) or two pieces of meaningful information (e.g., fuzzy set theory - an element and a membership function).

Knowledge factors are considered as basic internal factors in the modelling of cognitive agents, since agents must have particular knowledge capabilities to perform and learn their tasks. In a description of the knowledge of cognitive agents we identify the importance/weight of the factor for the performance of the task; time or factor existence/non-existence; and other specific internal multifaceted properties, for example the property (level, grade, degree) of the factor.

In particular, knowledge of the cognitive agent is described by a set of knowledge factors; each factor is defined by multiple characteristics. A set of such factors forms a knowledge profile (Plekhanova, 1999a). Each factor is represented by qualitative and quantitative information. Quantitative description of the *i*th knowledge factor is defined by an indicator characteristic, property, and weight. In a simple way, a profile can be defined as follows (see Figure 2):

The profile theory is used for formalisation of cognitive systems and cognitive processes, and for the identification of critical areas in learning performance where improvement should be taken. In particular, engineering the cognitive processes is considered to provide improvement of learning process by means of integrating adaptive machine learning into the profile theory. In order to model cognitive processes the profile theory is combined with machine learning methods, which are applied to the initial available knowledge capabilities of the cognitive system to define learning methods. (It is expected that different initial knowledge capabilities of the cognitive system require different hybrid learning methods.)

Machine learning methods are used for formalisation and modelling of learning processes via applications of the profiles. It allows consideration of dynamics in learning processes (i.e., modelling of the *i*th profile factor $e_i(t) = <\varepsilon_i(t),\ v_i(t),\ w_i(t)>$ in the profile b). We should analyse existing machine learning methods, match them to learning tasks with relevance to available knowledge capabilities of cognitive agents and consider cognitive processes. A profile is considered as a model for the description of cognitive processes. That is, a new machine learning method will be developed and incorporated into an engineering framework for cognitive processes.

This research considers knowledge factors as critical variables in learning processes and addresses problems in the formation of a cognitive system that can be capable of learning. In particular, a cognitive system is defined by knowledge-interrelated agents, their flexible cognitive structure and cognitive processes. A teacher is defined as a learning oracle. Soft factors may be defined as a “noise”

Figure 2. Definition of the profile

A profile b is defined as a set of factors $b_1, b_2, ..., b_n$: $b = \{ b_i ,\ i = \overline{1, n} \}$, where the ith factor b_i is represented by a pair $b_i = (\iota_i , e_i)$ with

- n - a number of factors
- ι_i - an identification of the ith factor, that is, a name or label or type of the ith factor
- e_i - the 3-tuple of the ith factor as the Cartesian product: $e_i = <\varepsilon_i ,\ v_i ,\ w_i >$, where
    - o ε_i - indicator characteristic, which indicates the factor presence in the description of a cognitive agent, the existence of certain conditions; for example, ε_i may represent a binary case; a number of times of factor utilisation; or may be defined as a time characteristic $\varepsilon_i = \varepsilon_i(t)$
    - o v_i - property of the ith factor: $v_i \geq 0$; v_i can be defined as a function of time $v_i = v_i(t)$
    - o w_i - weight of a factor which defines either the factor importance or the factor priority: $w_i \geq 0$; w_i can be also considered as a function of time $w_i = w_i(t)$.

in data modelling for the training sets in machine learning.

This work addresses the problems of knowledge integration of the cognitive system in order to provide a better learning performance. A challenge for learning is to ensure the existence of a desired level of performance of a cognitive system. There is a need to make a formal analysis of the available knowledge of cognitive agents in order to ensure the learning of the tasks at a desired performance level while utilising the available knowledge capabilities effectively and efficiently.

This research deals with the problem of agent allocation in a cognitive system. This problem addresses not only task scheduling as in traditional approaches but also scheduling machine learning methods and knowledge of cognitive agents. The proposed project will develop a new scheduling approach where the agent allocation problem has specific emphasis on the following aspects: cognitive agents are allocated to tasks according to their multiple knowledge capabilities; the agent's knowledge capabilities must satisfy the particular combination of knowledge required for a task; agents of the cognitive systems should be compatible with each other (Plekhanova, 1999b); and learning methods are relevant to the available knowledge capabilities of the cognitive agents and system. The consideration of all these aspects defines a problem of knowledge integration in cognitive systems. This work will use formal methods for an integration of cognitive capabilities and compatibilities, and for an analysis of how system capabilities satisfy the learning of the tasks.

Capability and compatibility factors have considerable impact on the process of system integration. An integration model encompasses integration criteria, priorities of the knowledge profiles and knowledge integration goals. Knowledge integration goals are the improvement of available knowledge or generation of new/novel knowledge for better learning performance.

This work addresses problems of effectiveness of the learning processes, their convergence (Vapnik, 1998), stability and accuracy.

Therefore, the adventure in this research is that cognitive processes will be incorporated into multi-agent system development by a synthesis of systems engineering with knowledge engineering and machine learning methods. The combination of machine learning methods with profile theory will provide a more flexible adaptive framework for cognitive tasks performance. That is, the proposed method for the modelling and engineering of cognitive systems and cognitive processes can be used in systems engineering and machine learning for a formalisation of cognitive processes, cognitive systems, and capability and compatibility aspects.

NOVELTY

The proposed project is particularly novel in its approach to learning processes that incorporate a synthesis of systems engineering, knowledge engineering and machine learning methods. There are no formal methods for knowledge integration and scheduling for learning of cognitive systems where capability and compatibility factors are critical variables. Existing machine learning approaches do not address scheduling problems in learning methods. We will develop a new scheduling approach where we consider scheduling machine learning methods and knowledge of cognitive agents versus task scheduling in traditional approaches. New machine learning methods will be developed and incorporated into an engineering framework for cognitive processes. Moreover, the proposed project brings together work in cognitive systems, systems engineering, knowledge engineering and machine learning for the modelling of cognitive processes.

The proposed project is timely because of the availability of new formal methods for engineering cognitive systems. The work is highly topical at present as demonstrated by a large interest in academia and great needs of industry, in particular, in:

- Software/Systems Engineering: Project resource capability and compatibility aspects have become the focus of performance process improvement. However, most contemporary approaches to the formation of project resources (Norman et al., 2003) do not examine their capability and compatibility factors. There is a need to develop evaluation techniques for people's capability, resource capability and compatibility in order to provide support for effective solutions to resource integration management in cognitive systems (Plekhanova, 2002). In particular, methods are of particular merit that incorporate a comparison of cognitive processes, resource capabilities and compatibilities.
- Scheduling: Contemporary approaches to resource scheduling are based on the detailed description of tasks assuming that a resource pool is given and defined by a manager and resources are capable of performing any project task. Existing resource scheduling methods address the issues of resource availability and utilisation, and are not concerned with the capability and compatibility of project resources. Furthermore, in traditional scheduling approaches, the objectives for the allocation of limited resources are to determine the allocation of resources that maximise total benefits subject to the limited resource availability. Contemporary approaches to resource allocation are founded on the assumption that different tasks require equal capability resources, and only one skill is involved. Hence, they cannot be successfully used for software projects where different software tasks require changing different sets of multiple knowledge and skill capabilities in an overall system (Plekhanova, 1998).
- Software Tools for Resource Scheduling: There are many scheduling tools that provide different approaches: event-oriented (PERT), activity-oriented (CPM), actions-oriented (TASKey PERSONAL), or offer a wide variety of scheduling options (SAP). Nevertheless, there are no tools that support an analysis of resource capabilities/compatibilities and their impact on project scheduling (Plekhanova, 2000c). Most existing tools (Microsoft Project, SAP, Up and Running) have facilities for entering new resources, but do not deal with an analysis of cognitive processes, and resource quality based on which resources can be added to the resource pool. Therefore, the existing scheduling tools cannot be effectively used for management of processes where resources are a critical variable.
- Theory/Tools in Machine Learning: Existing machine learning techniques (e.g., Boosting (Schapire, 1999), Lazy Learning (Aha, 1997), Neural Nets, Decision Tree Learning (Quinlan, 1990; Utgoff, 1989), Support Vector Machine (Vapnik, 1998), Reinforcement Learning (Sutton & Barto, 1998)), and contemporary machine learning tools (e.g., WEKA, AutoClass, mySVM) have not yet been examined in terms of agents' capability/compatibility and scheduling problems.

There is a direct relationship between the representation and the learning mechanisms. In many cases the underlying representations in machine learning have been of limited structure (e.g., vectors, trees, networks). A hybrid integration of various machine learning mechanisms for engineering of structured objects is novel and will be examined in this project in the context of the profile theory.

BENEFICIARIES

- Engineering the Complex Systems: Research in engineering of complex systems will provide insight into new methods and approaches to learning in cognitive systems. Research in machine learning will deliver adaptiveness to knowledge integration and scheduling of learning methods. Scientists in cognitive systems research will receive a formal method for modelling of cognitive processes. By developing integration metrics using the profile theory we can provide analysis, development, integration, modelling and management of complex systems and their elements where weight, time and other internal multifaceted properties are critical variables. Further development of the profile theory will establish a new branch in mathematics and extend its applications.
- Industry**:** New evaluation techniques could provide support for a solution to the resource-based problems in cognitive processes in software and IT

projects such as team formation and integration in connection with process tasks.

The application of a new approach could provide learning organisations with:

- superior management of resource capabilities and compatibilities;
- streamlining of process development through better management of project resources and tasks;
- increased opportunities for organisations to implement process improvement based on the constructive criticism derived from self analysis.

It is apparent that there is a worldwide interest in the application of this research. Since most modern processes are cognitively driven our method can be used for the formal modelling of cognitive systems. It is important for the future competitiveness of the software and IT industry to employ a scientific (vs. heuristic) approach to the engineering of cognitive processes.

- Technology: The profile-based approach assures a virtual prototyping of system development within different environment settings. An important application of this approach is that it gives the means of providing systemic methods of study, analysis, prediction, improvement, control and management of a system development. Moreover, this technology demonstrates a modelling flexibility that permits one to represent a fine-granularity of system components as well as to generate different system models of a wide diversity of system development processes. Thus, any traditional system model becomes a special case of the capability- and compatibility-based modelling framework.

Formal modelling of the capability and compatibility of cognitive systems ensures the automation in system modelling. It leads to development of new technologies in system modelling. Some of the enhancements that we intend to offer through this method are to provide support for development and engineering of new knowledge capabilities of cognitive systems, that is, innovative technologies.

KEY TERMS

Agent: A complex system constituting elements that are individual performers, which can be described by their interrelationships, knowledge/skill, performance and constraints factors.

Agent's Compatibility: A capability of agent to work with other agents without adaptation, adjustment and modification.

Cognitive Process:

- The performance of some composite cognitive activity.
- A set of connected series of cognitive activities intended to reach a goal. Cognitive activities can be considered as a function of their embodied experience.

Cognitive System: A complex system that learns and develops knowledge. It can be a human, a group, an organization, an agent, a computer, or some combination. It can provide computational representations of human cognitive processes to augment the cognitive capacities of human agents.

Complex System: A collection of interrelated elements organised to accomplish a specific function or a set of functions. Complexity can be considered in terms of a number of elements and/or complexity of relationships.

Machine Learning: The ability of a machine to improve its performance based on previous results.

Multi-Agent System: A set of interrelated agents that work together to perform tasks.

Legal Expert Systems in Adminstrative Organizations

Jörgen S. Svensson
University of Twente, The Netherlands

INTRODUCTION

The term *expert system* comes from the world of artificial intelligence. Originally, it comprised the idea that computer programs can be devised to solve complex problems of decision making, as well as, or even better than human experts. Although in some technical domains this ambitious goal is still valid, it is generally relaxed for applications in legal and administrative domains. Here the term *expert system* – or *knowledge-based system* – refers to a category of computer programs that use coded knowledge to help solve problems of decision making. One simple, everyday example is a computer program that helps a tax payer fill in his tax returns and informs him about the implications his answers will have in terms of the amount of tax to be paid. A second, quite different example is a system which, based on a textual summary of a case at hand, can help a legal professional in finding applicable case law.

BACKGROUND

At the core of an expert system is a so-called knowledge base, a formal model of knowledge that is used to make inferences to arrive at relevant decisions. This knowledge base can have different forms and in general a distinction is made between rule-based and case-based systems. In a rule-based expert system, reasoning is based largely on production rules, that is, hundreds or even thousands of coded rules in the form of IF-THEN statements. For example, IF a client's total capital is below • 10.000 THEN the client is exempted from paying wealth tax. By combining many such rules, very complex inferences can be made. In a case-based system, the knowledge base consists of a larger number of coded case descriptions and the system bases its inferences on automated procedures (usually of a mathematical or statistical kind) to compare the case at hand with the different cases in the knowledge base (e.g., Brüninghaus & Ashley, 2003).

In the early years of legal expert systems, it was assumed that the development of such systems was particularly useful for more complex legal reasoning tasks, in situations where a human expert would be faced with personal limitations in knowledge and skills (Bench-Capon, 1991). Nowadays, however, legal expert systems are more often regarded as important tools to control administrative processes and to enhance administrative efficiency, that is, the use of expert systems in public and private bureaucracies to process large numbers of cases in a standardized and controllable manner.

Four important types of applications of expert systems in administrative organizations can be distinguished:

- Knowledge-based information services for citizens/clients: while in the Internet era many organizations have started to put all kinds of rules and statutes on their Web sites, research shows that most people find it very hard to apply such written rules to their personal situation. In such circumstances expert system technology may help to personalize the information. Banks, for example, may add expert system modules to their Web sites to help the customer understand which of the different mortgage plans is most suitable in his particular situation (Stranieri et al., 2001).
- Knowledge-based acquisition of citizen/client information: in combination with the above application, expert systems may be used to help gather information from citizens and organizations, so that their cases can be processed more easily. An example is the Taxis system in Greece, which helps companies in submitting their VAT declarations in a correct manner (Tsiavos et al., 2002).
- Semi-automated decision making in street-level bureaucracies: in many government agencies, the application of legal statutes is the responsibility of so-called street level bureaucrats, that is, lower-level staff with at most limited legal training. Expert systems can be used to support these bureaucrats in making formally correct decisions. An example is the use of expert systems by the Australian Department of Veterans Affairs in determining individual entitlements to disability pensions (Johnson, 2000).
- Automated application of legal rules in high-volume administrations: some administrative agencies are responsible for the repetitive application of the same regulation to very large numbers of cases.

Here expert systems may be used for fully automated processing of the bulk of these cases. An example is the fully automated fining of speeding offenders in the Netherlands (Zouridis, 2000).

EVALUATION STUDIES

The use of legal expert systems in public administration has been the topic of intense debate between enthusiasts on the one hand and skeptics on the other.

When, in the 1970s and –1980s the idea of expert systems proliferated and the opportunities in the legal domain became evident, scientists and entrepreneurs from very diverse backgrounds started experimenting in this field and built the first examples of legal expert systems – to investigate and demonstrate what could be done. Evaluation studies such as that by Nieuwenhuis (1989) were carried out in carefully controlled laboratory settings and led to a heightened enthusiasm and sometimes to oversimplified claims: the suggestion that expert systems could be designed that were superior to human decision makers and that would solve all existing problems of bureaucratic administration.

This, of course, antagonized many scholars in the fields of law and public administration, who rightly criticized the experiments for their subjectivity and limited validity and who argued that there were serious limits to what machines could and should do in administrative practice. Thus, as the stories of really intelligent expert systems proliferated, this in some cases only fed existing computer *angst*: the Terminator type of vision that we were entering a future in which we would trust machines with decisions of life and death.

In recent years, however, various examples of expert systems have entered the market and the opportunities for administrative and legal scientists to do their own objective and critical research has increased dramatically. As a result of this some interesting case studies have begun to appear (e.g., Groothuis, 2004; Smith, 1994).

These new evaluation studies of real applications used in administrative practice indicate that also among legal scientists and students of public administration, opinion is shifting in favor of the use of such systems. Today, even more skeptical observers acknowledge that legal expert systems are actually being used and in some cases really provide opportunities to improve legal decision making in public administration (both in terms of legal quality and efficiency). Particularly where street level bureaucracies are expected to work with a multitude of formal rules, an expert system can clearly help improve quality and efficiency by systematizing decision making and automating the application of complex tables and calculations.

CRITICAL ISSUES OF LEGAL EXPERT SYSTEMS IN PUBLIC ADMINISTRATION

There are, however, still various practical, ethical and philosophical issues related to the broader introduction of expert systems in public administration, and the most important of these are the following.

Expert Systems Can Contain Errors

When legal expert systems are used to make serious decisions about people's lives, it is essential that they are reliable; that they indeed produce correct decisions that conform to the formal rules and the legal status quo. This, however, may be impossible to guarantee. As legal expert systems are generally used in rather complex domains with ever-changing regulations, the question is if and how these systems can be kept formally correct, reliable and up-to-date. It is clear that the issue of expert system validation requires very serious attention, not in the least because the translation of administrative regulations into formal computer rules is not always as straightforward as it may seem. In addition to this, there is still a need for adequate design methodologies and validation tools.

Garbage in is Garbage Out

Even if expert systems are formally correct, they will produce erroneous results when fed with inappropriate data. As the experiments by Nieuwenhuis (1989) showed, users of expert systems may make unintended errors when entering relevant case data, but they may also try to manipulate such systems intentionally. This incorrect use may, of course, seriously influence the conclusions reached by these systems

Expert Systems Cannot Deal with "Hard Cases"

In legal science, special attention is paid to the distinction between clear and hard cases. Simply put, a clear case is one in which there is not much discussion about what the problem is and what the decision should be. With a hard case, however, there are one or more of the following problems involved: (a) the characteristics of the case are not easily matched to existing rules, (b) the existing rules do not deliver a clear conclusion and/or, (c) application of the existing rules leads to unacceptable results.

Expert systems in principle do nothing more than apply fixed rules to case data provided by the user. They have no real understanding of the case and therefore treat all cases as clear, even if, to any human observer, it is evident that they are not (Leenes, 1999; Smith, 1994). This implies that even when a formally correct legal expert system is fed with formally correct data, it may still produce outcomes that are not applicable and need correction.

Expert Systems Require Knowledgeable and Critical Usage

Given the previous critical issues, it is clear that expert systems should be used with care, by administrative staff who have been trained in their application, who understand their possibilities and limitations and who may intervene in expert system conclusions when needed.

There is however some evidence that the use of expert systems in public administration leads to a process of deskilling among personnel. Because "the expert system knows all", street-level bureaucrats may lose their ability to critically evaluate decisions themselves and may start to depend too much on the correctness of the system. This can lead to uncritical application of the system's results and even to neglecting responsibilities for tasks the system does not support (Dijkstra, 2002; Groothuis & Svensson, 2000).

In her recent dissertation study, Groothuis (2004) argues that the co-operation between a computer system and its human user is actually the weakest link in the practical application of expert systems. In this human-computer interaction various problems may arise as a result of false assumptions and misunderstandings.

FUTURE TRENDS

In recent years there has been an increase in the application of legal expert systems in administrative organizations. This increase seems to be connected to the increasing domination of formal rules. Especially in public administration, the provision of services is bound to large numbers of formal rules and regulations, which generally evolve over time to become more and more complex. This provides an excellent two-sided argument for the introduction of expert systems (Svensson, 2002). On the one hand, regulations often become so obscure and complex that it may be hard for human decision makers to administer them correctly by hand. On the other, these formal regulations provide an excellent basis for building rule-based experts systems.

In addition to this there are several other factors that stimulate the future take-up of legal expert systems, such as:

- The increased focus in public administration on efficiency, on decision quality and on auditable decision processes;
- The increased use of the Internet as a vehicle for instant personalized advice on legal and bureaucratic issues;
- The increased availability of personal data in electronic form, which can be processed by means of legal expert systems.

CONCLUSION

Expert systems are important tools for administering complex regulations to individual cases, and administrative organizations increasingly use these systems. There are however several critical issues connected to their application, which means that the development and implementation of these systems has to be handled with care. Since some administrative decisions can really affect people's lives, legal expert systems should be developed using excellent methodologies and when finished, they should be carefully validated and evaluated (Hall et al., 2003). They should be transparent in their functioning, and before implementation, the administrative staff has to be trained in their application and to be informed about their possibilities and limitations. Also there is a need for clear independent appeal procedures for people who are confronted with the decisions made by these systems.

KEY TERMS

Case-Based Expert System: An expert system that uses modeled representations of previous cases and decisions to make inferences about new cases.

Clear Case: A case that experts agree can be solved in an acceptable manner by simply applying the existing legal rules to it.

Expert System: Computer program that uses coded knowledge to (help) solve problems of decision making of some complexity.

Hard Case: A case that cannot be solved by simply applying formal rules, either because: (a) the characteristics of the case are not easily matched to the formal rules, (b) the formal rules do not deliver clear conclusions and/or (c) applying the formal legal rules leads to unacceptable results.

Rule-Based Expert System: An expert system that applies a knowledge base consisting of if-then statements that can be combined to make more complex inferences.

Transparency: Systems supporting decision making in administrative organizations should be transparent to users so that it is clear to all actors involved (street-level bureaucrats, clients, legal and administrative supervisors, appeal boards) how certain conclusions have been reached.

Validation: The process of determining whether an expert system to be used in an administrative process is correct. This involves a combination of methods of which the most important are: letting domain experts verify the knowledge in the knowledge base, using automated procedures to check the system for consistency and applying the system to a larger number of test cases.

Legal Issues of Virtual Organizations

Claudia Cevenini
CIRSFID, University of Bologna, Italy

INTRODUCTION

In the present economic context, organizations, especially of small and medium dimensions, can draw a substantial advantage by collaborating and setting up flexible, temporary ICT-enabled networks.

Identifying the legal issues relevant for virtual organizations can provide a knowledge basis to regulate their activities, thus providing support for their creation and management.

BACKGROUND

The concept of virtual organization (VO) finds its origins in the United States in the early 1990s, when some authors start to give it a first theoretical outline.

Since then, a certain scientific debate has opened, and several attempts to define and concretise it have been made. The most active research sectors with respect to this appear to be business and computer science. Until recently, however, the legal research has substantially disregarded VOs, with few exceptions.

REGULATING VOS

VOs are far from being a consolidated reality; being fluid and flexible structures, they continually evolve over time and are difficult to grasp.

The starting point for their regulation is to provide a definition for the purposes of legal research: "VO's are ICT-enabled collaborations between legally independent subjects aimed at the joint provision of goods or services, where each partner contributes to specific activities. They do not aim at achieving an autonomous legal status but appear as one organization towards third parties."[1]

As a second step, a wide range of legal issues concerning them can be identified. By developing a legal taxonomy, it is possible to aggregate legal problems in major research areas. This makes it possible to focus on those issues most connected with the particular structure and nature of the VO.

The third step is to examine the identified issues in the light of the applicable legal framework at national and international level, considering the nationality of the partners and their reciprocal agreements.

A TAXONOMY OF VO-RELATED LEGAL ISSUES

Hereinafter, a synthesis of the most relevant issues is presented.

Identity and Nationality of the Virtual Organization

The VO does not embody a formal institution separate from its partners, although it may appear as a separate, autonomous entity.

National legal orders will tend to consider the VO as a structure without legal personality and, consequently, also without nationality, provided that the partners do not opt to formally adhere to a company type as foreseen by the national law of one of them.

Role of the Virtual Organization Broker

A VO can be set up and managed without the intervention of a VO broker. This, however, would imply higher coordination costs, more complex negotiations, and a slower speed of action.

The legal status of the VO broker depends upon its actual role and activities in the VO. The broker will be subject to and have to comply with the applicable legal framework set for the legal structure it has opted for in the state in which its head office is located, as well as with the state- and contract-based rules applicable to the same VO.

Virtual Organization Framework Agreement

The VO framework agreement is a set of rules aimed at governing the internal relationships between the partners of a VO.

It has to be signed before the beginning of any activity and is generally drafted with the support of the broker, who may propose business templates on the basis of which the detailed final provisions can be negotiated with the partners.

The absence of a clear agreement would possibly lead to difficulties in the management of the operation stage and, later, to possible disputes between the partners.

Contracting with Third Parties

Having no legal personality, the VO cannot directly close contracts with third parties. Therefore, if its members are to enter into contractual relationships, this will not be feasible for the VO as a separate subject; agreements can only be closed between third parties and some or all the individual members.

Once a partner—or a group of partners—has been selected, the other members can grant to it the power to act in their name and on their behalf to the purpose of closing contracts binding for all of them, or to take care of other jural acts, as it happens with mandates.

The Resolution in Disputes

The involvement in a lengthy dispute resolution procedure can cause severe economic damage or even disrupt a temporary entity like the VO. For this reason, before the final framework agreement between the partners is signed and, later, before the signing of every agreement with third parties, attention has to be placed upon developing and agreeing upon adequate dispute resolution mechanisms, which may range from legal actions before courts, to arbitration and mediation.

Liability Issues

It would be difficult to configure a liability on the VO as such, as there are no legal instruments to construct it. It thus appears more feasible to identify a liability on the individual partners. All of them may be held jointly and severally liable for the damages that can be imputed to the VO. Whenever one partner is held liable, those who have been sued without having contributed to causing the damage which is the object of the claim can resort to an internal redress.

Intellectual Property Rights

The VO activities are based on the reciprocal disclosure of relevant data and possibly on the sharing of immaterial goods. These can, in some cases, enjoy a precise legal protection, as happens with copyright, software, patents, and databases.

This applies both to the data and goods to which the individual partners are already entitled, as well as to the outcome of their collaboration. In the former case, the legitimate owner can grant to the other partners a right of economic exploitation, for example, through licensing contracts. As to the latter case, specific agreements are to be clearly set.

If the individual contributions are not to be clearly identified, it can be assumed that all partners will be entitled to the data and goods produced by the VO and of the relative rights, on the basis of a coownership.

Data Protection

All the different activities of the VO imply the processing of personal data. Within the present data protection framework, attention has to be placed, in particular, on a series of elements, such as the processing through automatic means, the disclosure of data to third parties, and the transfer of data between European Union (EU) and non-EU countries. The VO partners will actually carry out most processing with ICT tools and may need to process data originally collected by one or more of them and perform cross-border data transfers.

Competition Law

Should a VO achieve a substantial dimension in terms of its overall turnover, attention shall be placed by the partners to its compliance with rules on antitrust and the protection of competition applicable to the partners. Specific procedures may be imposed in order to get the authorization of antitrust bodies, as well as to verify the law-abidingness of the collaboration.

ICT-Related Issues

The nature of ICT-enabled entities possessed by VOs requires their compliance with the applicable rules on the use of specific technology tools, for example, with reference to security, electronic signatures, e-commerce, or teleworking. Should certain ICT-based interactions not be specifically regulated, reference shall be made to analogically applicable norms.

FUTURE TRENDS

The present economic and legal scenario does not point toward the drafting of an ad hoc legislation for VOs. However, the growing relevance of collaborative entities, such as industrial districts, coupled with the strong support of the techno-legal scientific community, will make VOs known to a wider audience and stimulate targeted initiatives.

CONCLUSION

A coherent and certain legal framework applicable to regulate VOs is presently still absent, and a clear qualification of their legal identity by the legislator is missing. Besides, their international character would require a level of harmonisation among contrasting rules that does not always appear easy to achieve, while their massive use of rapidly evolving information and communication technologies contrasts with the slow law-making process.

This makes it extremely difficult to envisage a state-based regulation for them, or the drafting of international treaties or agreements, at least in the short term.

This enhances the fundamental role of normative tools, such as codes of conduct and best practices, and especially of contractual agreements and intraorganisational rules drafted by the VO partners, developed on the basis of a clear identification of the relevant legal issues.

KEY TERMS

Arbitration: A private form of conflict resolution. The litigating parties may voluntarily submit a dispute to one or more independent, neutral experts (arbitrators), who decide upon the case similarly to a court, generally upon a shorter period of time. Arbitrations are usually regulated by law.

Intellectual Property Rights: Copyright and connected rights that include, *inter alia*, the right of copying, modifying, and distributing the protected work.

Legal Order: The set of legal norms that make up the legal system of a particular country.

Legal Personality: The capacity of a legal person (e.g., a corporation) to be holder of rights and duties.

Mediation: An alternative dispute resolution method. The litigating parties may voluntarily submit a dispute to a neutral, independent mediator. This latter does not issue a decision but supports the parties in finding a mutually agreed upon solution.

Personal Data: Any information concerning a natural or legal person that can identify it.

Virtual Organization: An ICT-enabled collaboration between legally independent subjects aimed at the joint provision of goods or services, where each partner contributes to specific activities. It does not aim at achieving an autonomous legal status but appears as one organization toward third parties.

VO Broker: A subject who acts as an intermediary for the setting up of the virtual organization by identifying a possible business opportunity, contacting the potential partners, and proposing agreement templates.

Liability for System and Data Quality

Robert D. Sprague
University of Wyoming, USA

INTRODUCTION

Accompanying the proliferation of computers in almost every facet of life is an underlying risk to financial well-being related to computer system and data quality. The viability of a business often depends upon the continual and reliable operation of its computer system. The consequences of low-quality computer hardware and software are not infrequent or insubstantial. A recent report from the U.S. Department of Commerce states that total U.S. software sales in 2000 were approximately $180 billion (RTI, 2002). The report estimated that the lack of an adequate software testing infrastructure costs U.S. software users over $38 billion per year, principally through error avoidance and mitigation activities.

In just about every instance, a computer system is acquired, software is used, or data are accessed through a contract-based commercial transaction. Therefore, whether a computer, software, or data vendor will be held liable for defects or errors depends on the language of the contract itself and the law of contracts. Most contracts impose scant liability for vendors. Although aggrieved users have pursued other avenues of relief through non-contract-based legal theories, they have met with little success. For computer, software, and data users, the Latin maxim of *caveat emptor* still applies—let the buyer beware.

BACKGROUND

In the United States, commercial transactions are governed by contract law; a collection of rules of law which provides a basis for predicting whether a court will permit a certain contract provision to be enforced. Most courts and legal commentators now agree that in transactions in which an ultimate software product is to be delivered, the software is classified as a "good" and the associated contracts are governed by the Uniform Commercial Code (UCC or "Code") (Horovitz, 1985; Rodau, 1986). Article 2 of the UCC applies to contracts for the sale of goods. Technically, most software is acquired through a license rather than a sale. As far as the courts are concerned, however, software licenses are treated as ordinary contracts accompanying the sale of products, and therefore are governed by the UCC (ProCD, 1996).

Aggrieved computer and software users, and particularly users of inaccurate information, have sought redress through non-contract-based theories based on a separate body of law known as torts. However, without being able to show some form of injury to a person or destruction of physical property, these claims generally fail.

SOFTWARE CONTRACTS

Application of the UCC to software contracts means that the Code's provisions relating to warranties, consequential damages, and disclaimers of liability will also apply. Warranties can provide legal protection to the buyer regarding the quality of the goods (such as computer hardware or software) that are the subject of the contract. The UCC, however, also allows the seller to limit or exclude any or all of the warranties. When a vendor does provide a limited warranty—for example, that a hard disk drive will function properly for one year after purchase or that a software program will carry out its basic instructions with minimal errors—it is usually accompanied by a limitation of remedies. By contract, the purchaser agrees that in the event the product does not live up to its represented quality, the purchaser's remedies (and, hence, the vendor's liability) will be limited by the terms of the contract's limitation of remedies clause—usually a repair or replace option for defective hardware or a refund of the purchase price of software.

Often a computer hardware or software customer suffers damages beyond the cost of the hardware or software if there is a problem. The customer's business may be effectively shut down, or severely curtailed, if the computer system is not functioning properly. This type of damages is known as consequential damages—occurring indirectly as a result of the problem with the product. The UCC provides that consequential damages may be limited or excluded unless the limitation or exclusion is unconscionable. Limitation of consequential damages for injury to the person in the case of consumer goods is, on its face, unconscionable, but a limitation of damages where the loss is commercial is not.

The exclusion of consequential damages in commercial transactions under the UCC is considered merely an allocation of unknown or indeterminable risks and is almost always upheld. It has become standard practice in the computer industry, particularly for software publishers, to provide very limited express warranties, disclaim all other warranties, and severely limit remedies in the event of a breach of contract. These disclaimers and limitations of remedies are invariably enforced by the courts.

The initial premise under which disclaimers and limitations are allowed is that the parties negotiate the terms of the underlying agreement. In today's software transaction, however, "bargaining," at least on the part of the buyer, often consists of clicking on an "I Agree" button during software installation. Most software is acquired through a shrinkwrap (or clickwrap or browsewrap) agreement. Despite the lack of bargaining power on the part of the purchasers, in nearly all cases, shrinkwrap agreements have been held enforceable. The result is that a vast amount of software is acquired through a form contract with no opportunity to bargain for warranties or remedies.

The historic context of contracts was that the parties negotiated the terms of the agreement. In particular, it was believed that the purchaser was willing to assume some risk that the acquired product may not meet all expectations—through limited warranties and remedies—in exchange for a lower price. In the modern computer-related contracting scenario, however, the purchaser assumes all the risk. Despite theoretical underpinnings surrounding the creation of the UCC to provide buyers and sellers equal protections (Alces, 1999), the reality is that modern contracting practices provide no protection against the substantial losses businesses may encounter, and have encountered, when they cannot operate their business because data are lost or the computer system fails to operate properly.

TORT-BASED FORMS OF LIABILITY

Since software is generally considered a product for contracting purposes, it is logical to consider whether a vendor would be held liable for damages resulting from defective hardware or software under the doctrine of products liability. Products liability law protects those who suffer injuries as a result of a defective product. The law imposes upon a vendor strict liability for placing a defective product in the stream of commerce. This liability applies regardless of the amount of care exercised by the vendor in the preparation and sale of the product.

However, the vendor of a defective product is only strictly liable for certain types of damages suffered by the product's users: personal injury or damage to other physical property. To date, there has been no reported successful products liability lawsuit regarding defective computer hardware or software. All courts that have directly addressed the issue of whether products liability applies to defective computer hardware or software have ruled against application on the basis that the damages sustained are categorized as *economic loss*—a remedy not available under products liability law.

The "economic loss rule" provides that where no person or other property is damaged, the resulting loss is purely economic (East River, 1986). A few computer purchasers have argued that data lost due to defective hardware or a defective computer system constitutes damage to "other property." The courts that have considered this argument have uniformly rejected it. The courts consider the data as integrated into the computer system (Transport Corporation of America, 1994).

Even when the software vendor knows of a defect in the software and fails to notify the user, if the damages suffered are limited to economic losses, a tort claim of negligence will also fail (Hou-Tex, 2000). The economic loss rule provides a substantial barrier to any recovery for defective computer hardware or software, regardless of whether the purchaser pursues a claim for products liability or negligence.

LIABILITY FOR PUBLISHING INACCURATE DATA

The Internet has revolutionized the mass delivery of information. However, information was delivered online long before the commercialization of the Internet. A critical dimension of online information delivery is the speed at which information is disseminated, not necessarily the extent of that dissemination. Due to the speed of dissemination, however, information delivered online is not always accurate. The legal issue that arises is whether someone who claims damages as a result of an inaccuracy can hold the electronic publisher of that information liable for those damages. As a general rule, they cannot.

Historically, the courts have generally not held publishers liable for inaccuracies in the information they have published. There is an almost absolute immunity for publishers of information they do not author (Birmingham, 1992). Where the publisher does not author or guarantee the contents of the publication, it has no duty to investigate and warn its readers of the accuracy of the contents of its publications.

Courts have, however, carved out an exception when the information involved is highly technical in nature. For example, some courts have held a publisher liable for injuries suffered as a result of inaccurate aeronautical charts, considering the charts highly technical tools (Saloomey, 1983). Likewise, one legal commentator has argued that producers of Geographic Information System (GIS) mapping and database analysis may be under a similar threat of liability for inaccuracies (Phillips, 1999). However, as with "traditional" products liability and negligence laws, without a physical injury or damage to other physical property, a publisher will not be held liable for inaccurate information, regardless of the type of information published.

The laws relating to liability for inaccurate information are somewhat different when the publisher is also the author of the information. An author who provides false information in the course of its business as part of a commercial transaction is liable for loss suffered by the recipient's justifiable reliance upon the information, if the author fails to exercise reasonable care or competence in obtaining or communicating the information (Restatement, 1977).

However, before a publisher/author of inaccurate information can be held liable for damages resulting from that inaccurate publication, a special relationship must exist between the publisher and reader—the publisher must owe a specific duty to the reader. The fact that the subscriber obtains the information through an online subscription does not, in itself, create a special relationship.

FUTURE TRENDS

Time and again, courts recognize that the parties to a commercial transaction allocate risk, even when there has been no negotiation and the parties do not enjoy equal bargaining power. The result is that all of the risk for defective computer hardware/software or inaccurate data has been shifted to the purchaser. As long as the purchaser bears all the costs of these defects or inaccuracies, the vendor has no incentive to increase or guarantee quality. If the law was to impose more risk upon vendors, would quality improve?

Microsoft has been the subject of much criticism for producing shoddy software, particularly software with blatant security vulnerabilities (Menn, 2002). The issue of defective software has become so severe that commentators (Computer Science and Telecommunications Board, 2002; Sager & Greene, 2002) and legislators (Menn, 2002) have called for new standards of liability for software publishers. In early 2002, Microsoft Chairman Bill Gates published a company-wide memo outlining a strategic direction for Microsoft to produce software that is available, reliable, and secure (Schneier & Shostack, 2002). In the memo, Bill Gates is quoted as saying, "We must lead the industry to a whole new level of Trustworthiness in computing." Bill Gates is also quoted in the memo as saying, "So now, when we face a choice between adding features and resolving security issues, we need to choose security."

If Bill Gates and Microsoft are reacting to the threat of additional liability for the lack of quality in their software, this supports the contention that computer hardware, software, and data vendors, if faced with the potential of being held liable for the lack of quality in their products, will begin to assume greater responsibility for minimizing defects in hardware/software or inaccuracies in data.

The pressure continues. In late 2003, a class-action lawsuit was filed in California against Microsoft, claiming that Microsoft should bear some of the financial responsibility for its software's vulnerability to computer viruses (Krolicki & Stevenson, 2003).

CONCLUSION

The law allows computer system and data vendors, by contract, to disclaim any guarantee of quality, as well as prohibit any recovery for damages suffered by the purchaser where there is a lack of quality. The courts have consistently upheld such contract provisions. In addition, the type of damages usually suffered by disappointed purchasers or users are economic in nature—exactly the type of damages that are not recoverable in a tort action. The result is that between the contract and the courts, purchasers and users who suffer damages as a result of defective computer hardware/software or inaccurate data simply have no meaningful recourse. *Caveat emptor!*

KEY TERMS

Browsewrap Agreement: Generally pertains to accessing information on a Web page. A notice is placed on the Web site informing the user that continued use of (browsing) the Web site constitutes acceptance of a license agreement (the terms of which are usually made available by the user selecting a link on the Web site).

Clickwrap Agreement: Applies to software acquired without any packaging (e.g., when it is copied to a computer ("downloaded") from a Web site or is pre-loaded on a computer). When the buyer installs the software, a dialog box is displayed containing the license agreement. The user is instructed to select a button to accept the terms of the license agreement and complete the installation.

Negligence: A tort theory that applies to conduct that falls below the standard established by law for the protection of others against unreasonable risk of harm. An action for negligence must establish that: (1) one party (the first party) owed a duty of care to a second party; (2) the first party's lack of care (negligence) breached that duty of care; and (3) the first party's breach of the duty of care proximately caused the damages suffered by the second party.

Shrinkwrap Agreement: Derives its name from software contained in a box wrapped in plastic (shrinkwrapped). The agreement pertaining to the software is either printed on the box and readable through the plastic, or there is a notice that the agreement is contained within the box. In either event, opening the box and installing and using the enclosed software is considered acceptance of the terms of the agreement. The shrinkwrap agreement has evolved into the "clickwrap" agreement, as well as the "browsewrap" agreement.

Tort: A civil wrong committed by another. Tort law recognizes that individuals or businesses may owe a duty of care to others with whom they have contact. If that duty of care is breached, and the breach results in damages, the party that owed the duty of care may be liable for the resulting damages.

Unconscionability: Generally involves a lack of meaningful choice on the part of one of the parties to a contract together with terms that are unreasonably favorable to the other party. Unconscionability also refers to a contract that is so unfair or one-sided that a judge cannot in good conscious enforce the contract.

Uniform Commercial Code (UCC, or "Code"): A uniform collection of laws relating to commercial transactions. Specific provisions of the Code which relate to the sale of goods (Article 2) have been enacted by all of the states.

Warranty: A representation by a vendor regarding the quality of the product.

Library Management and Organizational Change

INTRODUCTION

As academic libraries continue to develop a virtual presence, they must cope with the rapidly evolving rate of change and respond proactively to their changing environment in order to take advantage of the opportunities for increasing their visibility, restructuring to meet the needs of their users, and achieving their objective of remaining the preeminent source of information within the academy.

COMPONENTS OF ORGANIZATIONAL CHANGE

The literature reflects four major areas in organizational change: the *structural* (or planning) aspect of change, the *cultural* aspect of change, the *personal* (or *individual human*) reaction to change, and the *political* aspect of change. Lewin's (1958) fundamental description of structural change has been incorporated into many process-oriented models of organizational change developed for organizations to better understand and direct the process of systemic change (Schein, 1987). Since cultural change often affects organizational identity, managers should focus on communication, leadership, and emotional components of change (Caldwell, 2003). Personal transition stages of individuals in the change process include the release of individual identity, ambiguity, and establishing a new beginning (Miller, 2002). The political aspect of change is reflected by Bolman and Deal (2003) in the use of reframing through the use of organizational metaphors as one of the skills of the "new" manager.

MANAGING CHANGE

Effective and successful organizational change incorporates and manages perspectives and models concurrently. As managers develop infrastructures (processes and values, and organizational capabilities) that are more effective (Christensen & Overdorf, 2000) or change institutional identity to assist in the creation of processes and values (Newman & Chaharbagi, 2000), it is important to understand why change does not happen. Mutually reinforcing barriers to implementing change are: top-down or *laissez-faire* management style; unclear strategy and conflicting priorities; an ineffective senior management team; poor vertical communication; poor coordination across functions; and inadequate down-the-line leadership skills and development (Beer & Eisenstat, 2000).

Although libraries of colleges and universities are changing faster than their respective parent institutions, library administrators must still address patron needs, provide services and handle service provision networks, initiate collaborative arrangements, improve staff skills and abilities, and enhance the image of the library (how the organization is regarded by important oversight bodies), and cope with new ways of funding and performing services (Spies, 2000).

Implementing Large Scale Programmatic Change

Innovation, defined as new ways of thinking of, generating, and coping with change (Jarratt, 1999), often means dramatic organizational change, such as cross-functional teams and the creation of new functional units and programmatic areas (Bishop, 1999). Implementing these innovations involves managing both the strategies and the elements of the organization that will have to be changed to enable the organization to anticipate, respond to, and shape future challenges (Morton, Brookes, Smart, Backhouse,& Burns, 2004). Even short-term change initiatives that focus on costs and/or changing established working practices have immediate and inevitable impact on the organization may be highly traumatic for staff (Hailey, 1998). Therefore, one needs to "marshal knowledge about changes, organizations, and corporate behavior—so that corrective actions may be undertaken to bring back balance and relative stability" (Geisler,1997, p.4) .

The judicious use of human resource interventions, the maintenance of organizational identity, and the supportive actions of its line managers help staff through the process of change (Hailey, 1998). More important than a manager's commitment to change is the commitment of line managers to people management. According to Hailey (1998), commitment to the management of people by supervisors ensures that staff members are counseled on a regular basis, both formally and informally; that their personal career development is discussed (with or without vertical career opportunities); and that they receive regular feedback on their performance. If these things are already in place, department heads and supervisors can facilitate change within their departments or units. Middle managers, who see themselves as change agents, are critical to encouraging adaptive change by staff. By doing "real" work themselves, demonstrating optimum skills, and encouraging and assisting staff to do their best possible work (Lamsa & Savolainen, 2000), managers can focus on a few key measures in critical areas and promote the belief that they are accountable for their work.

Performance Measurement

Performance measurement systems can create an essential feedback and learning mechanism in support of key management decisions, especially when criteria measures institutionally focused performance. A successful system also functions as a communication and information system, particularly for senior staff and administration. Basically, performance assessment should allow: up-to-date job descriptions that will ensure staff membersknow what is expected of them; continuing communication between supervisors and staff; recognition of staff for doing well; and staff development processes (Lubans, 1999). Effective people management assists line managers in handling change management.

What are core competencies in existing and potential staff as multiple assignments and opportunities emerge within the library? The literature on change management emphasizes three core competencies: a demonstration of interpersonal competence, personal integrity, and the capacity to think systemically and in an integrated way about how work systems and people need to collaborate. If these skills are present (or can be developed) within existing staff, staff may obtain a variety of professional competencies for managing individual and team projects, as well as system-level initiatives.

Managing Structural Change

Marketing, business, and annual operational plans, with formal objectives for individual staff, follow strategic planning. Wide variations in management practice indicate the need for major improvements, particularly in terms of adopting a strategic approach to the planning and delivery of library and information services. A clear framework of strategic objectives and priorities, formulated through a participative planning process, facilitates delegation of decisionmaking and resource allocation, allowing quick, flexible responses to identified customer needs. As libraries become more "virtual." academic library administrators must determine if the existing management and structure is both responsive to the changing user needs and utilizing technology to its best advantage (Spies, 2000).

Managing Cultural Change

To manage change successfully, library directors must choose the appropriate change path and design its implementation to suit their own situation. This requires an understanding of key internal organizational features, such as staff identity, aspects of the organization they wish to preserve, the degree to which the organization as a whole is aware of the need to change, and the level of capability for change possessed at all levels (Oliver& Roos, 2003). The culture shifts created during virtual library projects are similar to the changes libraries encountered during the mid-1980s when they purchased library management systems to automate circulation, acquisitions, and cataloging functions. At that time, library administration assured its faculty and staff of their continued importance and value within the then new organizational structure and to see innovation as a positive aspect of change.

Managing and Motivating Personal Change (Human Resources)

From a management perspective, the establishment of the team process can be an overall success. With autonomy within the teams and empowerment to tackle the team's charges, and, if necessary, to alter or change them to fit the parameters of the work, team members experience better communication and satisfaction. Further, teams that include both paraprofessional and professional staff lessen the artificial "class" structure often found in academic libraries.

Managing the Political Aspect of Change

From the perspective of the political, change processes are considered to be predominantly bargaining, consciousnessraising, persuasion, influence and power, and social movements (Bolman & Deal, 1991). The political aspect of change requires the reframing of organizations, which is impacted by the structural, cultural, and personal components of change. Combining models can create points of convergence, thereby creating a common ground on which to successfully implement and move through a change process. The distinctive characteristics and contexts of higher education require administrators to creatively balance internal (library) and external (university) forces and to often serendipitously leverage change (Nozero & Vaughan, 2000).

Quality Control

A strategic plan represents how the values, purpose, and operating principles in an organization are connected to its vision and strategy. Strategic objectives must be tied to the everyday operating environment and be measured through well-reasoned, logical performance criteria. (APQC, 1999). Sea changes in a strategic plan often dramatically impact technology-dependent library projects; yet, smaller issues also impact teams and individual work assignments. The library administrator must monitor the place of the team within the organization as the goals and structure of the organization change. To stay aligned, teams need to talk to one another and to the organization. By setting a clear direction, the organization also sets the boundaries within which teams work (Forrester & Drexler, 1999). Furthermore, teams require both individual and team accountability.

Sometimes, leaders of change also must be managers of change. Building job assignments and evaluation capacities into team positions is difficult and requires the use of concrete performance measures. However, without the accountability for staff time (within both regular and team assignments), organizations cannot have an accurate picture of the time, staff, and effort actually involved in projects or other aspects of organizational change. This is particularly true in the case of "volunteer" projects, which tend not to build in or use the necessary administrative tools to measure work performed outside one's normal job duties. Without mechanisms in place to ensure performance or delivery of product, it is extremely difficult, if not impossible, to track actual hours spent, review concrete workflow processes, or have product created. Further, it also makes it difficult to place "volunteer" tasks in relation to ongoing library duties, e.g., supervisors and department heads may feel that "volunteer" library work infringes upon actual duties.

Recommendations

There are six major lessons that administrators need to learn when working with organizational redesign or with team-based organizations. First, an organization's clarity of vision is critical and is subject to change based upon external forces, such as changes in the mission, vision, and values of the university. As the institution's priorities evolve, it is critical that administrators reevaluate and update a working document to ensure mission congruence.

Second, management should not underestimate the power of personal relationships. One of the most important aspects of inter-organizational networking is creating and sustaining the personal relationships among the parties (Lamsa & Savolainen, 2000). For a team to be effective, high-trust mutual relationships need to be developed, i.e., each member believes the others to be honest, capable, and committed to shared goals.

Third, do not let a team take itself too seriously; an innovation is not an ideology. Ironically, those who initially position themselves as change agents may aggressively resist the eventual integration of their project.

Fourth, the rest of the organization should not be ignored. It is important to avoid resentment by making sure that other groups are equitably considered for rewards and recognition, as well as challenged by meaningful assignments. Edwards and Walton (2000) indicate that a number of factors (including perception, limited resources, departmentalization and specialization, nature of work activities, role conflict, inequitable treatment, violation of territory, and environmental change) are major sources of conflict in academic libraries.

Fifth, do not let the rest of the library ignore the team. One of the "meaningful challenges" should be achieving the skills to fulfill the team's mission, e.g., all collection development librarians should work with virtual resources, all catalogers with metadata, and all reference librarians with innovative services and bibliographic instruction.

Finally, do not leave department/unit managers out of the loop, and make sure that goals are clear and clearly evaluated. Without measurable goals, there can be no team. An organization's precision and accuracy in marking progress should be clearly communicated to managers, staff, and teams. With clear communication of expected goals and outcomes, all members of an organization can focus on accountability, evaluating how well goals are achieved, and by specifying exactly who is responsible for what.

CONCLUSION

There are potential advantages in organizational restructuring to achieve more effective collaboration in planning and delivering information services by libraries. The hierarchical, "top-down" management style of the past is rapidly giving way to a system where employees take responsibility for their own actions and leadership comes from employee teams (Pierce & Kleiner, 2000). It does not mean that leadership always makes decisions at the lower levels, but rather that they oversee the decisions that are made and evaluate their congruence with the direction of the organization. This has a direct effect on the organizational composition. Flatter and more flexible structures are emerging, moving away from traditional structures to multi-skilled, multi-tasked, and cross-organizational teams that more effectively tailor services and resources to particular patron requirements. Further, a strong leadership emphasis on team goals, clear expectations from team leaders, attention to team development, and an emphasis on coaching and challenging (rather than directing) are critical for successful change management when utilizing a team-based structure.

FUTURE ISSUES

In the rapidly evolving environment of academic libraries, Collier and Esteban (2000) see library leadership as being the systematic capability diffused throughout the organization to encourage creativity, and generating processes and practices that translate into organizational learning. Administrators exercise this through influence and intention, openness and communication, and autonomy and accountability. Successful leadership of libraries requires the capacity to see change as a legitimate and positive aspect for organizational learning and development.

However, change requires a more thoughtful approach; major projects can and will have a significant impact on the organizational culture and structure. Nearly two decades ago, Soudek (1983) formally defined the relationship between the organizational climate and professional behavior of academic librarians. A good organizational climate is high in individual autonomy, low in job structure, high in reward and recognition of achievement (personal or organizational), and high in consideration, warmth, and support (Soudek, p. 337). Successful organizational change should include these measures as outcomes of the change process.

Almost a decade ago, Pritchard (1995) emphasized that as the roles for librarians change to accommodate new technology and user needs, it is important to remember that these challenges are evolving out of those roles that librarians have always done: connecting users to information; designing and managing complex, interconnected systems and organizations; selecting and organizing information resources; teaching and consulting; creating logical and intuitive insights about information; and formulating and articulating information policy. These basic services are still current today.

Finally, the key tasks for academic library administrators are to articulate future directions, based on a vision shared by all stakeholders and informed by ongoing environmental appraisal; to secure the financial and other resources required to achieve agreed-upon goals; and to inspire and support colleagues as partners in exciting collaborative ventures (Smith, 2003). The information environment of the 21st Century offers libraries the opportunity to play a central role in the academic community, but it will require bold and confident leadership along the way.

KEY TERMS

Change: To give a different position, course, or direction to an activity, process, or business.

Change Management: Successfully implementing a new position, course, or direction for individuals, processes, or products.

Performance Assessment: The measurement of an activity, process, or product to see if it meets an established objective or benchmark.

Trust Relationship: A relationship in which each party is assured of the reliability of the character, ability, strength, or truth of someone.

Vision: Discernment or foresight to create a path toward excellence, often used in regard to a future state of desired activity, production, or being for individuals, as well as for corporate entities.

Life Cycle of ERP Systems

Cesar Alexandre de Souza
University São Judas Tadeu (USJT), Brazil

Ronaldo Zwicker
University of São Paulo (USP), Brazil

INTRODUCTION

The 90's witnessed an impressive growth of Enterprise Resource Planning (ERP) systems in the market of corporate IT solutions. For instance, O´Leary (2000) reports that a single ERP system (SAP´s R/3) is used by more than 60% of the multinational firms. Among the explanations for this phenomenon are the competitive pressures suffered by the companies that have forced them to seek alternatives for cost reduction, differentiation of products and services and integration of their business processes. The ERP systems evolved exploiting the need for quick deployment of integrated systems to meet these new business requirements, while companies were (and still are) under pressure to outsource all the activities that are not embraced by their core business.

The ERP systems are introduced in companies following some well-defined stages. In this context, their life cycle encompasses the stages of decision, selection, implementation, stabilization and utilization. This chapter presents aspects involved in each stage of this life cycle, based on the referenced bibliography.

BACKGROUND

Enterprise Resource Planning (ERP) systems are integrated information systems acquired as commercial software packages with the aim of supporting most of the operations of a company. Markus and Tanis (2000) define them as commercial packages that enable the integration of data coming from transactions-oriented information systems and from the various business processes throughout the entire organization. Although companies may internally develop systems with similar characteristics, the term ERP is associated to commercial packages. Examples of ERP systems found on the market are the R/3 of the German company SAP and the PeopleSoft EnterpriseOne of the American Peoplesoft. Some authors present and describe characteristics that, if taken as a whole, permit to differentiate the ERP systems from systems developed within the companies and from other types of commercial packages (Souza & Zwicker, 2001; Markus & Tanis, 2000). These characteristics may be summarized as:

- ERP systems are commercial software packages;
- They include standard models of business processes;
- They are integrated information systems and use a corporate data base;
- They have a large functional scope;
- They require adjustment procedures to be used in a given company.

When deciding to use ERP systems, companies hope to achieve manifold benefits, like the integration of business processes, the increase of possibilities to control the company's operations, the technological updating, IT cost reduction and access to quality information in real time for decision taking (spread over the complete production chain). However, there are also problems to be considered. Table 1 synthesizes the benefits and difficulties of the ERP systems mentioned by many authors (Lozinsky, 1998; Hecht, 1997; Bancroft, Seip & Sprengel, 1998; Davenport, 1998; Stedman, 1998; & Cole-Gomolski, 1998), and relates them to the characteristics of ERP systems.

ERP SYSTEMS LIFE CYCLE MODEL

The life cycle of information systems represents the various stages through which a project of development and utilization of information systems passes through. In its traditional form, the systems development life cycle encompasses project definition, system study, design, programming, installation and post-implementation stages (Laudon & Laudon, 2001). Two different approaches for system development are the *waterfall* model, where stages are executed sequentially and only once for each system, and *prototyping,* where the stages are repeated, refining an initial solution (prototype) until it can be used as the definition for the system to be built or as the system itself.

Table 1. Benefits and difficulties of ERP systems

Characteristics	*Benefits Sought*	*Possible Difficulties*
Commercial Package	- IT costs reduction - Focus on the company's core activities - Technological updating - Backlog reduction	- Supplier dependence - Lack of knowledge on the package - Time for learning of interfaces not specifically developed for the company - Loss of former systems functionalities - Costs regarding the continued adjustment - Excess of screens and fields to be typed in - Lack of adequate managerial reports
Best Practice Business Models	- Knowledge on best practices - Access to other companies' experience - Reengineering of processes	- Need to adjust the company to the package - Need to change the business procedures - Need of consulting for implementation - Resistance to change
Integrated System	- Greater control on the company's operation - Real time access to data and information - Elimination of interfaces between isolated systems - Improvement of information quality - Synchronization between activities of the value chain enhancing global planning of the company	- Higher implementation complexity and costs - Difficulty to update the system as it requires agreement among various departments - One module not available may interrupt the functioning of the others - Resistance due to increase of work in the areas responsible for data input - Resistance due to increase of demands to the areas responsible for data input
Corporate Data Base	- Standardization of information and data definitions - Elimination of discrepancies between information of different departments - Information quality improvement - Access to information for the whole company - Cultural change to a view of dissemination of information from the departments to the entire company	- Cultural change of the view of "owner of the information" to that of "responsible for the information" - Responsibilities attribution on files shared between areas - Overload of the data base causing performance problems
Great Functional Scope	- Maintenance elimination of multiple systems - Standardization of practices - Reduction of training costs - Interaction with a single supplier	- Dependence upon a single supplier - If the system fails the entire company may stop - Support difficulties in the stabilization phase

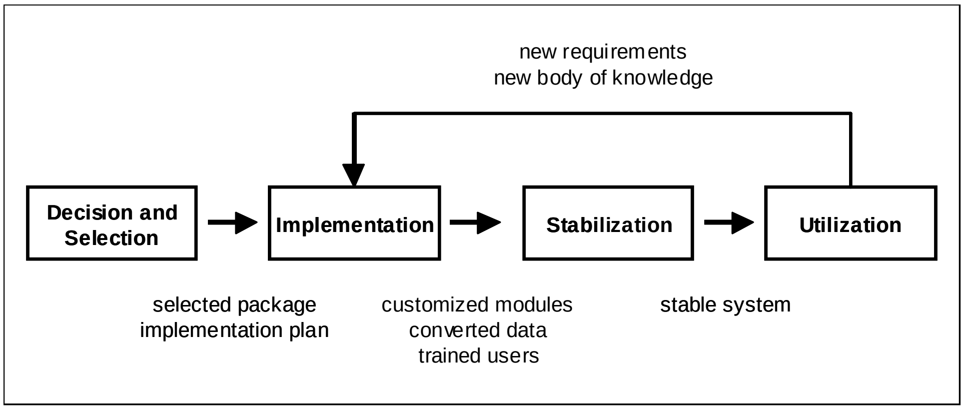
In the case of use of commercial software packages, it is, prewritten and precoded application software programs commercially available for sale or lease, the stages must be considered in a different manner. For instance, in the system study stage the focus is not on obtaining a detailed system specification from the users for programming the system, but instead, verifying the functionality of the many choices available from vendors, against a set of requisites from the users that will guide system adaptation or customization.

Like any commercial software package, ERP systems exhibit differences in their life cycle in relation to traditional systems development projects. But because of their large functional scope and their integration between its various modules, these differences are deepened. Some authors present models for the life cycle of ERP systems (Esteves & Pastor, 1999; Markus & Tanis, 2000; Souza & Zwicker, 2001). Souza and Zwicker´s model is shown in figure 1 and includes the stages of decision and selection, implementation, stabilization and utilization and is used next as a framework to present aspects involved in each stage of the life cycle.

(a) Decision and Selection

At the decision and selection stage the company decides to implement an ERP system as an IT solution and chooses the supplier. A series of issues must be taken into account at this stage. For instance, Davenport (1998) analyzes the decision from the point of view of the compatibility

Figure 1. ERP systems life cycle model (Souza & Zwicker, 2001)



between the organization and the characteristics of the ERP systems. Hecht (1997) presents criteria that may help in this choice: adjustment of the package's functionality to the requisites of the company, the technical architecture of the product, the implementation costs, the quality of post-sales support, the financial health of the supplier, and his view of the future. The main product of this stage is a detailed implementation plan, where the modules to be implemented, the implementation approach, the project schedule, the implementation team and responsibilities are defined.

(b) Implementation

Implementation comprises the second stage of the ERP systems' life cycle, although the term is also used to represent the full life cycle. The implementation of an ERP system may be defined as the process by which the system's modules are put into operation within a company. Implementation entails adjustment of the business process to the system, eventual customizing of the system, the loading or conversion of initial data, hardware and software configuration, training of the users and managers and the offer for support and help. This stage encompasses the tasks ranging from the end of implementation plan's concept to the beginning of the operation.

The implementation stage is reported to be the most critical of all (Bingi, Sharma & Godla, 1999). Difficulties are mainly due to the organizational changes that imply in changes of the tasks and responsibilities of individuals and departments and transformations in the relationships among the different departments. In an ERP system implementation it is generally pursued the optimization of the global processes of the company, which may cause as a counterpart changes in the activities in most of the departments involved. The need of intense participation and commitment of the company's top management and the requirement of permanent communication among the involved units is brought about by the size and complexity of this change and of the conflicts it may generate among those involved.

The process of adjustment of the ERP system to the company's processes is part of the implementation stage and is achieved by the adjustment of parameters or software customizing (development of programs to modify or complement the existing functions). At the implementation stage, the decision on how the start of the operation of the ERP system (the "go-live") will take place is also important. All modules may start operating: in all divisions or plants of the company simultaneously (*big bang)* or in one division or plant after the other (*small bangs)*. The start may also occur in *phases* (one or some modules start operating in one division or plant after the other, also called *roll-out*). The approach used to implement an ERP system is an important decision in its implementation project as it greatly affects the configuration of the system, the allocation of resources, and the management of the project and its risks. It will also play a decisive role at all the stages of the ERP system's life cycle.

The integration of processes pursued by ERP systems entails difficulties for the implementation stage. These difficulties are related to three types of changes in the way people do their work (Souza & Zwicker, 2001):

1) The integration aspect transfers to departments that produce the information the responsibility to insert it properly. This includes data used by other departments only (for instance, typing of an accounting bill in a production entry) and as a consequence, the users feel that their tasks are increased.

2) Information must be recorded into the system at the best-suited moment for the process and not at the best-suited moment for a specific department. Thus, there is a need to change the order and form in which tasks are carried out and other departments begin to demand the information they rely upon.
3) The activities of a department become transparent to all others and this has the inconvenience to require "explanations" for everything it does.

However, once these shortcomings are overcome, many users feel that they grew as professionals, since they start to have a broader view of the company's activities and to have a clearer perception of their role and importance in business processes. Training of end users for the work at an integrated system, taking into account the quoted aspects, is an important consideration for the success of the implementation process.

(c) Stabilization

In the first moments after the beginning of the ERP system operation there is a critical stage for the project's success: the stabilization. At this moment, the ERP system, that until then was only an abstraction, gains reality and starts to be part of the company and of the people's daily life. This is when the highest amount of energy, be it managerial or technical, is required. It is a stage in which problems, that could not have been easily detected at the implementation stage, become apparent. This is a particularly critical stage, as the company is already relying upon the system for its activities and which causes major pressure for the speedy solution of problems. The length of this period depends on the company and takes about eight weeks (Zwicker & Souza, 2004).

Two critical aspects may be highlighted at this stage: difficulties of the end users and problems of the ERP system (in programs and their adjustment to the company). Regardless of the fact that users have been trained in functions of the new system, they operate slowly in the early moments as they have doubts and feel insecure about the appropriateness of their actions. Besides the difficulties of adjustment to the functions of the new system, there is the issue of the cultural adjustment of people to the requirements of work in an integrated environment. While users face these difficulties, the detection of errors in customized programs and parameter settings also take place, hindering the normal operation. The simultaneous occurrence of use difficulties and system faults, associated with the recent familiarity of the project team to the new system, make the identification of the problems real causes even more difficult at this stage.

The exact characterization of this stage is related to the operation-starting mode chosen by the company. If operation of the ERP system started by means of a *big bang*, the stage of stabilization can be clearly distinguished from those of implementation and utilization. However, in companies that implement the modules in phases, or even in *small-bangs*, the stabilization stage is less characterized and merges with the implementation stage of the remaining modules. It can be stated that the stabilization stage in the case of implementation by phases starts with the operation of the first module and ends only when the last module implemented, in the last locality of the company, becomes stabilized. This longer implementation and stabilization time in general entails loss of focus of the project and may be viewed as a risk factor for the implementation in phases (for further details on the influence of ERP *go-live* approach on its life cycle, see Zwicker & Souza, 2004).

(d) Utilization

Finally, at the fourth stage the system starts to belong to the day-by-day operations. This does not mean that all its possibilities of usage are known, or that they are properly equated. Orlikovski & Hofman (1997) report on the difficulty within a company to know, beforehand, all use possibilities of the new information technologies. This knowledge is only achieved after a certain period of continued use of the technology, through the ideas that emerge during the utilization process. Therefore, the stage of utilization feeds back the stage of implementation with new possibilities and needs that may be solved through new modules, parameter adjustments, or software customizing. In the case of implementation in phases, the already implemented modules may impose restrictions upon new modules caused by already defined parameters or customizations. Indeed, new modules should not imply in changes of already configured and operational modules, usually a difficult task.

It is also observed that some time after the beginning of the operation, the implementation of customizations or new modules becomes more difficult. New modules not included in the original plans or improvements in the ERP system exhibit difficulties, characterizing that the new situation is decidedly refrozen. As a rule, these difficulties are associated to changes in priorities of the company and of the IT department, to the appearance of new projects and to the difficulty to bring together again, all departments and users needed for the implementation of the wished changes. Therefore, there are implicit difficulties for the realization of the continued adjustment recommended by the above referenced authors. According to the authors' model, knowledge of the possibilities and functionalities of ERP systems is only consolidated after the operation start, however, it was noted that companies have difficulties to implement new ideas and solutions at that stage. A possible explanation for this discrepancy may be the fact that the case analyzed by the authors dealt with a collaborative computer system that, although of great importance for the company under study, had less functional scope than an ERP system. Apparently, the high functionality of ERP systems and the impact they cause on the organization constitute inflexible barriers against the continued adjustment stage.

Markus and Tanis (2000) point out that it is only in this stage that the organization is finally able to ascertain the benefits (if any) of its investment in the ERP system, due to continuous business improvement, additional user skill building, and post-implementation benefits assessment. Esteves and Pastor (1999) also point out an interesting phase of the life cycle, the "retirement" stage, in which the ERP system would be substituted for other solution or solutions. What is being observed is that companies go through great efforts and costs each time a new version upgrade is needed (McMahon, 2004). Every time the decision to upgrade or not is posed to the organization it is also an opportunity to analyzing other ERP vendors or technologies (Kremers & van Dissel, 2000).

FUTURE TRENDS

The introduction of an ERP system changes the focus of the IT area. Normally the area evolves from a technical approach to a business processes approach. It is also apparent that the role of the users in the management of an ERP system is much more important and fundamental than in the case of internally developed systems.

There are also new challenges at the day-by-day management of IT in an ERP system context. For instance, maybe there are relationship problems with the supplier that demand the attention of the IT manager. Some of this type of difficulties apparently stem from the continued need of system updating that cannot always be strictly accomplished when the supplier sends new patches and releases. Indeed, the IT areas adopt alternative procedures to keep their updating efforts at levels consistent with their possibilities. Apparently, companies that possess ERP systems continue to be subject to the need of carrying out substantial upgrades requiring time and significant resources. At the time of internally developed systems, those aspects possibly were much less significant (Zwicker & Souza, 2004). A more detailed contextual analysis of this myriad of details opens an interesting possibility for future research in the ambit of the ERP utilization stage.

CONCLUSION

During the second half of the nineties, the implementation of ERP systems was one of the central points of attention regarding IT utilization in companies. History shows that implementation of ERP systems is not a simple matter since there are some reported failures (see Jesitus, 1997; Barker & Frolick, 2003).

Research on the subject, developed as from the end of the last decade, studied mainly the factors governing successful implementation and showed that a process of cultural change is involved. One critical factor for success is to avoid that the endeavor be handled as an information technology project (Willcocks & Sykes, 2000). Dedication and involvement of top management, strong participation of users and change management were aspects considered essential for the success of these implementation projects (Bingi, Sharma, & Godla, 1999).

This chapter presented a model for ERP systems life cycle that tries to encompass the complexities involved in implementing ERP systems in companies. To achieve this purpose, several aspects relating to the decision and selection, implementation, stabilization and utilization stages were presented.

The recommendation for companies that are deciding for ERP systems utilization and for companies that are already in the implementation stage is the careful analysis of the difficulties associated which each ERP systems´ life cycle stage. With a better knowledge about these difficulties, the process can be improved though better planning and better action on the inherent difficulties of such an organizational change.

KEY TERMS

Big-Bang Approach: Implementing all modules of an ERP system in all locations or plants of the company simultaneously.

ERP Decision and Selection Stage: Stage at which the company decides to implement an ERP system and chooses the supplier.

ERP Implementation Stage: Stage of an ERP project at which the ERP system's modules are put into operation.

ERP Stabilization Stage: The first weeks after the beginning of an ERP system operation in the company.

ERP Systems: Integrated information systems purchased as commercial software packages with the aim of supporting most operations of a company.

ERP Systems' Life Cycle: The various stages through which a project of introducing an ERP system in a company passes through.

ERP Utilization Stage: Stage of an ERP project at which the system starts to belong to the day-by-day operations of the company.

Phased Approach: Implementing the modules on an ERP system in sequential steps, comprising one or more modules in one or more locations or plants, until the system is completely installed. Also called roll out.

System Development Life Cycle: The various stages through which a project of development and utilization of information systems passes.

Limited-Perspective Bias in Technology Projects

Jo Ellen Moore
Southern Illinois University Edwardsville, USA

Lisa A. Burke
Louisiana State University Shreveport, USA

INTRODUCTION

Limited-perspective bias is a human tendency to overestimate the completeness of what we know and to act on our own (limited) perspective of what is important (Moore & Burke, 2004a). In organizations, each person possesses a view that evolves from what he or she experiences and observes on a daily basis. Given one's location or role in an organization, these views often differ and can affect one's perspective on a problem or situation (O'Reilly & Pondy, 1979). Each individual perspective, however, is by and large "valid" in that it represents a distinct cognitive reality within that firm.

But for truly effective decision making to occur, on both the day-to-day level and strategic level, the individual perspectives must integrate to create a fuller and more accurate view of situations and issues. In other words, limited-perspective bias often needs to be managed, and efforts to counter the bias are particularly crucial in dynamic organizations that depend on empowered employees to make decisions and figure out the right things to do. Left untended, limited-perspective bias (LPB) can lead an individual to formulate decisions and take actions that are ineffective, possibly even detrimental to the organization.

The purpose of this article is to summarize the present formulation of the limited-perspective bias construct, indicating why it is highly pertinent in information systems and technology (IS/IT). The occurrence of LPB in technology projects is then discussed and directions for future research are extended.

BACKGROUND: THE NATURE OF LPB AND ITS OCCURRENCE IN IS/IT

The existence of cognitive biases is established in the psychology and organizational behavior literature. For example, researchers have identified biases of consistency (Janis & Mann, 1977), escalating commitment (e.g., Staw & Fox, 1977), representativeness (e.g., Nisbett & Ross, 1980), and the fundamental attribution error (Ross, 1977). Limited-perspective bias (Moore & Burke, 2004a) is a newly conceptualized type of cognitive bias, presently positioned for further theoretical development and empirical investigation. Within the three-stage model of construct evolution (Reichers & Schneider, 1990), limited-perspective bias is in the "introduction and elaboration" stage, where a concept is discovered and efforts are made to present the new concept to fellow researchers and practitioners and to legitimize and refine it.

In providing a conceptual foundation for LPB, Moore and Burke (2004a) propose five situational factors that contribute to its occurrence: interdependence, uncertainty, ambiguity, deadline-driven work pace, and role incompatibility. All five of these characteristics are common in IS/IT organizational environments. Endeavors to apply technology dictate an interdependence among IS/IT and business personnel. For example, in technology implementations, a number of individual perspectives (e.g., the business user's perspective, technology infrastructure specialist's perspective, application developer's perspective, among others) are pertinent and necessary for the effort to culminate in an effective and useable solution. Such interdependence begs for management of LPB, as these single, specialized perspectives must be integrated and eventually merged in order to produce a proper end product for the organization within the time frame that it is needed.

Uncertainty and ambiguity are also proposed to contribute to occurrences of LPB in information systems and technology. Efforts that involve new technologies, new tools, or new methodologies, as well as projects that attempt to apply technology in novel ways, are inherently laced with uncertainty and ambiguity. LPB can aggravate and increase the difficulties encountered when working through such unknowns by restricting one's understanding of the situation, reducing one's resources for resolving the problem or issue, and ultimately causing one to head in a less than optimal direction.

A frenzied and deadline-driven work pace ("we need it yesterday") also contributes to LPB, as prior research suggests that time pressure adversely impacts information search and processing. Time pressure can prevent a person from recognizing that limited-perspective bias is happening and, even if a person recognizes the possibility of this bias, looming deadlines can prevent one from taking time to gather and assimilate information from perspectives other than one's own. Furthermore, managing the aforementioned factors of interdependence, uncertainty, and ambiguity takes time, so the frenzied work pace in which IS/IT so often operates compounds the likelihood that those factors lead to negative effects of LPB.

Finally, role incompatibility is intuitively associated with LPB. Whetten and Cameron (1998) identify role incompatibility as a source of conflict that is greatly exacerbated by resource scarcities, which are seemingly pervasive in organizations today. For example, in technology application projects, the development team is nearly always focused on producing a fully featured and quality product, believing that time and budget constraints should change to accommodate functionality (Dobson, 2001), but, upper management is likely focused on budgetary issues and getting the product in place as soon as possible because of the business process improvements associated with it. Although these two parties undoubtedly experience role incompatibility (e.g., management focusing on the time constraint and saying we need it now, the development team focusing on the functionality of the system and saying they need more time), if both parties can overcome their limited-perspective bias, role incompatibility can dissolve and true organizational priorities can be determined to better direct efforts of both parties.

MAIN THRUST OF THE ARTICLE: EFFECTS OF LPB ON TECHNOLOGY PROJECTS

Because technology implementation projects tend to possess elements of interdependence, uncertainty, ambiguity, challenging deadlines, and role incompatibility, they provide fertile ground for limited-perspective bias and its harmful effects. An example of how LPB can operate in a technology project is found in the area of project status reporting:

Application development and technical teams were hard at work in a banking institution to develop and implement the firm's first web-based application. The initial target date to deploy the application was June 15th. According to plan, the technical team had the infrastructure in place by that date. This technical platform included a contract outsourcing the web-hosting function for a monthly fee of $30,000, and the contract was signed to begin the services (and corresponding payments) on June 1st.
As June neared, however, the development team delayed the deployment date to September 15th. To meet that date, the new application had to be migrated to the pre-production environment for final user testing on September 1st. In the last week of August (mere days prior to final user testing and less than three weeks from the go-live date), the development team reported they were not ready. The team later delivered new completion estimates, which dictated a major postponement to December 15th. (Moore & Burke, 2004b)

All five proposed antecedents to LPB seem to be present in this project. Interdependence between the development and technical teams is apparent, and ambiguities and uncertainties were likely encountered by the developers in constructing this first-of-its-kind application for the organization. Clearly, the developers were operating under time pressure, striving to meet deadlines that became impossible to meet. They likely faced role incompatibility as well, since management undoubtedly was eager to have this application deployed.

LPB is observable in the project status reporting behavior of the development team. Considering they were so far from product completion, they probably knew for some time that the delivery date was not going to be met, yet they chose not to communicate this to management and other stakeholders. Many ramifications of LPB ultimately resulted, but one is clearly quantifiable from this short description of the project – the company could have saved $180,000 on the Web hosting contract had the development team reported the true status of their project.

In choosing to avoid revealing the true project status, the perspective of the development team likely included concern about negative effects that an inability to bring the product in on time might have on their work reputations, the anticipated unpleasantness of delivering bad news, and perhaps a hope that they could get things back on schedule before anyone needed to know the project was in trouble. Unfortunately, though, the development team operated on a *limited* perspective of what was important and what could be done.

The development team failed to perceive how their decisions and actions (such as not accurately reporting their progress) could adversely affect other important organizational functioning. They also operated on a limited perspective of what could be done to correct the situation and bring the project back under control. Whitten (1995) recognizes that many severe problems that occur in projects are not solvable by the individuals or specific group encountering them. LPB prevented the develop-

Table 1. Recommendations to minimize LPB (from Moore & Burke, 2004a)

General practices:
✓ Recognize that LPB occurs, in yourself and in others.
✓ Actively share your unique perspective, by routinely providing reasons for your decisions and actions.
✓ Seek out other valuable perspectives in an effort to broaden your own.
When faced with a specific dilemma or problem:
✓ Ask "what is best for the company?"
✓ Focus on what is right, rather than who is right.
✓ Remember our human tendency to underestimate situational factors others may be facing and inquire about those.

ment team from considering the ability of others in the organization to make necessary adjustments to support their efforts, as well as the ability of others in the organization to assist in remedies (e.g., by contributing resources or making adjustments in specifications or design).

In addition to illustrating the existence of LPB antecedents and consequences in technology projects, this example shows how easy it is for LPB to occur; that is, just how "human" it is. Because LPB is a natural tendency, deliberate and proactive effort is required to prevent it from occurring. Table 1 provides a summary of general recommendations from Moore and Burke (2004a) for minimizing LPB.

FUTURE TRENDS: RESEARCH OPPORTUNITIES

Because the limited-perspective bias construct is in the early stages of development, it provides fertile ground for exciting and timely investigation. Researchers are encouraged to form operationalizations of LPB and, when a reliable and valid measure is established, to begin studies to empirically define its nomological net. As a starting point, the five antecedents proposed by Moore and Burke (2004a) should be examined to determine the extent to which they contribute to LPB.

An additional angle to LPB that will be interesting to explore is that of national culture. The initial conceptualization of LPB appears to be grounded in the U.S. national culture. One would expect individualistic cultures, such as that of the U.S., to be more vulnerable to LPB, as workers in such cultures are apt to make decisions by themselves without checking with colleagues or soliciting input from others (Greenberg, 2002). Comparative analyses involving cultures that differ on dimensions such as individualism-collectivism are needed to determine the extent to which national culture influences LPB.

Researchers are also encouraged to examine LPB within the bounded (or limited) rationality decision-making framework (e.g., March & Simon, 1993). The theory of bounded rationality contends that although decision makers try to be rational, they are constrained by limited cognitive capabilities and incomplete information. They do not consider all alternatives or all consequences, and relevant information is frequently not sought. Of particular interest would be the examination of LPB in regard to the limitations that have been identified as contributors to bounded rationality: attention, memory, comprehension, and communication. March (1994) notes that division of labor to mobilize and utilize specialized talents (common in technology application efforts) encourages differentiation of knowledge and leads individuals to use different frameworks for understanding and simplifying their worlds. One manifestation of these different frameworks may be LPB.

Finally, efforts are encouraged to identify mechanisms we can employ to minimize LPB in technology projects and organizations. For example, what specific practices can individuals adopt to make the sharing of their perspective a routine and efficient part of what they do in the course of their workday? And what mechanisms can an individual put in place to ensure that he or she receives a steady flow of other perspectives deemed to be key to his or her position in an organization or project?

CONCLUSION

Laurence J. Peter (1982) may have said it best in the September 24th entry of *Peter's Almanac*: "Some problems are so complex that you have to be highly intelligent and well informed to be undecided about them." In today's world of new and complex problems, alleviating limited-perspective bias may be essential in arriving at the best solutions.

KEY TERMS

Ambiguity: Something difficult to interpret, difficult to understand, unclear. A situational factor proposed to contribute to the occurrence of LPB.

Bounded Rationality: A theory of individual decision-making that contends decisions are not made in a purely rational manner, due to limited cognitive capabilities and incomplete information.

Frenzied and Deadline-Driven Work Pace: A work environment characterized by persistent time constriction and pressure to meet challenging deadlines. A situational factor proposed to contribute to the occurrence of LPB.

Interdependence: Mutual dependence between parties in an organizational setting. A situational factor proposed to contribute to the occurrence of LPB.

Limited-Perspective Bias (LPB): A cognitive bias that reflects a human tendency to overestimate the completeness of what we know and to act on our own (limited) perspective of what is important and what can be done.

Role Incompatibility: A situation in which each party perceives its concerns or needs to be mutually exclusive (or antagonistic) to the other party's concerns or needs; that is, role incompatibility exists when one perceives his or her needs cannot be met if the other party's needs are met. A situational factor proposed to contribute to the occurrence of LPB.

Uncertainty: Something unknown, unreliable, or changeable. A situational factor proposed to contribute to the occurrence of LPB.

Macromedia Flash on the Client and the Server

Robert Barone
Buffalo State College, USA

INTRODUCTION

The Internet and more specifically the World Wide Web is a global communication environment. Either via a personal or commercial Web site, we seek to express ourselves as individuals or as organizations through this technological forum. We desire to provide an experience that will bring visitors back to our site. Providing rich multimedia content is the contemporary paradigm in achieving these ends. The software company Macromedia has addressed this need with their commercial product known as Flash. Macromedia Flash is used to create interactive multimedia environments in the client. There are also server-based technologies that communicate via Flash directly or indirectly.

BACKGROUND

Macromedia Flash has been evolving at a considerable pace. Up to Flash 4.0, the user interface was menu driven. From version 5.0 on, the user interface is palette oriented. Flash MX is version 6.0. MX designates a suite of programs. The Flash version at the time of this writing is MX 2004 (version 7.2). Components, introduced in Flash MX, allow the rapid building of user interfaces (analogous to HTML form elements). Flash MX 2004 introduces a new component architecture, called version 2 (or simply v2) with features not found in the previous (version 1 or v1) Flash MX component architecture (Statler, 2003). MX 2004 sees a branching of Flash into two separate applications, Flash MX 2004, incorporating the standard elements of the application, and Flash MX 2004 Professional, an extended version. A history of Flash is available at *www.macromedia.com/macromedia/events/john_gay/index.html*.

FLASH AND THE CLIENT

Flash is much more than a graphic arts program. This application allows the designer and the developer to create a true and unique graphical user interface (GUI). This GUI can be precisely programmed to support end user interactivity. Flash has found tremendous treatment in the World Wide Web, although it is not limited to this arena.

Flash employs vector graphics as the primary medium in content delivery. Vector graphics are described by mathematical formulas. These formulas are solved by the video processor of the client computer and a raster image is rendered. Raster graphics are bitmap images. They are composed of pixels that require a large number of bits to convey the information. Bitmap file sizes are inherently larger even when lossy compression techniques like JPEG (Joint Photographic Experts Group) (Knuckles & Yuen, 2005), a standard graphic file format, are utilized. Vector graphics are scalable and retain information when enlarged, although they suffer from aliasing (Bardzell & Bardzell, 2004). Raster graphics are not scalable and become unintelligible when enlarged. Flash makes use of streaming. The information contained in the streaming wave file is displayed in the browser as it is received. The browser does not wait for the entire contents of the file to be downloaded first. These two features, vector graphics and streaming, combine to make Flash a successful medium for providing multimedia content even with low bandwidth connections. Furthermore, the programming aspect of Flash further enhances and extends the Web sites usability by bringing interaction to the forefront.

Concepts in Flash are hierarchical in organization. Drawing on the stage with any of the tools creates a drawing object. These are the basic building blocks of a Flash movie. Objects can be selected, copied, grouped, transformed, skewed, stacked, deleted, and so forth. Essentially any designer's demands can be met with the drawing object. Flash also supports importing of images.

The next level of hierarchy is the symbol. If the desire is to motion animate (motion tween) the drawing object, it must first be converted to a symbol. Interestingly shape morphing (shape tweening) is performed on a drawing object. There is a subtle importance here which cannot be underestimated. Once a symbol is created, it is automatically placed inside a container known as the library. If the designer wishes to re-use the symbol, it is dragged and dropped from the library onto the stage. Multiple occurrences of the symbol on the stage are referred to as instances of the symbol. An instance on the stage may be thought of as pointing to the symbol in the library. Since the symbol is only stored once and reused many times in the form of an instance, file size remains at a minimum.

Another advantage is file-to-file reusability of symbols. A library from one Flash file can be opened in a completely separate file and the symbols reused.

There are three symbol types, *movie clip, button,* and *graphic*. Movie clips are self-contained Flash movies that can be treated as instances. Once on the stage they cycle through their animation sequences independently of the main movie. Movie clips are also programmable. Buttons maintain an up state, an over state, a down state, and a hit state. The first three states can be animated and buttons are also programmable. Graphic symbols are simply used to create motion tweens and are not programmable in the sense that an action cannot be directly attributed to one.

The stage also maintains a hierarchy in the form of layers. Think of the stage as a deck of playing cards (a typical analogy). Each card in the deck is a layer—the card at the top being the highest in the hierarchy and those below it are lower. Typically, one animation per layer is the rule. It is not enough to recognize that a symbol must be on the stage to work with. Identifying the corresponding layer it resides in is just as important.

The timeline is the backbone of a Flash movie. A celluloid film strip is composed of still images that are rapidly moved across a movie projector to give the illusion of continuous movement. The same is true of a Flash movie. Each layer has a timeline that is subdivided into frames. A symbol is placed into a layer. Movements of symbols on the stage are broken across a series of frames in the layers timeline. As the software play head moves form one frame to the next, the symbol is given the illusion of movement. When the play head reaches the last frame, it loops back to the beginning and plays over unless a programmable command is given to interrupt the process. Consequently, it is seen that certain symbols can be programmed via the timeline, directly via their instance, as well as the actions and objects that can be attributed in a given situation.

A Flash movie is created in a file with extension *.fla*. This file can create many file types. For Web delivery, the common types are *.html* (hypertext markup language) and streaming wave file *.swf* (streaming wave file or small Web file). The client's browser requests the html from the server. Once the browser has loaded the html file, the browser calls the streaming wave file from the server.

Flash incorporates a programming language know as ActionScript, which was introduced in Flash version 5.0 (Mohler, 2001). ActionScript, like many other scripting languages, is considered loosely typed and prototype based (Hall & Wan, 2003). This means that variables do not have to be declared before they are used and that the data type stored in a variable may change depending upon how program logic flows. Flash MX 2004 introduces ActionScript 2.0, whose distinguishing features are the ability to define a true class, case sensitivity of all identifiers, and strong (or strict) data typing (Statler, 2003). The developer has the ability to choose the version of ActionScript and Flash Player the movie will run in. ActionScript is ECMA (European Computer Manufacturers Association) compliant (Williams, 2002).

With ActionScript, the developer is handed an object toolbox to use. The Flash architects have designed an immense collection of functions and objects which can be utilized to manipulate instances of symbols. Once the concept of using an object in a program is understood, what remains is becoming familiar with the myriad of object methods and properties. It should also be noted that ActionScript and JavaScript can communicate on the client side. Typical examples are pop-up windows.

The end result, the Flash movie, is essentially a unique stand-alone miniature GUI application that executes on a desktop or in a browser window delivered via disk or network.

FLASH AND THE SERVER

Communication to and from a Flash movie, especially from the client back to the server, is possible. One method is to use middleware. Middleware is a server side script that resides and executes on a server computer. Examples of server side scripting environments are Active Server Pages, ASP, by Microsoft (now ASP.NET); ColdFusion by Macromedia; Java Server Pages, JSP, by SUN; and Personal Home Page, PHP, an open source technology. Perl (Practical Extraction and Report Language) (Castro, 2001) was one of the first languages used to build a Common Gateway Interface, CGI, for server side interactivity.

The idea here parallels the concept of creating an ordinary FORM tag in a traditional HTML (hypertext markup language) page and using GET or POST method to send the data collected in the FORM to a server side script that processes it. This is where Flash will make use of program-controlled text boxes and components to produce HTML FORM behavior.

The server side script will process the data and respond in many different fashions. One way is to create an HTML page and send it back to the browser. Another is to store the data in a database manager first and then send a page back to the client. There are many variations of theme depending upon the Web application.

An important consideration (Chambers, 2002) when using a Flash movie to interface with middleware is the following: a Flash movie is loaded into the browser once and can handle many data transfers to and from the middleware. Middleware can build content for a Flash movie without building a new Flash movie (Muller, 2003). An HTML file loaded into the browser interacts with the middleware, and the middleware must dynamically generate an entirely new HTML page to be retuned to the browser for every data transfer.

Flash MX also allows the passing of data between client and server using XML (extensible markup language) (Jacobson & Jacobson, 2002; Weiss, 2004). Flash can be programmed to recognize and parse XML data into meaningful graphical content in the movie. Flash MX 2004 Professional supplies a tailored XML connector component that provides the application with access to an external data source that returns or receives XML (Webster, 2003). Macromedia has also designed their own markup language. The Macromedia Flex Markup Language, MXML, is an XML-based markup language that also incorporates the logic ability of ActionScript (Coenraets, 2003). XML lays out user interface components while ActionScript handles the interaction.

Flash Remoting is basically the Flash Client–Middleware–Data Source model, where the data source can be a database, legacy system, or some other messaging system. However, it is a stand-alone product utilizing a proprietary protocol known as Action Media Format, AMF. Flash Remoting is primarily used in enterprise-level applications (Webster, 2003).

Flash can integrate with Web services (Weiss, 2004), which can provide the same functionality as middleware, but return information in the form of an XML document termed a Web Service Description Language, WDSL. Web services are usually free and are becoming more prominent. Google and Amazon are common examples. Flash MX 2004 Professional supplies Web service connector components.

Macromedia Generator was a server-based tool that accepted data and dynamically returned a Flash movie to the client. It has been phased out due to middleware and Macromedia's current design philosophies. Macromedia has introduced Flash Communication Server MX. This is a server side technology that combines streaming with real-time animation, messaging, audio, and video (www.macromedia.com/macromedia/proom/pr/2002/flash_com_mx.html).

Flash MX Communication Server also allows Remoting (Lozbin, 2002). In this scenario the Communication Server is positioned between the Flash client and the middleware. This provides a more streamlined, less complex, optimized enterprise application.

Finally, Macromedia has introduced Central (Lynch, 2003), an application that runs on the desktop and allows the managing of information obtained from distributed sources outside the browser. It is mentioned here because Central provides Flash developers with a pre-built infrastructure for creating and distributing applications. Macromedia has provided a SDK (software development kit) for this purpose (www.macromedia.com/support/centraldev/).

FUTURE TRENDS

With wireless becoming more affordable and accepted, we may see more of an effort to offer higher quality Flash movies and interactivity on handheld wireless devices. Macromedia has worked tirelessly in making Flash communicate with other Web technologies. We can always expect this trend to continue. With the introduction of Central, we hope to see more desktop interactivity and development. Finally, incorporating video into a Flash movie is another important aspect of the application. We can expect more video intensive development for Flash.

CONCLUSION

The vastness of this application cannot be understated. A person or team needs to be devoted almost exclusively to this application if the full potential is to be realized. It is an exciting cutting-edge application that combines all elements of the Web into a content-rich multimedia environment. With greater emphasis being placed on content as well as presentation, Flash has kept pace and provides some benefits not realized in static environments. As the Web continues to evolve and expand, new challenges and issues will arise that Flash must expand to incorporate.

KEY TERMS

Components: Small pre-defined program snippets within Flash that allow reuse of elements. Examples are buttons, pull-down menus, text boxes, and text areas.

European Computer Manufacturers Association (ECMA): Standardizes information and communication systems.

Flash Player: A multiple-platform client that Web users must download and install (a browser plug-in) in order to view and interact with Macromedia Flash content.

Middleware: A server side scripting technology used to facilitate data transfer and communication between a client and a data source.

Software Development Kit (SDK): A set of development tools that allows a developer to create applications for a certain software package, hardware platform, or operating system.

Tween: A term coined at Walt Disney. The master animator creates the key animation frames of a sequence and the apprentice creates all the in between (or tween) frames.

Web Service: Data provided over the Internet, usually in a WSDL (Web service description language), meant as communication between computer software.

Management Considerations for B2B Online Exchanges

Norm Archer
McMaster University, Canada

INTRODUCTION

Information systems that link businesses for the purpose of inter-organizational transfer of business transaction information (inter-organizational information systems, or IOIS) have been in use since the 1970s (Lankford & Riggs, 1996). Early systems relied on private networks, using electronic data interchange (EDI) or United Nations EDIFACT standards for format and content of transaction messages. Due to their cost and complexity, the use of these systems was confined primarily to large companies, but low-cost Internet commercialization has led to much more widespread adoption of IOIS. Systems using the Internet and the World Wide Web are commonly referred to as B2B (business-to-business) systems, supporting B2B electronic commerce.

Technological innovations have led to several forms of B2B Internet implementations, often in the form of online exchanges. These are virtual marketplaces where buyers and sellers exchange information about prices, products, and service offerings, and negotiate business transactions. In addition to substituting proprietary lines of communication, emerging technologies and public networks have also facilitated new business models and new forms of interaction and collaboration, in areas such as collaborative product engineering or joint offerings of complex, modularized products. During the years 1999-2001 a number of online exchanges were introduced, but many of these failed (Gallaugher & Ramanathan, 2002), due mainly to an inability to attract participating business partners. Those that have survived are often owned by companies or consortia that are also exchange customers or suppliers.

The objective of this overview is to describe the evolution and the characteristics of B2B Internet implementations, and to discuss management considerations, the evaluation and adoption of B2B applications, and the technical infrastructure supporting these systems. We also indicate some of the open issues that remain as the technology and its adoption continues to evolve.

BACKGROUND

Although there are many classification schemes available for online exchanges (Choudhury, 1997; Kaplan & Sawhney, 2000), we will use a more generic and functional focus, with three categories: sell-side, buy-side, and neutral/market-type applications (Archer & Gebauer, 2001). Early B2B sell-side applications featured online catalogs, made available to the Internet community by distributors and manufacturers, often complemented by features such as shopping baskets and payment functionality. Many now provide customized and secure views of the data, based on business rules from contract agreements with individual customers. In some cases, buying processes of the customers are supported, including features such as approval routing and reporting. While some sophisticated applications exist to support collaborative forecasting or the configuration of complex products, many sell-side systems handle only the simpler transactions, such as maintenance, repair, and operation (MRO) supplies. Recently, more advanced features have become more widely available, such as CPFR (collaborative planning, forecasting, and replenishment) to support joint initiatives between customer and supplier (Holmstrom, Framling, Kaipia & Saranen, 2002).

Buy-side applications support procurement, moving order processes closer to the end user, and alleviating structured workloads in functional departments such as purchasing and accounts payable. For smaller companies, an affordable alternative is to work through hosted solutions, using Internet browsers to access procurement functionality provided by a third-party vendor or application service provider (ASP). Some applications provide functionality beyond the automation of highly structured procurement processes, including production tendering, and multi-step generation requests for proposals, as they are relevant for the procurement of freelance and management services. Interfacing purchasing systems to internal systems such as enterprise resource planning systems (ERP) makes it possible to automate many transactions, thus greatly increasing processing speed and reducing costs. Buy-side solutions that involve long-term inter-organizational relationships are typically set up by the purchasing organization, which then controls catalog content, data format, and back-end system functionality. Benefits include a reduction in maverick buying, and freeing purchasing and accounts payable personnel from clerical work to handle more strategic tasks. Suppliers typically benefit from long-term relationships, and in many cases the relationships between the buyer and its suppliers were in place before the buy-side operation was established.

The third group of applications, often referred to as B2B electronic markets or hubs, can either bring together multiple buyers and sellers on an ad hoc basis involving various types of auctions, or support more permanent relationships (a many-to-many relationship, equivalent to IOIS). Those that have been more successful are likely to have been sponsored by a consortium (e.g., GlobalNetXchange, in the retail industry, sponsored by buying organizations, and Global Healthcare Exchange in the health care industry, sponsored by selling organizations). They may feature auctions, electronic catalogs, and auxiliary value-added functions, such as industry news and online forums. The initiator typically controls the catalog content, aggregates supplier input, and provides additional functionality and standardized data access to buyers. These marketplaces may eliminate the need for market participants to link directly to their business partners, circumventing costly value-added EDI network services. Their business models typically include service charges based on transaction volume and setup costs. They provide a standard for suppliers to deliver catalog content, increase flexibility if they support access to suppliers and customers outside pre-established relationships, and create customer value through competitive pressure. Participation in such marketplace solutions may also provide a low-cost alternative for SMEs (small and medium enterprises).

MANAGEMENT CONSIDERATIONS

A market assumes an intermediary role that supports trade between buyers and suppliers, including (Bailey & Bakos, 1997): a) matching buyers and sellers, b) ensuring trust among participants by maintaining a neutral position, c) facilitating market operations by supporting certain transaction phases, and d) aggregating buyer demand and seller information. Supporting the marketplace through an electronic exchange has characteristics of (Bakos, 1991): 1) cost reductions, 2) increased benefits with the number of participants, 3) potential switching costs, 4) capital investments but economies of scale and scope, and 5) significant uncertainties in benefits. Many of the management issues of B2B electronic commerce systems relate to the need to coordinate decisions and processes among multiple firms, often through differences in business processes, information systems, business models, and organizational cultures.

Early transaction cost theory recognized markets and hierarchies as the two main methods of governance for coordinating flows of goods and services. Markets such as stock exchanges coordinate the flow through supply and demand forces, with price as the main coordination vehicle. Hierarchies such as production networks consist of predetermined relationships among customers and suppliers, and rely on managerial decisions to coordinate flows. There are many intermediate forms of governance, such as network organizations and strategic alliances (Gulati, 1998). A common theme among all these governance structures is collaboration among the participants, but the level of collaboration varies. These levels can be described as cooperation, coordination, and collaboration (Winer & Ray, 1994). In cooperation, there is little sharing of goods, services, or expertise; coordination requires mutual planning and open communication among participants, who share resources; collaboration involves deeply synergistic efforts that benefit all parties. Collaboration at different levels between buyers and sellers is emphasized by online exchanges, but this can also take place among buyers and among sellers (Wang & Archer, 2004).

In recent years there has been a "move to the middle," with a growth of outsourcing arrangements and more cooperative, integrated long-term inter-organizational relationships with a relatively small number of preferred suppliers (Clemons, Reddi & Row, 1993). Distribution of market power is often an overriding factor. For example, auto manufacturers, as a concentrated industry, will be likely to adopt an approach that involves long-term collaborative relationships among business partners rather than the short-term market-driven relationships that traditionally characterized this industry. On the other hand, companies in fragmented industries such as construction are characterized by short-term relationships and low levels of trust, where transactions such as online procurement are more likely to be through B2B tendering and auctions (Stein, Hawking & Wyld, 2003).

EVALUATION AND ADOPTION

The task of evaluating an electronic exchange becomes difficult when network effects are taken into account (benefits from participating are usually positively related to the number of participants). As a result of complications such as these (strategic necessity, dependence on the commitment of business partners, additional risk, external effects, etc.), the evaluation of an electronic exchange is much more complex than for systems deployed within organizations (Gebauer & Buxmann, 2000). B2B market mechanisms focus on four factors that favor one market mechanism over another: degree of fragmentation, asset specificity, complexity of product description, and complexity of value assessment (Mahadevan, 2003). These have a significant impact on the choice of an appropriate market mechanism for B2B interactions.

From the organizational perspective of setting up a successful B2B application, there are initiators and (potential) participants. Initiators bear the majority of the cost and risk, but on the other hand also enjoy the majority of the benefits, and they typically decide on technology infrastructure, type of systems used, corporate identity, representation of partners, and selection of participants. Success of the system depends on the participation of a critical mass of business partners. Supplier participation considerations in a buy-side solution, for example, include investments necessary to prepare and upload catalog data, integration with back-end systems, training of staff, and adjustments of business processes. Depending on individual arrangements, benefits include reduced time and costs for order processing, improved customer service, increased customer reach in a globalized marketplace, and an increase in revenues from long-term and trusted customer relationships. Neutral intermediaries in such markets face a difficult balancing task, as they have to be careful to satisfy suppliers as well as buyers, and a business model must be chosen that will attract the desired participants.

Although B2B exchanges have received a great deal of attention in the press and among researchers, their rate of adoption by business has not been high. While their aggregate transaction growth rate is higher, they are still (in 2004) outranked by at least a factor of 10 in transaction volume by EDI installations, which are still firmly in place in many large corporations (Jakovljevic, 2004). In addition, by utilizing EDI over the Internet, companies and organizations also benefit from the ability to facilitate a seamless bridging between XML and EDI that can now coexist on the same infrastructure and use common protocols to handle electronic procurement, invoicing, and logistics information. With the need to electronically exchange volume-intensive catalogue and product specification information, organizations can significantly reduce the high cost of this exchange by using Internet EDI. Although EDI is able to support only text content, the combination with XML provides support for images and graphics (Hamdar, 2002).

SMEs can and often do handle B2B transactions through e-commerce solutions without fully automated transaction management systems, including hosted procurement applications. Supply-side solutions with Web access can also be used as parallel and partially automated channels for larger businesses that wish to deal with small suppliers or customers. In practice, SMEs execute small numbers of transactions and may not wish to make the investment in resources, training, and internal integration required to link to their business partners (Archer, Wang & Kang, 2003). Motivations for joining online exchanges include (Gebauer & Raupp, 2000): a) coercion (through market power), b) long-term commitment to business relationships and reduction of associated uncertainty, c) subsidies to support system installations for potential partners, and d) general system improvements that result in improved efficiencies and effectiveness. SMEs that link to online exchanges are most likely to be motivated through pressure from their larger partners and by long-term commitments. Many use alternative interactions utilizing a combination of manual and online functions. For example, a medium-sized value-added retailer might use ad hoc purchasing procedures such as searching the Web for catalogue information on major suppliers, and then use the telephone to negotiate prices and delivery schedules (Archer et al., 2003).

TECHNICAL INFRASTRUCTURE

Software products to support B2B interactions are continuing to mature as more complex functions are added, such as collaborative planning, forecasting, replenishment, negotiation and decision support, and procurement and asset management of complex and highly customizable items and systems (Paul et al., 2003). Linking data from many different sources, including legacy systems, through Web services (Iyer, Freedman, Gaynor & Wyner, 2003) is still in its infancy, but supported by diffusion of industry standard Extensible Markup Language (XML). Technical issues are complicated by the critical role of security and confidentiality in inter-organizational settings, particularly when using public networks such as the Internet as compared to the private networks that were traditionally used for EDI implementations. Meeting these needs may require significant investments in software, training, business process reengineering, technical support, and time, all of which favor larger organizations.

Complexity of transactions is an important adoption factor, and is determined by factors such as the number of sub-processes and organizational units that are involved, as well as their possible interactions, interdependencies and relationships with the process environment (Gebauer & Buxmann, 2000). This in turn depends on the type of goods or services. Acquiring indirect or non-production supplies and services is the least complex type of transaction, followed by direct goods, and capital goods and other types of ad hoc purchases tend to be the most complex. A high degree of automation is economically viable only for high volume, less complex transactions. As complexity increases and volume decreases, human intervention is more likely to be needed to handle exceptions and ad hoc transactions.

B2B applications can have major impacts on interorganizational business processes, depending on the level of IOIS integration required (Stelzer, 2001). After planning and designing the system business model and infrastructure, a careful plan of how to implement it, how to train employees, and how to adapt business processes is the next step towards a successful project (Archer & Gebauer, 2001). Partner adoption, catalog management, and integration with a heterogeneous system of back-end applications are frequently listed as major stumbling blocks. For example, an organization could start out by reengineering and then automating an inefficient process that causes long lead times and possibly frequent complaints, such as management approval of end-user requests. As a next step, putting together an online catalog that contains the offerings of preferred suppliers can be useful as a first step to reduce "maverick" buying outside pre-established contracts. While the exact steps will depend on the situation within the individual firm, the stepwise approach will also allow frequent adjustments during the project planning and implementation process, including the addition of new requirements. The adoption of a B2B e-commerce solution is a strategic company decision and it is important to evaluate the potential overall impact of this innovation on the firm before proceeding (Pant & Hsu, 1996), as it may require substantial reengineering before it will be effective (Maull, Childe, Smart & Bennett, 1995).

FUTURE TRENDS

There is little doubt that rapid growth will continue in the relative value of B2B transactions handled through electronic commerce solutions, especially as they become less costly and easier to implement in SMEs. However, most of the growth in such offerings is likely to be in sell-side or buy-side online exchanges, as there has been significant supplier resistance to participating in neutral market-type exchanges. Although these exchanges offer the greatest theoretical benefit because of the potential for standardized linkages among participating companies, and the collaborative functionalities offered by such systems, this does not outweigh resistance from suppliers who see declining profit margins due to transaction cost payments and competitive price bidding. Meanwhile, EDI systems continue to link many large companies, due to their reluctance to give up related investments or to change business processes to accommodate the newer solutions.

CONCLUSIONS

A clear understanding of the possibilities of emerging technologies is crucial to take advantage of new opportunities in the B2B marketplace. There have been failures in this environment due to a lack of consideration of the wide range of technical, managerial, and economic issues involved. No widely adopted frameworks have been developed to assist in the choice of level of integration or in reengineering boundary spanning business processes. Although technology continues to develop, it is still immature in many areas. In particular, the integration with current IT infrastructures is often extremely complex and difficult to justify for medium to low transaction rates. Meanwhile, B2B applications continue to evolve, changing the rules of the game in subtle ways, but providing fruitful areas for research and new developments.

KEY TERMS

Application Service Provider (ASP): An ASP is a service company that can support and relieve a firm from the daunting challenges of finding, hiring, inspiring and training technical personnel to manage an application in-house. An ASP provides software applications on a pay-per-use or service basis via the Internet and leased lines.

Collaborative Planning, Forecasting, and Replenishment (CPFR): CPFR is a global, open, and neutral business process standard for value chain partners to coordinate the various activities of purchasing, production planning, demand forecasting, and inventory replenishment, in order to reduce the variance between supply and demand and share the benefits of a more efficient and effective supply chain.

Electronic Data Interchange (EDI): A standard used to govern the formatting and transfer of transaction data between different companies, using networks such as the Internet. As more companies are linking to the Internet, EDI is becoming increasingly important as an easy mechanism for companies to share transaction information on buying, selling, and trading. ANSI (American National Standards Institute) has approved a set of EDI standards known as the X12 standards. Although not yet a global standard, because of EDIFACT, a standard developed by the United Nations and used primarily in non-North American countries, negotiations are underway to combine the two into a worldwide standard.

Enterprise Resource Planning (ERP): A business management system that can integrate all facets of the business, including planning, manufacturing, sales, and marketing, through a common database. As the ERP methodology has become more popular, software applications have been developed to help business managers implement ERP in business activities such as inventory control, order tracking, customer service, finance and human resources.

Extensible Markup Language (XML): Document type definitions that can be used to specify or describe various types of objects. When a set of these is used on the Web to describe product information, it is referred to as cXML or commerce XML. It works as a meta-language that defines necessary information about a product, and standards are being developed for cXML in a number of industries, performing a function similar to that of EDI for non-Web-based systems. It will help to standardize the exchange of Web catalog content and to define request/response processes for secure electronic transactions over the Internet. The processes include purchase orders, change orders, acknowledgments, status updates, ship notifications and payment transactions.

Inter-Organizational Information System (IOIS): (Sometimes referred to as an IOS). An automated information system, built around computer and communication technology, which is shared by two or more companies. It facilitates the creation, storage, transformation, and transmission of information across a company's organizational boundaries to its business partners.

Maintenance, Repair, and Operations (MRO): Supplies and services purchased for use internally in the company, often referred to as indirect or non-production supplies and services (such as office supplies, computer equipment and repairs, cleaning supplies, etc.). These tend to be low unit cost, low volume, and off-the-shelf purchases.

Small and Medium Enterprise (SME): The definition of small and medium enterprises varies from country to country. If the definition is based on number of employees, SMEs in the U.S. have from 1 to 499 employees. The dividing line between a small and medium business is variously defined as being either 50 or 100 employees.

Management of Cognitive and Affective Trust to Support Collaboration

Diane H. Sonnenwald
Göteborg University & University College of Borås, Sweden

INTRODUCTION

Cognitive trust focuses on judgments of competence and reliability, and affective trust focuses on interpersonal bonds among individuals and institutions. Both cognitive and affective trusts play an integral role in organizations and institutions that rely on collaboration among individual members to achieve their goals and realize their vision.

Collaboration is increasingly important in the knowledge-based economy, as well as in scientific research and development where no one individual has all the prerequisite knowledge and resources to solve complex problems, develop sophisticated products and services, or complete multi-faceted work tasks. Collaboration is not possible without cognitive or affective trust. Yet cognitive and affective trust may be more difficult to manage in organizations and teams that are geographically distributed (i.e., not physically collocated), because mechanisms, such as informal face-to-face interactions and observations that typically are used in building and maintaining trust, are not universally present. Previous research has shown that when organizations are geographically distributed, trust among members is negatively impacted (Handy, 1995; Jarvenpaa & Leidner, 1995; Rocco et al., 2001).

BACKGROUND

Definitions of Trust and Distrust

There are many definitions of trust arising from different disciplinary perspectives. When synthesizing these definitions, Rosseau et al. (1998) found that scholars fundamentally agree that trust is a "psychological state comprising the intention to accept vulnerability based upon positive expectations of the intentions or behavior of another" (p. 395). Trust involves risk (the probability of loss) and interdependence (reliance on others).

Distrust can be defined in opposite terms (i.e., negative expectations of the intentions or behavior of another) (Lewicki et al., 1998; Sztompka, 1999). It involves a lack of risk and no dependence on others. Trust and distrust can exist simultaneously in individuals (Lewicki et al., 1998). They can be conceptualized as a continuum with high trust to high distrust as endpoints; that is, a continuum from high trust to low trust to low distrust to high distrust.

Evolution of Trust and Distrust

Feelings of trust and distrust can change over time (Jones & George, 1998; McKnight et al., 1998). These changes occur as a result of observation of and reflection on behavior (Whitener et al., 1998). That is, trust and distrust are not behaviors, but psychological conditions that influence an individual's behavior.

An individual's behavior influences others' behaviors, both of which may be assessed by the individual (Figure 1) (Sonnenwald, 2003). This assessment is often based on prior experiences, knowledge of the context in which the behaviors occurred, and beliefs. The results of the assessment influence perceptions of trust and distrust, and future assessments (through the modification or reenforcement of prior experiences, knowledge of the context, and beliefs). Thus, trust and distrust shape one's own behavior and others' behavior, whose assessment in turn shapes trust and distrust.

Two Types of Trust and Distrust: Cognitive and Affective

Two types of trust—cognitive and affective—have been identified as important in organizations (McAllister, 1995; Rocco et al., 2001). Cognitive trust focuses on judgments of competence and reliability. Can a co-worker complete a task? Will the results be of sufficient quality? Will the task be completed on time? These are issues that comprise cognitive trust and distrust. The more strongly one believes the answers to these types of questions are affirmative, the stronger is one's cognitive trust. The more strongly one believes the answers to these types of questions are negative, the stronger is one's cognitive distrust.

Affective trust focuses on interpersonal bonds among individuals and institutions, including perceptions of colleagues' motivations, intentions, ethics, and citizenship. Affective trust typically emerges from repeated interactions among individuals, and experiences of reciprocated interpersonal care and concern (Rosseau et al., 1998). It is also referred to as emotional trust (Rocco et al., 2001) and relational trust (Rosseau et al., 1998). It can be "the grease that turns the wheel" (Sonnenwald, 1996).

Interaction among Cognitive and Affective Trust and Distrust

Cognitive trust and distrust may exist in conjunction with affective trust and distrust (Table 1). High cognitive and affective trust typically yields tightly coupled collaboration in which tasks and ideas are openly and frequently shared. Scientists talk of friendship and of liking each other when affective and cognitive trust is high. Risk and vulnerability caused by collaboration is perceived as low.

In comparison, high affective distrust and high cognitive distrust can be sufficient to dissuade individuals from collaborating at all. No friendship exists or develops, and individuals may proactively limit their interaction with others they cognitively and affectively distrust. Collaboration and interaction is perceived as high risk with a high degree of vulnerability.

EVERYDAY MANAGEMENT OF TRUST AND DISTRUST

A trust-distrust match between cognitive and affective trust can yield problematic situations that require explicit management. Feelings of high cognitive distrust and high affective trust will serve to limit collaboration. Primarily, non-critical or unimportant tasks will be given to individuals that are cognitively distrusted. However, friendship as a result of affective trust may exist or emerge. Controls to monitor task completion and support task completion efforts may be used. For example, mentoring and training may be employed to help a friend who is not cognitively trusted.

Feelings of high cognitive trust and high affective distrust can result in competitive collaboration, which can be managed through discussions that identify issues and perceptions. Specific data should be presented and goodwill expressed to counter perceptions. Solutions include changes in work plans and information, and equipment sharing. Controls to monitor and constrain task or work activities can be employed to manage affective distrust. The saying, "Keep friends close and enemies closer" appears applicable in these types of situations. Professional relationships may exist or emerge, but friendship and the perception that the collaboration or interaction is fun may never emerge. Affective distrust can be reduced or accommodated, but may not disappear for some time.

THE ROLE OF INFRASTRUCTURE IN MANAGING TRUST

Organizational Structure

Cognitive and affective trust throughout an organization or team are implicitly encouraged when management exhibits high levels of cognitive and affective trust towards each other and members of the organization. The example provided by leadership sets expectations for others.

To encourage trust and to help resolve issues regarding trust, a management team that includes a site coor-

Figure 1. The evolutionary nature of trust and distrust

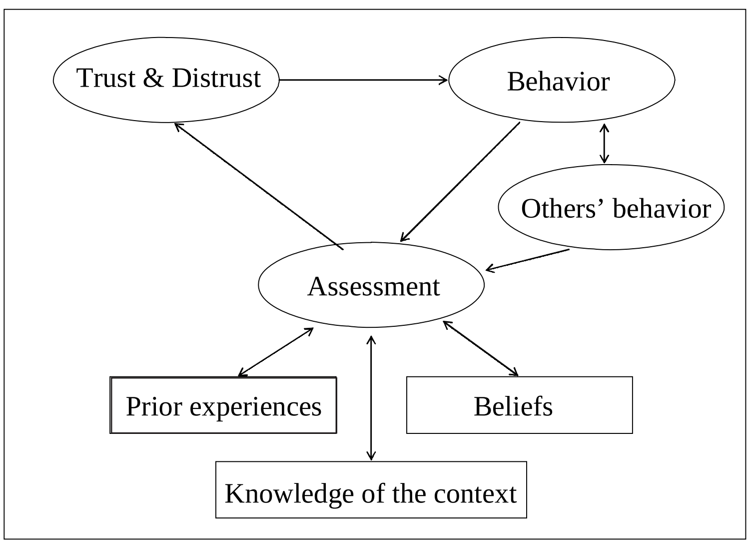

Table 1. Relationships among cognitive and interpersonal trust and distrust

		Cognitive: Trust	Cognitive: Distrust
Affective	Trust	Tightly-coupled collaboration Frequent collaboration Friendship Low risk	Limited collaboration Limited, non-critical task responsibility Controls to monitor & support efforts Friendship
Affective	Distrust	Competitive collaboration Controls to monitor & constrain activities "Keep friends close & enemies closer" Professional relationship	No collaboration No friendship Limited interaction High risk

dinator for each participating location, as well as coordinators for specific activities, can be established. Site coordinators can handle location-specific administrative issues, ranging from reserving a videoconference room for weekly meetings to distributing allocated budget funds. The participation of representatives from each physical location provides ongoing dialog about challenges, progress, perceptions, and ways of working at each location, which are important for building and maintaining cognitive trust. It facilitates learning about different ways of working and collaborative problem solving when members from different locations suggest how practices at their location may solve problems at other locations.

Similarly, coordinators for specific types of activities, domains, or areas of specialization help to manage cognitive trust among these diverse domains. For example, such coordinators can provide feedback to other team members and coordinators regarding the validity and reliability of the research or work methods proposed by members in the same domain, helping to establish cognitive trust.

Power

Boulding (1990) describes three types of organizational power: destructive, economic, and integrative. Destructive power—the power to destroy things—can be used as a prelude to production, where things are destroyed or altered to make way for production and for carrying out a threat. An example of destructive organizational power is the firing of employees who are seen as resisting change in an organization. Economic power is used in all organizations. It involves the creation and acquisition of economic goods, including intellectual property, through production, exchange, taxation, or theft. Integrative power involves the capacity to build organizations, inspire loyalty, bind people together, and develop legitimacy. It has a productive and destructive aspect. In a negative sense, it can create enemies and alienate people. All organizations have some integrative power or they could not survive. Some, however, rely on integrative power more than others; these include religious organizations, political movements, volunteer organizations, and clubs.

Successful organizations and teams that must rely on collaboration among distributed members appear to use a combination of integrative, economic, and destructive power; however, a primary type of power used in successful teams and organizations appears to be integrative. For example, organizations and teams can use integrative power to develop their vision, mission, and goals. Integrative power is also a mechanism to increase cognitive trust. For example, Hart and Saunders (1997) discuss the use of integrative or persuasive power in building trust across organizations in the context of electronic data interchange adoption. Tucker and Panteli (2003) found the use of integrative power positively related to trust in a study of 18 virtual teams within a global, high-tech company.

In any organization, destructive or economic power is used when members do not meet expectations or keep commitments (i.e., when cognitive distrust emerges). Such decisions, however, may be best reached through the use of integrative power and are based on cognitive trust among team members.

Information and Communications Technology

When a team or organization is geographically distributed, it must utilize information and communications technology (I&CT) as a mechanism to realize its vision and mission, or to incur expensive monetary and temporal travel costs. Typically, this has meant using traditional information and communications technology, such as the telephone, fax, file transfer, mail, and e-mail in ways typical of other R&D organizations and scientific disciplines (Daft & Lengel, 1984). It has also meant using newer technologies, such as video conferencing and Web pages, in innovative ways to support the organization's vision, facilitate collaboration, and manage cognitive and affective trust and distrust. Tucker and Panteli (2003) found that distributed teams with a high degree of trust among team members regularly communicated using synchronous IC&T, such as telephony and video conferencing.

New social protocols to compensate for constraints imposed by video-conferencing technology, and operations protocols to help reduce technical problems are needed and can be developed and implemented by working with team members and technical staff (Sonnenwald et al., 2002). For example, one drawback to the video-conference meetings is their inherently formal nature, if they are held in a specially equipped meeting room or if they require members to prepare for the meeting in new ways, such as creating PowerPoint™ slides, instead of writing on a whiteboard. This formality can negatively impact affective trust.

Several things can reduce the formality and increase the interactive nature of these meetings. Managers and key members can introduce informal aspects into their presentations (e.g., use the drawing features of the electronic board to modify their slides in real time). In addition, new practices of having non-work communication before a presentation can be initiated. Interpersonal communication has also been shown to increase affective trust among distributed team members (Rocco et al., 2000) and facilitate collaboration (Sonnenwald, 1996), a byproduct of cognitive trust.

Asynchronous technology may also facilitate trust building through documenting and sharing general information. For example, a Web site can be created to share news, expectations, and resources among team or organization members and to communicate information about the team to stakeholders. The content of the Web site should evolve to meet the needs of the team. Examples of information that could be included in a Web site include the group's vision statement, contact information, annual reports, call for proposals, virtual tours of lab facilities, meeting schedules, member directory, personal member Web pages, a news bulletin with press releases and announcements of awards and other recognitions received by members, and forms to be used by members (e.g., a confidentiality agreement). This type of content can help form a shared identity and affective trust across distances (Rocco et al, 2000).

The Web site could also contains pointers to resources that provide work, career, and personal assistance to members, such as information about suppliers, conferences, job interview processes, and apartment hunting services. This type of information supports a general anonymous mentoring function, allowing members to anonymously find information to assist in their careers and personal life. Thus, these pages have the possibility of positively influencing feelings of cognitive and affective trust toward the team or organization.

FUTURE TRENDS

Additional research is needed to increase our understanding of trust across distances. Issues to investigate include the sustainability of trust over time across distances, and the long-term consequences of distrust. Emerging IC&T should also be evaluated with respect to its roles, both positive and negative, on the development of trust. IC&T that provides a higher degree of situation awareness (Sonnenwald et al., 2004) may help facilitate the development of trust across distances.

CONCLUSION

Trust management is important in any organization, but it is especially important in organizations and teams that are geographically distributed and dependent on collaboration among members in different locations. For example, when organizations need to address large, complex, and challenging problems in which collaboration among experts (irrespective of discipline, department or institution affiliation) is required, cognitive trust and affective trust are both necessary to create a shared working understanding and new knowledge.

Typical trust mechanisms (i.e., informal face-to-face interactions and observations) to build and maintain trust are not inherently present in these organizations. Infrastructure that explicitly supports the creation and maintenance of trust appears vital. Participation in management by representatives at each physical location, early and continuing dialog between organization members and management, and use of integrative power, are three infrastructure mechanisms to manage cognitive trust.

Information and communications technology is a necessity in any geographically distributed organization today, and yet it can limit the creation and maintenance of cognitive and affective trust. However, interactive video-conferencing and Web sites that share organizational information and news, in conjunction with changes in practices, may help overcome the inherent limitations of I&CT to manage trust. Future I&CTs that incorporate advanced features (e.g., opportunistic floor control that allows synchronous execution of commands) and provide higher quality and control of video- and audio-conferencing, as well as better integration with other commonly used applications, hold the promise of facilitating collaboration to a greater extent than today's technology (Sonnenwald et al., 2004). However, it should be noted that face-to-face interaction is currently recommended to augment interaction mediated by technology (Handy, 1995; Olson & Olson, 2001; Rocco, et al., 2000), and a lack of face-to-face interaction may limit the growth of affective trust.

Tightly coupled collaboration appears to only emerge in situations where highly cognitive and affective trust simultaneously exists. No collaboration will emerge in situations where highly cognitive and affective distrust exists. Limited collaboration emerges when affective trust and cognitive distrust exist concurrently. Non-critical work tasks may be given to individuals in these situations, and controls to monitor and support task completion may be utilized. In comparison, competitive collaboration emerges when cognitive trust and affective distrust exist concurrently. Controls to constrain work activities may emerge to manage affective distrust. Limited and competitive collaboration may be manageable, but neither situation is ideal.

KEY TERMS

Trust: A "psychological state comprising the intention to accept vulnerability based upon positive expectations of the intentions or behavior of another" (Rosseau et al., 1998, p. 395).

Distrust: Negative expectations of the intentions or behavior of another (Lewicki et al., 1998; Sztompka, 1999).

Cognitive trust: Judgments regarding a person's competence and reliability.

Affective trust: Interpersonal bonds among individuals and institutions, including perceptions of a person's motivation, intentions, ethics, and citizenship.

Collaboration: Human behavior that facilitates the sharing of meaning and completion of tasks with respect to a mutually shared goal; takes place in social or work settings.

Integrative power: The capacity to build organizations, to inspire loyalty, to bind people together, and to develop legitimacy (Boulding, 1990).

Destructive power: The power to destroy things. It can be used as a prelude to production in which things are destroyed or altered to make way for production, and for carrying out a threat (Boulding, 1990).

Economic power: The creation and acquisition of economic goods (including intellectual property) through production, exchange, taxation, or theft (Boulding, 1990).

Managing Hierarchies and Taxonomies in Relational Databases

Ido Millet
Penn State Erie, USA

INTRODUCTION

The need to maintain classification and retrieval mechanisms that rely on concept hierarchies is as old as language itself. Familiar examples include the Dewey decimal classification system used in libraries and the system for classifying life forms developed in the 1700s by Carolus Linnaeus. A more recent example is Yahoo's subject taxonomy.

Information technology has led to an explosive growth in digital documents, records, multi-media files, and Web sites. To facilitate end-user access to these resources, topic hierarchies are frequently maintained to allow intuitive navigation and searching for resources related to specific categories. Maintaining such document, Web site, and knowledge taxonomies within relational databases is not trivial since the management of any hierarchical data in relational databases poses significant challenges (Millet, 2001). Taxonomies pose an additional challenge due to the typical need to classify a single document, concept, or Web site under multiple topics and due to the typical reliance on intelligent keys (Millet, 2003).

While, according to some views, non-relational database technologies and dynamic classification schemes may offer better ways for achieving our objectives, the use of relational database technology and concept taxonomies remains a contemporary practice and challenge.

BACKGROUND

Consider a document database where each document is classified into a hierarchy of topics shown in Figure 1.

Since each document may belong to more than one parent topic, we cannot record the data for this hierarchy by specifying in each topic record the topic above it. Figure 2 shows a data model for this situation. Note that the classify table allows us to assign a single document to multiple topics. If instead of a topic hierarchy, we need to assign each subtopic to more than one parent topic, we would insert a topic assignment table to represent such taxonomies.

To demonstrate the difficulty of hierarchical data retrieval against the normalized data model in Figure 2, consider the following requests:

- Show a list of all documents (at all levels) under Topic 1.
- Show how many documents (at all levels) are classified under each topic at level 1 of the hierarchy.

Using SQL, we can easily join each topic to all the documents associated with it via the classify records. However, we cannot easily identify the documents indirectly associated with a topic via its subtopics (at all levels). This difficulty in locating parent or child nodes at any given level is at the heart of the problem.

SQL-BASED SOLUTIONS

A request to show how many documents belong to each main topic, including all subtopics below it, can be handled using the SQL:1999 (ANSI/ISO/IEC 9075-2-1999) query shown in Listing 1. This query starts by creating a table expression (TOPIC_PATHS) populated with all main topic records as parents of themselves and appends (UNION) records for all paths of length one from these nodes to the topics directly below them. The RECURSIVE option continues the process to build all indirect paths from each topic to all its descendants.

The query then joins the end points (Topic_Below) of all paths in the TOPIC_PATHS result set to the documents assigned to these topics. By limiting the start points of these paths to main topics (topics at level 1) and

Figure 1. A topic hierarchy

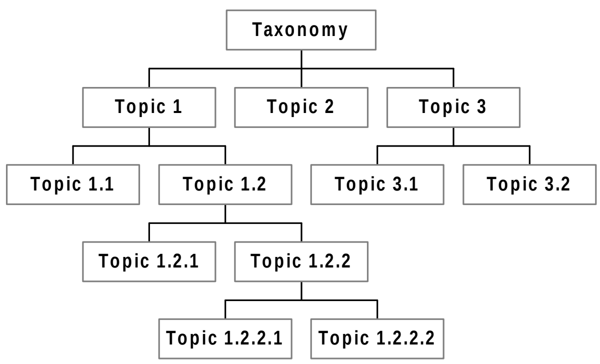

Figure 2. A normalized data model with a topic hierarchy

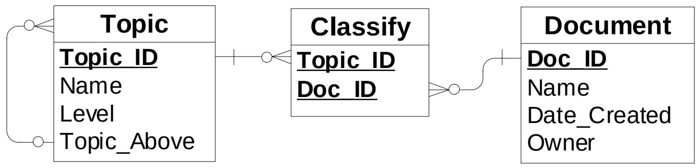

Listing 1. Recursive hierarchy retrieval using SQL:1999

```
WITH RECURSIVE TOPIC_PATHS (topic_above, topic_below, level) AS
(SELECT topic_id, topic_id, level FROM TOPIC
UNION ALL
SELECT TOPIC_PATHS.topic_above, TOPIC.topic_id, TOPIC_PATHS.level
FROM TOPIC_PATHS, TOPIC
WHERE TOPIC_PATHS.topic_below = TOPIC.topic_above)

SELECT TOPIC_PATHS.topic_above, DistinctCount (CLASSIFY.Doc_ID)
FROM TOPIC_PATHS, CLASSIFY
WHERE TOPIC_PATHS.topic_below = CLASSIFY.Topic_ID AND
TOPIC_PATHS.level = 1
GROUP BY TOPIC_PATHS.topic_above;
```

grouping the end result by those topics, we get the requested information. Avoiding double-counting of documents that were assigned to multiple topics is achieved by using *DistinctCount*(Classify.Doc_ID) rather than *Count*(Classify.Doc_ID).

Relying on such complex SQL is probably beyond the reach of many IT professionals. This can be addressed by implementing the complex portion of these SQL statements as database views. However, someone has to write the SQL for these views and the intensive nature of the required processing may lead to slow performance in reporting applications with large hierarchies and frequent queries.

Celko (2000) reports on a technique leading to significant improvements in query speeds by storing the hierarchy data not as parent-child relationships but as "nested sets" using a somewhat complex numbering scheme. However, alternative approaches can achieve very significant query performance gains while maintaining intuitive data storage and SQL syntax.

THE PATH TABLE APPROACH

The path table approach uses a "navigation bridge table" (Kimball et al., 1998) with records enumerating all paths starting from each node to all nodes in the branch above it, including itself. This approach provides flexibility in the sense that each subtopic node can belong to multiple direct parent topics and there is no limit on the number of levels in the taxonomy.

As demonstrated by Table 1, topic 1.1.1 would require four records in the path table reflecting the paths up to itself, topic 1.1, topic 1, and topic 0 (the top node of the hierarchy). These are just 4 of the 37 records required to capture all paths for the sample hierarchy in Figure 1.

To demonstrate how the path table can simplify data retrieval, consider the same challenge of showing how many documents belong to each main topic, including all subtopics below it. By joining the tables as shown in Figure 3, we can easily select all documents that belong to topics below each main topic. Since the path table includes a zero-length path between each topic and itself, documents that belong directly to a main topic would be included in the result set. Again, the classify table allows us to associate the same document with multiple topics.

Other requests for information can use the same approach or variations such as connecting to the topic table via the Topic_ID column in the path table or adding path length and terminal node information to the path table (Kimbal et al., 1998).

One limitation of the path table approach is that the number of records in the path table can grow quite large for deep hierarchies. The following section describes another approach that avoids that problem.

THE DENORMALIZED TOPIC TABLE APPROACH

The denormalized topic table approach maintains information about all higher-level topics within each topic

Table 1. A path table for the sample hierarchy

Topic_ID	Topic_Above
1.1.1	1.1.1
1.1.1	1.1
1.1.1	1
1.1.1	0

record. The classify table still allows each document to be assigned to multiple topics, but this approach restricts the topic taxonomy to a strict hierarchy whereby each sub-topic can have only one direct parent topic.

As demonstrated by Figure 4, if we assume that our topic hierarchy will not exceed six levels, we need six more columns to maintain this information. Each node will be indicated as its own parent at its own level. For example, topic 1.1.1 in Figure 1 would have 0 (the topic_id for the top node in the hierarchy) as its Topic_Level_1, 1 as its Topic_Level_2, 1.1 as its Topic_Level_2, 1.1.1 (itself) as its Topic_Level_4, and Null values for Topic_Level_5 and Topic_Level_6.

To demonstrate how the denormalized topic table can simplify data retrieval, consider again the challenge of showing how many documents belong to each main topic, including all subtopics below it. By joining the tables as shown in Figure 4, we can easily select and group all topics according to Topic_Level_2. Documents classified directly under that topic would be included in the result set because each topic is its own parent at its own level. Listing 2 shows that using this approach, a simple SQL statement can generate the requested information.

Note that in order to return the topic name we resorted to adding an aliased (Topic2) copy of the topic table to the SQL statement.

The denormalized topic table is less flexible since it limits the topic taxonomy to a strict hierarchy. However, the path table approach requires more complex joins due to the addition of one more physical table. Another disadvantage of the path table approach is that for deep hierarchies, the size of the path table can grow quite large, degrading query performance. A key issue with both approaches is the question of maintaining the redundant data required by these methods.

MAINTENANCE OF DENORMALIZED HIERARCHY DATA

This section suggests methods that can simplify and automate the maintenance of redundant hierarchy data. The proposed approach provides a concrete example of an "incremental evaluation system" for handling recursive SQL queries as advanced by previous literature (Dong et al., 1999; Libkin & Wong, 1997).

Because the denormalized topic table allows for simpler maintenance logic, the remainder of this article uses that approach as the assumed data structure.

A key observation is that the redundant information maintained for each topic is a simple extension of the redundant information already maintained for its parent topic. Consider a situation where Topic 1.2.2.2 in Figure 5 is moved from under Topic 1.2.2 to under Topic 3.2. The

Figure 3. A path table connects each classification with all its parents.

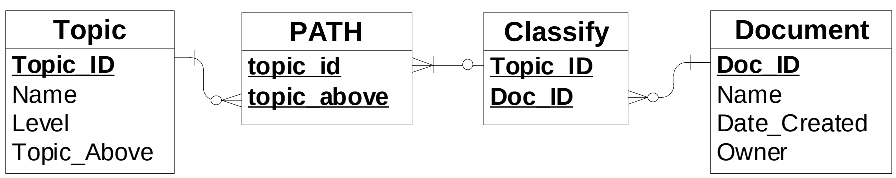

Figure 4. Using a denormalized topic table

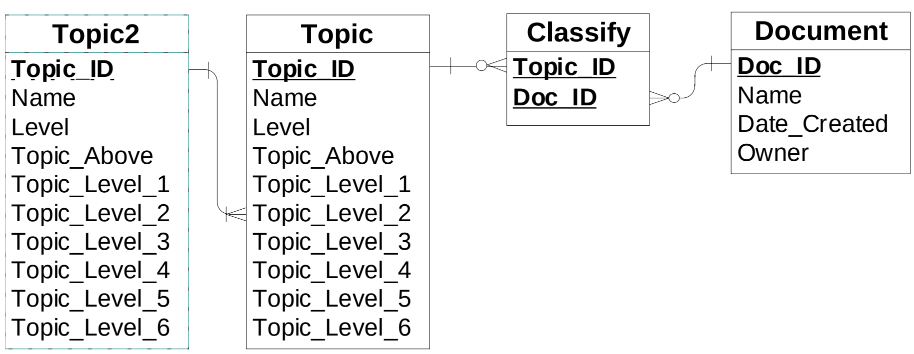


Listing 2. Retrieval via a denormalized topic table

```
SELECT TOPIC2.Name, DistinctCount(CLASSIFY.Doc_ID)
FROM (TOPIC2 INNER JOIN TOPIC ON TOPIC2.topic_id = TOPIC.Topic_Level_2)
INNER JOIN CLASSIFY ON PATH.Topic_Level_2 = CLASSIFY.topic_id
GROUP BY topic.Topic_Level_2;
```

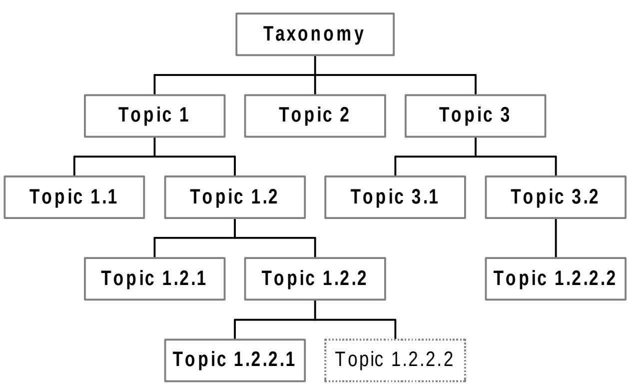
Topic_Level_N columns from the new parent node can simply be copied to the updated topic record (Topic 1.2.2.2). We then simply add the topic as its own parent at its own level and update the level column to the level of the parent node plus one.

Topic taxonomies (such as the Dewey decimal classification system used in libraries) frequently use "intelligent" primary keys reflecting the position of each topic within the taxonomy. In our example, we would neeed to change the primary key from 1.2.2.2 to 3.2.1. Using referential integrity, the database management system can automatically cascade such primary key updates to the foreign keys in documents as well as in Parent_Level_N columns.

The remaining challenge is to handle situations where a whole branch (a topic with subtopics) is moved in the hierarchy. Consider, for example, moving topic 1.2.2 in Figure 5 from under Topic 1.2 to under Topic 1.1. The procedural logic would update the redundant data for Topic 1.2.2, but we now need to update the information for all its decendants. The most elegant solution is to recursively extend the procedural logic by applying it to all descendant nodes, as if their Topic_Above column was updated as well.

Using this update logic, users would update the structure of the hierarchy by specifying only the Topic_Above information for each node. The maintenance of the redundant data can be done either under the control of the application or through database triggers.

Figure 5. Moving Topic 10 from Parent 6 to Parent 4



FRONT-END LOGIC OR DATABASE TRIGGERS

Each time a user changes the Topic_Above column, the application can call a function with the Topic_ID and its new Topic_Above as arguments. After completing the logic for that topic, the function would use embedded SQL to identify the descendants of the topic and call itself recursively against all these descendants.

One limitation of using such front-end logic to maintain the redundant hierarchy data is that it would require multiple communications between the client and the server. A much more important limitation is that we are dependent on uniform and full compliance by all client applications. The integrity of the hierarchy data can be compromised if some screens neglect to call or implement the update function appropriately.

As described in detail by Millet (2003), the update logic can be implemented via recursive Update and Insert triggers declared on the Topic_Above column of the TOPIC table. Moving the procedural logic from front-end functions to back-end triggers removes the threat of multiple points of failure and achieves better performance.

FUTURE TRENDS

The current trend in addressing the challenges of maintaining hierarchical data in relational databases is to provide more complex but more powerful data retrieval syntax. The SQL standard has added recursive queries. Similarly, proprietary SQL extensions such as the START WITH and CONNECT BY clauses provided by the Oracle DBMS are also useful mechanisms for retrieving hierarchy data from normalized data structures.

Clearly, the trend so far has been in the direction of maintaining the simplicity of the data structure at the expense of more complex queries. In the long term, I hope DBMS vendors realize the value of also supporting the opposite approach whereby queries are simplified at the expense of complicating the data structure. Declarative statements are all that is needed today to ask a DBMS to apply referential integrity logic to the data. In a similar way, we can envision a future where declarative statements identify to the DBMS the link between parent and child nodes and the Parent_Level_N columns that should be maintained by the DBMS.

CONCLUSION

Topic hierarchies are used to classify and search for documents, Web sites, and knowledge areas. Beyond the data retrieval and data maintenance challenges posed by any hierarchy domain, the need to support classifying the same document under multiple topic nodes leads to different table designs and requires care in avoiding biased aggregate results due to double counting. Since topic taxonomies frequently utilize intelligent rather than surrogate primary keys, updates to the location of topic nodes may require updates to the primary keys as well.

Fast and simple data retrieval against topic hierarchies can be achieved by maintaining redundant information. The approach of denormalizing the topic table may be preferred over maintaining a separate path table because the path table can grow too large and requires more complex data maintenance logic.

The limitation of denormalized and redundant hierarchy information is that updates to the hierarchy require special processing logic in order to avoid update anomalies. To efficiently refresh the hierarchy data we can exploit the redundant information already maintained for the specified parent topic as topic records are inserted or updated. The process can then be extended recursively for lower level nodes.

If the necessary trigger options are available for the DBMS in use, it is recommended that the processing logic for maintaining the redundant hierarchy information be implemented as triggers. This removes the burden of hierarchy maintenance from client applications. It also ensures that client applications cannot circumvent the hierarchy maintenance logic.

KEY TERMS

Database Trigger: A procedure that gets invoked by the database management system whenever a specific column gets updated or whenever a row gets deleted or inserted.

Denormalized Data Tables: A database design that violates principles of good (normalized) data models. Such database designs may lead to various problems such as data redundancy, reduced flexibility, and update anomalies.

Intelligent Key: An intelligent key contains data that has a meaning beyond the unique identification of a database record. For example, a vehicle identification number (VIN) contains information about the manufacturer, model, and other attributes of the vehicle.

Recursive: A recursive procedure is one that has the ability to call itself.

Relational Database: A method of storing data in tables and columns and operating on that data through a set-oriented query language (SQL) and specialized software the takes care of the procedural and physical aspects of data storage and manipulations. Invented by E.F. Codd at IBM in 1970.

SQL (Structured Query Language): A widely accepted standard for retrieving information from and updating relational databases.

Taxonomy: A classification system used for analysis or information retrieval.

UNION Query: By inserting the key word UNION between multiple SQL SELECT statements, the resulting rows from these statements are appended into a single result set (provided the number and data types of the columns match).

Managing Strategic IT Investment Decisions

Tzu-Chuan Chou
Warwick Business School, UK

Robert G. Dyson
Warwick Business School, UK

Philip L. Powell
University of Bath, UK

INTRODUCTION

IT can have a significant impact on organizational performance, but it can also be a major inhibitor of change and can be a resource-hungry investment that often disappoints. Organizations can best influence the success of IT projects at the decision stage by rejecting poor ones and accepting beneficial ones. However, little is known about IT decision processes. Research demonstrates the importance of managing strategic IT investment decisions (SITIDs) effectively. SITIDs form part of the wider range of corporate strategic investment decisions (SIDs) that cover all aspects that the organization might wish to invest in. SIDs will then have different degrees of IT intensity that may impact on outcome. IT investment intensity is the degree to which IT is present in an investment decision. Here, IT investment intensity is defined as the ratio of IT spending to total investment. The higher IT investment intensity, the more important IT is to the whole investment. For example, Chou et al. (1997) find IT investment intensity to be negatively associated with SID effectiveness. The concept of IT intensity is similar to, but also somewhat different from, the concept of information intensity. Information intensity may be defined as the degree to which information is present in the product or service of a business (Porter & Millar, 1985).

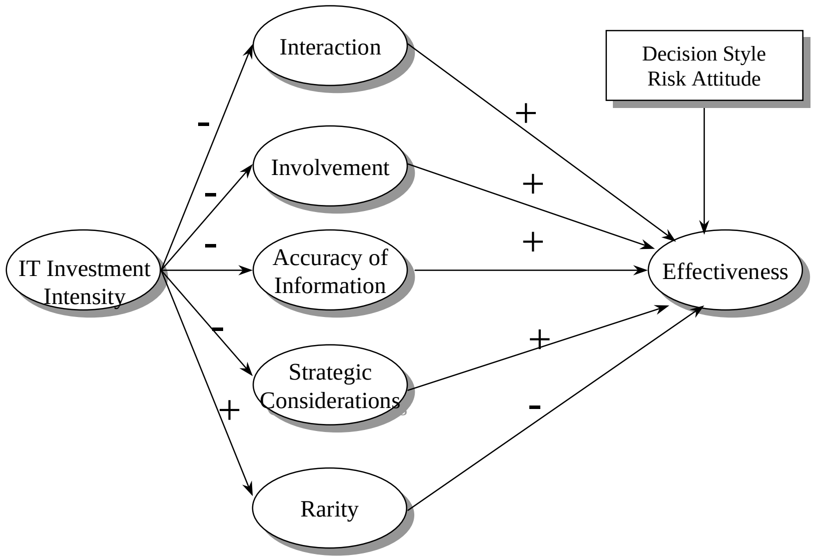
Management may use different processes in order to make different types of decisions (Dean & Sharfman, 1996). The link between decision process and outcome is so intimate that "the process is itself an outcome" (Mohr, 1982). This may imply that the link between IT investment intensity and SID effectiveness is not direct but that the impact of IT investment intensity may be through the decision process. If different IT intensity in projects leads to different decision processes, leading to different outcomes, then it is important to know what factors act in this, in evaluating and managing SITIDs. This chapter presents an integrative framework for exploring the IT investment intensity-SID effectiveness relationship.

BACKGROUND

Studying decisions involves "contextualism" (Pettigrew et al., 1988), which integrates process, content and context, as all decisions need to be studied in context. Content refers to the decision itself, exploring the nature and scope of SIDs. Process refers to actions, reactions and interactions as managers allocate resources for the decision. The context includes the outer context of economic, political and social actions, while the inner context involves on-going strategy, structure, culture, management and political processes.

In the IT investment intensity-SID effectiveness link, the roles of process, content and context are unclear. While unclear, it is likely that the links between variables are not direct; rather they are mediated or moderated by other variables or processes. Moderators and mediators are functions of third variables. A moderator "partitions a focal independent variable into subgroups that establish its domains of maximal effectiveness in regard to given dependent variables," while a mediator function "represents the generative mechanism through which the focal independent variable is able to influence the dependent variable of interest" (Baron & Kenny, 1986). Sambamurthy et al. (2003) employ the moderator concept in their work on reshaping agility through digital options. They, for example, see IT competence as an antecedent of firms' competitive actions but the relationship is mediated by dynamic capabilities. Sambamurthy et al. demonstrate theoretically that IT investments and capabilities influence firm performance through organizational capabilities – agility, digital options and entrepreneurial alertness, and through strategic processes involving capability building, entrepreneurial action and co-evolutionary adaptation. This, they claim, is valid at the enterprise level, for business units and for processes. They finally call for empirical research that might validate their theoretical developments. This chapter takes a slightly different route, as it focuses on IT at the project or at the decision

Figure 1. The theoretical model (adapted from Chou et al., 1997)



level and it is based on data that back up the model development.

Here, the proposal is that the impact of IT investment intensity on SID effectiveness is through decision processes. Accordingly, decision process constructs should have a mediating effect. Greater IT intensity in projects leads, inter alia, to a more technically orientated project, which impacts on SID effectiveness. The decision content has a mediating effect on the IT involvement-SID effectiveness link. The investment context impacts the outcome. Therefore, context constructs should act as covariances that impact SID effectiveness. Decision context, content and process will involve many individual constructs, some unrelated to IT investment intensity. Two criteria can be employed in order to select the constructs of interest here. First, the decision construct is expected to vary with IT investment intensity. Second, it must impact at the decision level. Figure 1 outlines the basic model.

A hypothesized negative impact of IT investment intensity on several constructs suggests projects with high IT investment intensity are more challenging than those with low IT content. Effectiveness compares actual performance against planned target, outcomes and policy objectives, measured by project success, correct choice, unexpected negative outcomes, learning, and satisfactory process (Butler et al., 1993).

Decision Context

The context of any investment is affected by the firm's financial health, its market position, industry pressures, culture, and business strategy. SIDs often involves major change to the organization and environment. This suits managers with an innovative risk attitude. From a style perspective, decision quality is dependent on resources the leader is able to utilize. Consensus-driven management seems able to acquire more information than directive management, and leads to more effective decisions. Management's *attitude to risk* and *decision style* are predicted to relate to SID effectiveness, since other factors impact at an organizational level.

Decision Process

Strategic decision processes involve comprehensiveness, rational activity, participation, duration and conflicts (Rajagopalan et al., 1993). Comprehensiveness measures rationality and is the extent to which the organization attempts to be exhaustive in making and integrating strategic decisions. This includes formal meetings, assignment of primary responsibility, information-seeking and analytical activities, the systematic use of external sources, stakeholder involvement, use of consultants, reviews of historical data, functional expertise (Papadakis, 1995), and informal interaction. Hickson et al. (1986) define "politicality" as the degree to which influence is exerted on the outcome through a decision process. Strategic decision-making is not a matter of explicating alternatives and choosing on the basis of readily available criteria all participants perceive as appropriate (Fahey, 1981). It might be expected that interaction and involvement are related to IT investment intensity.

Interactions are contacts between people. Higher IT intensity reduces interaction and SID effectiveness. Decision-makers' IT knowledge, experience, and educational are associated with alienated attitudes towards IT. Higher IT investment intensity leads to more technically oriented projects. Without IT knowledge, managers cannot discuss the project knowledgeably. It, therefore, reduces interaction and impacts upon decision quality. This article suggests that higher IT intensity reduces *involvement*, reducing SID effectiveness. Less involvement leads to less collective information and reduced decision effectiveness. This suggests that *IT investment intensity reduces interaction and adversely impacts decision effectiveness* and that *IT investment intensity reduces involvement and adversely impacts decision effectiveness.*

The evaluation process is important for investment decisions. An IT investment decision is problematic because the cost and benefits are hard to identify and quantify. Therefore, uncertainty of information used in evaluating IT investment is greater. The higher the information uncertainty, the lower the *information accuracy*. This article expects that lower accuracy of information reduces decision effectiveness; that is, *IT investment intensity reduces information accuracy and adversely impacts decision effectiveness.*

It can be argued that the IT evaluation problem is one of alignment. This article expects that management may fail to link IT's strategic purpose with organizational strategy, reducing decision effectiveness. This suggests that *IT investment intensity reduces strategic considerations and adversely impacts decision effectiveness.*

Decision Content

A strategic decision is characterized by its novelty and complexity. Complexity relates to the number and variety of factors in the environment that impinge on decision-making behavior. SIDs evolve from the organizational context and have their own characteristics. Constructs that contribute to decision complexity include rarity and importance. Uncertainty is due to *rarity*. Rarity assesses the novelty of the decision to the firm. If a firm repeatedly makes similar decisions then it will gain experience; conversely, a rare decision is likely to be more problematic. Importance is common to all SIDs irrespective of IT investment intensity, as they are all strategic. New technologies often require investments of a different nature because of high uncertainty, widespread organizational impact, and greater strategic importance. Even compared with other new technologies, the IT life cycle is short, so that the IT component of projects is constantly changing, increasing rarity. Rarity inhibits effective feedback and learning. This article expects that the higher IT investment intensity, the higher decision rarity, reducing decision effectiveness; *IT investment intensity heightens decision rarity and adversely impacts decision effectiveness.*

In order to investigate these proposals, empirical work investigated a single strategic investment project in each of 80 Taiwanese manufacturers. IT investment intensity is measured by the ratio of IT spending to total investment in the project, while the measure of decision effectiveness is subjective. In order to capture the whole process from decision to outcome, only projects that were complete were researched. Thus each project had a decision process and an outcome to allow assessment of success.

DISCUSSION

A principal components factor analysis highlights five important factors in these decisions - information accuracy, strategic consideration, interaction, involvement, and rarity. However, only three proposed mediators, interaction, information accuracy and strategic consideration are significant in predicting mediators.

The model as a whole is significant in predicting SID effectiveness. When contextual variables are added, IT investment intensity is still significant in predicting SID effectiveness. Interaction, information accuracy and strategic consideration have a negative correlation with IT investment intensity, but a positive correlation with SID effectiveness. Hence, the impact of IT investment intensity is transmitted to interaction, information accuracy, and strategic considerations and, through that, adversely impacts decision effectiveness. This suggests that *IT investment intensity does reduce interaction and adversely impacts decision effectiveness.* It is also the case that IT investment intensity reduces information accuracy and adversely impacts decision effectiveness, and that IT investment intensity reduces strategic considerations and adversely impacts decision effectiveness. However, IT investment intensity is not found to reduce involvement and adversely impact decision effectiveness, nor does IT investment intensity heighten decision rarity and adversely impact decision effectiveness.

Three process-related constructs, interaction, strategic considerations, and information accuracy act as mediating factors in linking IT investment intensity and SID effectiveness, as they reduce the effects of IT investment intensity. Content-related constructs do not act as mediators. Although decision rarity is negatively associated with SID effectiveness, it is unrelated to IT intensity.

Interaction in the formulating process has a mediating effect on the linkage. Interaction is important in developing group behavior. IT investment intensity lowers interaction, reducing SID effectiveness.

Strategic considerations act as a mediating variable. The higher IT intensity, the lower the strategic considerations, leading to reduced SID effectiveness. This demonstrates that the IT evaluation problem is really one of alignment.

Information accuracy acts as a mediating variable. The higher IT investment intensity, the lower information accuracy, reducing SID effectiveness. This supports Freeman and Hobbs (1991), who find managers ignoring reject signals given by capital budgeting techniques, and identify senior management's preference for qualitative information and IT investment as an "act of faith" (Powell, 1993). This suggests that high information uncertainty leads to a limited use of capital budgeting techniques.

IT investment intensity is still significant when interaction is tested as a mediator. This indirect transmission of influence from IT investment intensity to SID effectiveness via interaction shows that the effect of IT investment intensity on effectiveness is only partially mediated by interaction. The effect of IT investment intensity on SID effectiveness is completely mediated by strategic consideration and information accuracy - two evaluation-related constructs. This implies that, in seeking a better outcome of SITIDs, research that focuses on evaluation factors may be insufficient to capture the complexity of SITIDs.

FUTURE TRENDS

As demonstrated, the two evaluation-related constructs are highly correlated. From an IT investment perspective, alignment of IT and business strategy is problematic if there is a lack of accurate information for evaluation. However, evaluation of IT investments is problematic if there is a lack of alignment of IT and business strategy. To improve the effectiveness of IT investment, management needs to increase alignment of IT and business strategy and information accuracy for evaluation techniques simultaneously. This points to the issues to which management needs to attend in the future.

CONCLUSION

Much work on SITIDs ignores the continuous nature of decisions and the relationships between SITIDS and non-IT SIDs. This article proposed a model that explores mediators in the link between IT investment intensity and SID effectiveness. Survey data show that interaction, information accuracy and strategic considerations are important factors that mediate the impact of IT investment intensity. Willcocks (1992) emphasizes that management faces a Catch-22 situation with IT investment. They know how important IT is, but they do not know how to evaluate IT projects. The implication is that managers need to pay special attention to the problematic nature of IT investment intensity in SIDs. They should focus on facilitating interaction, ensuring integration of IT strategy with corporate strategy and improving information accuracy.

KEY TERMS

Contextualism: Integrates process, content and context to study organizational decision-making.

Decision Content: Content refers to the particular decision under study. Content explores the basic nature and scope of decisions.

Decision Context: The context includes the outer context, which refers to the national economic, political and social context for an organization, and the inner context that is the on-going strategy, structure, culture, management and political process of the organization. Context helps to shape the process of decision-making.

Decision Process: Refers to the actions, reactions and interactions of the various interested parties as they seek to make a commitment to allocate corporate resources. Process incorporates both the formulation and evaluation processes.

IT Investment Intensity: A concept similar to, but also somewhat different from, the concept of information intensity. Information intensity is the degree to which information is present in the product/service of a business. The degree to which IT is present in an investment decision reflects the IT level of intensity of that decision. Here, IT investment intensity is defined as the ratio of spending on IT to total investment.

Moderators and Mediators: In the social sciences, moderators and mediators have been identified as two functions of third variables. These are sub-groups of independent variables that affect given dependent variables via a mediator function.

Strategic IT Investment Decisions: Significant, long-term decisions to invest in projects that have substantial information systems or information technology components. They form part of corporate strategic investment decisions.

Managing the Organizational Impacts of Information Systems

Neil F. Doherty
Loughborough University, UK

Malcolm King
Loughborough University, UK

INTRODUCTION

Information technology is now a ubiquitous and increasingly critical part of the fabric of the modern organization, supporting its day-to-day operations and all aspects of the decision-making process, as well as its strategic positioning. It is, therefore, not perhaps surprising that the implementation of a new technology or information system is likely to result in wide array of impacts to the organization as well as the working lives of individual employees. There is a growing consensus within the literature that many such impacts are not deterministic and cannot therefore be easily predicted prior to a system's implementation (e.g., DeSanctis & Poole, 1994). The corollary of this is that many of the consequences of an information system's implementation will be unanticipated (Robey & Boudreau, 1999). While some of these unanticipated consequences, or incidental side effects, may be of a positive nature, negative impacts are also quite common, as IT-induced organizational change often results in user resistance and, in extreme cases, possibly even system rejection (Martinsons & Chong, 1999).

While there is strong evidence that information systems projects are not totally predictable, it can be argued that many of their organizational impacts only remain unanticipated, because systems developers are reluctant to tackle the human and organizational aspects of IT. Systems development projects have typically been viewed as exercises in technical change, rather than socio-technical change; *"most investments in IT are technology-led, reflecting too technical an emphasis"* (Clegg, 2000). This is a dangerous strategy, because unforeseen and unresolved negative impacts may increase the likelihood of systems failure. Moreover, beneficial impacts, of both a planned and incidental nature, may not be fully realised without an appropriate programme of organizational change. We would argue that if systems development projects are viewed as an exercise in organizational change, in which all potential organizational impacts are proactively and systematically analysed, then many previously unanticipated impacts could be predicted (Doherty & King, 2002). While the importance of treating organizational issues is now widely acknowledged (e.g., Clegg et al., 1997; Eason, 2001), little progress has been made in the development of practical treatment approaches that have succeeded in making the transition from research laboratory to widespread commercial usage. The primary aim of this article is to present an innovative new approach for their proactive treatment. However, in advance of this, it is important to establish the importance of treating organizational issues.

BACKGROUND: THE NEED TO TREAT ORGANIZATIONAL ISSUES

The information systems' literature is very clear on two points; general levels of failure are far too high and the primary cause of this problem is the failure to adequately treat organizational issues (Clegg et al., 1997; Ewusi-Mensah & Przasnyski, 1994). In this context, the term *"organizational issue"* relates to those organizationally-oriented facets of systems development projects that need to be treated to ensure that the resultant impacts of an information system are likely to be desirable. A comprehensive checklist of important organizational issues, that was originally drawn from the literature, but then validated over a series of studies (e.g., Doherty & King, 1998, 2001, 2003), is presented in Table 1.

To treat a specific organizational issue, it is necessary to firstly evaluate the likely organizational impact associated with it, and then if necessary take steps to ensure that the resultant impact is likely to be desirable. For example, if it is found that a proposed system is likely to be poorly suited to an organization's working practices, then it will be necessary to either modify the system's technical specification, so that the mismatch is avoided, or redesign the working practices so that they are well aligned with the system. In essence, the treatment of organizational issues is the mechanism by which the project team should align

Table 1. Checklist of organizational issues to address

Issue	Description
Current business needs	The system's ability to satisfy the organization's current business needs.
Information systems strategy	The system's alignment with the current information system strategy
Prioritisation of needs	The prioritising of development effort on those aspects which address the most important business needs.
Future needs of organization	The system's ability to satisfy the organization's likely future business needs.
Process design	The system's impact on the design of key business processes.
Health & safety / ergonomic factors	The likely ergonomic and health & safety implications of the system, such as RSI and eye strain.
User motivation / needs	The system's ability to satisfy user needs and support user motivations.
User working styles and personal skills	The implications of user working styles and personal skills for the system's design and ongoing use.
Job redesign	The proposed system's impact on the design of working practices.
Timing of Implementation	The interaction of the system's implementation with other planned concurrent changes.
Organizational disruption	The temporary organizational disruption that may be caused by the implementation of the proposed system.
Organizational structure	The system's effect on the organizational structure, and the lines of authority.
Organizational culture	The proposed system's impact on the culture in the organization (*i.e., the set of important assumptions (often unstated) which members of an organization share in common).*
Organizational power	The proposed system's political implications for the distribution of power in the organization.

the capabilities afforded, and the constraints imposed, by the technical system with the requirements and characteristics of an organization and its individual employees.

System developers typically view the system development process as a science, rather than art, which requires the use of structured methods that focus upon the delivery of technically effective systems, on time and within budget. They are extremely reluctant to tackle intangible, ill-defined and politically-sensitive organizational issues (Doherty & King, 2001), for which they're ill-equipped, in terms of training, competencies and motivation (Clegg, 2000). Consequently, approaches to the treatment of organizational issues have typically been reactive rather than proactive (Clegg et al., 1996) – get the system implemented and then worry about its organizational impacts. There is, therefore, a pressing need to find ways to encourage the systems development community to become more actively engaged in the treatment of organizational issues. One obvious strategy is through the creation of methods, tools and techniques, which are specifically designed to facilitate the treatment of organizational issues. A wide variety of organizationally-oriented approaches have now been proposed, which can be categorised as follows:

1. **Socio-technical methods:** Socio-technical methods attempt to produce information systems that are technically efficient and coherent, while also being sensitive to organizational and human needs, for example, Ethics (Mumford, 1996) or Multi-view (Avison, Wood-Harper, Vidgen, & Wood, 1998).

2. **Tools and techniques for the treatment of specific issues:** Many researchers (e.g., Clegg et al., 1996) have attempted to develop tools and techniques to aid in the treatment of specific organizational issues.
3. **An organizational impacts analysis:** The *"organizational impact analysis"* (e.g., Sauer, 1993) is typically a one-off study to determine the ways in which a proposed system will affect the organization's decision-making, power, structure, culture, working practices, and so forth.

While each of the above contributions has been very useful in increasing our understanding of the nature and treatment of organizational issues, there is little evidence that these contributions have made much of an impact on the practice of systems development (Clegg, 2000). This is probably, at least in part, due to technical specialists' continuing preference for the more technically oriented tools and techniques. However, if a comprehensive, coherent and easy-to-use approach could be found, that complemented their existing methods, then it might have a greater chance of adoption. The remainder of this section describes one such approach, that can best be described as an example of organizational impact analysis.

APPROACH FOR THE TREATMENT OF ORGANIZATIONAL ISSUES

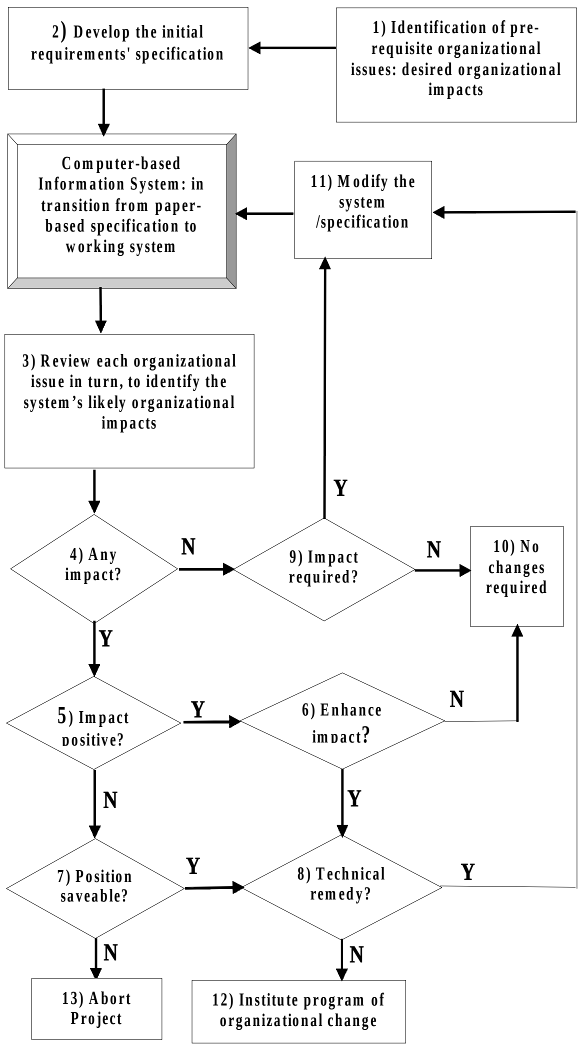
The proposed approach has been formulated from an extensive review of the literature, and the authors' experience working in this domain for the past few years (e.g., Doherty & King, 1998, 2001, 2004). A schematic representation of the approach, which has been conceptualised as a flow diagram, is presented in Figure 1. Each of the major processes and decision points on this diagram, all of which have been numbered, is reviewed in the following:

1. **Identification of planned organizational impacts:** While many organizational issues will not be treated until a systems development project is well under way, others, such as the system's ability system to satisfy *"current organizational needs"*, will need to be considered right at the very outset, if they are to be the planned outputs of the project.
2. **Development of initial requirements specification:** The development of the initial requirement's specification is a fundamental component of all development methods, and can be conducted using the proprietary or in-house method of the developers choosing.

While the previous two stages occur only once, at the project's outset, it is envisaged that the following stages will be repeated at key stages in the systems development process, for each of the organizational issues in the checklist (see Table 1), in turn.

3. **Review of organizational issues:** Assess the system's likely impacts, with regard to each organizational issue. The process is designed to ensure that the planned impacts will ultimately come to fruition, while any incidental impacts will be effectively identified and managed.
4. **Determine existence of organizational impacts:** The output of the review procedure, described previously, will be an assessment of whether there is a significant organizational impact, associated with each organizational issue.
5. **Evaluation of desirability of impacts:** The desirability of each identified impact must be assessed, to determine whether it is likely to be of a positive or negative nature. For example, an assessment of the system's impact on the motivation of users might identify a negative impact, such as user resistance or resentment, due to changes in their work practices. Potential solutions might be of a technical nature, such as changing the system's design to give the user more control over their work, or an organisational orientation, for example, improving the users' terms and conditions, by way of compensation.
6. **Assessment of potential for increasing desirability of impacts:** If the previous stage has identified a desirable impact, associated with an organizational issue, it is important to consider whether the impact could be made even more positive if the information system design were to be modified.
7. **Is the situation retrievable?:** In situations where a potentially undesirable impact of the system's operation has been identified then it is necessary to consider whether the situation is retrievable or not.
8. **Is the remedy technical?:** Having identified potentially negative, yet retrievable, impacts, associated with the system implementation, a decision must be made as to whether the remedy is of a technical or organizational nature.
9. **Evaluation of potential for impacts:** If it has been discovered that there is no impact, associated with a particular organizational issue, then it is important to question whether there should be an impact. If, for example, it has been determined that the system is unlikely to change working practices, questions might be raised as to whether the system could be used to stream-line or enrich the design of jobs.

Figure 1. Approach to treatment of organizational issues



10. **No changes required:** In the cases where there is no actual impact or potential for any specific organizational issue then there is no requirement to either change the system's specification or institute a programme of organizational change.
11. **Modification of specification:** In many situations, the organizational issue's review process will necessitate changes to the system's specification, in order to correct a negative impact, or evoke a more positive impact.
12. **Development of program of organizational change:** In situations where organizational impacts have been identified that have judged to be desirable, it is important that a programme of organizational change is planned and implemented to ensure that the impact is realised.
13. **Abort project:** In situations where it has been found that the introduction of an information system is likely to result in significant organizational impacts, of a negative nature, then the project should be aborted.

At a minimum, it is envisaged that the organizational impacts will be assessed, using this approach, at the following key stages of the development process (Figure 2): on completion of the requirements specification, then again at the end of the development phase and then very soon after implementation. However, for very complex projects, or those that are likely to be the catalyst for significant organizational change, it is recommended that the analysis should be repeated more frequently, particularly during the design phase. Moreover, it is recommended that the organizational impact analysis be repeated a number of times over the systems working life. This would be one way of operationalising Orlikowski, Yates, Okamura, and Fujimoto's (1995, p.424) concept of *"technology-use mediation"*, which they define as:

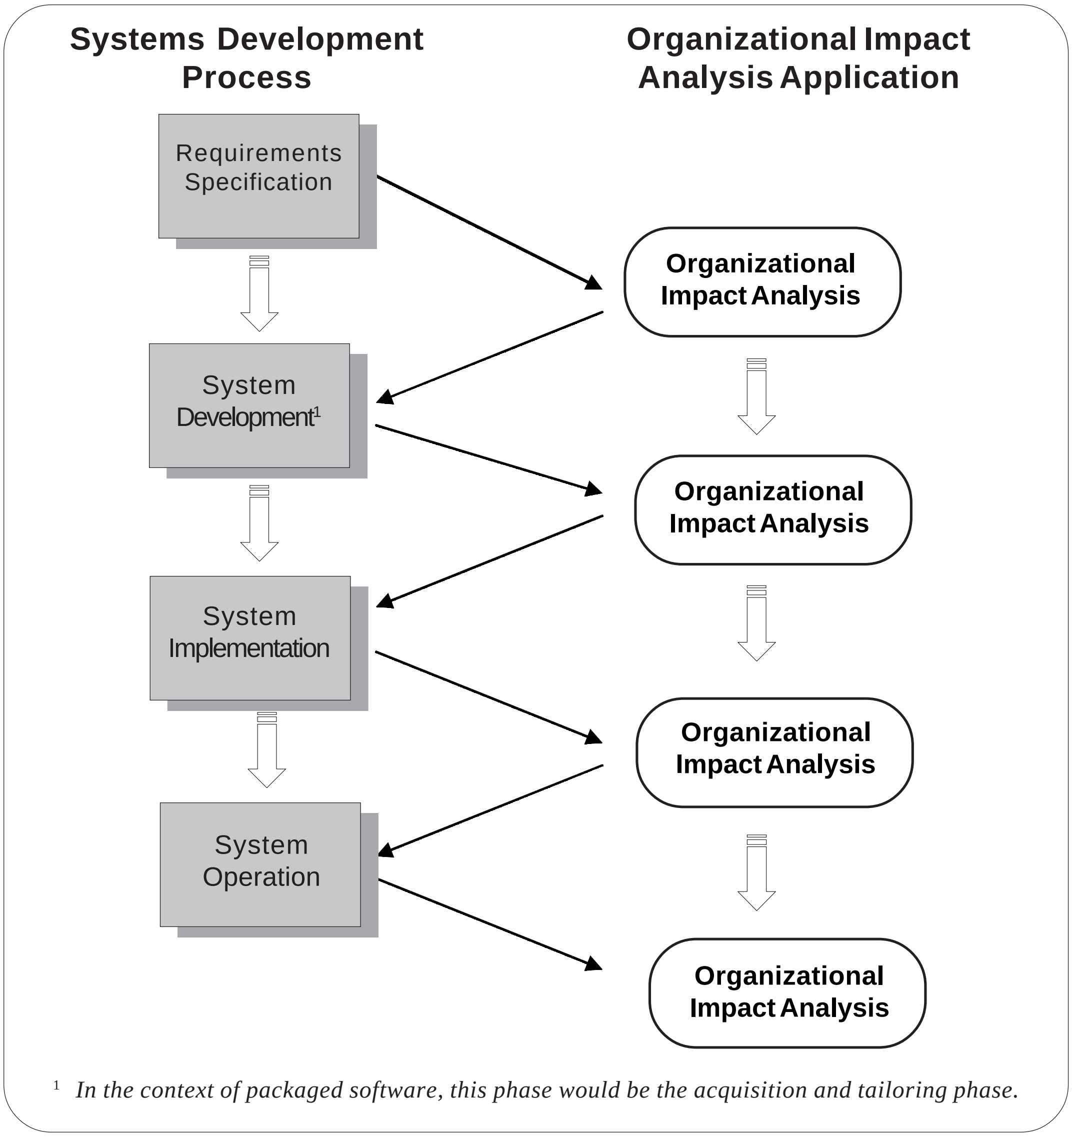
"deliberate, ongoing and organizationally sanctioned intervention within the context of use that helps to adapt new technology to its context, modifies the context as appropriate to accommodate the use of the technology, and facilitates the ongoing effectiveness of the technology over time."

It should be noted that once the system goes live, the organizational impact analysis procedure will not need to address the full range of organizational issues, as some – such as prioritization, timing of implementation, and organizational disruption – will no longer be relevant in an operational context.

While there will be a number of separate applications of the organizational impact analysis, they are not totally independent, as it is envisaged that the outcomes and findings of any given iteration of the of the approach might prompt or flag-up issues that need to be addressed in a subsequent iteration. It should also be remembered that many organizational impacts are interdependent and consequently changes made with respect to one specific issue might engender impacts in other areas. One of the obvious benefits of adopting an iterative approach is that it allows changing requirements to be monitored and accommodated, on an on-going basis.

In terms of who is involved in the analysis of the impacts and the identification of appropriate changes to the system or the organization, to ensure the impacts will ultimately be desirable, it is recommended that the exercise be very inclusive. As a key objective of socio-technical approaches is to achieve consensus among all the system's stakeholders, it is envisaged that the pro-

Figure 2. Relationship between systems development process and application of the organziational impact analysis



posed approach will act as a mechanism for channeling a debate about organizational change. As Markus and Benjamin (1997, p.55) put it:

"the hard reality of IT-enabled transformation is that change is everyone's job."

FUTURE TRENDS

As the scope and strategic importance of information systems continues to grow, so does the need to find better ways of matching them to their organizational context, to ensure that they deliver a significant contribution to organizational performance. Consequently, there is an urgent need for practical and easy-to-use methods to aid systems development professionals in managing the organizational impacts of the systems for which they are responsible. To this end, our immediate priority is to test the provisional framework on a variety of systems development projects, and use the feedback from these exercises to further define exactly how different organizational impacts can best be analyzed and managed.

CONCLUSION

Many information systems researchers have recognised the need for more effective socio-technical tools and methods to be developed. While the work described in this article is not trying to develop a highly specific tool or technique, it does propose a more general framework to promote the systematic and coherent treatment of organizational issues. The chief benefits of the proposed approach are that it presents systems developers with a systematic framework which obliges them to confront organizational issues and provides them with the means to effectively navigate their way through a very complex decision-making process. Moreover, a comparison of this approach with some of its predecessors allows the following distinctions to be made:

- **Complementary:** The proposed approach complements, rather than replaces, existing development tools and methods. There is no requirement for systems developers to abandon there tried and tested practices.
- **Straightforward:** The approach adopts a common-sense perspective, and it should, therefore, be relatively easy to learn and apply.
- **Proactive:** By using this approach, organizations will ensure that potential problems are recognised and opportunities are identified and exploited in a timely and effective manner.
- **Comprehensive:** The approach is comprehensive and can cope with a wide range of potential impacts.
- **Flexible:** The approach is highly flexible and can be adapted to suit the requirements of a wide variety of information systems projects

In essence this approach is inviting systems developers to periodically stand back from the systems development process and, in conjunction with a wide variety of stakeholders, assess the likely impacts of their work on the design and operation of the organization. While there are a number of potential benefits to the proposed approach, it is also important to issue a health warning: These ideas are provisional and exploratory, and there is much further work required to translate them into a robust and reliable tool.

KEY TERMS

Incidental Impacts: Impacts that are un-planned, by-products of the system's development process that had not, or could not, have been envisaged at the project's outset.

Organizational Impact Analysis: A one-off study to determine the ways in which a proposed system will affect the organization, in areas such as power, structure, culture, working practices, and so forth.

Organizational Issues: Those issues which need to be treated during the systems development process to ensure that the individual human, wider social and economic impacts of the resultant computer-based information system are likely to be desirable.

Planned Impacts: The anticipated outcomes of a systems development project that were identified at the project's outset, and are typically critical to its ultimate success.

Socio-technical Methods: Development methods that attempt to produce systems that are both technically efficient and organizationally sensitive.

Systems Failure: Systems abandoned before completion, systems completed but never used, under used or failing to deliver key aspects of functionality, and projects that are significantly over budget or schedule.

Managing Value-Creation in the Digital Economy

John C. Mc Intosh
Bentley College, USA

Keng L. Siau
University of Nebraska – Lincoln, USA

INTRODUCTION

Value-creation and maintenance of a sustained revenue stream in the digital economy continue to elude most businesses. With the exception of advanced firms such as Dell™, Virgin®, Yahoo!®, and eBay®, relatively few firms have been able to leverage Internet technologies to create sustainable business models. From a strategic perspective, although firms are freed of the strictures of vertical integration, they face the daunting task of orchestrating a constantly changing web of suppliers and partners to create appealing products for increasingly sophisticated, fickle customers.

Contemporary research, often based on frameworks such as Porter's Five Forces (Porter, 1984), has proliferated myriad, largely static business models. For example, Tapscott et al. (2000) proposed five distinct models—agoras, aggregations, alliances, distribution networks, and value chains, while Weill and Vitale (2001) proposed six—direct to customer, content provider, full-service provider, portals, shared infrastructure, and whole of enterprise. By not explicitly accounting for today's dynamic business environment, these models offer limited prescriptions for sustained value-creation. Fundamental to sustainability is business model evolution, which often entails the transfer of knowledge, processes, partnerships, and relational capital from one group of customers to another. For the IT-enabled firm, sustainable value-creation increasingly depends on its ability to combine intangible assets (i.e., brand, information resources, relational capital) with those of its network partners (Brandenberger & Nalebluff, 1996; Gulati et al., 2000; Tapscott et al., 2000).

This entry synthesizes research from strategic management and IT to develop a framework for understanding sustained value-creation. In contrast to much of the literature on IT-enabled competition (Afuah & Tucci, 2001; Osterwalder & Pigneur, 2002; Weill & Vitale, 2001), it does not focus on e-business models per se, but instead reinterprets the traditional three stages of strategy making (conceptualization, planning, and implementation) to describe how distinct types of information may be used for sustained value-creation. We chose to focus on the strategy aspect of value-creation, because business models are tangible representations of a firm's strategic intent. In other words, they are the outcome of a firm's strategy. Hereinafter, we use the term "product" to describe both tangible products and intangible services and the term "strategy" to describe the protocol that firms use to create valuable products and services.

This article is organized into two sections, first, drawing on two features of information: velocity (rate of change) and interoperability (the extent to which information can be combined with other information to create value). It develops a 2×2 matrix depicting four fundamental types of information necessary to understand information-driven competition (Figure 1). Next, it develops a conceptualization of sustained value-creation by using the information typology and IT's considerable information-gathering and coordination capabilities as a lens to reinterpret the three stages of strategy.

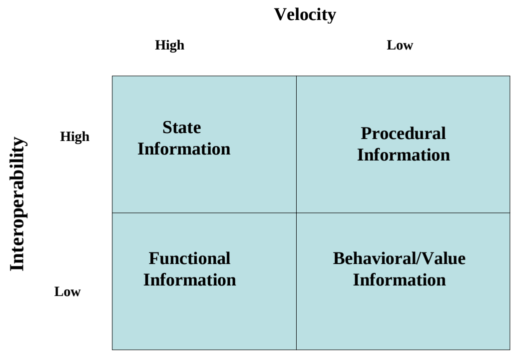
FOUR FUNDAMENTAL INFORMATION TYPES

This section draws on two characteristics of information—velocity and interoperability to develop a typology (Mc Intosh & Siau, 2001). Each type is discussed.

State Information

Typically descriptive in nature, state information changes rapidly (high velocity) and can be easily combined with other information to create value (high interoperability). Examples of state information include the price of a commodity at a specific day and time; the quantity of a product in inventory; and the chronology of a product's journey through a firm's value chain. General Motor's information system, for example, provides state information concerning the number of engine assemblies in inventory and the mix of automobiles on a car carrier in the distribution system (Mc Intosh & Siau, 2001).

Figure 1. Typology of information based on velocity and interoperability



Procedural Information

Procedural information, characterized by low velocity and high interoperability, refers to the steps or protocols required to conduct a process or perform a service. It can be combined with other information to create efficient business processes. For example, best practices for a particular industry may be combined with knowledge of company-specific practices to improve business processes. Procedural information therefore tends to be more explicit and relatively easily codifiable (Mc Intosh & Siau, 2001).

Functional Information

Functional information describes how components and subsystems of a tangible product interact and how those interactions give rise to the performance features that characterize a product. The most common, engineering knowledge, is high velocity (applied technical information changes rapidly), of low interoperability (applicable to a narrow domain), and is grounded in an understanding of the technologies that constitute a product and how variations in those technologies can affect overall system performance. In PC design, functional information regarding microprocessor speed, hard drive access time, and the amount of RAM permits engineers to design systems with differing performance characteristics. Unlike procedural information, functional information tends to be more complex, tacit, and cannot be as easily captured and represented in an organization's databases as can state and procedural information (Mc Intosh & Siau, 2001).

Behavioral/Value Information

This information type, characterized by low velocity/low interoperability, refers to the way large-scale, complex systems interact under different environmental conditions. It may be used to predict the future actions of complex systems, such as the trajectory of a hurricane, the competitive outcomes from adding a new partner to a value web, or customer response to a new channel. For example, capturing information about individual customers and buying preferences might allow the firm to create a model of consumer preference for particular product offerings and thus enable it to fine-tune its marketing and sales initiatives (Mc Intosh & Siau, 2001).

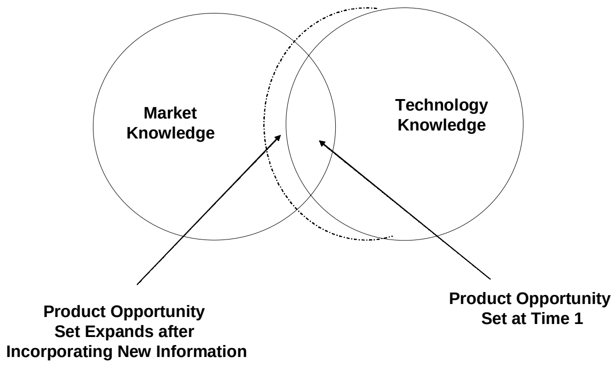
UNDERSTANDING SUSTAINED VALUE-CREATION

The Internet is a double-edged sword for today's managers. Freed from the constraints of vertical integration and costly coordination, managers enjoy unprecedented flexibility to create appealing products and services by mixing and matching resources and capabilities from their value-webs. Nevertheless, the Internet's dynamic nature, hypercompetition (D'Aveni, 1995), and accelerating global competition, force managers to cope with shorter, more frequent design–build cycles, quicker market feedback, and greater opportunities for product evolution. Despite this, most business models, operating under assumptions of linearity, constrain managerial action to the proverbial single-board chess game. Stated differently, the linear, three-stage conception of strategy (conceptualization/planning/implementation) now becomes iterative, with each cycle offering opportunities for learning, adaptation, and sustained value-creation. This arises from IT's information gathering and coordinative capabilities that enable managers to incorporate, at any stage, new information, resources, and capabilities, from the firm's value-web. The chess game, now played on three boards, permits horizontal and vertical moves.

Chess Board 1: Conceptual Stage

Proponents of the resource-based view (Barney, 1991; Grant, 1995; Wernerfelt, 1984) demonstrate that product conceptualization is conditioned by the firm's resources and capabilities. Managers use the firm's market knowledge (i.e., customer tastes and preferences) and technology knowledge (what technological capabilities can be used to meet market demands) to create products. The overlap of these two domains (Figure 2) represents the firm's product opportunity set. By allowing managers to access knowledge resources from value-web partners, IT expands both knowledge domains to offer a broader product opportunity set (Hamel, 2000; Piller et al., 2000; Spencer, 2003). For example, a firm in the automobile performance components industry may combine procedural information (from a value-web partner possessing expertise in carbon-fiber composites) with functional information (concerning how air flows within an intake system) to offer a lightweight, high-performance manifold.

Figure 2. Product opportunity set expansion after new knowledge is added



Chess Board 2: Planning Stage

Management education, steeped in concepts such as specialization (Porter, 1980), business processes (Chowdhury, 2002), and value chains (Porter & Millar, 1985), has fostered a firm-centric view of products. Consequently, managers often create offerings that meet a narrow set of customer needs. Customers, however, focus less on product characteristics and more on services that meet their idiosyncratic needs. Firms tend to focus on specific products, while customers tend to focus on a bundle of services that satisfy particular needs. We advance a customer-centric view of value-creation by proposing the "activity chain" concept. Much like the firm's value chain, a customer's activity chain defines the steps necessary to achieve a particular goal. For example, a consumer desiring to move cross-country would engage in the following: research neighborhoods, find a home, buy that home, hire a moving company, turn on utilities at the new location, and convert licenses and vehicle registrations.

Prior to commercialization of the Internet, specialized firms (such as realtors) tended to create firm-centric, atomistic products that satisfied selected steps in the customer activity chain. IT-enabled companies such as Homefinders.com, taking a customer-centric view, offer a menu of atomistic services from which users may create product bundles that meet their idiosyncratic needs. This is typically achieved by using behavioral/value informationBehavioral /Value Information (to construct a stylized activity chain describing tasks associated with moving) and procedural information (concerning how each web partner delivers its atomistic service). Additional value may be created by offering customers a mortgage application wizard (based on procedural information) or tracking services to monitor the progress of a moving truck transporting their possessions (based on state information).

Chess Board 3: Implementation Level

IT's information-gathering and coordinative capabilities significantly reduce transaction costs associated with finding appropriate value-web partners, certifying their capabilities, mitigating opportunistic behaviors, and reducing switching costs in the event a partnership fails (Mc Intosh & Kim, 1998). Reduced risk and greater coordination allow firms to focus on core activities while hiving off noncore activities to "best-in-breed" partners, thereby conferring unprecedented levels of strategic flexibility (Andersson et al., 2002; Dyer, 1997; Madhok & Tallman, 1998; Tsai & Ghoshal, 1998). These advantages, however, are not without costs, because electronic "arm's length contracting" requires a significant element of trust. This places a premium on managing the firm's social and relational capital (Burt, 1997; Granovetter, 1985). Managing relationships with value-web partners increasingly requires the use of all four types of information. Coordinating a simple buyer–supplier relationship requires state information. Firms relying on just-in-time deliveries need detailed information of inventory stocks and the physical locations of components in the logistic chain. Managers desiring to adopt best practices or transfer learning across organizations require a keen understanding of procedural information to successfully absorb new practices. Additionally, as firms jointly develop new products and processes, procedural information concerning partners' business processes is increasingly important to facilitate synchronized action. Last, arrangements such as strategic alliances or mergers require very high levels of interdependence. In cases where partners are culturally dissimilar, a keen understanding of behavioral/value information is of paramount importance to organizational effectiveness.

CONCLUSION

We proposed a framework for sustained value-creation. The framework consists of three stages: the conceptual stage, the planning stage, and the implementation stage. Four types of information are discussed: state, procedural, functional and behavioral/value. The use of these four types of information in the three stages of the framework to sustain value-creation is discussed in the second section of the chapter. The contributions of the framework are threefold. First, in contrast to traditional business models, the framework is not a static model. Second, the framework integrates strategy management with IT. Third, the framework discusses the use of different types of information to support the three stages of value-creation.

KEY TERMS

Behavioral/Value Information: Information that represents how large-scale, complex systems, including social systems, interact under different environmental conditions and in conjunction with different stimuli.

Functional Information: Information, based on engineering knowledge, that describes how components and subsystems of a tangible product interact and how these interactions give rise to different product features and varying levels of product performance.

Procedural Information: Easily codifiable information that depicts the steps or protocols that are required to conduct a business process or perform a service.

State Information: Information that describes the state or condition of a physical product or information good (i.e.,a stock price or the number of SKUs in inventory).

Market of Resources for Agile/Virtual Enterprise Integration

Maria Manuela Cunha
Polytechnic Institute of Cávado and Ave, Portugal

Goran D. Putnik
University of Minho, Portugal

INTRODUCTION

Enterprise Networking and Dynamics

Fast change, uncertainty, and strong competition are challenges of the actual worldwide economic context. Competitiveness is a main requirement of enterprises, whose satisfaction requires the definition of new organisational concepts, with extremely high performances that are strongly time-oriented while highly focused on cost and quality. Several factors appear as supreme factors of competitiveness: (1) the organisations' capability to achieve and explore competitive advantages in synergy, by using or integrating the optimal available resources for the functions that the organisation undertakes; (2) the capability of fast adaptability to the market; together with (3) the capability of managing all business processes independently of distance, to be achieved through the recent virtual enterprise (VE) organisational models (Cunha & Putnik, 2002; Cunha, Putnik, & Ávila, 2000).

The need to keep a close alignment with the market environment in permanent change implies the high dynamics of the organisations' structure reconfigurability, introducing a new concept of dynamically reconfigurable global networked structures, corresponding to the emerging agile/virtual enterprise (A/VE) model (Cunha & Putnik, 2004).

The Market of Resources is the environment proposed by the authors to enable A/VE dynamic integration and business alignment.

BACKGROUND

Critical Factors against Networking and Dynamics

Two critical factors against networking and enterprise dynamics are as follows:

1. The *transaction costs*, i.e., the firm reconfiguration cost, associated with partners search, selection, negotiation, and integration as well as permanent monitoring and evaluation of partnership performance. Resource allocation in the market is normally guided through prices, but within the firm, work/job is done through decisions and commands of management (Coase, 1937). Activities are collected in a firm when transaction costs incurred in using the price mechanism exceed the cost of organising those activities through direct managerial controls, i.e., the decision of keeping a function/activity in-house results from the comparison between expected economic loss that can result from an outsourcing contract (transaction costs and contractual risks), and the expected economic gains.
2. *Preservation of firm's knowledge* of organisational and management processes, as it is the firm's competitive factor. The firm incurs the risk of leakage of private information when opt by performing an activity by an independent market firm.

For the efficient implementation of A/VE, it is necessary to conceive tools to overcome the networking and dynamics disabling factors.

Tools for Managing, Controlling, and Enabling Networking and Dynamics According to BM_VEARM Approach

The main tools conceived by the BM_virtual enterprise reference model (BM_VEARM) (Putnik, 2000) for managing, controlling, and enabling networking and dynamics, overcoming the two critical factors, are:

- The Market of Resources is the environment for enabling and managing efficient configuration, and assuring virtuality, at low transaction costs and reduced risk of knowledge leakage.
- The broker or organisation configuration manager[1] is the main agent of agility and virtuality, acting

either between two operations of the A/VE (off-line reconfigurability, providing agility only) or online with the operation (online reconfigurability, providing virtuality and a higher level of agility).
- Virtuality makes possible the transition from one physical structure (instance) to another in a way so that the enterprise or process owner is not affected by the system reconfiguration and is not aware of the reconfiguration—the underlying service structure and reconfiguration process are hidden.

Additionally, A/VE must satisfy the highest level of integration and (geographic) distribution of the A/VE partners.

MARKET OF RESOURCES CHARACTERIZATION

Market of Resources Definition

Market of Resources is an institutionalised organisational framework and service assuring the accomplishment of the competitiveness requirements for A/VE dynamic integration and business alignment. The operational aspect of the Market of Resources consists of an Internet-based intermediation service, mediating offer and demand of resources to dynamically integrate in an A/VE, assuring low transaction costs (demonstrated in Cunha & Putnik, 2003a, 2003b) and the partners' knowledge preservation. Brokers act within the Market of Resources as intermediation agents for agility and virtuality.

In this "virtual" environment, *offer* corresponds to *resources providers* (individuals, enterprises) that make their *resources* (products, components, operations) available, as potential partners for A/VE integration.[2] *Demand* corresponds to *client*, the A/VE owner, the entity looking for resources to create/integrate/reconfigure an A/VE to satisfy the *Customer*. *Customer* is the entity giving rise to a business opportunity and is considered outside the Market of Resources.

The service provided by the Market of Resources is supported by the following:

1. A knowledge base of resources and history of previous performance results
2. A normalised representation of information
3. Computer-aided tools and algorithms
4. Brokers
5. A regulation, i.e., management of negotiation and integration processes, as well as contract enforcement mechanisms

It is able to offer knowledge for resources search and selection and its integration in an A/VE, specific functions of A/VE operation management, and contracts and formalising procedures to assure the accomplishment of commitments, responsibility, trust, and deontological aspects, envisaging the accomplishment of the A/VE objectives.

Information technology (Internet and WWW technologies, agent technology, e-marketplaces, etc.) supports or automates purchasing activities, helping from procurement processes up to the search for partners for a partnership, including electronic automated negotiation, electronic contracting, and market brokerage services. Although the basic IT infrastructures and tools are necessary as support, the added value comes from the higher-level functions, to support search, selection, and integration of resources under the format of an A/VE, coping with the high reconfigurability dynamics requirements (overcoming the disabling factors) intrinsic to the A/VE (Cunha, Putnik, Carvalho, & Ávila, 2002).

Market of Resources Functionality

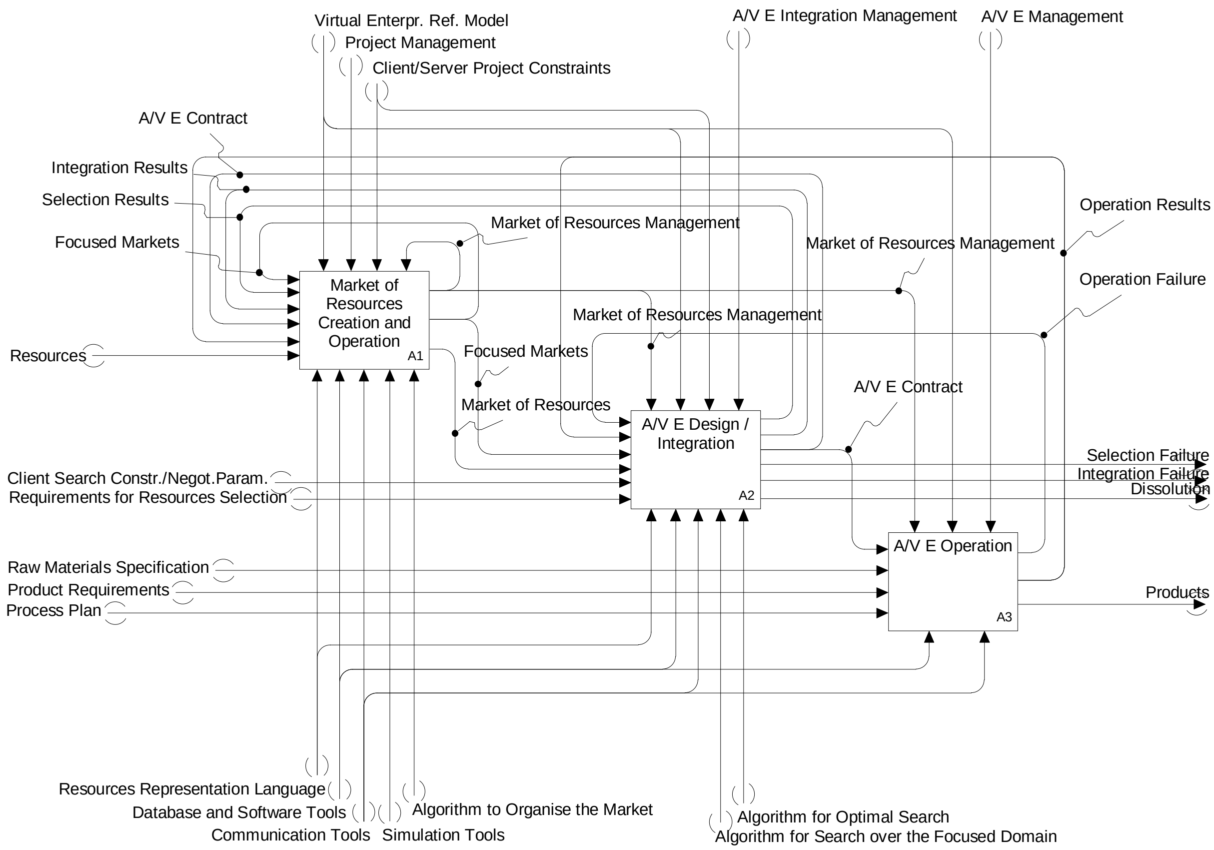
The Market of Resources is designed to offer the following (Cunha, Putnik, & Ávila, 2003; Cunha, Putnik, & Carvalho, 2002):

- Reduction of negotiation time and of time-to-contract, as one instantaneous physical structure (one instance) of an A/VE may last (on a limit) for only a few days or even hours
- The permanent alignment of the A/VE with business requirements, trust of participants, and accomplishment of contracts, requiring a dynamic process of A/VE performance evaluation, monitoring the performance of participating resources, and identifying reconfiguration opportunities
- The ability to find the right potential partners and further efficient negotiation
- Enforcement and risk minimisation by a contractual agreement between the involved parties
- Provision of knowledge/advisory guidance in A/VE design, validation, and reconfiguration, through appropriate algorithms and expert brokerage functions

Market of Resources Organisation

The overall functioning of the Market of Resources (Figure 1) consists of the creation and management of the Market as the environment (Process A.1.) to support the design and integration of the A/VE (Process A.2.) and the A/VE operation (Process A.3.), offering technical and

Figure 1. IDEF0 representation of the global process for the market of resources creation and operation, and for A/VE design, integration, and operation



Source: *Cunha, Putnik, and Gunasekaran, 2002.*

procedural support for the activities of identifying potential partners, qualifying partners, and integrating the A/VE, as well as providing coordination and performance evaluation mechanisms. The model respects the *BM_VEARM*.

The Market of Resources has two components: the organisational or managerial component that integrates the criteria for resources selection, management procedures, control, and environment evaluation; and the infrastructural or informational component (databases). Figure 2 represents how the two components (organisational and informational) are created, for the first time (Process A.1.1.); how the organisational component is maintained (Processes A.1.2. and A.1.3.); and how the Market of Resources operation is managed (Processes A.1.4. and A.1.5.).

Virtual Enterprise Extended Life Cycle

The VE life cycle presented in the literature as comprehending the phases of creation, operation, and dissolution of the partnership (where reconfiguration is a possibility to be considered during peration), traduces the limited ability of the traditional VE model to support dynamics. The extended life cycle introduced by the authors is directly tied with the *BM_VEARM* and the Market of Resources as supporting environment, and includes in it the "traditional" VE life cycle (Figure 3).

It starts with *Identification of the Opportunity* to create an A/VE, followed by the selection (by the A/VE owner) of a Market of Resources where support can be found. After the *contratualisation* with a Market, the process of *A/VE design*, and the search and selection of resources providers toward the *A/VE integration* takes

Figure 2. IDEF0 representation of process A.1—Market of resources creation and operation

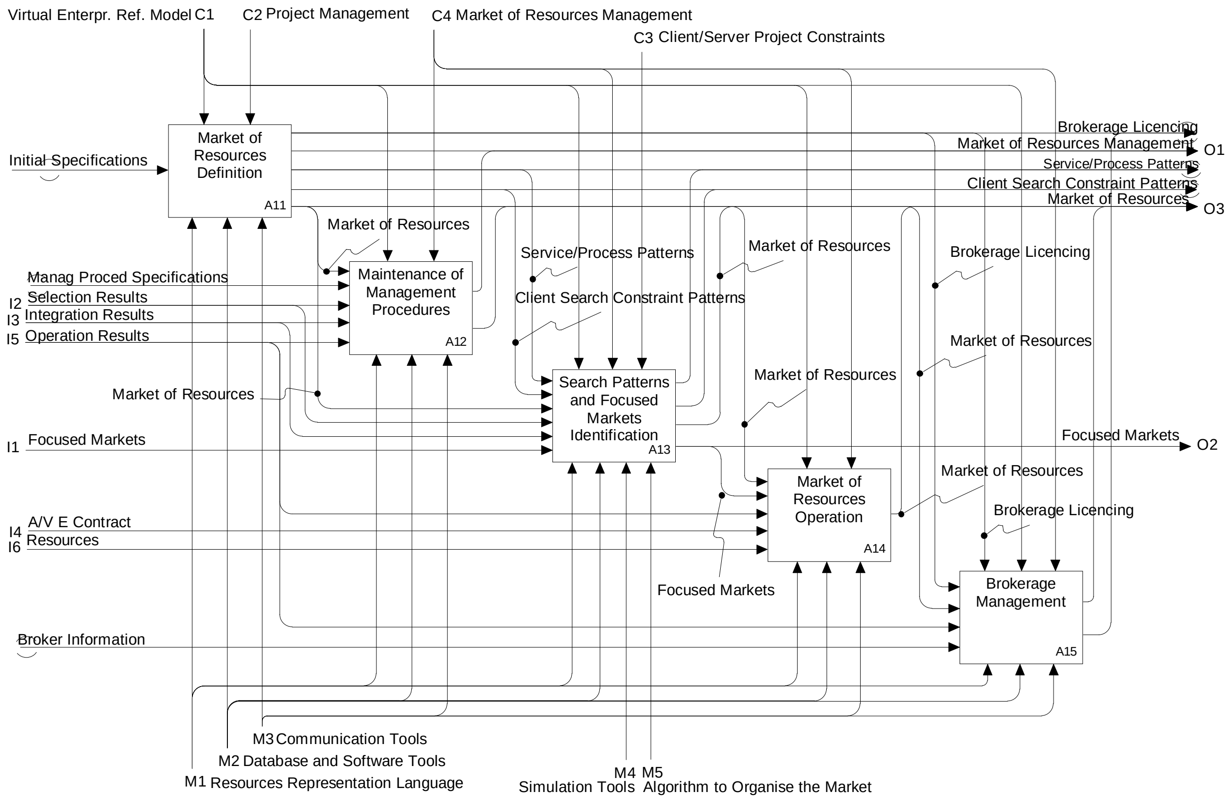


Figure 3. Virtual enterprise extended life cycle (the A/VE life cycle)

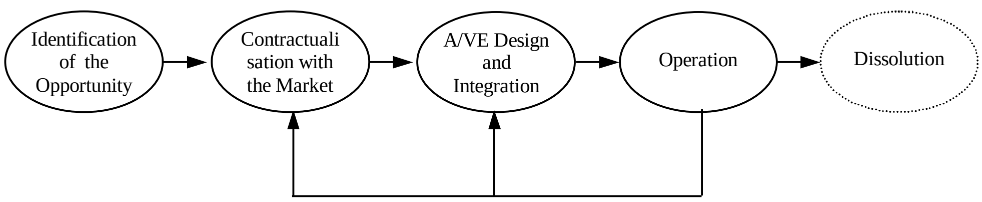

Source: Cunha, Putnik, and Ávila (2004)

place. During the *Operation* phase, the A/VE can suffer reconfiguration, or the A/VE owner can even decide to contractualise with another market as an alternative or complementarily. Finally, we have the *Dissolution* phase. Inclusion of the Market of Resources in the A/VE life cycle is necessary to enable the A/VE reconfigurability dynamics.

Supporting Technologies

Table 1 lists some of the Market of Resources functionalities and the corresponding supporting technologies.

Implementation

The Market of Resources is an independent organization, i.e., company, independent both from the offer and the demand sides of A/VE integration, i.e., independent from the Market participants, in order to assure impartiality, fairness, and trust, being able to monitor the activities of all the participants (including brokers) and to enforce the accomplishment of contracts between parties.

In its nonregular implementation, the Market of Resources can be considered as a product and implemented as a function in one company. This implementation loses

Table 1. Technologies to support the main functionalities of the market of resources

Market of Resources functionalities	Supporting technologies and tools
Market contents: user/buyer profile, catalogs, historic, database of resources	- Database management systems - Distributed database management systems - e-Business development platforms - Portals
Negotiation: request for quotes, auctions, optimal selection	- Intelligent agent technology - Electronic negotiation tools - Algorithms or protocols - Regulation of negotiation - Intelligent decision-making systems
Transactions: payment, contractualisation	- Electronic payment - Digital signature - Certification - Other security mechanisms
Management: monitoring, performance evaluation, analysis of operation results, decision making	- Simulation tools - Workflow technology and collaboration techniques - Regulation
Brokerage: expert advice, monitoring, and coordination	- Messaging and conferencing - Algorithms - Management procedures
Integration: file translation, collaboration	- Standards for product/services description - Collaboration tools - Data translation standards and tools - Communication protocols
Resources: final selection	- Algorithms, heuristics, and computer-aided tools - Intelligent decision-making systems - Artificial intelligence

Source: Cunha (2003)

the impartiality as it corresponds to a "buyer-centric" e-marketplace.

Other Contributions Toward A/VE Integration Support

Other similar Market of Resources concepts, services, and products include the new generation of high value-added electronic marketplaces, e-alliances, breeding environments, electronic institutions, and virtual clusters.

FUTURE TRENDS

The Market of Resources is part of an umbrella of research projects under development at the University of Minho addressing virtual enterprise theory, design and control tools and technologies, and the corresponding environment. In particular, the practical objective of the underlying reference model (BM_VEARM) is to serve as a framework for cooperation and coordination of this group of research projects.

Future developments include a more detailed characterisation of the Market of Resources, extended from virtual enterprises to virtual organisations, to cover environments or application domains, such as education (virtual universities), health care, etc., with intrinsic specificities not included in our actual model. The new paradigms and developments in the field of information technologies, such as ubiquitous computing and systems, intelligent software, data mining tools, and intelligent knowledge bases, should also be considered.

CONCLUSION

The A/VE model is of increasing relevance in the organisational panorama, due to its intrinsic agility, dynamic adaptability, and efficiency. The authors introduce the Market of Resources as an environment and enabler that, overtaking the disabling factors of networking and dynamics, is able to cope with the A/VE requirements of reconfigurability dynamics and business alignment.

KEY TERMS

Agile/Virtual Enterprise: Dynamically reconfigurable global networked organisation, networked enterprise, or network of enterprises, sharing information, knowledge, skills, core competencies, market and other resources and processes, configured (or constituted) as a temporary alliance (or network) to meet a (fast-changing) market window of opportunity, presenting as its main characteristics agility, virtuality, distributivity, and integrability (see Putnik, 2000). The factors against A/VE are transaction (reconfiguration) costs and preservation of enterprises', or firms' (partners in A/VE) knowledge.

A/VE: Agile/virtual enterprise (see *Agile/virtual enterprise*).

BM_VEARM: BM_Virtual Enterprise Architecture Reference Model: BM_VEARM is a VE reference model conceived to enable the highest organisational/structural/reconfiguration and operational interenterprise dynamics of VE or A/VE (see *Agile/virtual enterprise*), employing three main mechanisms for VE dynamic creation, reconfiguration, and operation: *Market of Resources*, *Broker*, and *Virtuality*. Additionally, BM_VEARM implies the highest level of integration and (geographic) distribution of VE elements (partners in the VE network).

BM_Virtual Enterprise: A virtual enterprise in a total or partial conformance with the BM_Virtual Enterprise Architecture Reference Model (BM_VEARM) (see *BM_VEARM*).

Broker: Also called organisation configuration, structure, organization or architecture manager, it is the main agent of agility and virtuality in A/VE, acting either between two operations of the A/VE (off-line reconfigurability, providing agility only) or online with the operation of the A/VE (online reconfigurability, providing virtuality and a higher level of agility).

Business Alignment: Actions to be undertaken by an organisation, to answer to a market opportunity with the provision of the required product, with the required specifications, at the required time, with the lowest cost, and with the best possible return.

Dynamics (of Organisation): Change in an organisation's structure (see *structural dynamics*) or operation (see *operational dynamics*) along the time, when time as a parameter is indispensable for the organisation, or some aspect of organisation, description and analysis. Otherwise, although the organisation's state changes, if the time as a parameter can be disregarded, the organisation, or some aspect of the organisation, is considered static. The organisation's state changes frequency, state change time, and intensity are examples of an organisation's dynamics features and performance measures.

Enterprise Dynamic Integration: (See *Organisational dynamics*.)

Enterprise Dynamic Reconfiguration: (See *Organisational dynamics*.)

Enterprise Integration: (1) Consists of the establishment of effective and efficient interactions, as well as interaction improvement, among the enterprise's elements, or organisational units and functions, and provides an easy enterprise reconfiguration ["without significant conversion (reconfiguration) costs"]—*intraenterprise integration*. (2) In the case of a virtual enterprise, *enterprise integration* consists of the establishment of effective and efficient interactions among the partners of the VE network and one of the enablers of the VE dynamic reconfiguration—*interenterprise integration*.

Market of Resources: An institutionalised organisational framework and service assuring the A/VE dynamic integration, reconfiguration, and business alignment. The operational aspect of the Market of Resources consists of an Internet-based intermediation service, mediating offer, and demand of resources to dynamically integrate in an A/VE, assuring low transaction costs and partners' knowledge preservation. Brokers act within the Market of Resources as the intermediation agents for agility and virtuality. Its implementation is as an independent organization/company, independent from the offer and the demand sides of A/VE integration, i.e., independent from the Market participants, in order to assure impartiality, fairness, and trust, being able to monitor the activities of all the participants (including brokers) and to enforce the accomplishment of contracts between parties.

Operational Dynamics: Change in an organisation's operation, while the organisation's structure remains unchanged (static), along the time, when time as a parameter is indispensable for the organisation's operations, or some aspect of organisation's operations, description, and analysis [see *Dynamics (of organisation)*]. In the case of A/VE (see *Agile/virtual enterprise*), the operational dynamics refers to *interenterprise operational dynamics*.

Organisational Dynamics: Changing of an organisation's structure, where structure consists of organisation's (company's) elements and relations among them along the time parameter, when time as a parameter is indispensable for the organisation's structure, or some aspect of the organisation's structure, description, and analysis [see *Dynamics (of organisation)*]. In the case of A/VE (see *Agile/virtual enterprise*), the organisational dynamics refers to the changes in the network structure or configuration along the time parameter. Also, *Enterprise dynamic integration*, *enterprise dynamic reconfiguration*.

Resource: This is the entity (individual or organisation) that can contribute or add value to a product, providing either a product (component, assembly) or an operation.

A resource is (a view of) an enterprise object used to perform (or to support the execution of) one or more processes, and it is a subject of control. A resource can be primitive or complex. In the case of A/VE (see *Agile/ virtual enterprise*), a person or enterprise (company), partner in A/VE.

Virtual Enterprise: (See *Agile/virtual enterprise*.)

Virtuality (of Organisation): The specific organisational structure between VE elements/partners and brokers, BM_VEARM (see *BM_VEARM*), providing the feature of virtuality as a further requirement for achievement of the highest VE dynamics. Virtuality makes possible the transition from one A/VE's physical structure (instance) to another in a way that the enterprise or process owner is not affected by the system reconfiguration and is not aware of the reconfiguration—the underlying service structure and reconfiguration process are hidden.

ENDNOTES

Marketplace Architecture for Enterprise Integration

Hamada H. Ghenniwa

Michael N. Huhns
University of South Carolina, USA

INTRODUCTION

Businesses today must be fast and flexible, responsive to customers, and cost effective in their operations. They must collaborate more frequently with partners to build virtual organizations and supply-chains that reduce times-to-market and costs. *E-business* is the use of the Internet along with other electronic means and technologies to conduct within-business, business-to-consumer, business-to-business, and business-to-government interactions. A basic model of an e-business is the *e-shop* model, which is based on providing a self-service storefront to a customer by displaying the company catalogs and product offers on a Web site. An *e-procurement* model focuses on the buying aspect of the business. A typical architecture for *e-procurement* consists of a browser-based self-service front-end to the corporate purchasing system or its ERP. The supplier catalogs are presented to end-users through a single unified catalog, thereby facilitating a corporate-wide standard procurement process. Online auction models have also received much attention for automating dynamic trading. Other models are based on creating value-chain businesses, such as service provisioning of specific functions for the value-chain, and electronic payments or logistics.

Although each of the above models attempts to provide an e-business solution, none of them addresses the challenge of how to create and leverage services and supply operations in a way that seamlessly integrates business entities (customers, suppliers, partners, and competitors) in a dynamic trading community. A very important and promising model is the *e-marketplace*. It supports value-chain integration and provisioning in its structure and services. The objective is to develop an e-business solution that relieves business entities of much of the burden of participating effectively in the e-business domain. This model combines the advantages of the sell-side, the buy-side, and the value-chain models.

BACKGROUND AND LITERATURE REVIEW

There have been several recent attempts to promote e-marketplace models by the academic and industrial communities. For example, the Electronic Market-Place (Boll, Gruner, Haaf & Klas, 1999) is an attempt to develop a business-to-business system architecture. It is viewed as a DBMS solution to support many-to-many relationships between customers and suppliers. The Global Electronic Market system (Rachlevsky-Reich, Ben-Shaul, et al., 1999) attempted to develop a logical market framework and infrastructure. In this system, the market provides trading mechanisms that include bids and offers. A more complex architecture for an e-marketplace is MAGMA (Tsvetovatyy, Gini, Mobasher & Wieckowski, 1997), with its special focus on the infrastructure required for conducting commerce on the Internet. OFFER (Bichler, Beam & Segev, 1998) proposed a brokering-based architecture marketplace. A customer can search for a service either directly in the e-catalog of the supplier or use the e-broker to search all the e-catalogs of the suppliers that are registered with this broker. E-brokers employ a simple auction mechanism. MOPPET (Arpinar, Dogac & Tatbul, 2000) proposed an e-marketplace system as agent-oriented workflows. MOPPET viewed the market as a workflow management system carried out by several types of agents: task, scheduling, facilitator, and recovery agents.

Another approach was driven by the bottom-up modeling of market processes with self-organizing capabilities (Arthur, Holland, LeBaron, Palmer & Tayler, 1997). The objective was to develop a computational study of economies modeled as evolving systems of autonomous interacting agents, and known as agent-based computational economics (ACE) (LeBaron, 2000; Timmers, 1999). The ACE researchers relied on computational laboratories (McFadzean, Stewart & Tesfatsion, 2001) to study the evolution of decentralized market economies under controlled experimental conditions.

Several companies have emerged to automate logistics and re-supply within specific industrial segments. For example, Ariba (2000) developed a marketplace based on procurement portals and dynamic exchanges for horizontal marketplaces. The SAP Service Marketplace (SAP AG) is an Internet portal for the SAP community. It provides basic online services, such as catalog browsing, matchmaking, and ordering from SAP and its partners. Other approaches were directed to support vertical marketplaces, such as PaperExchange (PaperExchange Marketplace), which enable customers and suppliers to negotiate pricing and transact directly with one another. VerticalNet (VerticalNet® Marketplaces) also built a set of Web-based marketplaces for specific industrial segments, such as financial services, healthcare, and energy. Each Web site forms a community of vendors and customers in a specific area.

Another direction adopted by major software vendors is to develop Internet-based commerce platforms. Examples are IBM CommercePOINT (IBM Corporation CommercePOINT Payment), Microsoft Site Server Commerce Edition (Microsoft Corporation. Internet Commerce, 1998), Oracle Internet Commerce Server INTERSHOP (Intershop Communications, Inc., 1998), and Sun JavaSoft JECF (Java Electronic Commerce Framework, Sun Microsystems). These proprietary attempts focus on providing infrastructure services, such as security payment directories and catalogs, to be integrated with existing systems and the Web.

In our research work, we view e-marketplace as a cooperative distributed system that integrates participating business entities, including consumers, suppliers, and other intermediaries. This architecture enables and facilitates common economic services and commerce transactions between the buyers and sellers, such as brokering, pricing, and negotiation, as well as cross-enterprise integration and cooperation in an electronic supply-chain. In this architecture, the e-marketplace exists as a collection of economically motivated software agents.

DESIGN ISSUES AND TRENDS

As e-business grows and becomes viable in the real world, its corresponding e-marketplaces must expand to support a broader base of services ranging from baseline interaction and directory services to specialty services, such as dynamic trading, cooperative supply-chain integration, and management. In this new e-marketplace environment, there are significant interactions among the systems deployed by the participating business units of an enterprise, their customers, and other businesses. Therefore, designing e-marketplaces requires embodying greater levels of business knowledge within the e-marketplace transactions, activities, and service definitions. Additionally, it requires a greater degree of communication, coordination, and cooperation within and among the business entities and their systems in the e-marketplace. In other words, the e-marketplace architecture represents an integrated body of people, systems, information, processes, services, and products.

Enterprise Model and Ontologies

At the heart of the integration architecture for an e-marketplace is a model of the enterprise. It is an abstract representation of the structure, activities, processes, information, resources, people, behavior, goals, rules, and constraints of the e-marketplace. From an operational perspective, the enterprise model captures what is planned, what might happen, and what has happened. Therefore, it supplies the information and knowledge necessary to support the operations of an e-marketplace. An appropriate e-marketplace architecture should support enterprise-modeling ontologies. An ontology is a vocabulary along with some specification of the meaning or semantics of the terminology within the vocabulary. The objective is to provide a shared and common understanding of a domain that can be communicated to people, application systems, and businesses. In an e-marketplace model, ontologies are integrated or related to support reasoning among the elements of the model.

Market Structure and Economy Model

An important aspect of the e-marketplace is the economic model of its structure. A market structure governs the trading process and defines the formal rules for market access, traders' interactions, price determination, and trade generations. In classical economic theory there are several market models for specific trading situations and structural behaviors. In the commodity market model, various suppliers and consumers participate to trade goods/services (commodity) of the same type. The market price is publicly agreed upon for each commodity independent of a particular supplier. All consumers and suppliers decide whether and how much to buy or sell at each agreed-upon price. The challenge in this market structure is to deploy a pricing methodology that produces price adjustments that bring about market equilibrium (i.e., equalizes supply and demand). In an auction-based market, each participant (both consumers and suppliers) acts independently and contracts to buy or sell at a price agreed upon privately. An auction-based e-marketplace is a form of centralized facility, or clearinghouse, by which costumers and suppliers execute trades in an open and competitive bidding process.

There are many situations where effective coordination cannot be entirely determined by the market forces. In bargaining, both customers and suppliers have their own objective functions, and they negotiate with each other as long as their objectives are met. The participants can engage in direct negotiations with each other using their respective bargaining strategies to arrive at a "fair" price for a particular item. This market structure does not support a specific negotiation protocol; rather, the participants will use an unrestricted bidding protocol. A major challenge in this structure is how to enable any participant to determine the "fair" price.

Supply-Chain Integration and Management

An e-marketplace can be treated as a physically and logically distributed system of interacting autonomous business entities. Yet, there is a need for well-accepted interoperability standards, which must be meshed for supply-chain integration to meet business demands. Conceptually, a supply-chain manages coordinated information and material flows, production operations, and logistics of the e-marketplace. It provides the e-marketplace with flexibility and agility in responding to customer demand shifts without conflicts in resource utilization. The fundamental objective is to improve coordination within and between various participant business entities in the supply-chain. In an e-marketplace setting, supply-chain management can be viewed as a cooperative distributed problem-solving activity among a society or group formed by autonomous business entities that work together to solve a common problem (Smirnov & Chandra, 2000). The group is responsible for coordination throughout the supply chain, whereas each member provides specialized expert knowledge and product and process technology to the supply chain. The decision-making process is centralized for the group, but decentralized for the local decisions of each member.

Foundation Architecture for Integration

The architecture of the e-marketplace provides the foundation to integrate and leverage the participants' resources, such as applications and databases. Traditionally, the foundation technology that enables enterprises to connect resources together is known as *middleware*. Mainstream middleware solutions focus on integration at the data level. There are several commercial middleware products and standards, such as OMG CORBA™ (Object Management Group, Inc. 1995), J2EE™ (Java™ 2 Platform, Enterprise Edition), and .NET (which has superseded DCOM, the Distributed Component Object Model), that focus on providing infrastructure tools and frameworks of integration. Enterprise application integration (EAI) is a trend that has recently emerged in designing middleware technology with an objective to ease the burden and lower the costs of application integration. However, different EAI solutions are developed to accommodate different levels of integration requirements. Object-level integration provides synchronization of data between different applications or databases. Business process-level integration extends the object level by supporting multiple, distributed, and heterogeneous applications. Finally, cross-enterprise process-level integration involves multiple, distributed, heterogeneous business-process applications across different enterprises. While EAI solutions focus on technology-centered integration, other approaches focus on integration as an architectural aspect. One approach is a mediator-based architecture (Wiederhold, 1992), which comprises a layer of "intelligent" middleware services to link data resources and applications, such as integrating data from multiple sources in a way that is effective for the client application. Another approach is the facilitator (Genesereth, 1992), in which integration is based on the principle that any system (software or hardware) can interoperate with any other system without the intervention of human users or their developers. This level of automation depends on supporting ontologies to describe the resources. Facilitators use meta-level information in converting, translating, or routing of data and information.

FUTURE TRENDS: AGENT-ORIENTED E-MARKETPLACE

The development of an architecture for an e-marketplace requires a new design paradigm, improved integration architectures, and services. In this architecture, the e-marketplace is a cooperative distributed system composed of economically motivated software agents that interact cooperatively or competitively, find and process information, and disseminate it to humans and to other agents. The architecture also supports common economic services and commerce transactions, such as pricing, negotiation, and automated supply chains, as well as cross-enterprise integration and cooperation.

Fundamentally, integration can be viewed as an abstraction level at which a distributed system environment can be described as a collective coherent universe of cooperative entities. In a cooperative distributed system, integration is captured at the foundation architecture that supports all the entities' individual architectures, and therefore, the complete computing environ-

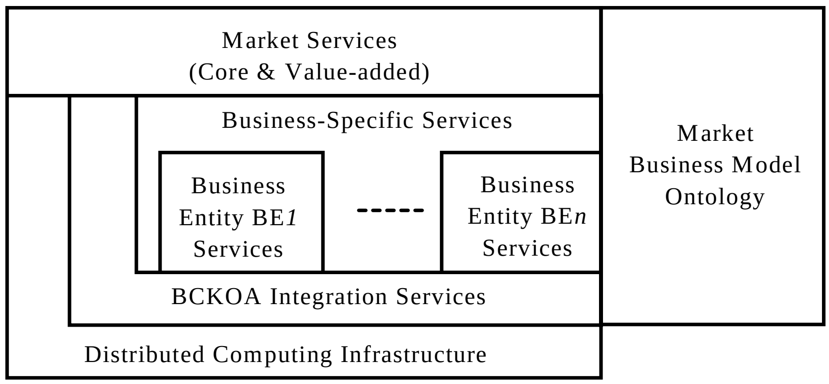
(a) Abstraction layers for *e-marketplace*



(b) BCKOA-based *e-marketplace*

ment. Here we describe a business-centric knowledge-oriented architecture (BCKOA) for cooperative distributed systems. The main elements of BCKOA include domain services, integration services, and a domain ontology. Furthermore, BCKOA provides three families of integration services: ontology and semantic integration services, coordination and cooperation services, and wrapping services. Based on our premise that an e-marketplace is a coherent service-oriented universe, the BCKOA-based e-marketplace is shown in Figure 1(b), which builds upon the abstraction architecture of the e-marketplace in Figure 1(a) (Ghenniwa, 2001).

All services (business, market, and integration) in a BCKOA-based e-marketplace usually involve complex and non-deterministic interactions, often producing results that are ambiguous and incomplete. Auctions and *ad hoc* service integrations are some examples. In addition, the dynamic nature of the environment requires that the components of the system be able to change their configuration to participate in different, often simultaneous roles in e-marketplaces. These requirements could not be accomplished easily using traditional ways of manually configuring software. For this domain, we strongly believe that agent-orientation is a very promising design paradigm for integration. In fact, such a paradigm is essential to model an open environment such as an e-marketplace, especially considering the multiple dynamic and simultaneous roles a single business entity may need to participate in, given e-marketplace sessions.

Agent technology provides the next step in the evolution of paradigms for computational modeling, programming methodology, and software engineering (Huhns, 2001, 2003). The first principle of agenthood is that an agent should be able to operate as a part of a community of cooperative distributed systems, including human users. In our view, an agent model such as Coordinated Intelligent and Rational, Agent (CIR-Agent) (Ghenniwa, & Kamel, 2000) can be described as an individual collection of primitive components that provide a focused and cohesive set of capabilities. In the context of a BCKOA-based e-marketplace, an agent has a role that is related to a specific service category and is able to coordinate, cooperatively or competitively, with the other agents, including humans. An agent's role can be categorized as user-interface, business-specific service, business-entity service, market service, or integration service.

User interface agents play an important and interesting role in many applications. The main functionality of user interface agents is to support and collaborate with users in the same work environment to achieve the users' goals.

Business-specific service agents are specialists that provide a collection of business services available in the e-marketplace. Performing the functionality of a business service is typically the cooperative integration of several agents, including business-entity agents and market service agents.

A business-entity service agent may be a representative in the e-marketplace for some functionality that is based on legacy applications or libraries, such as a product catalog Web site. Market service agents are specialists that provide a collection of functions for the generic e-business in an e-marketplace environment in which a single entity (usually an agent) can perform its tasks in the e-marketplace.

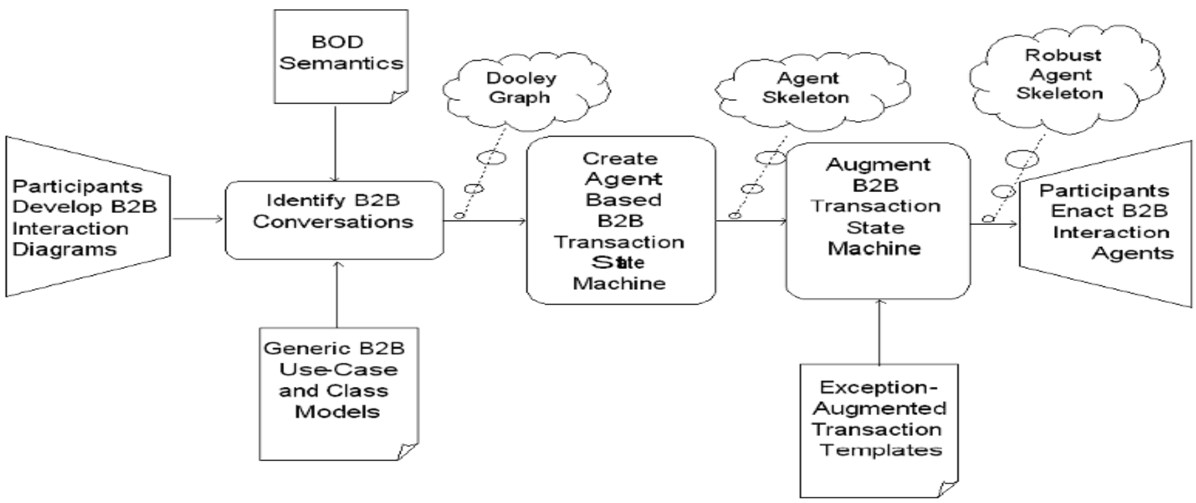
Market service agents are horizontal, in the sense that they are used in several business domains by several business entities. Examples of core services are dynamic trading services, such as commodity market and Vickery auctions (Wellman, 1993; Varian, 1995), and supply-chain integration and management. The commodity market service governs the trading behavior of the participant business entities in the session. This service recognizes three types of agents, namely, market-mediators, consumers, and suppliers. Consumers and suppliers are roles assigned to agents of type business-entity service or user interface. These roles are assigned upon registration with the market session. Each market session is assigned to a mediator to coordinate the actions taken by consumers and suppliers in a way that will eventually clear its respective market. An alternative market session is the auction market. It recognizes three types of agents, representing suppliers, an auctioneer, and buyers. However, the trading process mainly involves the auctioneer and buyers (or bidders). Each bidder agent declares its valuation function to the auctioneer. Under the general Vickery mechanism, it is in the interest (the dominant strategy) of the bidder to report its true valuation function.

Agent-based supply-chain integration and management, in an e-marketplace, is a cooperative distributed problem-solving service. Using this service, business participants need only describe their supply processes using OAG standard business documents and UML interaction diagrams. The methodology, summarized in Figure 2, uses—and begins to formalize—the business object documents (BODs) that OAG and RosettaNet are standardizing. It provides a basis for the convergence of multiple standards for supply-chain management, which could become ready-to-use technology by different participant business entities in the e-marketplace.

Integration agents are specialists that provide a collection of integration functions for a cooperative distributed system in which a single entity (agent, component, object, etc.) can perform its tasks. Integration services are used by several distributed entities.

To validate and experiment with our analyses and foundations described in the previous sections, we have developed a prototype of an agent-oriented BCKOA for an e-marketplace with virtual business entities. They register with the e-marketplace for both purchase and sales services. Both services use a BCKOA-based computation environment. Individual customers or business-entity personnel in the e-marketplace can participate in the market through their user interface agents. Similarly, an agent in the e-marketplace represents each business-entity service. These agents provide thin, intelligent, autonomous interfaces for the business-entity services, which might be based on legacy applications. The implementation utilizes the JADE platform (Bellifemine, Poggi & Rimassa, 1999), which is a software framework to develop agent applications in compliance with the FIPA specifications (The Foundation for Intelligent Physical

Figure 2. Agent-based coordination methodology for B2B automation



Agents, 1998) for multi-agent systems. Although our implementation takes advantage of the JADE platform and FIPA specifications, the architecture of the economic market structure and the application agents is based on the CIR-Agent model and BCKOA.

CONCLUSION AND FUTURE WORK

This article presented state-of-the-art research on developing an agent-oriented architecture for an e-marketplace that provides intelligent enterprise integration. The objective is to establish an engineering foundation for an e-marketplace. To this end, several business and design issues have been discussed and analyzed for e-marketplaces. This article has emphasized an agent-based business-centric and knowledge-oriented approach. An agent-oriented architecture provides an abstraction of the domain entities and applications independent of any specific technology. An e-marketplace supports several types of agents, namely, user-interfaces, business-specific services, market services, and integration services. In continuing the research, our main concern will be investigating the computational effectiveness of agent-oriented e-marketplaces, as well as exploring the appropriate techniques to support secure, reliable, and effective transactions.

KEY TERMS

Agent Orientation: The next step in the evolution of computational modeling, programming methodologies, and software engineering paradigms. Aspects of agent orientation include both cooperative and competitive interactions, knowledge, economic and logical rationality, and learning, all of which are useful for designing distributed computations in open dynamic environments.

Auction-Based Market: A form of centralized facility or clearinghouse by which consumers and suppliers execute trades in an open and competitive bidding process.

Commodity-Based Market: A form of a market in which various suppliers and consumers participate to trade goods and services, i.e., commodities, of the same type. The market price is publicly agreed upon for each commodity independent of any particular supplier. All consumers and suppliers decide whether and how much to buy or sell at each agreed-upon price.

E-Business: The use of the Internet along with other electronic means and technologies to conduct within-business, business-to-consumer, business-to-business, and business-to-government interactions.

E-Marketplace: An electronic marketplace. It is a business model for a particular kind of e-business, which aggregates potentially large numbers of business partners (including buyers, sellers, and intermediaries) and allows them to interact according to a variety of market structures, such as a commodity market, an auction, or an exchange. The result can be significant cost savings.

Enterprise Integration: Refers to the plans, methods, and tools aimed at modernizing, consolidating, and coordinating software applications among a group of businesses or organizations that interact as consumers and suppliers. Enterprise integration might involve developing a total view of the organizations' businesses and applications, seeing how existing applications fit into the new model, and then devising ways to efficiently reuse what already exists while adding new applications and data. Enterprise integration is done for the mutual benefit of all organizations involved.

Market Structure: Governs the trading process and defines the formal rules for market access, traders' interactions, price determination, and trade generations.

Ontology: A representation of knowledge specific to some universe(s) of discourse. It is an agreement about a shared conceptualization, which includes conceptual frameworks for modeling domain knowledge and agreements about the representation of particular domain theories.

Supply-Chain Management: All services that help an enterprise manage its procuring, purchasing, warehousing, distributing, consuming, and monitoring of the supplies it utilizes in its operation. These services enable management to receive the information needed for making decisions along the chain, from acquiring raw materials to manufacturing products to distributing finished goods to retailers. The services consist of consulting, project design, compliance reporting, deployment of resources, and product qualification along the entire chain.

Measurement Issues in Decision Support Systems

William K. Holstein
The College of William and Mary, USA
The Graduate School of Business Administration-Zurich, Switzerland

Jakov Crnkovic
University at Albany, State University of New York, USA

INTRODUCTION

The past decade has seen tremendous progress in systems for information support-flexible and adaptable systems to support decision makers and to accommodate individual needs and preferences. These model- or data-driven or hybrid systems incorporate diverse data drawn from many different internal and external sources. Increasingly, these sources include sophisticated enterprise resource planning systems, data warehouses, and other enterprise-wide systems that contain vast amounts of data and permit relatively easy access to that data by a wide variety of users at many different levels of the organization. Decision support and decision support systems (DSS) have entered our lexicon and are now common topics of discussion and development in large, and even in medium-sized, enterprises. Now that DSS is well established, attention is turning to measurement and the metrics that populate such systems.

BACKGROUND

Decision making as we know it today, supported by computers and vast information systems, is a relatively recent phenomenon. But the concept has been around long enough to permit the methods and theories of decision making to blossom into "a plethora of paradigms, research schools, and competing theories and methods actively argued by thousands of scientists and decision makers worldwide" (Robins, 2003).

Early computer systems focused primarily on accounting and financial data. It is said that information systems are about transforming data. We could say that early systems transformed data into aggregated or summarized data-for example, wage rates, hours worked, benefits and tax data, and so forth, transformed into departmental or corporate payroll reports.

In the mid-1960s, the development of the IBM System 360 and rapidly proliferating competitive systems from other vendors ushered in the era of management information systems (MIS). Applications quickly moved beyond finance and accounting data and into operations. Transaction processing systems began to generate order, usage, and customer data that could be analyzed with (what quickly became quite sophisticated) models. The transformation of data into information became commonplace. For example, data on sales and usage, costs, supplier lead times, and associated uncertainties were transformed into reorder points, safety stocks, and comprehensive inventory management and production scheduling systems.

Despite the broader reach of MIS, such systems are characterized by highly structured, infrequent reports, often with standard formatting. Frequently, because it was 'easier' (for the IT staff), each manager in a given function (e.g., marketing) received the same voluminous report-even though a manager of activities in Japan could not care less about data relating to New Jersey. Despite the tremendous advance of MIS over previous-generation systems, contemporary MIS systems draw most of their data from enterprise resource planning (ERP) systems that contain mostly internal data on transactions, and therefore suffer from many of the same problems as older systems (an internal, historical, and financial focus).

DSS "evolved from the theoretical studies of organizational decision making done at the Carnegie Institute of Technology during the late 1950s and early '60s and the technical work on interactive computer systems, mainly carried out at the Massachusetts Institute of Technology in the 1960s" (Keen & Scott Morton, 1978; Power, 2003). By the end of the 1970s, it was clear that model-based decision support had become a practical, useful tool for managers.

A 1970 article by John Little of MIT clarified the concept of decision support (Little, 1970). In a 1979 paper he provided a definition that is paraphrased here:

"…a coordinated collection of data, systems, tools, and techniques along with requisite software and hardware, by which an organization gathers and interprets relevant

information from the business and environment and turns it into a basis for action." (Little, 1979)

Another useful definition of a DSS is:

"Decision support systems couple the intellectual resources of individuals with the capabilities of the computer to improve the quality of decisions. [They comprise] a computer-based system for management decision makers who deal with semi-structured problems." (Gorry & Scott Morton, 1989)

In these two definitions, we see some important concepts-gathering and interpreting relevant information (related to the decision at hand, not just to transactions), using the intellectual resources of managers, and providing information that can be used as the basis for action. The 'new idea' here was that managers need more than information, they need decision support. If provided with good data, and models and tools to transform the data into useful information, their effectiveness will improve.

METRICS OF BUSINESS AND MANAGEMENT PERFORMANCE

Decision support means supporting managers who are running the business. Increasingly, it refers to supporting middle-level managers who rely on a mix of internal and external data that is steadily tilting towards external data on customers, markets, competitors, and the political, regulatory, and economic environment. If we define the process of *control* as tasks undertaken by middle- and lower-level managers to *ensure that plans come true*, we see clearly the role of data and information in decision support: managers use data and convert it into information to *monitor* the implementation of plans to ensure that strategic goals are met. If the monitoring indicates that plans will not be fulfilled, corrective *action* must be taken *in time* to ensure that the plan is, in fact, met. If the information from a decision support system cannot serve as the basis for action (i.e., cannot first help the decision maker to decide to do something, and then help to decide what to do), the information will not be used and the system will therefore be useless.

The key words in the previous paragraph that lead to action are *monitoring* and *in time*. Monitoring is the management function that is the primary target for DSS implementation. Timeliness is crucial. Advance warning without enough time to steer around the iceberg, or to make the necessary changes to ensure that strategic plans are successful, is not the kind of decision support that managers seek.

As we think about supporting management decision making, we must think of how managers work at decision making. What they do is easy to describe (despite the fact that it is fiendishly difficult to do it): managers abhor irregularities and plans that do not come true, yet they thrive on exceptions. They look for things that don't fit, for things that look funny, for things that are out of line. Then they ask 'why?' Much of their time is spent trying to answer that simple question and searching for actions that will make perceived problems disappear and bring things back to 'normal expectations'. Examples of the 'whys' that plague managers of large companies include: Why can't Cadillac attract younger buyers? Why did the PC manufacturers who dominated the market in the 1990s lose so much share to Dell Computer? Why do practically none of the profits of the newly merged HP/Compaq come from PCs? Which of the newly merged HP/Compaq's 85,000 products should survive? (Abruptly killing off redundant products might scare customers and deflate revenues. But overlap is costly.)

For each of these questions, one can imagine a manager who is conjuring the question as a response to a perceived exception that needs to be 'fixed'. What Cadillac sales manager thinks that his/her product is not attractive to young buyers? What HP manager thinks that Dell's share should be where it is? What former Compaq manager thinks his/her product should be dropped?

We cite this process and these questions to focus clearly on metrics of business performance and management performance. Measurement and metrics are the tools for identifying exceptions. Exceptions, in turn, drive management to seek and find actions that will deal with the exceptions and achieve strategic goals. But think for a moment about traditional metrics. The Cadillac manager knows how to measure the average age of Cadillac buyers. But how does s/he measure the potential attractiveness to younger buyers of a proposed new model? Of a proposed advertising campaign? Of a proposed discount or rebate program? This is where judgment, experience, and intuition come into play-and these are precisely the areas where managers need decision support.

In the current environment, measurement must be related to business matters, business strategies and goals-the stuff that managers deal with in their everyday environment. They are trying to formulate and monitor plans that reflect the strategic mission and goals of the business, that is, accomplish strategic tasks. They need IT that can add value to the business in ways that they can clearly understand.

FUTURE TRENDS

Pulling together what we have stated thus far, we see a situation that precludes significant progress in the development and implementation of decision support systems unless:

- new metrics that focus more clearly on business and management performance are developed and implemented; and
- more attention is given to metrics that focus on monitoring strategic activities, or activities that will have an important effect on the outcomes of strategic initiatives and high-level company goals.

An early initiative in which MIT aimed to provide decision support to higher-level executives (Executive Information Systems or EIS) worked to include 'critical success factors' as the basis for metrics in information systems (Rockart, 1979; Rockart & Treacy, 1982). These systems were broader than DSS and provided a wide variety of information-critical success metrics (metrics for areas of activity in which results, if they are satisfactory, will ensure successful competitive performance for the organization, and which should receive constant and careful attention from management), key performance indicators, reports with the ability to drill down to underlying detail, budget information, plans and objectives, competitive information, news, and more. More recently, the Balanced Scorecard and other initiatives have made it clear that traditional MIS systems and business metrics rely too heavily on financial and accounting measures. Today, the issue of metrics is very active, with performance management systems, digital dashboards and cockpits, and scorecards to drive organizational performance measurement and management down to the individual level in order to support alignment with business strategies (Volonino & Watson, 1990-1991; Power, 2003).

Financial measures tend to be hard, historical, and internal, rather than soft (including judgmental data and estimates that, while 'inaccurate,' are vital to future planning), future oriented (and therefore, by definition, soft), and external (related to the customer, the market, and the environment). We see, therefore, that an important question in the future of metrics in decision support systems is not just *what* to measure, but *how* to measure, and in which areas of the business to seek meaningful metrics.

We turn now to implementation issues surrounding these ideas and suggest some guidelines for DSS development incorporating new metrics.

IMPLEMENTATION GUIDELINES

Breadth in Measurement

A first guideline, as we have discussed, is that breadth in measurement (beyond financial and accounting measures) is important. The ideas behind the Balanced Scorecard (Kaplan & Norton, 1992) should be understood and implemented in decision support systems. Breadth, however, does not imply complexity.

Consider the following quote-it may be true since it does not say "*only* three things"-and it fits the point here:

"The ability of companies to boost profits depends on three things: how high they can lift their prices, how much they can increase output per worker, and how fast wages are rising." (Mandel, 2002)

The ability to raise prices, often described as 'pricing power,' is related to many different metrics and measures. Some of these measures are financial, profitability of other divisions, products and services, and capital structure; but many are not, customer perception of the company's value proposition, features and benefits of products and services, embedded technology, total quality (not just product quality), competitive position in the marketplace, relationship with customers, suppliers, and workers. Increasing worker productivity involves similarly complex metrics.

Simplicity

A second guideline is simplicity. Metrics must be easy to understand and communicate. They must relate to relevant activities and tasks, and be 'drivable,' that is, managers must be able to use the measures to determine (drive) actions that will affect future results.

Selectivity

Our third suggestion relates to simplicity: DSS designers must avoid the impulse to measure everything. The focus must be only on the most important metrics from the user's (the decision maker's) point of view. Metrics should be built in hierarchies, with more details for lower-level managers, and fewer, more summarized measures for higher-level managers.

Research and Learning

Fourth, DSS design should emphasize data and data collection, not just for reporting, evaluation, and auditing, but for research and learning, for finding exceptions, for learning the root causes of exceptions, and for exploring alternative courses of remedial action. 'Research' is perhaps a strange term to use in the context of management practice, but research, in the best sense of the term (investigate, study, explore, delve into, examine) is required to find, first, meaningful measures of exceptions and then their causes.

Benchmarking

As a fifth guideline, we cannot overemphasize the importance of benchmarking against credible external targets. Indeed, without a firm connection to good external benchmarks (best practice, best-of-class indicators), companies can fall victim to *manumation*, simply automating old, outdated, manual processes. A formula for manumation has been around for years:

> OP + NT = EOP
> (**Old Processes** plus **New Technology** equals **Expensive Old Processes)**

Benchmark analysis can identify problems and suggest solutions, and can serve as an excellent idea bank for new metrics. Benchmarks or comparatives are important because metrics need anchor points for comparison. Without a benchmark for 'normal' or 'best in class', how can you gauge results?

Simple benchmarks might include your own past performance, current goals, customer expectations for things like order-to-delivery time, percentage defects, or on-time delivery. In particular, you should know how you compare to others in your industry and leaders in your functional area. Be sure to think carefully about which comparatives will lead to valid conclusions and sensible action.

In some industries and functions, there are a growing number of highly useful benchmarks from trade associations, consulting companies, and other organizations. An example of a widely used set of metrics is the Supply Chain Council's Supply Chain Operations Reference (SCOR) model (Supply-Chain Council, 2004). SCOR allows companies to objectively measure their supply chain practices and compare them against benchmark standards gathered from the more than 700 manufacturing and related companies that are members of the Supply Chain Council. The SCOR model groups supply chain functions into five process categories: Plan, Source, Make, Deliver, and Return. Metrics at each level of the model are supported by progressively more detailed metrics for processes at lower levels.

The following quote highlights the importance of metrics to support process change when new factors, such as Web-enabled processes, are introduced:

"Updating performance metrics for Web-enabled supply chain operations became important the day your company migrated from an information-only Web site to one with interactive customer capabilities. Whether you're tracking customer orders or collaborating with partners on products and processes, your new business dynamics likely don't fit the old criteria, and you may need to update your basic supply chain performance measurements to match an advanced level of attainable objectives." (Schultz, 2001)

Benchmarking is useful beyond performance measurement. It can help to answer the 'why?' when exceptions are identified. For example, is a manufacturer's frequent late delivery an inventory-level issue? Or is it caused by slow order-reaction-time on the part of one or more of the supply chain's participants? Benchmarking can help to target on the exact answer, which can then lead to needed adjustments.

Time

As a sixth and final guideline, we suggest careful consideration of collapsing time. Speeding up of business processes and reaction times has become almost a cliché, but time is the most important element in many new metrics to support decision making. Consider this example from the previously quoted article:

"If I said today that I need 30 percent more of something, how fast can my suppliers, and their component suppliers, deliver that? [Only] part of the answer is in manufacturing lead time. [The other, equally important] part is administrative lead times-getting the information, sharing it, and synchronizing it."

CONCLUSION

The previous quote deftly summarizes much of what we have discussed. We see a clear exception-the need to increase output by 30%, quickly-and the immediate following need to organize the required information internally, and then to communicate that information externally to suppliers and on to their suppliers.

The key element in the processes that are involved here is time, not cost. So, first, metrics to ensure that these process are working properly will be drawn largely from non-financial data.

Next, there is a pressing need to focus only on the most important, but not necessarily the most obvious issues, and to collect relevant data to support understanding of how the task will be accomplished. Much of the learning will be based on intensive communication, with suppliers and their suppliers, probably much of it Web based.

Previous benchmarking outside the organization with suppliers and processes would be highly valuable at this point-indicating who can perform and who cannot.

Summarizing our implementation guidelines for the development of metrics for decision support systems:

- Think beyond ROI and payback metrics for IT investments (Renkema, 2000); measurement for business and management performance is more important.
- Think beyond financial measures.
- Focus only on the most important, but not necessarily obvious issues, and collect relevant data to support exploration, analysis, and understanding.
- Benchmark outside the organization and build relevant knowledge to support change.
- Do it fast, and make it possible for users of the system to work quickly as well.

KEY TERMS

Actionable Information: Information that can be used as the basis for a decision, or for taking action, usually to change something.

Balanced Scorecard: An approach for measuring business and management results that goes well beyond financial metrics. Several ‘perspectives’ are suggested, e.g., financial, customer, internal processes, and learning and innovation (Kaplan & Norton, 1992).

Benchmark: A standard, usually from outside sources and usually representing the best or better-than-average performance against which an activity’s metric is compared. For example, world-class competitors have 35 defects per unit within the first six months; we have 85.

Decision Support System (DSS): Decision support systems couple the intellectual resources of individuals with the capabilities of the computer to improve the quality of decisions. They comprise a computer-based system for management decision makers who deal with semi-structured problems (Gorry & Scott Morton, 1989).

Hard Data: Historical, usually accurate, data, often from transaction processing systems.

Measurement: The process of determining values representing performance, or the results of the process. For example, the measurement process is now started, or the measurement was 35 days.

Metric: A predetermined measure that will be used as the basis for a measurement process. For example, percentage of customer calls answered within one minute.

Soft Data: Judgmental, qualitative data, often from external sources. Any data involving the future.

Measuring Collaboration in Online Communication

Albert L. Ingram
Kent State University, USA

INTRODUCTION

Collaboration has become a key concept in the workplace, in research laboratories, and in educational settings. Companies want members of different departments located far apart to work together. Various government agencies try to establish collaborative relationships with private organizations. Academics and corporate researchers collaborate with far-flung colleagues to produce new knowledge. Students at all levels of our educational system are increasingly being asked to learn collaboratively. In addition, more work is being done online. Businesses communicate over the Internet, and increasing numbers of educational experiences are being delivered at a distance. Virtual high schools, traditional and for-profit distance education institutions, and colleges and universities are all among the current users of the Internet in education.

In all of these situations—educational and non-educational, face-to-face, and online—several questions need to be addressed. First, what is collaboration? The word is sometimes used as if everyone already understands what it means, but we can find a variety of different definitions in the literature. Second, when we form groups to collaborate, how do we know when they have done so? Is it possible to measure the extent to which collaboration has occurred in a given group and setting? Third, what actions and conditions enhance the collaboration that does take place? And finally, does collaboration work? That is, do groups that are more collaborative produce better results or learning than groups that are less collaborative?

This brief article will not attempt to answer all these questions, but it will concentrate on a specific issue: What methods can be used to determine whether, and how much, collaboration has occurred in online groups in various settings? We will explain our preferred definition of collaboration, based on previous research, and then discuss some of the implications of these ideas for online collaboration and for research into that issue.

BACKGROUND

Collaboration can be generally described in a variety of ways, but perhaps a typical definition is "working in a group of two or more to achieve a common goal" (McInnerney & Roberts, 2004, p. 205). Such a general definition, however, does not tell us how reliably to identify when collaboration has taken place or, assuming that there can be degrees of collaboration, how much of it is going on. To make such measurements, we need an operational definition of collaboration. Recently, Hathorn and Ingram (2002) proposed such a definition. They maintained that collaboration consists of at least three key ingredients: interdependence (Johnson, Johnson & Smith, 1998), a product that is achieved through genuine synthesis of information and contributions from all members (Kaye, 1992), and independence from a single leader (Laffey, Tupper, Musser & Wedman, 1998). In education, this would likely be independence from the class instructor. In other settings, it would mean relative independence from supervisors or others who might otherwise control the process too tightly.

Under this definition, collaboration contrasts sharply with what can be called a *cooperative* way of working. In this characterization, cooperation occurs when a group agrees to divide the work among them, with each taking part of the project. The final product, then, is the sum of separate contributions from each member, rather than being a true synthesis as in a good collaborative effort (Hathorn & Ingram, 2002; Ingram & Hathorn, 2004; Dillenbourg, Baker, Blaye & O'Malley, 1996).

Hathorn and Ingram (2002) operationalized their definition by looking at ways of measuring each of the three components of collaboration. Positive interdependence occurs when group members share information and test their ideas on one another. When individuals in a collaborative group work toward their common goal, they often achieve things that would not have been possible individually (Henri, 1992; Kaye, 1992). Synthesis occurs as the group attains new insights as a result of working together (Henri, 1992; Kaye, 1992). Finally, independence requires that the group function on its own without too much centralized direction (Laffey et al., 1998). Otherwise, it is a directed project, not a collaboration among equals.

MEASURING COLLABORATION

In the literature we can find a variety of ways to measure collaboration that have been used by teachers and researchers. In general, these break down into a few major categories: teacher or leader observations, student and participant self-ratings and self-reports, and quantitative analysis of discussion transcripts. Here we look briefly at each of these in turn.

Teacher/Leader Observations

Sometimes an instructor or a team leader can have a very good "feel" for how well a group is collaborating. By scrutinizing the team in action and examining the products that result from the group work, these observers can often tell who is participating fully and contributing to the results, and who is not. Frequently, however, teachers and others may assume that simply putting people into groups automatically results in high-quality collaborative work. This assumption is false: good collaboration requires many factors, and casual observations may not reveal what is really going on. In many cases, online collaborative groups can be easier to observe than face-to-face groups, because all the conversations may be recorded automatically, depending on the software and systems used.

Student and Participant Self-Ratings and Self-Reports

In many instances, members of groups may know how well they are working together. For instance, a frequent complaint of students doing group work for classes is the uneven distribution of the workload. Finding ways to get clear and reliable self-reports from students and other participants in collaborative groups can lead to better understanding of how the groups operate. There is a danger in this, however, because group members may not have a clear understanding of what it means to collaborate effectively. This is especially true if they have never experienced high-quality collaboration themselves. Many groups, especially in education, seem to prefer a "divide-and-conquer" cooperative strategy that appears to them to be collaborative. In fact, it lacks both the interactions and synthesis necessary for good collaboration, because each member of the group works on just part of the whole project. Therefore, in order both to increase the actual collaboration among group members and to improve the reliability and validity of the self-reporting, it is necessary to teach people the characteristics of good collaboration, how to recognize those characteristics, and how to produce them.

Quantitative Measures

Finally, we look at quantitative measurements of whether collaboration has occurred and of its extent. One approach was taken by Wilczenski, Bontrager, Ventrone, and Correra (2001). They measured the behaviors in a group that facilitated and detracted from the collaboration, under the assumption that groups with more facilitative behaviors would be more collaborative. The study showed that groups exhibiting more facilitative behaviors did better on several measures.

Hathorn and Ingram (2002; Ingram & Hathorn, 2004) also took a quantitative approach. Based on the definition of collaboration cited above, they developed measures of its three main components: interdependence, synthesis of contributions, and independence. Specifically, they applied these concepts to asynchronous threaded discussions, although the same ideas could be useful in other contexts as well (e.g., synchronous online chats). They relied on close and detailed content analysis of the discussions themselves (Silverman, 1993). Rourke, Anderson, Garrison, and Archer (2001) noted that a key step is to develop a way of coding the discussions to illuminate the questions one wants to answer. Hathorn and Ingram (2002; Ingram & Hathorn, 2004) developed such a system for the construct of collaboration, noting the inadequacy of many previous schemes for analyzing online collaboration specifically.

In order to use these measures, one needs complete transcripts of the discussions. Online textual discussions are especially useful in this regard since the transcripts are usually kept automatically in both synchronous and asynchronous discussions. Conceivably, the actual medium of communication could be instant messaging/chat, e-mail (including listservs), threaded discussion boards, or other text-based systems, as long as the technology can keep complete logs of the discussions. In Hathorn and Ingram's (2002) system, coding is based on "statements" made in the discussions. Statements are sentences or complete ideas within sentences that represent individual idea units. A single message can contain just one statement or numerous statements on a variety of topics. Indeed, a single sentence can contain multiple statements.

Interdependence is identified using several criteria. First, it requires roughly equal participation among all members. Without that, it is difficult to see how the members can be meaningfully interdependent. Participation is measured primarily by the number of messages and/or statements contributed by each group member. The count of statements is probably a more accurate measure of actual participation than number of messages, sentences, or words would be. It is unlikely in any group that the members participate exactly equally by any measure, so the requirement for good collaboration is that there be at least roughly equal participation. A simple test for this is a chi-square analysis on the participation of the group members. If the test shows significance, it is likely that the members were not participating equally enough for the group to be considered collaborative.

Beyond simple participation, we can measure interdependence by looking at interactions among the group members. In particular, Hathorn and Ingram (2002) focused on direct participation in the substantive discussion (as opposed to off-task comments and other such contributions). The patterns of discussion that indicate actual interaction are threads where different participants refer, explicitly or implicitly, to one another's comments. The minimum length of such a thread that would indicate true interaction is three statements: an initial comment, a response to that comment, and a synthesizing response. The more such threads (and longer ones) appear in a discussion, the more interaction there is and, all other things being equal, the more collaboration is taking place. A useful technique at this point is to diagram the discussion, using the statement as the unit. Each statement appears in a separate box, and lines connecting them show the patterns. It is important not to diagram the messages, because in our experience these do not reflect the substantive patterns that are revealed by the statement-level analysis.

Next, the question of synthesis arises. True collaborations result in products that cannot be identified as resulting from individual efforts. This can be measured in two ways. First, the patterns of interactions noted above include the necessity for synthesizing responses, so that was the first and more detailed measure of synthesis. The other measure focused on the final group product and whether it was written by an individual or the entire group.

Finally, independence from a central authority can be measured by examining both the basic participation of the group members in relation to the instructor and the number of interactions that take place without the instructor's or leader's participation.

Thus, in this quantitative view, the extent of collaboration is revealed by conducting a close content analysis based on the transcripts of the online discussions. Measuring the three elements of collaboration depends on several key pieces of data: overall participation based on the number of statements made by each individual, the types of statements they make (on-task, off-task, and others), and the patterns of interaction, represented especially by the basic unit of collaboration consisting of comment-response-synthesis. The nature of the actual product developed by the group is also important.

Measuring Collaboration in the Real World-An Example

Jim is project manager for a medium-sized information technology firm. His team is scattered around in several locations and needs to work together using a variety of different technologies. Specifically, his supervisor expects him to ensure that they are collaborating well in spite of the distance, the different time zones, and other obstacles. Naturally, the most important concern for Jim and his supervisor is the quality of the work. So far, this has been acceptable, but not outstanding. Jim thinks his team can do better if they learn to collaborate more effectively.

Being a systematic sort of person, Jim decides to approach the problem carefully. So far, simply exhorting the team to do better has not worked, so he wants to find out where they might be failing to collaborate well. To do that, he needs some data about their current efforts. One advantage he has is the fact that much of the work done by the team is online and text based; frequently there is an automatic record kept of the conversations that people have. For example, the team's private collaborative Web site includes a threaded discussion board where everyone can read all the messages and contribute to the conversation. In addition, all documents produced by the team are stored in the online repository in their space. Finally, there is the opportunity for synchronous chats among members while they are working on specific pieces of the project. Jim has decided to record and archive those chats for future use.

Jim's first step in deciding whether his team is collaborating productively is to scan the communications that they have made. At first glance, it looks as if they are all participating and making contributions, although he did not read everything in detail. He decides to try something else before he goes through that lengthy chore.

First, Jim sends an e-mail to everyone in the team asking them to assess the level of collaboration in the team and to e-mail him back by Friday. Very quickly he receives numerous questions about how he defines collaboration, what the request means, and so forth, so he decides to try another approach. This time, Jim does a little research about what is meant by collaboration and sends a more specific e-mail message to the group. Now, instead of asking a global question, he asks people to rate whether the members of the team participate roughly equally and respond well to one another, whether they synthesize each other's contributions, and whether they work independently of the leader. (That last one is tricky for team members, since Jim *is* the leader.)

This time, people are able to answer, and the responses are interesting. In general the team thought they were participating equally and responding to each other. They had mixed views on whether their resulting products were really the result of synthesizing ideas from many sources within the group. They all agreed (tongue in cheek?) that they could get along without Jim for most of their work.

Now Jim has a choice. Is the information he received from the group enough to make decisions about the direction he needs to take? One possibility is that he could arrange to train his team on collaborative techniques, especially using online technologies. Training can be expensive, though, and Jim does not relish taking people away from their jobs for the time it would take. If the team would benefit, then he believes it would be worth it. He is still not sure that they will (or will not) gain enough from such training.

Perhaps the self-reports of his team members are good enough for Jim to make the decision. If the stakes are high enough, however, Jim might want to look further. In that case a more detailed content analysis might pay off. His team members might overestimate the extent to which they respond to each other's message. Often an online discussion proceeds more as a series of monologues than as a true collaborative conversation. Sometimes what seems to be a synthesis of ideas is really one person dominating the group. Or perhaps the team is not as independent of Jim as they think. If Jim can pinpoint more specific problems with their collaborative skills, then it is more likely that he can arrange to have them trained in the relevant skills. In turn, that could lead to more tangible benefits from the collaborative team structure that he has developed than he is seeing now. He will not really know until he finds a way to measure the actual collaboration taking place.

FUTURE TRENDS

Online collaboration is likely to become even more important in the future for education, research, business, and other fields. In many of these areas, it will be important to ensure that groups working online are actually collaborating. Often in job settings working groups are composed of people with different knowledge and skill sets. If they do not truly collaborate, then their products (reports, designs, and other substantive materials) may be incomplete and substandard. In educational settings group work may produce high-quality learning outcomes primarily in groups that collaborate, rather than those using a less effective "divide-and-conquer" strategy in which group members learn only the pieces that they work on.

One indication of the trend toward more online collaboration is the increasing number of software packages aimed at improving the efficiency and effectiveness of online collaboration. For example, Groove *(www.groove.net)* is inexpensive peer-to-peer software designed specifically for small groups and containing a variety of tools beyond basic synchronous and asynchronous discussion capabilities. Convea *(www.convea.com)* is similarly inexpensive Web-based software designed for much the same purpose. Such packages are increasingly under scrutiny as collaborative tools (Ingram & Parker, 2003; Ingram, Pretti-Frontczak & Parker, 2003).

These trends mean that we need more and better ways to assess the presence, amount, and nature of online collaborative processes. Such measures will be useful in research, in education, and in practical application. Which measures are used depends on the questions being asked and on the purposes to which the assessment will be put. Some measures are extremely subjective and not firmly grounded in theory and previous research. Others may rely too heavily on the untutored impressions of participants. On the other hand, one drawback of a detailed quantitative approach such as the one we outlined here is the time it takes to complete. An approach being pursued by the present author and his colleagues is using the detailed research approach to develop better surveys of team members that will allow the identification of good and poor collaboration more quickly and efficiently. Such tools would have wide applicability.

CONCLUSION

This article has discussed several ways that collaboration in small online working groups might be measured. The need for such measurements seems clear: high-quality work in a variety of fields demands good collaboration. In turn, managers, researchers, educators, and others need to be able to identify the presences, amount, and nature of the collaboration that does or does not take place in different circumstances.

All of the measurement methods discussed here have strengths and drawbacks. Some are quick and easy to use but may give misleading results. Others are precise and based on some of the best research available, but demand significant effort and time to implement. One direction for future research and practice may be to develop measurement tools that are both accurate and quick.

KEY TERMS

Asynchronous Discussion: Online discussions that occur independent of time and space. Participants do not have to be online simultaneously, and can read and contribute to the conversation on their own schedules.

Collaboration: Occurs when small groups of people work together toward a common goal in ways that produce new products and knowledge that are unlikely to be developed by individuals. Three essential elements of collaboration are interdependence, synthesis, and independence.

Cooperation: Cooperative groups work together on group projects in ways that do not necessarily result in high-quality interaction, and new products and knowledge. A typical cooperative strategy is to divide up the work among the members and stitch the various contributions together at the end of the project.

Independence: The independence of a group from a central authority, such as an instructor or manager, ensures that the group can truly collaborate among themselves and produce results that are unique and new.

Interaction: Interaction among members of a group is necessary to produce collaboration. It can be measured by examining the give-and-take nature of the discussion threads.

Interdependence: Interdependence among members of a small group is a necessary element of collaboration. It means that group members could not produce the results they did without one another.

Participation: The most basic requirement of collaboration; it may be measured by the number of postings made and read or by the number of statements contributed to a discussion.

Synchronous Discussion: Occur when all participants are online and actively involved in the discussion at the same time.

Synthesis: Occurs when the final product of a group effort includes information and other elements from all members in such a way that individual contributions are difficult or impossible to identify.

Media and Personal Involvement in the Perceptions of Data Quality

Andrew Borchers
Kettering University, USA

INTRODUCTION

This article introduces the concepts of data quality as described in the literature and discusses research results on how individual perceptions of data quality are influenced by media (World Wide Web versus print) and personal involvement with the topic. A search of literature on "data quality" and "media creditability" reveals that researchers in both the information systems and journalism fields have explored this topic. While these threads have developed separately, these streams of research approach similar issues of how people view the quality of information they receive from different sources.

This topic is important in that the Internet revolution has fundamentally changed how people share information. But with such access comes a challenge as stated by Gilster (as cited in Flanagin & Metzger, 2000): "When is a globe spanning information network dangerous? When people make too many assumptions about what they find on it. For while the Internet offers myriad opportunities for learning, an unconsidered view of its contents can be misleading and deceptive."

The importance of this topic is underscored by recent research and seminars on the topic of data quality on the Web. A 2003 conference in Wadern, Germany, for example, brought researchers together to discuss topics such as "criteria and measurement for quality of Web data, representation and exchange of quality information and usage and maintenance of data quality in Web querying and data integration". The conference included working groups that focused on quality assessment, trust, data integration, and metadata (*http://www.dagstuhl.de/03362/*).

BACKGROUND

The importance of data quality has been echoed among information systems and journalism practitioners for many years. Research by Redman (1998) summarizes the practical implications of poor data quality. He points out the consequences of poor data quality in areas such as decision-making, organizational trust, strategic planning and implementation, and customer satisfaction. Redman conducted detailed studies and found increased cost of 8-12% due to poor data quality. Service organizations can find increased expenses of 40-60% (Redman, 1998). Strong, Lee, Yang, and Wang (1997) support the seriousness of this issue in their study of 42 data quality projects in three organizations. Research by other authors note data quality issues in a number of settings including accounting (Xu, 2000; Kaplan, Krishnan, Padman, & Peters, 1998), airlines, health care (Strong et al., 1997), criminal justice (Laudon, 1986) and data warehousing (Ballou, 1999).

As for a formal definition of data quality, Umar, Karabatis, Ness, Horowitz, and Elmagardmid (1999) quote Redman (1998):

A product, service, or datum X is of higher quality than product, service, or datum Y if X meets customer needs better than Y.

Umar et al. (1999) go on to point out that this definition has been generally accepted and is consistent with author's work. The definition is somewhat incomplete, however, as it does not delve into the various dimensions of data quality.

A number of authors in the information systems field have gone further than Redman and written conceptual articles on "data quality" (Wand & Wang, 1996; Wang, Reddy, & Kon, 1995; Wang & Strong, 1996; Strong et al., 1997). This work suggests that data quality is a multidimensional concept (Wand et al., 1996) that can be viewed from a number of different perspectives. A panel discussion in 2000 (Lee, Bowen, Funk, Jarke, Madnick and Wand) found five different perspectives to discuss data quality. These included an ontological perspective (specification of a conceptualization) that include different views of reality based on actual observation versus computer influenced observations, architectural perspective (a view that focuses on system infrastructure and its influence on data quality), context mediation perspective (focusing on communication across space and time), time-based e-commerce perspective (focusing on the real-time nature of e-commerce) and an information product perspective (focused on data as a product of an organization).

In talking about "data quality", a key beginning is to determine from the literature just what is meant by the term. In a definitive work on the topic, Wang et al. (1996) provides a conceptual framework for data quality. In a way consistent with Redman's customer perspective, they start by defining "high-quality data as data that is fit for use by data consumers". Using a two-stage survey and sorting process, Wang develops a hierarchical framework for data quality that includes four major areas: intrinsic, contextual, representational, and accessibility.

Intrinsic data quality refers to the concept that "data have quality in their own right" (Wang et al., 1996). Intrinsic dimensions include accuracy, objectivity, believability, and reputation. Contextual data quality is based on the idea that data does not exist in a vacuum – it is driven by context. Contextual dimensions include relevancy, timeliness and appropriate amount of data. Representational data quality relates to the "format of the data (concise and consistent representation) and meaning of data (interpretability and ease of understanding)". Accessibility refers to the ease with which one can get to data (Wang et al., 1996).

Beyond the information systems literature, there is a second relevant body of literature that comes from the journalism field. Their focus is on perceptions of Internet credibility (Flanagin & Metzger, 2000; Johnson & Kaye, 1998). The major thrust of this literature is in comparing the Internet to traditional sources with respect to credibility. Note that when referring to "credibility", these authors say "the most consistent dimension of media credibility is believability, but accuracy, trustworthiness, bias and completeness of information are other dimensions commonly used by researchers." (Flanagin et al., 2000, p. 521). Hence, there is a rough correspondence of thinking about "credibility" in the journalism literature to the concept of "intrinsic" and "contextual" data quality in the information systems literature.

COMPARISON OF RESEARCH FINDINGS

Research on data quality and media differences has been undertaken by a number of scholars over the years. In this section, the author will focus on work by Klein (1999, 2001), Flanagin et al. (2000) and Borchers (2003). All of these authors have examined data quality in a similar way, focusing on perceived differences based on media (print versus Internet). In addition, Flanagin et al. (2000) examine whether Internet users verify what they find. Borchers (2003) extends the discussion by examining the effect of personal involvement in the topic.

Klein (1999, 2001) has studied perceptions of data quality by surveying a sample of approximately 70 graduate business students conducting class projects. In one early study, Klein (1999) found Web-based material to be more timely, but less believable and of lower reputation, accuracy and objectivity than printed material. In a more formal result, Klein (2001) found traditional text sources to be perceived as more accurate, objective and to have higher reputation and representational consistency. Internet sources were found to be stronger in timeliness and appropriate amount.

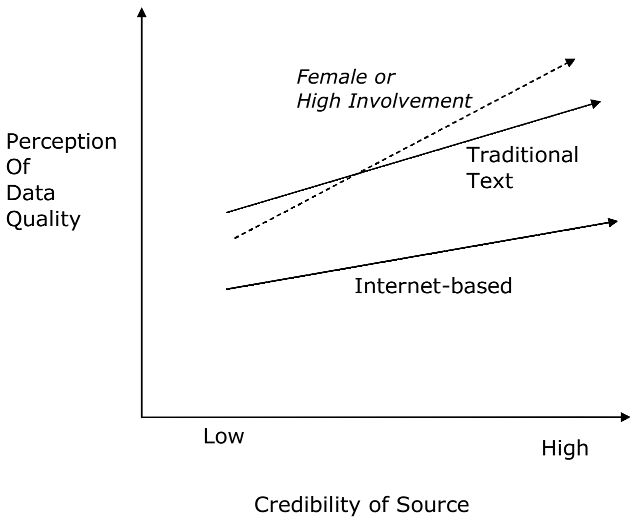
Flanagin et al.'s work (2000) focuses in three areas. First, they look at the perceived credibility of television, newspapers, radio and magazines compared to the Internet. The major finding, unlike Klein, is that there is little difference in credibility between media. Second, Flanagin et al. look at the extent to which Internet users verify what they receive. Here, they find that few Web users verify the information they receive. Those with limited Internet experience verify less than those with more experience. Third, and most important to this discussion, Flanagin et al. look at whether perceived credibility varies depending on the type of information being sought. Flanagin et al. cite Gunther in suggesting that "greater involvement with the message results in, first, a wider latitude of rejection."

Borchers (2003) considered the literature cited previously and examined a number of interesting questions. In keeping with Klein and Flanagin et al., he examined how people perceive Web-based material compared to printed material considering dimensions such as "timely", "believable", "reputation", "accuracy", or "objectivity". Second, Borchers studied whether individuals with personal involvement in a topic (e.g., cancer) are better discriminators of data quality than those who are not involved with a topic. Finally, given their role as health care acquirers (Bates & Gawande, 2000; Looker & Stichler, 2001), Borchers explores whether women are better discriminators of data quality than men on health related topics such as cancer.

Figure 1 demonstrates what Borchers hope to find. H0, his initial hypothesis, is that the perception of low creditable sources is significantly less than high creditable sources. Hence, the two lines for Internet-based and print-based text should have a positive slope. H1 suggests a significant gap between the lines for Internet-based sources and text-based sources on the timeliness, believability, reputation, accuracy, and objectivity dimensions. This assertion was based on prior literature by Klein (1999). H2 suggests that the slope of the lines should vary based on one's personal involvement in cancer. This is to say, that persons with high personal involvement in cancer should be better discriminators of data quality. Finally, H3 suggests that women are better able to differentiate credible from non-credible sources. Hence, the slope of the lines should vary based on gender.

Borchers studied 127 subjects on their perception of information on cancer based on exposure to Internet and print media. Subjects were drawn from mid-career students in MBA and MSIS classes at a Midwestern univer-

Figure 1. Research design (Borchers, 2003)



sity. His sample was strongly multi-cultural with significant U.S., Indian and Chinese representation. Subjects were randomly assigned to one of four groups.

These four groups were shown cancer information based on two sources of information presented in two different formats. One source was a Website of a highly credible national cancer organization. The second source of cancer information was a Website of low creditability, a site that touted alternative medical treatments. The third and fourth sources were identical to the first two with the exception that they were presented in printed form by way of a color document. Subjects were then asked about their perceptions of the data that they have viewed using Wang's intrinsic data quality dimensions (accuracy, objectivity, believability, and reputation) as well as contextual dimensions (timeliness, relevancy and appropriate amount of information) and ease of use. Further, subjects were asked about their personal and family experience with cancer as well as demographic questions (gender, age and country of birth).

After the data was collected, Borchers tested the dimensions using Cronbach alpha to be sure they were reliable. Each dimension had a value of .8 or higher. Second, Borchers generated a second set of statistics using a univariate ANOVA procedure to test each of the research hypotheses. H0 was tested for all eight measured data quality dimensions using the source reputation (high or low) and media (print or WWW) as fixed factors. In testing H2 and H3 cancer involvement or gender were added as random factors. The hypotheses were tested by looking at the product term for source reputation and cancer involvement (H2) or Gender (H3). Table 1 below summarizes Borchers' findings:

With respect to H0, Borchers found that his experimental design worked reasonably well. Subjects could easily discriminate between the low and high credible sources. In comparing Internet to print sources (H1), Borchers observed no difference. In examining personal involvement (H2), Borchers found that believability and reputation were impacted by personal involvement, but only for a subset of respondents. Borchers did not support the gender hypothesis (H3).

FUTURE TRENDS

Future work should be done to extend the work of Klein, Borchers and Flanagin et al. First, methodological issues need to be addressed. Instrumentation in particular is a major concern. How can researchers more accurately measure people's perception of data quality and personal involvement in a topic? Studies should also be conducted among participants other than college students. Experimental designs such as Borchers' can be extended to more precisely test hypotheses. Second, existing work focuses on print and the Internet (especially the WWW) as media. Further research could follow Flanagin et al.'s work in other media, such as TV and radio, or emerging media. Third, tests of personal involvement could be extended to topics other than cancer. The concept of "personal involvement" needs to be developed, perhaps turning to the marketing literature for a base. Finally, as the general population becomes more computer literate and Internet savvy, researchers may find that perceptions of data quality between different media converge (or perhaps diverge).

It should be noted that there are differences in research approach between these authors' work and that each work has methodological weaknesses that can be addressed in future research. For example, in Flanagin et al.'s and Klein's work subjects were asked to complete a one shot survey that asked about their perceptions in general of credibility of Internet and print sources. In Borchers' work subjects were randomly placed in groups that saw exactly the same material in both Internet and text formats. In his study, however, cultural differences among subjects confounded the analysis. All three researchers use college students as a primary source of respondents, an obvious weakness. Each of these authors also uses surveys as a data collection technique, a potential weakness.

Having noted these limitations and future areas of work, this line of research is important for several reasons. First, the Internet has become a de facto standard source of information for younger generations. Their perceptions of data quality, particularly compared to print, are a key factor in understanding how people will interpret what they see. Second, the question of personal involvement raises important concerns – do people become more

Table 1. Hypothesis testing results (Borchers, 2003)

Hypothesis	Dimension	F ratio	Significance
H0 – Initial difference due to reputation	Believable, accuracy, reputation, objectivity, and appropriate amount	10.526 to 24.489	.000 to .002
H0 – Initial difference due to reputation	Timeliness, relevance, ease of use	< 1.4	> .35
H1 – WWW compared to print	Timeliness Believable Reputation Accuracy Objectivity Appropriate amount Relevance Ease of use	2.587 1.036 .340 .483 1.132 .617 .030 .620	.110 .311 .561 .489 .290 .484 .865 .484
H2 – Personal involvement with cancer	Timeliness Believable Reputation Accuracy Objectivity Appropriate amount Relevance Ease of use	With all respondents F ratio < 4 US only respondents had significant interaction on believability and reputation	With all respondents F > .05 US only respondents were significant on believability and reputation
H3 – Gender	Believable Accuracy Reputation Objectivity Appropriate amount Relevance Ease of use	All < 4	All > .05

discriminating in evaluating data quality on topics that have significant influence to their lives? Finally, verification (as described by Flanagin et al.) is yet another interesting topic. To what extent do people verify what they read on the Internet or in print? Future research should address these and other areas.

CONCLUSION

The work of these three researches (Klein, 1999, 2001; Flanagin et al., 2000; Borchers 2003) seeks to understand how perceived data quality is affected by different media. Flanagin et al.'s work extends the discussion to verification of information. Borchers extends the case to include personal involvement.

Do people perceive data quality differently depending on the media that data is presented in? Flanagin et al. (2000) and Borchers (2003) suggest that media is not a significant factor. This comes in contrast to Klein's work (1999, 2001) which suggested a difference in perceived data quality on five dimensions: accuracy, objectivity, reputation, timeliness, and appropriate amount.

Do Internet users verify what they see on the Internet? Flanagin et al.'s work suggests that relatively few do so, and among inexperienced users even fewer verify what they find. This finding should be particularly distressing to academics and practitioners concerned with delivering high quality data. Will students be able to discern data quality in the myriad of Web resources available to them?

Do people become more discriminating of data quality for topics that they are personally involved in? Borchers' study provides a first look, at least for cancer information, and finds only limited support for this notion. Finally, does gender play a role in one's ability to discriminate between reputable and non-reputable sources of cancer information? Borchers' work would suggest that this is not so.

Data quality is an important topic that deserves continued research focus. The Internet revolution has fundamentally changed how people share information. How people perceive the quality of the information they view is an essential research topic for the information systems field.

KEY TERMS

Accessibility Data Quality: An aspect of data quality that refers to the ease with which one can get to data.

Contextual Data Quality: A concept that data does not exist in a vacuum, it is driven by the circumstance in which data is used. Contextual dimensions include relevancy, timeliness and appropriate amount of data.

Data Quality: A multi-faceted concept in information systems research that focuses on the fitness for use of data by consumers. Data quality can be viewed in four categories: intrinsic (accuracy, objectivity, believability and reputation), contextual (relevancy, timeliness and appropriate amount of data), representational (format of the data) and accessibility (ease of access).

Internet Credibility: A multi-faceted concept in journalism research that consists of believability, accuracy, trustworthiness and bias.

Intrinsic Data Quality: A concept that "data have quality in their own right" (Wang & Strong, 1996) including accuracy, objectivity, believability and reputation dimensions.

Representational Data Quality: A concept that data quality is related to the "format of the data (concise and consistent representation) and meaning of data (interpretability and ease of understanding)" (Wang & Strong, 1996).

MESH Object-Oriented Hypermedia Framework

Wilfried Lemahieu
Katholieke Universiteit Leuven, Belgium

INTRODUCTION

Hypermedia systems represent data as a network of nodes, interconnected by links. The information embodied within the nodes can be accessed by means of navigation along the links, whereby a user's current position in the information space determines which information can be accessed in the next navigation step. This property of navigational data access raises hypermedia systems as utterly suitable to support user-driven exploration and learning. The user autonomously determines the way in which he or she will delve into the information, instead of being confined to the rigid "linear" structure of, for example, pages in a book.

Although the World Wide Web contributed tremendously to the popularity of the hypermedia paradigm, it also amply illustrated its two primary weaknesses: the problem of user disorientation and the difficulty of maintaining the hyperbase. Indeed, whereas non-linear navigation is a very powerful concept in allowing the end user to choose his or her own strategy in discovering an information space, the resulting navigational freedom may easily lead to cognitive overhead and disorientation. The latter is called the "lost in hyperspace" phenomenon. The user becomes unable to assess his or her current position and sort out his/her navigational options. Equally stringent is the maintenance problem. Due to the absence of workable abstractions, many hypermedia systems implement links as direct references to the target node's physical location (e.g., the URL in a Web environment). To make things worse, these references are embedded within the content of a link's source node. As a result, hyperbase maintenance becomes a synonym for manually editing the nodes' content. Moreover, the inability to enforce integrity constraints and submit the network structure to consistency and completeness checks results in a hyperbase with plenty of dangling links. Needless to say that the consequences of inferior maintenance will also frustrate the end user and effect additional orientation problems.

BACKGROUND: A STRUCTURED APPROACH TO HYPERMEDIA AUTHORING AND NAVIGATION

This article introduces the *MESH* hypermedia framework, an acronym for ***M**aintainable*, ***E**nd user friendly*, ***S**tructured*, ***H**ypermedia*. So as to improve maintainability and facilitate end-user orientation, a structured approach is taken towards both authoring and navigation. MESH's fundaments are a solid underlying data model and a context-based navigation paradigm.

The benefits of data modeling abstractions to both orientation and maintainability were already acknowledged in Halasz (1988). They yield richer domain knowledge specifications and more expressive querying. Typed nodes and links offer increased consistency in both node layout and link structure (Knopik & Bapat, 1994). Higher-order information units and perceivable equivalencies (both on a conceptual and a layout level) greatly improve orientation (Thüring et al., 1995). Moreover, the separation of node content from data structure, along with the introduction of a dedicated link storage facility, allows for improved maintainability (Garzotto et al., 1993). Semantic constraints and consistency can be enforced (Ashman et al., 1997), tool-based development is facilitated and reuse is encouraged (Nanard & Nanard, 1995).

Consequently, hypermedia design is to be based on a firm conceptual data model. The pioneering conceptual hypermedia modeling approaches such as HDM (Garzotto et al., 1993) and RMM (Isakowitz et al., 1998) were based on the entity-relationship paradigm. Object-oriented techniques were mainly applied in hypermedia engines to model functional behavior of an application's components, for example Microcosm (Davis et al., 1992) and Hyperform (Wiil & Leggett, 1997). Along with OOHDM (Rossi et al., 2000) and WebML (Ceri et al., 2000), MESH is the first approach where modeling of the application domain is fully accomplished through the object-oriented paradigm.

MESH couples general-purpose object-oriented modeling abstractions to proprietary hypermedia concepts to provide for a formal hypermedia data model. Moreover, its context-based navigation paradigm builds upon the data model to reconcile navigational freedom with nested, dynamically created guided tours, which are to provide a disoriented end user with sequential paths as guidance. This article presents the two elementary concepts behind MESH, its data model and the context-based navigation paradigm, and proposes an implementation framework. As this is only an overview, the discussion is kept very brief. A more elaborate description of the data model and navigation paradigm can be found in Lemahieu (2003) and Lemahieu (2002) respectively.

THE MESH HYPERMEDIA FRAMEWORK

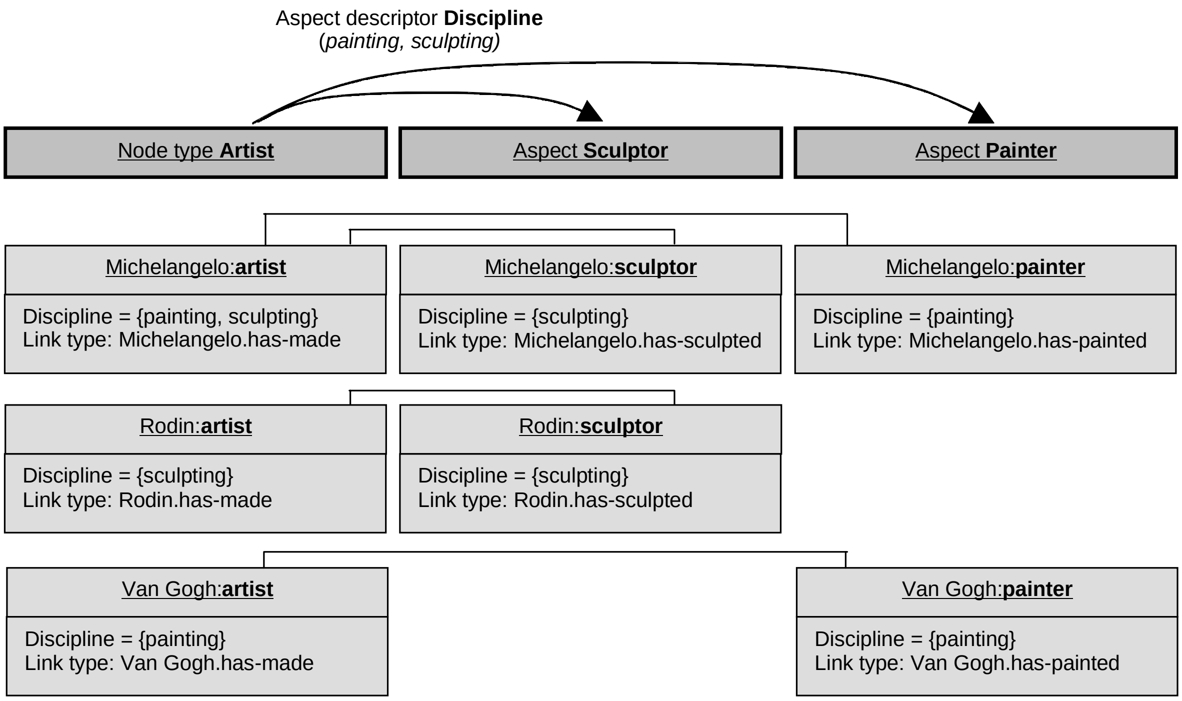
MESH's data model is looked upon as a hierarchy of node types. Each node is defined as an instance of exactly one "most specific type," which remains unchanged during the whole of the node's lifetime. All node types are assorted in an inheritance tree, each node type being compliant with the definition of its parent. Visual properties for a certain node type are abstracted in layout templates. These can be inherited and refined throughout the node type hierarchy. In this way, node instances representing similar real-world objects bear a similar, recognizable layout. In addition to the primary node classification criterion provided by the static node typing hierarchy, the aspect construct offers a means to attribute specific combinations of link and layout properties to certain sets of nodes. At run-time, a node's features can be altered by adding or removing aspects. As such, aspects provide secondary node classification criteria, which are independent of the node typing hierarchy and which, unlike a node's type, are allowed to be non-disjoint and variable over time.

So as to characterize node interaction, a node type is equipped with a set of link types. These classify the links according to the semantic interpretation of the relations they embody. Link type properties include domain, minimum cardinality, maximum cardinality and inverse link type. These can be seen as constraints imposed upon the respective links, in order to be feasible instances of their type. If a link type is inherited by a child node type, these constraints can be overridden, but may never be weaker than the ones imposed at the parent level. A final notable feature of MESH's data model is the concept of link subtyping. In common data modeling literature, subtyping is invariably applied to objects, never to object interrelations. However, in MESH, link types are full-fledged abstract types, which can be equally subject to subtyping. A child link type's instances are a subset of its parent's instances. It models a relation that is more specific than the one modeled by the parent, possibly reflected in more stringent constraints. Link types are deemed extremely important, as they not only enforce semantic constraints but also provide the key to context-based navigation.

An example is show in Figure 1: the node type artist has two aspects: sculptor and painter, denoted by a special attribute (a so-called aspect descriptor) discipline. The node Michelangelo is an instance of artist. Moreover, it has both the values "sculpting" and "painting" for its discipline aspect descriptor; hence Michelangelo has two aspects: a painter aspect and a sculptor aspect. Each such aspect contains discipline-specific properties of the artist Michelangelo. The artist Rodin only has the value "sculpting" for discipline; hence he only has a sculptor aspect. Van Gogh only has a painter aspect. An artist is linked to his artwork in general through a has-made link type. A sculptor is linked to his sculptures through a has-sculpted link type. A painter is linked to his paintings through a has-painted link type. This is an example of link subtyping: both has-sculpted and has-painted are subtypes of has-made. Rodin and Van Gogh only have has-sculpted and respectively has-painted links. Michelangelo has both: the paintings made by Michelangelo, denoted as Michelangelo.has-painted, will be a subset of all of Michelangelo's artwork, denoted as Michelangelo.has-made. We can say that Michelangelo.has made is the union of Michelangelo.has-sculpted and Michelangelo.has-painted. Please refer to Lemahieu (2003) for more details.

The navigation paradigm as presented in MESH combines set-based navigation principles (Kappe, 1999) with the advantages of typed links and a structured data model. The typed links allow for a generalization of the guided tour construct. The latter is defined as a linear structure that eases the burden placed on the reader, hence reducing cognitive overhead and, consequently, disorientation. As opposed to conventional static guided tour implementations, MESH allows for guided tours to be generated at run-time, depending on the context of a user's navigation. Such context is derived from the type of previously followed links. The context-based navigation paradigm defines navigation in two orthogonal dimensions: on the one hand, navigation within the current tour yields linear access to nodes related to the user's current focus of interest. On the other hand, navigation orthogonal to a current tour, changing the context of the user's information requirements, offers the navigational freedom that is the trademark of hypertext systems. In addition, the typed links sustain the generation of very compact overviews and maps of complete navigation sessions. An example of such overview is provided in Figure 2. The latter represents multiple guided tours, nested in one another. The "outer" tour Paris.Museums consists of all museums in Paris. The "current node" in that tour, that is, the museum currently visited, is the

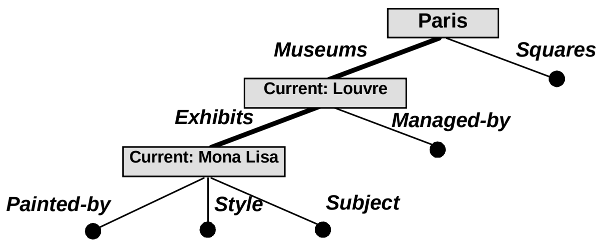
Figure 1. Node types, aspects and link types in MESH



Louvre. At this level, pressing the "next" button would lead to the next node in the tour, that is, another museum in Paris, becoming current. However, within the Paris.Museums tour, there is also a nested tour ongoing: Louvre.Exhibits, showing all artwork in the Louvre. Within that tour, the current node is *Mona Lisa*. For all artwork in the Louvre.Exhibits tour, the following information is visited consecutively: information about the artist (the painted-by link type), about its style (the style link type) and about the subject (the subject link type). If the "next" button is pressed at this level, another artwork in the Louvre is accessed. Upon completion of the Louvre.Exhibits tour (i.e., all artwork in the Louvre is visited), information about the museum's management (the Managed-by link type) becomes accessible. Thereafter, the next node in the Paris.Museums tour can be accessed. Upon completion of the Paris.Museums tour, a Paris.Squares tour will be started. This information can also be bookmarked; that is, bookmarks do not just refer to a single node but to the complete navigational situation, which can be resumed at a later date. More details are provided in Lemahieu (2002).

Although in theory MESH's data model and navigation paradigm can be implemented above any physical hypermedia architecture, this article presents one possible implementation framework that fully supports all of MESH's facets (cf. Figure 3). In broad outlines, this implementation architecture corresponds to the OHP framework proposed by the Open Hypermedia Community (Millard et al., 1998). The information content and navigation structure of the nodes are separated and stored independently. The resulting system consists of three types of components: the nodes, the linkbase/repository and the hyperbase engine. The nodes are considered as a potentially heterogeneous collection of entities, ranging from flat files (e.g., HTML or XML fragments) to objects in an object-oriented database, each containing one or more embedded multimedia objects. Optionally, a node can be endowed with the intelligence to tune its visualization to the context in which it is accessed; hence the so-called context-sensitive visualization principle. Links as well as metadata about node types and link types are captured in a searchable linkbase/repository, implemented in a relational database environment. Only here, references to physical node addresses are stored; these are never to be embedded in a node's body. According to the object-oriented information hiding principle, a node's internal content is shielded from the outside world by the indirection of link types playing the role of a node's public interface. The interaction mechanism can be compared to object-oriented method calls and return values, mediated by the hyperbase engine. This hyperbase engine is con-

Figure 2. Example of guided tours in MESH



ceived as a server-side application that accepts link selections from the current node, invokes a method on the correct destination node, keeps track of session information and provides facilities for generating maps and overviews. Since all relevant linkage and meta information is stored in the relational DBMS, the hyperbase engine can access this information by means of simple, pre-defined database queries, that is, without the need for searching through node content.

FUTURE TRENDS

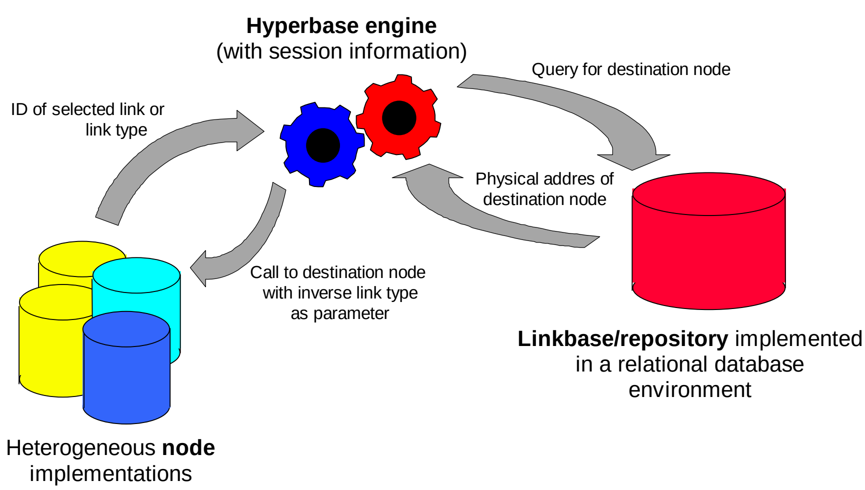
Future research is aimed at translating the platform-independent implementation framework into a Web based system, the hyperbase engine being conceived as a set of Web services. Currently, a standalone, read-only prototype already exists as a Java servlet. A future version is to offer support for authoring and distributed storage of node content and links. Another line of research is the application of Web usage mining techniques to support the personalized "advertising" of relevant guided tours.

CONCLUSION

MESH's structured approach to data modeling enables nodes and links to be treated as real objects, equipped with a unique OID that is independent of physical node location. The links, stored in a separate (and searchable) link facility, can map these OIDs to physical locations, which can be manipulated without the need for nodes to be re-edited upon reallocations. This guarantees a clean separation between authoring content and physical hyperbase maintenance. Authoring is greatly facilitated by object-oriented features such as inheritance and overriding, class properties and layout templates that allow for high-level specification and lower-level refinement of node properties. Authoring is also facilitated by suggestion of mandatory links and valid link destinations, based on metadata present in the linkbase/repository. Moreover, the constraints enforced by the data model permit the automated integrity checking that also exists in database systems. Dangling links and inconsistent link attributions can already be detected during the design phase. As to navigation, apart from the obvious benefit of a well-maintained hyperbase, typed nodes and links reduce cognitive overhead and permit a better comprehension of the semantic relations between information objects. The context-based navigation mechanism further reduces cognitive overhead by dynamically generating guided tours. The linear guided tours assist the user as well as improve his or her sense of position and ability to ascertain his or her navigational options. This effect is even increased by consistent node layout and context sensitive node visualization.

Other hypermedia approaches such as *RMM*, *HDM*, *OOHDM* and *WebML* are also based on conceptual modeling abstractions, either through entity-relationship or object-oriented techniques. RMM, HDM and OOHDM

Figure 3. Implementation framework for MESH



restrict themselves to a "standard" entity-relationship or object-oriented approach. WebML provides a recent, model-driven approach to Web site development, borrowing from entity-relationship modeling and UML. Also worth noting in the context of UML are W2000 (Baresi et al., 2001) and UHDM (Baumeister et al., 1999). These are positioned as frameworks for designing Web applications, that is, apart from hypermedia functionality, they also deal with operations and transactions that affect node content. For that purpose, they extend UML to accommodate for structural and navigational hypermedia abstractions. The underlying hypermedia constructs are borrowed from HDM and OOHDM, respectively. UWE (Koch et al., 2001), combining hypermedia constructs from RMM and OOHDM, stands for a UML-based approach to Web application design as well. However, none of these UML-based approaches allows for link subtyping and multiple specializations over both node and link types in the way *MESH* does.

MESH has the guided tour as default construct for navigating through a set of nodes. All kinds of indexes can be generated just as easily from the information in the linkbase/repository. RMM, HDM, OOHDM and WebML also feature specific topologies such as guided tours, indexes and so forth. A fundamental difference is that these are conceived as explicit design components, requiring extensive authoring efforts for query definitions, node collections and forward/backward links. In MESH, these are generated on-the-fly by the hyperbase engine, based on the current context. The author is not even engaged in their realization. RMM, HDM and OOHDM also in one way or another incorporate node visualization mechanisms that are sensitive to where a node is accessed. MESH, however, is the only approach to use a link's type to determine the destination node's visualization. It is also the only approach that stays true to the object-oriented paradigm by looking upon the associated link types as the public interface to a node, hiding its actual implementation. Finally, in MESH, a user has the unique ability to bookmark a complete navigational situation (instead of single nodes) in a very compact manner, with the possibility to resume navigation later on, from the exact point where it was left.

KEY TERMS

Aspect: Defines a set of related node properties, attributable to nodes with the same value for an aspect descriptor. For a given node, aspects can be added and removed at runtime by manipulating the values for its aspect descriptors.

Aspect Descriptor: Attribute for which each possible value defines an aspect of a node.

Authoring: The creation and organization of multimedia or hypermedia content.

Guided Tour: Combination of links that "guides" a user along a collection of hypermedia nodes that have some topic or concept in common. In MESH, guided tours are generated dynamically at runtime, based on the type of previously followed links by a particular user.

Hypermedia: Way of organizing data as a network of nodes and links.

Link: Navigation path between two nodes in a hypermedia environment.

Link Type: Type level definition of properties (domain, inverse link type, cardinalities) for a group of similar links.

Navigation: Means of accessing data in a hypermedia environment, by moving from node to node along the links.

Node: Unit of data (and navigation) in a hypermedia environment.

Node Type: Type-level definition of properties (layout template, link types, aspect descriptors) for a group of similar nodes.

Metadata for Electronic Documents Using the Dublin Core

Till Hänisch
University of Cooperative Education, Heidenheim, Germany

INTRODUCTION

The Dublin Core Element Set was developed at the OCLC/NCSA Metadata Workshop in Dublin (Ohio), 1995 (hence the name). It is maintained by the Dublin Core Metadata Initiative (DCMI).

The Dublin Core Element Set defines attributes, so called elements, which can be used for the description of electronic documents (Table 1).

Some of these elements can be qualified further. For example the "Date" element can be refined to "Created", "Issued", "Valid", "Available" or "Modified". Some elements can be refined by specifying the format or vocabulary used, for example, a qualifier can specify the scheme used to encode a date.

The Dublin Core standard itself does not specify a format (for example a XML schema) for the elements, usually the metadata are expressed either in HTML-documents (Figure 1) or in XML.

BACKGROUND

The definition of the semantics of Dublin Core elements is very flexible. Although, the DCMI recommends best practices for some elements, there is no definitive standard for their content. For example, the "Language" element should be specified according to RFC 3066 and ISO 639, which is a quite formal definition; but for the "Source" element it is recommended to "identify the referenced resource by means of a string or number conforming to a formal identification system" (DCMI, 2003), which gives each implementation a considerable amount of freedom regarding the system to be used. The advantage of these imprecise definitions is the resulting flexibility: Each implementation can use its own vocabulary specific to the actual application. The disadvantage is the lack of interoperability between applications which reduces the benefit of using a common standard.

The Dublin Core standard itself does not specify which elements are required and which are optional (all elements are optional, so an empty set of elements conforms to the Dublin Core). The selection and the concrete semantics of the elements to be used for a given application may be clarified by a so-called profile, for example, the DC-Library Application profile (DCMI, 2002) clarifies the use of the Dublin Core in library related applications. But profiles exist only for a small number of possible applications, so typically each implementation has to define its own semantics.

The Dublin Core element set mainly provides information about the content (for example "Title", "Description", etc.) and "Rights" related topics (for example "Cre-

Table 1. Dublin Core element set (DCMI, 2003)

Title	A name given to the resource
Creator	An entity primarily responsible for making the content of the resource
Subject	A topic of the content of the resource
Description	An account of the content of the resource
Publisher	An entity responsible for making the resource available
Contributor	An entity responsible for making contributions to the content of the resource
Date	A date of an event in the lifecycle of the resource
Type	The nature or genre of the content of the resource
Format	The physical or digital manifestation of the resource
Identifier	An unambiguous reference to the resource within a given context
Source	A Reference to a resource from which the present resource is derived
Language	A language of the intellectual content of the resource
Relation	A reference to a related resource
Coverage	The extent or scope of the content of the resource
Rights	Information about rights held in and over the resource

Figure 1. Example of HTML encoded Dublin Core elements

```

ator", "Publisher", etc.) of a resource. There is no (standard) way to include application specific information, for example, the timecodes of the different scenes in a video or the encoding quality of a MP3 file. This leads to a great variety of extensions, either specific for a single application or a class of applications. For example, Einhorn (2003) describes an extension for capturing metadata about presentations. DLmeta (see Abele, 2002) describes an extensible model for multimedia applications. These extensions enable applications to add necessary information to the metadata set, but since there is no common standard, this may lead to incompatibility.

Extending the Dublin Core results in a more complex set of metadata. A recent study (Ward, 2003) shows that even the unqualified elements are often used not completely: "two elements out of fifteen […] make up half the element usage in over half of the DPs [Data Providers]" (Ward, 2003). Nearly everybody (who uses Dublin Core) uses the "Title" and "Creator" elements. Some other elements (for example "Relation" and "Coverage") are rarely used. Maybe the original Dublin Core has too many elements (is too complex) for a lot of applications.

FUTURE TRENDS

There are two ways to solve the problems described above: Extend the element set or reduce it. Models like DLmeta (DLmeta, 2000) try to extend the Dublin Core to allow a more detailed description of electronic documents and their media specific properties and provide a certain degree of flexibility for specialized applications. Other models like the ABC-Model (Legoze, 2001) try to use a more abstract approach to allow the description of arbitrary objects and complex relationships, for example, in museum catalogs. The higher precision of the description when using these models may result in higher cost for the creation of the metadata and application development.

A different approach is to use a minimal common standard which is extensible according to the applications needs. One of the main reasons for using metadata is the ability to locate and retrieve resources. A minimal usable description should at least support this task. Kunze (2001) suggests the use of a set of only 4 elements (Table 2) to describe the basic properties of a resource. If necessary, these elements could be furthermore qualified and extended.

One important reason for a common metadata standard is the interchange of metadata. A local application like a digital library may use a propriety metadata model unless this information should be shared with others, for example, to enable cross domain resource discovery. One solution to this problem is that every application uses the same metadata, another solution is a common minimal subset used (only) for the exchange of information. The Open Archives Initiative (Lagoze, 2001) uses this approach. Metadata is exchanged between data providers using Dublin Core but every provider may deliver additional XML-formatted metadata.

CONCLUSION

The trend to use a more complex metadata set resembles the way, library cataloguing techniques have developed from simple schemes to today's complex standards like MARC. The large number of electronic documents to be described requires efficient techniques for their description. The currently used Dublin Core standard has several deficiencies, but it is not clear if a more complex or a simpler standard should be used. Combinations of a small metadata kernel used for data interchange with optional application specific elements may result in the advantages of both directions.

KEY TERMS

Catalog: The collection of records used to describe and locate the items contained in a library.

Dublin Core: A widely accepted standard for metadata about electronic documents. Maintained by the Dublin Core Metadata Initiative.

MARC: Machine Readable Cataloging Record. A Standard for the representation and communication of bibliographic and related information in machine readable form, developed by the Library of Congress.

Metadata: Data about other data. This is needed to find, catalogue and organize resources.

Resource: Any information resource like HTML-document, book, video etc.

RFC: Request For Comments. Internet standards are proposed and described in the form of RFCs. They are maintained by the Internet Engineering Task Force.

XML: Extensible Markup Language, an easy to use dialect of SGML, is a flexible technique for storage and interchange of data. One important aspect of XML is the combination of data and metadata in a single document

Methods for Understanding IS Failures

Darren Dalcher
Middlesex University, UK

INTRODUCTION

Researchers with a keen interest in information systems failures are faced with a double challenge. Not only is it difficult to obtain intimate information about the circumstances surrounding such failures, but there is also a dearth of information about the type of methods and approaches that can be utilised in this context to support such information collection and dissemination. The purpose of this chapter is to highlight some of the available approaches and to clarify and enhance the methodological underpinning that is available to researchers interested in investigating and documenting phenomena in context-rich and dynamic environments. The chapter concludes by introducing a new range of antenarrative approaches that represent future developments in the study of IS failures.

BACKGROUND

Contemporary software development practice is regularly characterised by runaway projects, late delivery, exceeded budgets, reduced functionality, and questionable quality that often translate into cancellations, reduced scope, and significant rework cycles (Dalcher, 1994). Failures, in particular, tell a potentially grim tale. In 1995, 31.1% of U.S. software projects were cancelled, while 52.7% were completed late, over budget (cost 189% of their original budget), and lacked essential functionality. Only 16.2% of projects were completed on time and within budget; only 9% in larger companies, where completed projects had an average of 42% of desired functionality (Standish Group, 2000). The 1996 cancellation figure rose to 40% (Standish Group).

The cost of failed U.S. projects in 1995 was $81 billion; in addition, cost overruns added an additional $59 billion ($250 billion was spent on 175,000 U.S. software projects; however, $140 billion out of this was spent on cancelled or over budget activities; Standish Group, 2000). In fact, Jones (1994) contended that the average U.S. cancelled project was a year late, having consumed 200% of its expected budget at the point of cancellation. In 1996, failed projects alone totalled an estimated $100 billion (Luqi & Goguen, 1997). In 1998, 28% of projects were still failing at a cost of $75 billion; while in 2000, 65,000 of U.S. projects were reported to be failing (Standish Group).

The Standish Group makes a distinction between failed projects and challenged projects. Failed projects are cancelled before completion, never implemented, or scrapped following installation. Challenged projects are completed and approved projects which are over budget, late, and with fewer features and functions than initially specified. Lyytinen and Hirschheim (1987) identify: correspondence failures (where the system fails to correspond to what was required), process failures (failure to produce a system or failure to produce it within reasonable budgetary and timescale constraints), interaction failures (where the system cannot be used or is not satisfactory in terms of the interaction), and expectation failures (where the system is unable to meet a specific stakeholder group's expectations). Many situations contain behavioural, social, organisational, or even societal factors that are ignored, and therefore the definition of failure needs to encompass a wider perspective. The general label *system failures* is often utilised in order to embrace a wider grouping of failures, including ones with undesirable side effects which may impact other domains and the organisational context (see, for example, Fortune & Peters, 1995). As information becomes more embedded in other domains, the scope and impact of failure becomes more wide-reaching. This was clearly evident from the extensive effort to minimise the impact of the "year 2000 bug" from any system containing computers and underscores our interest in utilising the term *IS failure* to describe a wider class of systems failures that impact on individuals, organisations, and societal infrastructure.

IS failure investigations start with extensive attempts to collate relevant evidence. However, in most cases the researcher is exposed to specific information post hoc, i.e., once the failure is well established and well publicised and the participants have had a chance to rationalise their version of the story. Most of the available sources are therefore already in place and will have been set up by agencies other than the researcher.

The purpose of a forensic investigation is to explain a given failure by using available information and evidence. The term *forensic* is derived from the Latin *forensis*, which is to do with making public. Forensic science is the applied use of a body of knowledge or practice in determining the cause of death, nowadays extended to include any skilled investigation into how a crime was perpetrated. Forensic systems engineering is the postmortem analysis and study of project disasters (Dalcher, 1994).

The work involves a detailed investigation of a project, its environment, decisions taken, politics, human errors, and the relationship between subsystems. The work draws upon a multidisciplinary body of knowledge and assesses the project from several directions and viewpoints. The aim of forensic analysis is to improve the understanding of failures, their background, and how they come about (Dalcher, 1997). The concept of systems is a central tool for understanding the delicate relationships and their implications in the overall project environment.

Forensic systems engineering is primarily concerned with documentary analysis and (post-event) interviews in an effort to ascertain responsibility lines, causal links, and background information. The primary mode of dissemination of findings, conclusions, and lessons is through the publication of case study reports focusing on specific failures. However, there are limited research methods to explore the dynamic and fragmented nature of complex failure situations. Lyytinen and Hirschheim (1987) noted that more qualitative research methods were needed for IS failure research as well as more extensive case studies that explored problems in more detail and viewed solution arrangements in light of what transpired. The same methods also need to account for group issues and cultural implications. Sadly, 16 years on, the same constraints in terms of methods are still in evidence.

DESCRIBING FAILURE

Making sense of IS failures retrospectively is difficult. In general, there is very little objective quantitative failure information that can be relied upon. This makes the utilisation of quantitative methods less likely until all relevant information is understood. Indeed, a specific feature of failure is the unique interaction between the system, the participants, their perspectives, complexity, and technology (Perrow, 1984). Lyytinen and Hirschheim (1987) pointed out that failure is a multifaceted phenomenon of immense complexity with multiple causes and perspectives. Research into failures often ignores the complex and important role of social arrangement embedded in the actual context. This is often due to the quantitative nature of such research. More recently, Checkland and Holwell (1998) argued that the IS field requires sensemaking to enable a richer concept of information systems.

Understanding the interactions that lead to failures likewise requires a humanistic stance that is outside the conventional positivist norm to capture the real diversity, contention, and complexity embedded in real life. Forensic analysis thus relies on utilising qualitative approaches to obtain a richer understanding of failure phenomena in terms of action and interaction.

The fact that a failure phenomenon is being investigated suggests that attention has already been drawn to the complexities, breakdowns, and messy interactions that such a situation entails (i.e., the investigation is problem-driven). Many such inquiries deal with subjective accounts, including impressions, perceptions, and memories. The aim of the researcher is to increase in a systemic way the understanding of a situation, yet do so from a position that takes in the complexity of the entire situation and incorporates the different perspectives and perceptions of the stakeholders involved.

Overall, the purpose of a failure research method is to enable the researcher to make sense of the complexity of detail and the complexity of interaction and chart the contributory role of different causes and issues in the buildup to failure. However, the armoury of research methods in this domain is often limited to case studies.

The term *case study* is an umbrella term used in different contexts to mean different things that include a wide range of evidence capture and analysis procedures. Yin (1994, p.13) defines the scope of a case study as follows:

“A case study is an empirical inquiry that:

- *investigates a contemporary phenomenon within its real-life context, especially when*
- *the boundaries between phenomenon and context are not clearly identified.”*

A case study can be viewed as a way of establishing valid and reliable evidence for the research process as well as presenting findings which result from research (Remenyi et al., 1998). According to Schramm (1971), the case study tries to illuminate a decision or a set of decisions and in particular emphasise why they were taken, how they were implemented, and with what results. A case study is likely to contain a detailed and in-depth analysis of a phenomenon of interest in context; in our case, the failure scenario. Table 1 summarises some of the main advantages of using case studies.

The general aim of the case study approach is to understand phenomena in terms of issues in the original problem context by providing the mechanism for conducting an in-depth exploration. They often result from the decision to focus an enquiry around an instance or an incident (Adelman, Jenkins, Kemmis, 1977), as they are principally concerned with the interaction of factors and events (Bell, 1999). The combination of a variety of sources offers a richer perspective, which also benefits from the availability of a variety and multiplicity of methods that can be used to obtain new insights about this single instance. A case study allows the researcher to concentrate on specific instances in their natural setting and thereby attempt to identify the interacting perceptions,

Table 1. Main advantages of using case studies

✓	ability to identify and focus on issues
✓	richness of detail
✓	multiple perspectives
✓	multiple explanations (no absolute truth)
✓	cross-disciplinary remit
✓	ability to recognise and minimise inherent complexity
✓	ability to handle conflict, disparity, and disagreement
✓	ability to show interactions
✓	ability to observe emerging patterns
✓	conducted in real-life setting
✓	encompasses original problem context
✓	ability to deal with interpretations
✓	can extend the boundaries to include aspects of wider system environment
✓	can be accumulated to form an archive of cases

Table 2: Main objections to the use of case studies

❖	sometimes viewed as soft data (but some argue it is hard research)
❖	biases inherent in accepting views and perceptions
❖	questions about generalisability of findings (especially from a single case), but it is possible to build a library of such cases
❖	issues regarding objectivity of approach and perceived lack of rigour
❖	negotiating access to settings
❖	boundaries are difficult to define, but this could also be a strength!
❖	mainly retrospective
❖	sometimes viewed as likely to take too long and result in massive documentation
❖	the observer effect
❖	reliability of conclusions
❖	there is little control over events, but this may also be a strength

issues, and processes at work, ultimately resulting in in-depth understanding. Crucially, the focus on a single incident thus enables the study of the particularity and complexity of a case, thereby coming to understand the activity within important circumstances (Stake, 1995).

There are a number of general objections that are associated with the use of case studies (see Table 2). However, one must recognise that case studies are more likely to be used retrospectively rather than as an ongoing perspective (especially from a failure point-of-view), as researchers are unlikely to know the potential for useful results and interest from the outset.

The richness of detail can be controlled through the careful placement of systems boundaries and consideration of the wider system environment that is relevant to the phenomenon under study. Case studies can be utilised as a source of understanding which is tolerant of ambiguity, paradox, and contradiction. A case study is viewed as interpretative when events in the real world are observed and then an effort takes place to make sense of what was observed, i.e., when one tries to make sense of a failure from the perspectives of participants. They also offer the potential for generating alternative explanations from the different stakeholder perspectives, thereby allowing the researcher to highlight contradictions, conflicts, and misunderstandings.

FROM CASE STUDIES TO CASE HISTORIES

The generally liberal use of the term *case study* requires a tighter definition of its meaning in failure research. While there may be a tradition of using case studies within the IS community, this is perhaps more often borrowed from the MBA culture than as a result of self-conscious effort to adopt them as a research approach (Cornford & Smithson, 1996; Walsham, 1995). Indeed, the case study is typically used more in its capacity as a teaching tool than as a *research tool*. The shift to studying the impact of issues within the organisational context renders case studies particularly useful for investigating failure scenarios. However, the use of the term often leads to some confusion.

Moreover, one of the major complications in failure investigations is in relating causes to effects (and possibly events) through extended time horizons (Dalcher, 2000). The implications of actions may not be witnessed for years or even generations. Delays between making a decision and observing the result distort the causal link between the two. As a result, people tend to associate a different level of severity to events occurring following a delay. The perceived severity is thus diminished, with the length of the delay further complicating the task of identifying patterns and interactions that contributed to a given failure. Failure researchers are thus required to provide adequate historical accounts of the interaction between actions, perceptions, and the passage of time.

Case studies have typically been used to explore issues in the present and the past and comprise ethnographic studies, single case studies, and comparative case studies (Jankowicz, 2000), as well as action research, evaluative, exploratory, explanatory, and descriptive case studies (Bassey, 1999). In our experience there is a need to add the failure case study as a special example of a case study focusing primarily on the background, context, perception, interactions, and patterns, especially as the failure investigation is likely to take place *after* the (failure) event. We thus propose the use of the label *case histories* to refer to the specialised historical research studies focusing on failure incidents.

The time dimension (sequencing) is critical to understanding interactions and identifying their impacts. Case histories are concerned with providing the background and context that are required to endow words and events with additional meaning. Background refers to previous history of the system itself, while context refers to interactions with the environment. As failures are time- and place-dependent, the case history framework enables readers to obtain an understanding of the intimate context surrounding the main event. The primary tool available to the community is the case histories of failures (derived from the use of the case study method). These represent a detailed historical description and analysis of actual processes. Their value is in tracing decisions (and recorded rationale) to their eventual outcomes by utilising techniques borrowed from decision analysis and systems engineering. Indeed, the historical description and presentation of a chronology of events are based on the recognition that real life is ambiguous, conflicting, and complex.

Case histories thus contain observations, feelings, and descriptions. They can be used to construct, share, dispute, and confirm meanings, interpretations, and scenarios in the context of real events. Rather than simply highlight a chronicled sequence of happenings, they convey a story encompassing a specific perspective, focus, and possibly some inevitable biases. The interpretation plays a key part in transmuting the chronicle into a meaningful story with plot, coherence, and purpose. However, constructing a convincing narrative of a complex story with competing meanings, alternative perspectives, and inherent prejudices is a challenge in itself.

FUTURE TRENDS

Failures, in common with other activities that take place in organisations, are based on stories. The verbal medium is crucial to understanding behaviour within organisations and systems, and researchers are thus required to collect *stories*, grounded in practice, about what takes place (Easterby-Smith, Thorpe, & Lowe, 2002; Gabriel, 2000). Understanding failures often entails the retrospective untangling of complicated webs of actions and events and emergent interaction patterns. Failure storytelling can thus be understood as a combination of narrative recounting of empirical events with the purposeful unlocking of meaningful patterns, or a plot.

Historically, storytelling has been an acceptable form of conveying ideas, experience, and knowledge of context. It plays a key role in communicating the cultural, moral, or historical context to the listener. Indeed, Arendt (1958) argued that the chief characteristic of human life is that it is always full of events, which ultimately can be told as a story. There are even strong claims that the narrative is the main mode of human knowledge (Bruner 1986, 1990, Schank 1990), as well as the main mode of communication (Denning, 2001; Fisher, 1987; Schank). Moreover, children are often initiated into culture (and its boundaries) through the medium of storytelling, offering models for emulation or avoidance.

In practice, the essence of any good case study revolves around the ability to generate an effective story line, normally with a unique style, plot, or perspective. In a large case, a general theme can be obtained from selected excerpts weaved together to illustrate a particular story. Personal stories that form part of a case study can thus be viewed as a valid source of data organised to make sense of a theme or problem. This is particularly useful when the researcher is trying to portray a personal account of a participant, a stakeholder, or an observer in an incident, accident, or failure. The implication is that the need to address personal aspects of interaction and story is fulfilled by the development of a research-valid narrative. Indeed, Remenyi et al. (1998) contend that a story, or a narrative description, is valid if the resulting narrative adds some knowledge. Furthermore, White (1973, p. 24) describes a story as "the process of selection and arrangement of data from the unprocessed historical record in the interest of rendering the record more comprehensible to an audience of a particular kind" by inserting a sense of perspective and purpose.

Narratives are neither discovered nor found: they are constructed. Understanding IS failures is therefore more complicated than the discovery of a simplistic chronology of events. Narrative inquiry is evolving into an acceptable research approach in its own right in the social sciences and in management research circles (Bell, 1999; Boje, 2001; Czarniawska, 1998; Easterby-Smith et al., 2002; Gabriel, 2000), as the story format provides a powerful way of knowing and linking disparate accounts and perspectives. When different accounts are combined, the story line benefits from the richness of multifaceted insights.

Developing a narrative requires plot as well as coherence, as a story is made out of events and the plot mediates between the events and the story (Boje, 2001; Carr, 2001; Kearney, 2002). In failure stories, the plot often emanates from the actions and perceptions of participants emerging out of the flux of events in (direct) contradiction with expectations. The storyteller is concerned with the perspective and purpose of participants as well as with the plausibility of the emerging plot. The combination of plot, purpose, and perspective dictates the selection of elements, the filling in of links, and the removal of "irrelevant" noise.

Postmodern interpretation contends that most real-life stories are fragmented, nonlinear, multivariate, and incoherent. This has already been highlighted as a feature of failure stories. Such stories also tend to be dynamic, polyphonic (multi-voiced), and collectively produced, as they occur in asymmetrical, random, and turbulent environments. The stories are not plotted as such and they appear to flow, emerge, and network, offering complex clustering of events, emergent phenomena, causes, and effects. Moreover, the accounts are often subjective, counterintuitive, and contradictory. This leads to interacting and conflicting webs of narratives, characterised by coincidences, predicaments, and crises.

Generally, stories appear to be improperly told, as a story is an "ante" state of affairs, existing previously to a carefully constructed narrative (Boje, 2001). The antenarrative, or the "real" story, is the fragmented, messy and dynamic, multi-vocal, multi-plotted, multi-version, and complex tale. Indeed, modern storytellers look for new ways and mediums for weaving and depicting a multi-vocal reality, as exemplified by Mike Finggis' digitally shot film *Time's Arrow*, where the screen is split in four to allow for four separate perspectives and substories that occasionally intersect or overlap. In the tradition of postmodern inquiry, a real-life researcher is often faced with fragments rather than a whole story to tell, and many of the fragments may reflect contrary versions of reality. This is potentially more acute when the accounts attempt to justify roles of participants in the lead-up to disaster. It would also appear from past analysis that there are hierarchies of stories and stories that exist within or interact with other stories. Using the terminology provided by Boje, the purpose of narrative methods is to take a complex situation characterised by collective (yet often conflicting) memory and an antenarrative and construct the plot and coherence that can be used to narrate the story of interest.

The reality in failure stories is of multistranded stories of experiences and reactions that lack collective consensus. Indeed the discipline of decision making has also recognised that making choices is about forming and selecting interpretations from a mosaic of possibilities (March, 1994, 1997; Weick, 1995). Not surprisingly, disasters or traumatic stories are hard to narrate, understand, and justify. Stories have three basic properties: time, place, and mind (Boje, 2001), which interact and build up as the story evolves. In forensic case histories, these are further clarified through the identification of the background and context, which clarify and justify the interpretation in the context of the emerging phenomena.

Boje (1991, 2001) and Kearney (2002) contend that the current view is of sequential single-voice stories and implies excessive reliance on the hypothetical-deductive approach (akin to simplistic causal pairings). The answer is not to develop Harvard case studies but to rewrite stories as polyvocal tapestries enabling different perceptions and interpretations to exist, thereby explaining webs of actions and interactions. What is new in this approach is the antenarrative reading, which enables narrative analysis methods to be supplemented by antenarrative methods, allowing previously fragmented and personal storytelling to be interpreted as a unified whole. This focus offers alternative discourse analysis strategies that can be applied where qualitative story analyses can help to assess subjective, yet "insightful" knowledge in order to obtain "true" understanding of complex interactions.

As for the long-term future, good stories can also benefit from pictures. Once we have mastered the techniques of telling complex, modern stories, we need to focus on composing that information. Even the most gripping story needs to be made attractive and believable. Textual information needs additional support not only in "emplotting" and in maintaining coherence and perspective, but also in ascertaining the plausibility of constructed stories and in differentiating between noise and narrative. Developing improved techniques for organising or visualising knowledge (such as Net maps) can therefore help in untangling some of the fragmented strands as well as in making the stories more readable and understandable, as well as ultimately more appealing.

CONCLUSION

With the benefit of hindsight it is possible to reconstruct a systematic retelling of events that have led to a failure. The narrated structure provides an explanation as to how and why failures occur. The purpose of the structure is to make sense of a rich tapestry of interactions and connections by following an identified story line that chronicles and links the relevant issues within the environment. Indeed, recounted life may prise open perspectives that would have been inaccessible using ordinary methods and thinking arrangements. Moreover, failure tends to highlight missing and incorrect assumptions and faulty defensive mechanisms and can therefore serve as a pretext to updating the frame of reference or the context for understanding.

KEY TERMS

Antenarrative: the fragmented and messy and dynamic stories of real life in their original context before a clear narrative is developed to explain away a certain aspect.

Case History: specialised historical research focusing on failure incidents. Case histories emphasise the background and context that can help in untangling relationships and causes.

Case Study: investigation of phenomena in naturalistic setting, conducted in order to enable in-depth analysis of that phenomena.

Challenged Projects: completed and approved projects that are over budget, late, and have fewer features and functions than originally specified.

Failed Projects: projects that are: cancelled before completion, are never implemented, or are scrapped following installation.

Forensic Systems Engineering: postmortem analysis and study of project failures and disasters aimed at uncovering causes and relationships.

Storytelling: a method of communicating and sharing ideas, experiences, and knowledge in a specific context.

Metrics for Data Warehouse Quality

INTRODUCTION AND BACKGROUND

It is known that organizations are very rich in data but poor in information. Today, technology has made it possible for organizations to store vast amounts of data obtained at a relatively low cost, however these data fail to provide information (Gardner, 1998). Data warehouses have appeared as a solution to this problem supporting decision-making processes and new kinds of applications as marketing.

A data warehouse is defined as a "collection of subject-oriented, integrated, non-volatile data that supports the management decision process" (Inmon, 1997). Data warehouses have become the key trend in corporate computing in the last years, since they provide managers with the most accurate and relevant information to improve strategic decisions. Also, the future for data warehouse is promising. Jarke, Lenzerin, Vassilou, and Vassiliadis (2000) forecast a market of 12 million U.S. dollars for data warehouse markets for the next few years. However, the development of a data warehouse is a difficult and very risky task. It is essential that we can assure the information quality of the data warehouse as it becomes the main tool for strategic decisions (English, 1999).

Information quality of a data warehouse comprises data warehouse system quality and presentation quality (see Figure 1). In fact, it is very important that data in a data warehouse reflect correctly the real world, but it is also very important that data can be easily understood. In data warehouse system quality, as in an operational database (Piattini, Genero, Calero, Polo, & Ruiz, 2000), three different aspects could be considered: DBMSs quality, data model quality, and data quality.

In order to assess DBMS quality, we can use an international standard like ISO 9126 (ISO, 1999), or some of the existing product comparative studies. This type of quality should be addressed in the product selection stage of the data warehouse life cycle.

Data quality must address mostly in the extraction, filtering, cleaning and cleansing, synchronization, aggregation, loading, and so forth, activities of the life cycle. In the last few years, very interesting techniques have been proposed to assure data quality (Bouzeghoub & Kedad, 2002).

Last but not least, data warehouse model quality has a great influence in the overall information quality. The designer must choose the tables, processes, indexes and data partitions representing the logical data warehouse and facilitating its functionality (Jarke et al., 2000).

Figure 1. Information and data warehouse quality

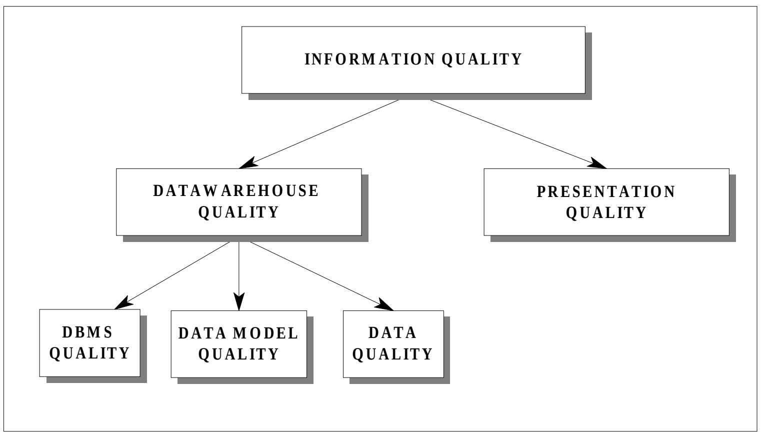

Figure 2. Example of a multidimensional data model design

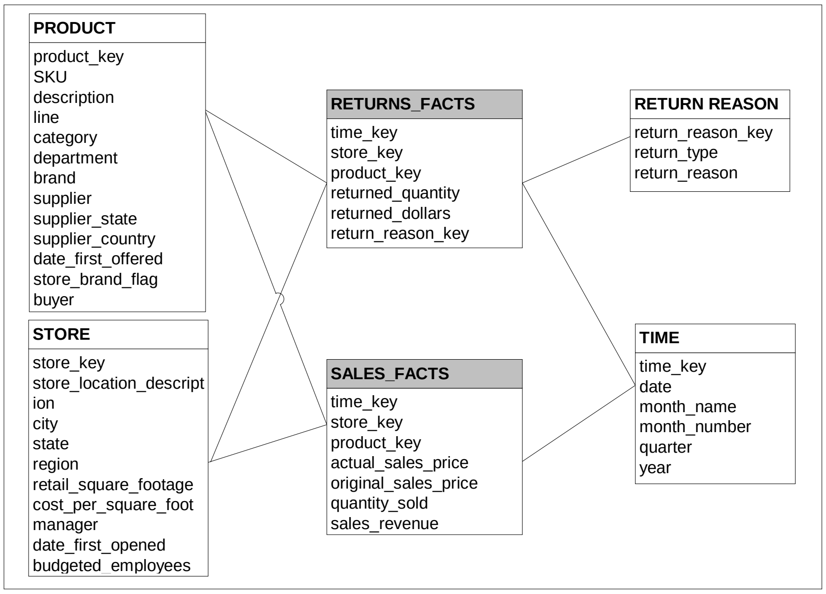


Multidimensional data models are used to design data warehouses (Petersen & Jensen, 2001). A multidimensional data model is a direct reflection of the manner in which a business process is viewed. It captures the measurements of importance to a business, and the parameters by which the measurements are broken out. The measurements are referred to as *fact* or *measures*. The parameters by which a fact can be viewed are referred to as *dimensions* (Adamson & Venerable, 1998).

Usually multidimensional data models are represented as star schemas, which consist of one central table and several dimensional tables. The measures of interest are stored in the fact table (e.g., sales, inventory). For each dimension of the multidimensional model, there exists a dimensional table (e.g., product, time) that stores the information about the dimension (Jarke et al., 2000).

In Figure 2, we present an example of multidimensional data model design, with two fact tables (Returns_Facts and Sales Facts) and four dimensional tables (Product, Store, Return_Reason and Time).

In recent years, different authors have proposed some useful guidelines for designing multidimensional data models (Bouzeghoub & Kedad, 2002; Jarke et al., 2000; Vassiliadis, 2000). However, more objective indicators are needed to help designers and managers to develop quality multidimensional data models (Hammergren, 1996; Kelly, 1997; Kimball, Reeves, Ross, & Thornthwaite, 1998). Also, interesting recommendations for achieving a "good" multidimensional data model have been suggested (Adamson & Venerable, 1998; Inmon, 1997; Kimball et al., 1998), but quality criteria are not enough on their own to ensure quality in practice, as different people will generally have different interpretations of the same criteria. The goal should be to replace intuitive notions of design "quality" with formal, quantitative, objective metrics in order to reduce subjectivity and bias in the evaluation process.

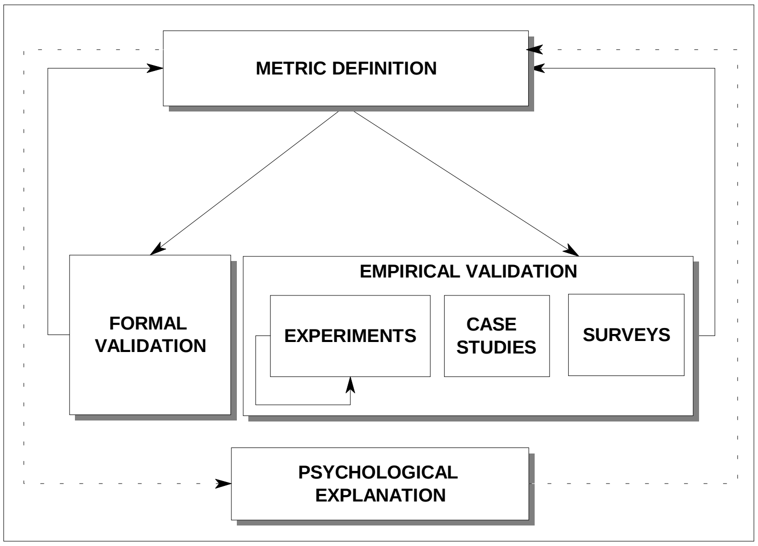
The definition of a set of objective metrics for assuring multidimensional data model quality is the final aim of our work. As we know, quality depends on several factors and characteristics such as functionality, reliability, usability, understandability... (external attributes) (ISO, 1999). Several of these characteristics are influenced by the complexity (internal attribute) of the multidimensional data model. We tried to obtain a set of metrics for measuring the complexity of datawarehouse models that help designers to improve the quality of their datawarehouses.

However, it is not enough with proposing metrics, and it is fundamental to be sure that these metrics are really useful for the goal they were conceived through different kinds of validations.

In this article, we will propose metrics for multidimensional data models quality, which can characterize their complexity and the different validations we have made with them.

In the next section, we will present the framework followed to define and validate metrics. The third section summarizes the proposed metrics, and in the fourth section, the formal validation of these metrics is described. Part of the empirical validations are presented in the fifth section and conclusions and future work will be presented in the final section.

Figure 3. Steps followed in the definition and validation of the metric



A FRAMEWORK FOR DEVELOPING AND VALIDATING DATA WAREHOUSE METRICS

As we have said previously, our goal is to define metrics for controlling data warehouse complexity. Metrics definition must be done in a methodological way, it is necessary to follow a number of steps to ensure the reliability of the proposed metrics. Figure 3 presents the method we apply for the metrics proposal.

In Figure 3, we have four main activities:

- **Metrics definition.** The first step is the definition of metrics. Although it looks simple, it is an important one in ensuring metrics are correctly defined. This definition has made taking into account the specific characteristics of the multidimensional data model we want to measure and the experience of database designers and administrators of these information systems.
- **Formal validation.** The second step is the formal validation of the metrics. The formal validation helps us to know when and how to apply the metrics. There are two main tendencies in metrics formal validation: the frameworks based on axiomatic approaches and the ones based on the measurement theory. The goal of the first ones is merely definitional. On this kind of formal framework, a set of formal properties is defined for a given software attribute, and it is possible to use this property set for classifying the proposed metrics. The most well-known frameworks of this type are those proposed by Weyuker (1988), Briand, Morasca, and Basili (1996), and Morasca and Briand (1997).

  The measurement theory-based frameworks (such as Zuse, 1998; Whitmire, 1998; Poels & Dedene, 2000) specify a general framework in which metrics should be defined. The strength of measurement theory is the formulation of empirical conditions from which we can derive hypothesis of reality.
- **Empirical validation.** The goal of this step is to prove the practical utility of the proposed metrics. Although there are various ways of performing this step, basically we can divide the empirical validation into experimentation, case studies and surveys.
- **Psychological explanation**. Ideally, we will be able to explain the influence of the values of the metrics from a psychological point of view. Some authors, as Siau (1999), propose the use of cognitive psychology as a reference discipline in the engineering of methods and the studying of information modeling.

As shown in Figure 3, the process of defining and validating metrics is evolutionary and iterative. As a result of the feedback, metrics could be redefined based on discarded formal, empirical validation or psychological explanation.

PROPOSED METRICS

In this section, we present the metrics we have proposed for multidimensional data models. As some metrics can be applied at table, star and schema level, we present them separately.

M

Table Level Metrics

In the last few years, we have researched different metrics for assuring relational database quality (Calero, Piattini, & Genero, 2001). Two of these metrics could be useful for data warehouses:

- **NA(T).** Number of attributes of a table.
- **NFK(T).** Number of foreign keys of a table.

In Table 1, we can find the values of the table metrics fort the star schema shown in Figure 2.

Star Level Metrics

- **NDT(S).** Number of dimensional tables of a star.
- **NT(S).** Number of tables of a star, which corresponds to the number of dimensional tables added the fact table.

  NT(S) = NDT(S) + 1

- **NADT(S).** Number of attributes of dimensional tables of a star.
- **NAFT(S).** Number of attributes of the fact table of a star.
- **NA(S).** Number of attributes of a star.

  NA(S) = NAFT(FT) + NADT(S)
  where FT is the fact table of the star S.
- **NFK(S).** Number of foreign keys of a star.

$$NFK(S) = NFK(FT) + \sum_{i=1}^{NDT} NFK(DT_i)$$

  where FT is the fact table of the star S
  and Dti is the dimensional table number i of the star S
- **RSA(S).** Ratio of star attributes. Quantity of attributes of dimensional tables per number of attributes of the fact table of the star.

$$RSA(S) = \frac{NADT(S)}{NAFT(FT)}$$

  where FT is the fact table of the star S.

Table 1. Values for table metrics

	NA	NFK
PRODUCT	13	0
STORE	10	0
RETURN REASON	3	0
TIME	6	0
RETURNS_FACTS	6	4
SALES-FACTS	7	3

- **RFK(S).** Ratio of foreign keys. Quantity of the fact table attributes which are foreign keys.

$$RFK(S) = \frac{NFK(FT)}{NAFT(FT)}$$

  where FT is the fact table of the star S

In Table 2, we can find the values of the star metrics for the star schema shown in Figure 2.

Schema Level Metrics

- **NFT(Sc).** Defined as a number of fact tables of the schema.
- **NDT(Sc).** Number of dimensional tables of the schema.
- **NSDT(Sc).** Number of shared dimensional tables. Number of dimensional tables shared for more than one star of the schema.
- **NT(Sc).** Number of tables. Number of the fact tables plus the number of dimensional tables of the schema.
  NT(Sc) = NFT(Sc) + NDT(Sc)
- **NAFT(Sc).** Number of attributes of fact tables of the schema.

$$NAFT(Sc) = \sum_{i=1}^{NFT} NA(FT_i)$$

  where FTi is the fact table i of the schema Sc
- **NADT(Sc).** Number of attributes of dimensional tables of the schema.

$$NADT(Sc) = \sum_{i=1}^{NDT} NA(DT_i)$$

  where DTi is the dimensional table i of the schema Sc
- **NASDT(Sc).** Number of attributes of shared dimensional tables of the schema.

$$NASDT(Sc) = \sum_{i=1}^{NSDT} NA(DTi)$$

Table 2. Values for star metrics

	Returns_Facts	Sales_Facts
NA	38	36
NFK	4	3
NDT	4	3
NT	5	4
NADT	32	29
NAFT	6	7
RSA	32/6	29/7
RFK	4/6	3/7

where DTi is the dimensional table i of the schema Sc

- **NA(Sc).** Number of attributes of the schema.

  NA(Sc) = NAFT(Sc) + NADT(Sc)
- **NFK(Sc).** Number of foreign keys in all the fact tables of the schema.

$$NFK(Sc) = \sum_{i=1}^{NFT} NFK(FT_i)$$

where FTi is the fact table i of the schema Sc

- **RSDT(Sc).** Ratio of Shared Dimensional Tables. Quantity of dimensional tables, which belong to more than one star.

$$RSDT(Sc) = \frac{NSDT(Sc)}{NDT(Sc)}$$

- **RT(Sc).** Ratio of tables. Quantity of dimension tables per fact table.

$$RT(Sc) = \frac{NDT(Sc)}{NFT(Sc)}$$

- **RScA(Sc).** Ratio of Schema Attributes. Number of attributes in dimension tables per attributes in fact tables.

$$RScA(Sc) = \frac{NADT(Sc)}{NAFT(Sc)}$$

- **RFK(Sc).** Ratio of foreign keys. Quantity of attributes that are foreign keys.

$$RFK(Sc) = \frac{NFK(Sc)}{NA(Sc)}$$

- **RSDTA(Sc).** Ratio of Shared Dimensional Tables Attributes. Number of attributes of the schema that are shared.

$$RSDTA(Sc) = \frac{NASDT(Sc)}{NA(Sc)}$$

In Table 3, we can find the values of the schema metrics for the star schema shown in Figure 2.

Table 3. Values for data warehouse schema metrics

Metric	Value
NA	45
NFK	7
NDT	4
NT	6
NADT	32
NAFT	13
RFK	7/45
NFT	2
NSDT	3
NASDT	29
RSDT	3/4
RT	4/2
RScA	32/13
RSDTA	29/45

METRICS FORMAL VALIDATION

As we have said, there are two basic tendencies in formal metrics validation: axiomatic approaches and measurement theory. In this section, we will present both validation techniques. The formal framework proposed by Briand et al. (1996) is an example of axiomatic approach and the Zuse's formal framework is based on measurement theory.

In Table 4, we present the results obtained for all the presented metrics on both formal frameworks.

METRICS EMPIRICAL VALIDATION

In the past, empirical validation has been an informal process relying on the credibility of the proposer. Oftentimes, when a metric was identified theoretically as an effective metric of complexity, then practitioners and researchers began to use the metric without questioning its validity. Today, many researchers and practitioners assume that validation of a metric (from a theoretical point of view) is not sufficient for widespread acceptance. They expect the empirical validation to demonstrate that the metric itself can be validated.

We have made several experiments (Serrano, Calero, & Piattini, 2002, 2003), and we have found that several metrics (like NT, NFT, NDT and NFK) seem to be a good quality indicator for logical data warehouse schemas.

CONCLUSIONS AND FUTURE TRENDS

If we really consider that information is "the" main organizational asset, one of our primary duties should be assuring its quality. Although some interesting guidelines have been proposed for designing "good" multidimensional models for data warehouses, more objective indicators are needed. Metrics are useful and objective mechanisms for improving the quality of software products and also for determining the best ways to help professionals and researchers.

In this way, our goal is to elaborate a set of metrics for measuring data warehouse quality which can help designers in choosing the best option among more than one alternative design.

M

Table 4. Summary of metrics formal validation

	BRIAND ET AL. (1996)	ZUSE (1998)
NA	SIZE	ABOVE THE ORDINAL
NFK	COMPLEXITY	ABOVE THE ORDINAL
NDT	SIZE	ABOVE THE ORDINAL
NT	SIZE	RATIO
NADT	SIZE	ABOVE THE ORDINAL
NAFT	SIZE	ABOVE THE ORDINAL
NFT	SIZE	RATIO
NSDT	SIZE	ABOVE THE ORDINAL
NASDT	SIZE	RATIO
RSA	NOT CLASSIFIABLE	ABSOLUTE
RFK	NOT CLASSIFIABLE	ABSOLUTE
RSDT	NOT CLASSIFIABLE	ABSOLUTE
RT	NOT CLASSIFIABLE	ABSOLUTE
RSDTA	NOT CLASSIFIABLE	ABSOLUTE

As a start of this work, we presented in this article some metrics that have been defined for measuring the data warehouse star design complexity. We presented the formal validation of these metrics, and we explained the first experiment we developed in order to validate them.

As a conclusion of the formal validation, we obtained that all the metrics are useful from the Zuse (1998) measurement theory framework point of view, and most of them are classifiable by the Briand et al. (1996) axiomatic formal framework. As a result of the experiments we performed, we found that several of the proposed metrics (NFT, NT, NDT and NFK) seem to be good quality indicators for logical data warehouse schemas.

Following the MMLC (Measure Model Life Cycle) of Cantone and Donzelli (2000) with this and other experiments, our research can be classified into the creation phase. At this moment, we are starting different collaborations with companies in order to go to the acceptance phase through the systematic experimentation in a context suitable to reproduce the characteristics of the application environment, with real business cases and real users.

KEY TERMS

Data Mart: A data warehouse that is designed for a particular line of business, such as sales, marketing, or finance.

Data Warehouse: Collection of subject-oriented, integrated, non-volatile data that supports the management decision process.

Multidimensional Data Model: A direct reflection of the manner in which a business process is viewed. It captures the measurements of importance to a business, and the parameters by which the measurements are broken out. The measurements are referred to as *fact* or *measures*. The parameters by which a fact can be viewed are referred to as *dimensions.* Multidimensional data models are used to design datawarehouses.

On-Line Analytical Processing (OLAP): Systems oriented to analyse huge amounts of data. These systems are optimized for querying and their functionality is characterised by dynamic, multidimensional analysis of historical data.

On-Line Transaction Processing (OLTP): Systems that are optimized for transaction handling. These kinds of information systems are used in day-to-day work.

Software Metric: The term metric or software metric has, for many years, been accepted as the standard term used to refer to the instrument of measurement in the field of software. The term software measure was introduced in the 80's. This new term was introduced because, in general, a metric captures two arguments and brings the distance between them, so from that point of view, a software metric cannot really be defined as a metric. This last term emphasises the fact that software metrics should be defined in accordance with the measurement theory. However, today both terms continue to be used.

Star Schema: A relational schema whose design represents a multidimensional data model. A star schema consists of one central table and several dimensional The measures of interest are stored in the fact table (e.g., sales, inventory). For each dimension of the multidimensional model, there exists a dimensional table (e.g., product, time) that stores the information about the dimension.

Metrics for the Evaluation of Test–Delivery Systems

Salvatore Valenti
Università Politecnica delle Marche - Ancona - Italy

INTRODUCTION

Most solutions to the problem of delivering course content supporting both student learning and assessment nowadays imply the use of computers, thanks to the continuous advances of information technology. According to Bull (1999), using computers to perform assessment is more contentious than using them to deliver content and to support student learning. In many papers, the terms computer-assisted assessment (CAA) and computer-based assessment (CBA) are often used interchangeably and somewhat inconsistently. The former refers to the use of computers in assessment. The term encompasses the uses of computers to deliver, mark, and analyze assignments or examinations. It also includes the collation and analysis of data gathered from optical mark readers. The latter (that will be used in this paper) addresses the use of computers for the entire process, including assessment delivery and feedback provision (Charman & Elmes, 1998).

A typical CBA system is composed of the following.

- Test-Management System (TMS) - that is, a tool providing the instructor with an easy-to-use interface, the ability to create questions and to assemble them into tests, and the possibility of grading the tests and making some statistical evaluations of the results
- Test-Delivery System (TDS) - that is, a tool for the delivery of tests to the students. The tool may be used to deliver tests using paper and pencil, or a stand-alone computer on a LAN (local area network) or over the Web. The TDS may be augmented with a Web enabler used to deliver the tests over the Internet. In many cases, producers distribute two different versions of the same TDS: one to deliver tests either on single computers or on a LAN and the other to deliver tests over the WWW (World Wide Web). This is the policy adopted, for instance, by Cogent Computing Co. (2004) with CQuest LAN and CQuest Net.

The TMS and TDS modules may be integrated in a single application as, for instance, Perception developed by Question Mark Computing (2004), or may be delivered as separate applications as it occurs for MicroTest and MicroGrade developed by Chariot Software Group (2004).

BACKGROUND

The interest in developing CBA tools has increased in recent years thanks to the potential market of their application. Many commercial products, as well as freeware and shareware tools, are the result of studies and research in this field made by companies and public institutions.

Thus, for instance, 42 quiz software products are referenced by the Soft411 (2004) directory, 23 by the Educational Software (2004) directory, and 8 by Assessment System Co. (2004). Moreover, it must be noted that almost all course management systems (Edutools, 2004) provide facilities for CBA. This noteworthy growth in the market raises the problem of identifying a set of criteria that may be useful to an educational team wishing to select the most appropriate tool for their assessment needs. The literature on guidelines to support the selection of CBA systems seems to be very poor since no other up-to-date papers are available on the Internet apart from the works by the author and his colleagues (Valenti, Cucchiarelli, & Panti, 2002a, 2002b).

The purpose of this paper is to provide a framework for the evaluation of a test-delivery system.

METRICS FOR THE EVALUATION OF A TDS

Three main functional modules roughly compose a TDS: a student interface, a question-management unit, and a test-delivery unit. Therefore, our framework for the evaluation of a TDS is defined in terms of criteria that may support the evaluation of each functional module and other criteria for the evaluation of the whole system, as shown in Table 1.

The evaluation of the interface is a qualifying aspect for the evaluation of a CBA system and obviously for a TDS. This becomes dramatically true if we take into

Table 1. Metrics for the evaluation of a TDS

Issue		Metrics
Component Level	Interface	❄ Friendly GUI (graphical user interface)
	Question Management	❄ Types of Questions ❄ Question Structure (retries, tutorial building)
	Test Management	❄ Help and Hints ❄ Restricted Availability ❄ Grading
System Level		❄ Security ❄ Survivability ❄ Communication

account the fact that neither the teacher nor the students involved in the use of a TDS necessarily have a degree in computer science, nor may be interested in acquiring skills in this field. According to Nielsen and Molich (1990), the interface must be easy to learn, efficient to use, easy to remember, error free, and subjectively pleasing. Some further criteria that may be adopted to evaluate the usability of the interface are summarized in the following list.

- speak the users' language (multilinguality and multiculturality)
- be accessible
- provide feedback
- provide clearly marked exit points

The question-management unit of a TDS can be evaluated with respect to its ability to provide

- multiple attempts at solving a question (retries),
- feedback and tutorials on the topic covered by the questions, and
- capabilities for the inclusion of multimedia in questions.

The ability of providing retries may be of great importance for self-assessment since it is useful to improve the knowledge of the student whilst reducing the need for providing feedback and/or tutoring. On the other hand, the impossibility to change the answer to a question during an examination is often perceived as unfair by the students (Valenti et al., 2002b). It is worth outlining that allowing multiple attempts at question answering may affect the use of adaptive systems whenever item presentation depends on previous responses.

The feedback may be provided after each question (this solution being preferable for self-assessment), after a set of questions covering a given topic, or at the end of the test, and can be based on the overall performance. Furthermore, the feedback may be used to indicate the correctness of the answer, to correct misconceptions, or to deliver additional material for deepening and/or broadening the coverage of the topic assessed by the question. Tutorials represent an extended approach to provide additional information to the students. The existence of some facility to ease inclusion of tutorials in the TDS represents an important feedback aid. As an example, Perception provides explanation-type questions that may be used for "information screens, title pages, or to display large bodies of text" (Question Mark Computing Ltd., 2004).

The use of questions incorporating multimedia, such as sound and video clips or images, may improve the level of knowledge evaluation. This aspect may be of great importance, for example, in language assessment, where the comprehension of a talk or a movie can be assessed by recurring to multimedia only. The use of multimedia can raise issues related to portability and interoperability since it may require special hardware and software, both for the server delivering the questions and for the client used by the students. Furthermore, it may raise the costs for the adopted solution. These issues may not represent a problem whenever a Web-enabled TDS is selected since the nature of the World Wide Web is inherently multimedial. In this case, the choice of standard plug-ins for the most common browsers may reduce risks of portability and of interoperability. Since most plug-ins used to grant access to multimedia sources are usually free of charge, their use may not interfere with cost problems.

Among the issues taken into account to evaluate the test-management unit of a TDS, we have identified the ability to

- provide help and hints,
- make tests available at a given time, and
- allow scoring procedures.

The capability of a TDS to provide directions about the completion of the test and hints that usually are related to the contents of the questions represents a further measure of the ease of use of the application from the student's point of view.

Tests can be made either available or unavailable at a specified date and time. This allows test designers to specify exactly when people can access a test. It should be possible to leave out either or both restrictions to provide maximum flexibility. This lends itself nicely to the computer-lab setting where students are required to complete an online test during a specified time frame on a specified day.

Obviously, any software for assessment should be able to compute student grades. Furthermore, grades must be delivered as feedback to the course coordinator, to the instructor, and to the students. Each of these categories of stakeholders may require a different kind of feedback on the grades associated with a test. For instance, a student needs to know where he or she stands with respect to other students and to the class average besides his or her own individual and cumulative grades. This need raises obvious concerns about privacy that may be faced through the security facilities provided with the assessment tool.

Among the issues taken into account to evaluate a TDS from a systemic point of view, we have selected

- security,
- survivability, and
- communication with other software.

There is a wide range of security issues related to the use of TDSs. In more detail, many concerns on the security of the availability of the test material, on the HTML (hypertext markup language) code that implements testing, and on the access-control privileges do exist. With respect to security concerns about the test material and its HTML code, it must be outlined that while commercial programs usually implement encrypting approaches, a lot of issues are raised by freeware. In fact, most freeware applications rely either on Perl/CGI (common gateway interface) or on JavaScript. In particular, since a CGI program contains an executable code, the use of CGI-based applications is the equivalent of letting the world run a program on the server side, which is not the safest thing to do. Therefore, there are some security precautions that need to be implemented when it comes to using CGI-based applications. The one that will probably affect the typical Web user is the fact that CGI programs need to reside in a special directory so that the server knows to execute the program rather than just display it to the browser. This directory is usually under direct control of the webmaster, prohibiting the average user from creating CGI programs. On the other hand, the assessment program cannot be completely hidden whenever using a JavaScript code that runs on the client side of the application, so a "smart" student can access the source, discovering the right answer associated to each question. Some sophisticated techniques can be used to partially overcome this problem (Cucchiarelli, Panti, & Valenti, 2000).

The ability of a TDS to perform under adverse conditions (i.e., survivability as discussed in Valenti et al., 2002a) is of great importance. In particular, no termination procedures should result in any loss of data. To ensure this, both student and system files should be updated after each transaction so that no data is lost if the test is terminated because of machine or power failure. The possibility of providing examination printouts may further enforce the survivability of the system. Furthermore, after a crash, the system should be able to restart from the point of termination with all aspects of the original status unchanged, including the answers already given and the clock still displaying the time remaining.

Communication with other existing software may be very useful both for exporting answers and for calling external applications. Furthermore, this feature is required to allow the integration of a TDS with a TMS distributed by different producers. Exporting answers is usually performed through test files and data-conversion utilities. This may be useful to customize the reports generated by the application or whenever an in-depth analysis is needed to evaluate the results obtained. Moreover, many available TDSs enable the calling of a program as a block within a question. The called program returns a score in points that may be added to the test score. This may be useful for assessing abilities that cannot be evaluated through the basic question-answer paradigm of most assessment tools.

Finally, some tools allow external applications to be called at the very end of the test phase for printing certificates for all users who pass the test, for the electronic submission of the answer file to a central location for analysis and evaluation, and for the storage of the results in a file to be accessed by a user program (Question Mark Computing Ltd., 2004).

FUTURE TRENDS

The software-evaluation process is a very complicated task because many, often contradictory, attributes have to be taken into account. Issues such as selection of appropriate attributes, creation of their hierarchy, assignment of relative weights to them, and application of a sound decision-aid methodology arise frequently both for nonexperienced and skilled users. Therefore, a first step toward providing support for the evaluation of test-delivery systems could be the construction of a Web site listing all the available software on the market, providing an independently reviewed, objective source of information to help educators in making the best decision for their institution. A further step in this direction could be the implementation of a decision support system to be used as an (semi) automated aid for helping the educator in selecting the most appropriate criteria and constructing the evaluation model.

CONCLUSION

In this article we have discussed a framework that may be useful in assisting an educational team in the selection of a TDS. Three main functional modules roughly compose a TDS: a student interface, a question-management unit, and a test-delivery unit. Therefore, we decided to organize our framework by identifying some metrics to support the evaluation of the functional modules and other metrics to support the evaluation of the system as a whole.

KEY TERMS

Computer-based Assessment: addresses the use of computers for the entire process of assessment including production, delivery, grading, and provision of feedback

CGI: CGI is the acronym for common gateway interface. A CGI program is any program designed to accept and return data that conforms to the CGI specification. CGI programs are the most common way for Web servers to interact dynamically with users. The program could be written in any programming language including C, Perl, Java, or Visual Basic.

HTML: HTML is the acronym for hypertext markup language, the authoring language used to create documents on the World Wide Web. HTML defines the structure and layout of a Web document by using a variety of tags and attributes. HTML is derived from SGML, although it is not a strict subset.

JavaScript: a scripting language developed to enable Web authors to add dynamic content to sites. Although it shares many of the features and structures of the Java language, it was developed independently. It is supported by recent browsers from Netscape and Microsoft.

Multiculturality: the term used to address the measures now being taken to provide graphical user interfaces with ad hoc icons and texts according to the cultural heritage of the user

Multilinguality: the term used to address the measures now being taken to provide graphical user interfaces with features for internationalization, that is, support of the character sets and encodings used to represent the information being manipulated, and presentation of the data meaningfully

Test-Delivery System: a tool for the delivery of tests to students. The tool may be used to deliver tests using a stand-alone computer on a local area network or over the World Wide Web.

Migrating Legacy Systems to the Web

Lerina Aversano
University of Sannio, Italy

Gerardo Canfora
University of Sannio, Italy

Andrea De Lucia
University of Salerno, Italy

INTRODUCTION

Business Process Reengineering (BPR) is defined as "the fundamental rethinking and radical redesign of business processes to achieve significant improvements of the performances, such as cost, quality, service, and speed" (Hammer & Champy, 1993). Most BPR projects aim at converting business organisations from hierarchical centralised structures to networked decentralised business units cooperating with one another. This conversion is assuming a strategic relevance as the Internet is changing radically business processes, not only because they are purposely reengineered, but also because the Internet and the information and communication technology, offer more convenient means of fulfilling their requirement.

Current business processes have been profoundly fitted to the available software. The technologies involved in process execution impact the way businesses are conceived and conducted. Abstractly, BPR should entail discarding the existing and legacy systems to develop new software systems that meet the new business needs. This is superficially attractive and human appealing. However, legacy systems cannot be simply discarded because they are crucial systems to the business they support and encapsulate a great deal of knowledge and expertise of the application domain. This entails that even the development of a new replacement system may have to rely on knowledge which is encapsulated in the old system. In summary, existing systems are the result of large investments and represent a patrimony to be salvaged. Therefore, to satisfy the goals of a BPR project, it is necessary to work intensively to search a trade-off between the constraints of existing legacy systems and the opportune BPR strategy.

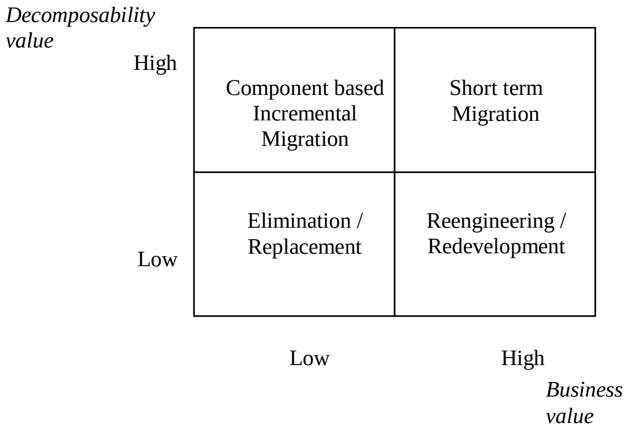
In this article, we discuss a strategy for migrating business processes and the supporting legacy systems to Web-centric architecture. The overall strategy comprises modelling the existing business processes and assessing the business and quality value of the supporting software systems. This is followed by the migration of the legacy systems, which can be in turn enacted with different strategies. The initial step consists of understanding and modelling the business processes together with the involved documents and software systems. The analysis of the existing processes is required to get an inventory of the activity performed, compare them with best practices, and redesign and/or reengineer them. Our overall approach is discussed in details in references (Aversano, Canfora, De Lucia, & Stefanucci, 2002a; Canfora, De Lucia, & Gallucci, 2002b), together with experience concerned with their applications. The final phase related to legacy system analysis and assessment is discussed in details in Aversano, Canfora, and De Lucia (2003) and briefly presented here.

BACKGROUND

Legacy systems are "large software systems that we don't know how to cope with but that are vital to our organization" (Bennett, 1995). There are a number of options available in managing legacy systems. Typical solutions include: discarding the legacy system and building a replacement system; freezing the system and using it as a component of a new larger system; modifying the system to give it another lease of life. Modifications may range from a simplification of the system (reduction of size and complexity) to preventive maintenance (redocumentation, restructuring, and reengineering) or even to extraordinary processes of adaptive maintenance (interface modification, wrapping, and migration) (Pigoski, 1997; De Lucia, Fasolino, & Pompella, 2001).

Several authors have identified possible alternatives for dealing with legacy systems and have proposed decision frameworks to select among the alternatives. In general, decision frameworks require that a legacy system be assessed from two points of views: a business dimension and a technical dimension (Bennett, Ramage, & Munro, 1999; De Lucia et al., 2001; Sneed, 1995). This information measures the complexity of the business processes and administrative rules that a system, or system's component, implements and their relevance to

Figure 1: A decisional framework



achieve business competitiveness. The technical value of a legacy system can be assessed through different quality attributes, such as the obsolescence of the hardware/software platforms, the level of decomposability, the maintainability, and the deterioration (De Lucia et al., 2001).

We assess the technical quality of a legacy system by considering the obsolescence and the decomposability level. In particular, we focus on making decisions on the actions to perform as a consequence of a BPR project aimed at taking advantage of the Internet. We assume that the obsolescence of the system is high, and therefore, extraordinary maintenance is required. Accordingly, the decision about the particular type of intervention to take will be made based on the decomposability and business value of the system.

Two different kinds of decomposability can be considered:

- *vertical decomposability*, which refers to the possibility of decomposing a system into major architectural layers;
- *horizontal decomposability*, which accounts for the possibility of decomposing a legacy system into independent and cooperating business components.

In particular, concerning the vertical decomposability, Brodie and Stonebaker (1995) refer that a software system can be considered as having three types of components: *interface components*, *application logic components*, and *database components*. Depending on how separated and well identified are these components, the architecture of a legacy system can be *decomposable*, *semidecomposable*, or *nondecomposable*. In a decomposable system, the application logic components are independent of each other and interact with the database components and system interfaces. In a semidecomposable system, only interfaces are separate modules, while application logic components and database services are not separated. A nondecomposable system is a black box with no separated components.

Figure 1 shows a decisional framework that takes into account the considerations described previously. The decision about the intervention to take on the legacy system with a high business value is mainly driven by the vertical decomposability of the system. If the vertical decomposability value is sufficiently high, that is, the system is decomposable or semidecomposable in the Brodie and Stonebaker terminology, the best strategy is a short term migration of the system, achieved through wrapping the application logic and/or data management functions (that define the server tier) and reengineering/redeveloping the user interface to a Web-centric style. This strategy represents a good alternative also in the case of a nondecomposable system, provided that the costs and risks of its decomposition are affordable (Canfora, De Lucia, & Di Lucca, 1999; Sneed, 1995). If the decomposability level of a system with high business value is too low, the complete reengineering / redevelopment alternative has to be preferred, as the legacy system can still be used.

For legacy systems with a low business value, the decision about the intervention to take is mainly driven by the horizontal decomposability. In particular, if the horizontal decomposability value is high, it is possible to use again the framework in Figure 1 to make different decisions for the different business components. This provides the basis for a component based incremental migration of the legacy system. Whenever both the business value and the decomposability of a legacy system are low, the only possible option is elimination/replacement. Indeed, in this case, there are no adequate business preconditions to evolve the existing system.

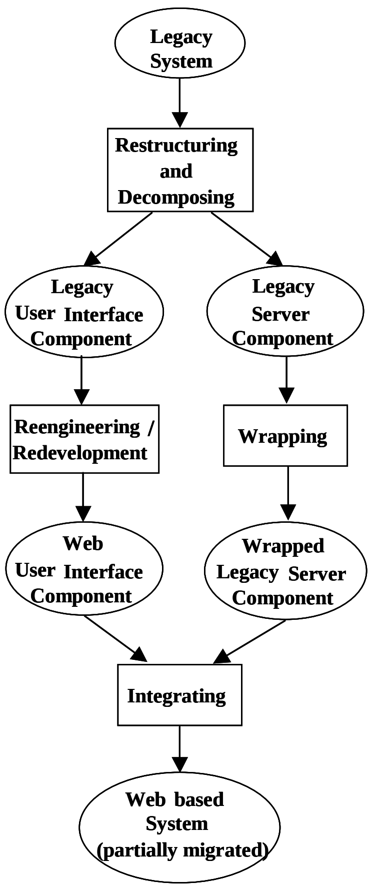
The migration of a legacy system entails the reuse of the system components while moving the system toward newer and more modern technology infrastructure. Brodie and Stonebraker (1995) propose an incremental approach, named Chicken Little, to migrate a legacy information system using gateways. A different approach proposed by Wu et al. (1997) is the Butterfly methodology, which eliminates the needs of accessing both the legacy and new database during the migration process, thus avoiding the complexity induced by the introduction of gateways to maintain the consistency of the data. Both the methodologies aim at migrating a legacy system mainly based on its vertical decomposability.

Migration strategies have also been proposed that take into account the horizontal decomposability. Canfora et al. (1999) and Serrano, Montes de Oca, and Carter (1999) present two strategies for incrementally migrating legacy systems to object-oriented platforms. The main difference is in the method adopted for identifying objects in procedural code. Both strategies use wrapping technologies to enable the coexistence of legacy and newly developed components. According to Mowbray and Zahari (1994), wrapping is the practice for implementing a software architecture using pre-existing components. Using object wrappers, the legacy code is encapsulated in a controllable way. The wrapper implements the interface through which newly developed objects access legacy resources; it is in charge of mapping incoming messages onto calls to the programs that implement the object methods. In the literature different approaches for wrapping have been presented (Arranga & Coyle, 1996; Canfora et al., 1999). The Web offers several other powerful mechanisms for wrapping legacy systems in a distributed environment. For example, XML is widely used by developers as a standard for data representation of the component's interfaces, message exchanging, and for defining scripting languages (Sneed, 2000).

MIGRATION STRATEGY

In this section, we present a Web-centric short term migration strategy based on vertical decomposability and on the use of wrappers. Full details of this migration strategy can be found in Aversano et al. (2003). This strategy applies to legacy systems with high business value and a high vertical decomposability level. Figure 2 shows the main phases of the migration process.

Figure 2: Short-term migration strategy



The first phase is the decomposition and restructuring of the legacy system to a client server style, where the user interface (client side) controls the execution of the application logic and database components (server side). The complexity of this phase depends on the decomposability of the system. Nondecomposable systems are the most difficult to be restructured, because decoupling the user interface from the application logic and database components can be very challenging and risky. Canfora, Cimitile, De Lucia, and Di Lucca (2000) present a method to identify the code implementing the user interface of these types of legacy systems. However, even migrating semidecomposable or decomposable systems might not be trivial. For semidecomposable or decomposable systems, the restructuring actions to be taken depend on the coupling between the user interface components and the other components. If all the data are exchanged through the calls between the client side and the application logic components, there is no need for restructuring. However, if the client and server components exchange some data through global data areas, data flow analysis and restructuring techniques are required to transform the global data into parameters to be exchanged across calls.

Once the legacy system has been restructured to a client server style, if needed, two phases can be conducted in parallel, namely the user interface reengineering and the wrapping of the server tier. The first phase aims at reengineering/redeveloping the user interface of the system by exploiting Web technologies. User interface reengineering entails using reverse engineering (Chikofsky & Cross, 1990) to abstract a user interface conceptual model and forward engineering to re-implement the user interface using Web technologies (Merlo et al., 1995; Moore & Rugaber, 1997). In particular MORPH (Moore & Rugaber, 1997) is a knowledge based approach that exploits transformation rules to restructure and transform the abstract model of the user interface into a new abstract model used to generate the target graphical user interface. We have used the MORPH guidelines to reengineer graphical user interfaces to Web interfaces (Aversano et al., 2003).

The transformation of the legacy user interface into the new Web interface should also be driven by the business needs. For example, if the new interface has to be used by the old users, a goal could be minimising the needs for re-training: in this case, in addition to establishing a one-to-one correspondence between the legacy and the new interaction objects, the mapping should be built maintaining a correspondence between the legacy panels and the new Web pages and forms (Aversano et al., 2003). However, in many cases the BPR process introduces new roles (for example, a legacy system in the reengineered process might be required to be accessed directly by a customer); in this case, the new interface must be radically redesigned to meet the new user needs (Sneed, 2000).

Wrapping the server tier is the key to reuse a legacy system with a high business value. In the last few years, the diffusion of the wrapping technology has had a significant impulse as a consequence of the use of Internet as a means of communication between remote programs. The final step of the migration strategy is the integration and testing of the new Web-based application. It is worth noting that once the Web-based migration of the legacy system is completed, the management of the new system will be based on a more general decision framework than the one in Figure 1 (see, e.g., De Lucia et al., 2001). In particular, the main factor to consider will be the business value, at least until the technical value of the system will be adequate to the evolving business needs. In other words, the migrated system will undergo periodical phases of evolution, to keep its functionality in line with the evolving business goals, interleaved with the ordinary maintenance of the system. Of course, a major shift in the technological business needs will entail a rapid increase of the obsolescence of the system, thus moving the management of the system to the decision framework of Figure 1.

The migration strategy has been applied in an industrial pilot project (Aversano et al., 2003). The project aimed at integrating into a Web-enabled architecture an existing online analytical processing COBOL system used by many banks for querying large archives of data for decision support through statistical and explorative analyses. The system has evolved over the past 15 years from a centralised mainframe version with a character-based user interface to a semi-decomposable client-server multiversion system composed of a graphical user interface running on a PC and several server components running on different platforms and accessed from the PC through a PC-host connection layer. In addition, a stand-alone version of the system working on the PC was available.

The need for migrating the system was imposed by the changes in the underlying business processes. The first and most important reason was the fact that the system was used by several banks to make decisions both at central and peripheral levels. In the old architecture, the PC-host connection layer had to be replicated on each client installation and this increased the application ownership costs. Most banks nowadays use Internet/intranet technologies for their information system infrastructure and this caused a push in the direction of Web migration. In addition, the new architecture adds flexibility; in particular, it opens the way to the migration of the stand alone PC version towards a distributed version which federates several archives/database host sources, thus eliminating the need for maintaining the different versions of the querying and analysis software.

After assessing the system, we opted for a short-term migration strategy with the aim of reducing, at a minimum, the time needed to have a working version of the Web-enabled system. Besides the graphical user interface component, the migrated part of the system consisted of 218 COBOL programs and more than 130 KLOC. The migration was achieved essentially through an extensive use of reverse engineering, to design the new user-interface, and wrapping, to implement the server side. In particular, the presentation layer of the original system was separated from the application logic and database components and re-implemented.

FUTURE TRENDS

Currently, highly dynamic and agile organisations models are emerging in order to compete in global marketplace. This poses significantly new problems for software development and maintenance, and software services are being promoted as the next big step forward in software engineering. A key issue is that services are something that the organizations use, not own. As a consequence, maintainability is not primarily a technical problem. Non-functional properties need to be incorporated into service models so that business drivers, as well as technical issues, can be addressed in maintaining and evolving software systems. Two key issues must be considered. The first is the nature of the service supply chain, enterprises tend to express their needs in models in which consumers and suppliers define requirements together. Real situations are more complex: consumers influence the type and method of supply and the supplier influences a consumer's business processes in order to adapt to their product.

The second issue is that the use of Web services requires a service-level agreement defining terms and conditions for use and maintenance. A critical success factor is the need for a negotiated and agreed architecture by which services can be used and maintained with minimum change.

CONCLUSION

This article has discussed a strategy for migrating business processes and the supporting legacy systems toward Web-centric architecture. The initial step consists of modelling the existing business processes and assessing the business and technical value of the supporting software systems. The analysis of the processes is required to get an inventory of the activity performed, and redesign and/or reengineer them. Based of the assessment, a decisional framework assists software managers to make informed decisions. This is followed by the migration of the legacy system, which can be in turn enacted with different approaches. In particular, the short-term system migration strategy decomposes and reengineers the system into its client and server components and uses wrappers to encapsulate the server components. Reverse engineering is used to abstract a model of the client components, and in particular the user interface, and redevelop them.

The short-term strategy was successful in reducing the time and the costs of migrating the system to adapt it to the new business scenario, however it did not change the quality of the server programs, which remain essentially unchanged, and therefore no benefits are expected in the future maintenance and evolution of the system. This is in contrast with other approaches that reverse engineer meaningful objects from the legacy code and wrap each of them separately. While more costly, such approaches offer more benefits on the long term as they enable incremental replacement strategies.

KEY TERMS

Business Process Reengineering (BPR): The fundamental rethinking and radical redesign of business processes to achieve significant improvements of the performances, such as cost, quality, service, and speed.

Legacy System: A software system which continues to be used because of the cost of replacing or redesigning it, despite its poor competitiveness and compatibility with modern equivalents.

Reengineering: The examination and alteration of a subject system to reconstitute it in a new form and the subsequent implementation of the new form.

Restructuring: The transformation from one representation form to another at the same relative abstraction level, while preserving the subject system's external behaviour.

Reverse Engineering: The process of analysing a subject system to (i) identify system components and their interrelationships and (ii) create representations of the system in another form or at a higher level of abstraction.

System Decomposability: The capability to decompose the system into a set of loosely coupled subsystems.

System Encapsulation: The definition and implementation of a software interface, called wrapper, that allows the access to the system, and its subsystems, from other applications.

System Migration: The incremental transformation of a legacy system toward newer and more modern technology. It entails the reuse of system components through their encapsulation.

Minorities and the Digital Divide

INTRODUCTION

Information and communication technologies (ICT) such as the World Wide Web, e-mail, and computers have become an integral part of America's entertainment, communication, and information culture. Since the mid-1990s, ICT has become prevalent in middle- and upper-class American households. Companies and government agencies are increasingly offering products, services, and information online. Educational institutions are integrating ICT in their curriculum and are offering courses from a distance.

However, while some are advantaged by the efficiencies and convenience that result from these innovations, others may unwittingly become further marginalized by these same innovations since ICT access is not spreading to them as quickly. The "digital divide" is the term used to describe this emerging disparity. Government analysts argue that historically underserved groups, such as racial and ethnic minorities, rural and low-income communities, and older Americans, are at a distinct disadvantage if this divide is not closed because American economic and social life is increasingly becoming networked through the Internet (National Telecommunications and Information Administration, 1995). The digital divide is not only an American social problem. Digital divide issues are of concern in developing countries as well as in information technology marginalized communities within developed nations.

Over the last decade, access to ICT has increased for most Americans, but does this mean that the problem of the digital divide has been solved? Is further research in this area warranted or has the digital divide become passé? In this article, we take on these questions by first reviewing major issues and trends in digital divide research. We do so by reviewing the digital divide literature as it relates to one historically underserved group, namely African-Americans. Next, we present a conceptual framework that contrasts 1) social and technological access perspectives, and 2) asset-based/resource and behavioral/use perspectives. The paper concludes with our recommendations for future research opportunities for examining digital divide issues.

BACKGROUND

There have been numerous definitions for the digital divide, government and industry reports about the digital divide, and competing interpretations of the statistics contained in these reports. For instance, the digital divide has been defined at the Whatis Web site as "the fact that the world can be divided into people who do and people who don't have access to — and the capability to use — modern information technology, such as the telephone, television, or the Internet." Others (PRNewswire, 2000) offer another definition: "arguably the single, largest, and segregating force in today's world. If it is not made a national priority, a generation of children and families will mature without these tools that are proving to be the key to the future."

Most of our knowledge about the digital divide in the U.S. is based on survey research on computer and Internet access in the home, at work, and in public places. The most cited statistics are found in the digital divide series produced by the U.S. Department of Commerce (National Telecommunications and Information Association, 1998, 1999, 2000, 2002). These studies have found that the divide cuts along the lines of ethnicity and race, geographic location, household composition, age, education, and income level. These and other studies have also documented that these gaps are persistent but closing (Goslee & Conte, 1998; Hoffman & Novak, 1998; Spooner & Rainie, 2001).

When we look at any particular demographic group, however, the analysis is much more complex and contradictory. For example, most research on the digital divide for African-Americans has centered on physical access to computers and Internet in the home, as well at technical skills to operate computers and information literacy skills to engage with content. These researchers have found that African-Americans are less likely to have ICT access and skills, even when controlling for other factors, such as income and education (Mossberger & Tolbert, 2003). The Pew Internet and American Life Project suggests that these gaps are closing, but African-Americans with access to the Internet do not go online as often on a typical day as whites do (Spooner & Rainie, 2000).

Blacks also tended to use ICT differently than other racial and ethnic groups. Novak, Hoffman, & Venkatesh (1997) summarize previous research on African-Americans with regard to different media as follows:

African-Americans have the highest participation in radio and TV and the lowest participation in newspapers. In terms of our classification, it means that historically, they have participated in greater measure in entertainment-oriented technologies rather than in information oriented technologies. Previous studies have also shown that African-American ownership of telephones is lower than white ownership, which may be due in part to differences in income.

They go on to theorize that culture helps to explain these results. African-Americans have found their social expression historically through the arts, and have been less successful in gaining entry to other dominant domains such as business, education, technical employment, and professional occupations. Culture may also help to explain Spooner & Rainie's (2000) observation that online African-Americans are 69% more likely than online whites to have listened to music on the Web, and are 65% more likely than online whites to have sought religious information on the Web. Music and spirituality has traditionally been integral components of African-American culture.

Although African-Americans may use ICT relatively less than other ethnic groups, they have more positive attitudes toward ICT than do similarly situated whites (Mossberger & Tolbert, 2003). Kvasny (2003) found that working class African-American women believed that ICT skills would prepare them for higher paying jobs, and improved their parenting abilities. In a study of ICT adoption in community technology project, Youtie et al. (2002) found that African-American women were among the highest adopters of cable TV-based Internet devices.

Although African-Americans harbored favorable attitudes towards ICT, these same technologies may have little impact on social inclusion. In a more recent study, Sipior, Ward, Volonino, & Marzec (2004) examined the digital divide in a public housing community in Delaware County, Pennsylvania. With 31 African-American participants with ages ranging from 13-65, these researchers concluded that effective community-based programs could help reduce the divide. While these interventions notably have improved computing skills about underserved groups, a one-time shot fails to eliminate or even reduce broader feelings of cultural isolation and economic deprivation among minority groups.

MAJOR ISSUES

When analyzing the digital divide literature, one of the foremost issues is whether a gap still exists. For example, in an article titled "True Nature of the 'Digital Divide' Divides Experts" (Jerding, 2000b), four technology watchers provided radically different standpoints. Mark Lloyd, an executive of the Civil Rights Forum on Communications Policy, states that technology inequality is the latest in a history of economic gaps. In his view, although private enterprise has put forth altruistic efforts, "real government action" was needed to bridge this void. Rick Weingarten, the director of the Office for Information Technology Policy, states that being connected wouldn't solve the problem. What is really at stake is the quality of access such as high-speed access and complex information literacy skills. Professor Jorge Schement believes that the digital divide will persist until Americans can put a face on the problem. So long as this is seen as a problem of the "Other," it can be more easily ignored and rationalized. The final panelist, Adam Clayton Powell II, denies the existence of a digital divide. Using the National Telecommunications and Information Administration studies, he argued that the gap between ethnic groups has dissipated. For him, the digital divide is largely a myth, and education rather than race or ethnicity was the highest barrier to technological access and effective use.

We contend that these debates about the existence of the digital divide result from a rather narrow treatment of a complex social phenomenon. In fact, many of the newer studies in this genre call for a rethinking of the digital divide (Warschauer, 2002; Gurstein, 2003; Hacker & Mason, 2003; Kvasny, 2003; Payton 2003). In what follows, we organize a discussion of the current trends in the digital divide discourse. We do so through a framework (*Table 1*) that contrasts two perspectives of access (technological and social) and two perspectives of use (asset-based and behavioral). Technological access focuses on the computing artifact, while social access focuses on know-how and competence. Asset-based perspectives view the divide as a deficiency in requisite resources, such as income or education, that enable ICT use, while behavioral perspectives tend to focus on the effectiveness of ICT use. Although these perspectives are presented as separate categories, authors tend to draw from both categories. For instance, the argument that the digital divide is based upon a lack of access to computing artifacts and computer skills suggests a technological access/asset-based perspective. An argument that the digital divide emerges from a lack of understanding about how to use ICT to further life chances adopts a social/behavioral perspective.

Table 1. Competing perceptions for examining the digital divide

Access Factors	Use Factors
Technological	Asset-based
Social	Behavioral

Technological and Social Access

The technological access view, with its focus on broad statistics on ICT diffusion and use rates, has led some policy analysts to assume that the answer lies in certain characteristics of the technology. Hence, policy solutions tend to employ technological fixes such as wiring public schools and libraries and providing computing resources with Internet access in poorer communities (Norris, 2001). We contend that an over reliance on descriptive statistics largely contributes to this technology-centric understanding of the digital divide. The more important question for studying as technological access increases is "what are people able to do with this access?"

We further argue that emphasis on quantitative descriptions of who has and who lacks access fuels debates about the degree to which the divide is temporary or permanent, whether the divide is widening or narrowing, or whether a divide exists at all. We have already seen the initial have/have not thesis superseded with the more complacent have now/have later prediction. Proponents of the have now/have later position argue that given enough time, competition will eventually alleviate any natural disparities in the marketplace.

Digital divide interventions informed by a technological access perspective are likely to subside once the technology gap has been narrowed through various programs and policies designed to distribute these resources more evenly. From this perspective, the digital divide would not warrant long-term policy remedies. High profile, short-term injections of government, foundation, or corporate assistance will occur until such time as the technology diffusion problem is lessened. Then, further critical attention to social inequities that are deeper than descriptions of technology access and use may be stifled. The digital divide will be simply defined away (Kvasny & Truex, 2001). For instance, in 2002 the Bush Administration declared the end of the digital divide and proposed deep cuts to federal digital divide programs. The biggest proposed cut was levied against the Technology Opportunities Program (TOP), a federal grant program designed to bring aid to communities that are lagging in access to digital technologies. Under the Clinton administration's 2001 budget, the program distributed $42 million in grants to 74 different non-profit organizations. In 2002, that number fell to just over $12 million (Benner, 2002) .

Analysts and researchers who adopt the social access perspective critique this shortsightedness, and assert that the technological access paradigm ignores social constraints, such as workforce literacy, income differentials, and the inevitable household tradeoffs required in making a PC purchase. Simply put, Maslow's Needs Hierarchy must be addressed from the most fundamental level if one is to progress to higher-order affiliation. The digital divide reflects not only differences in the structure of access, but also the ways in which historical, economic, social, cultural, political and other non-technological factors make such differences matter. Technology-centric solutions alone will do little to redress these aspects of the digital divide.

Asset-Based and Behavioral Perspectives

As access diffuses to historically underserved groups, use also becomes an important basis for studying the digital divide (DiMaggio & Hargittai, 2001; Patterson & Wilson, 2000; Warschauer, 2002; Gurstein, 2003). From an asset-based perspective, computer and Internet access are insufficient without the requisite skills and competencies to use the technology effectively (Mossberger, Tolbert, & Stansbury, 2003). These authors take historically underserved groups as their subjects, and point out the ways in which their use of ICT may be hampered. For instance, in a study of African-American youths, Payton (2003) found that these youths were all too aware that the digital divide is not merely about Internet access. Rather, it involves access to the social networks that ease the path to success in high-tech careers. Hargittai (2001) introduces the concept of "second level divides" to signify the disparities in computer skills and how these disparities are patterned along age, racial, gender and income categories. She found, for example, that search time was positively correlated with age, and negatively correlated with education and prior experience with technology.

In contrast, the behavioral perspective sees the digital divide in terms of disparities in benefits like social inclusion, economic opportunity and political participation that one derives from ICT use. These disparities provide primary justification for realizing that the digital divide is a public problem and not simply a matter of private misfortune (Warschauer, 2003). Groups that are historically underserved in their quality of employment, level of qualifications, level of income, quality of education, and consumption opportunities tend to also be marginalized in their access to and use of IT. The digital divide, therefore, is a political outcome rooted in these historical systems of power and privilege, and not simply a gap in access to technological artifacts. Promoting access and basic training to improve the computer skills of individuals is warranted, but may do little to redress the social forces that may limit these actions in the first place. From the behavioral perspective, the divide is about disparities in what individuals and groups are able to do with their ICT access. Gurstein (2003) contends that effective use of ICT occurs when people are able to use ICT purposively and independently to improve their life chances in culturally relevant domains such as economics, employment, health, education, housing, recreation, culture, and civic engagement.

FUTURE TRENDS AND CONCLUSION

Despite one's alignment regarding the nature and context (technological or social access; asset-based or behavioral use) of the digital divide, the topic warrants reconceptualization. Holistic approaches and frameworks will assist academic, government and industry leaders to first understand the "Other" and the social conditions under which these groups function. Technology access and skills can equip; however, taken in isolation, they cannot sustain, maintain, or offer access to the social, financial, or educational networks needed for empowerment of the "total person."

Thus, as digital divide research matures, there is a continued need to better understand the social dimensions of access. Kling (2000) contends that we do not have a good understanding of the ways that social access to the Internet is effectively supported for ordinary people at home and in public service agencies, such as schools and libraries. This is a topic that merits significant inquiry, since a large body of research points to its importance. He also argues that it is important to examine the specific kinds of networked services that will actually be of value to ordinary people. This goes beyond the current survey research and laboratory studies that contrast the use of ICT by various demographic groups. We need to understand why groups use ICT in the manner that they do, be appreciative of the culture relevance, and study how people use ICT in various contexts such as work, home, churches and public access facilities.

KEY TERMS

Content: The various genres of information available on the Internet. For instance, local content is information that is specific to a community, neighborhood, or area, such as businesses, housing, neighborhood services, and recreation activities. Community content is information about the neighborhood that promotes community development and facilitates community building. Examples include a listing of places where GED courses are offered, or a newsletter. Culturally relevant content is information that is significant to people with different cultural backgrounds.

Digital Divide: Refers to the gap that exists between these who have and those who do not have access to technology (telephones, computers, Internet access) and related services.

Effective Use: The capacity and opportunity to integrate information and communication technology into the accomplishment of self or collaboratively identified goals. What is most important is not so much the physical availability of computers and the Internet but rather people's ability to make use of those technologies to engage in meaningful social practices.

Historically Underserved Groups: Refers to those who lack access to computers and the Internet. Historically this has included Americans who have low incomes, live in rural communities, have limited education, and are members of racial or ethnic minorities.

Social Access: Refers to a mix of professional knowledge, economic resources, and technical skills to use technologies in ways that enhance professional practices and social life.

Social Inclusion: Refers to the extent that individuals, families, and communities are able to fully participate in society and control their own destinies, taking into account a variety of factors related to economic resources, employment, health, education, housing, recreation, culture, and civic engagement.

Technological Access: Refers to the physical availability of suitable information and communication technologies, including computers of adequate speed and equipped with appropriate software for a given activity.

Mobile Agent Authentication and Authorization in E-Commerce

Sheng-Uei Guan
National University of Singapore, Singapore

INTRODUCTION

With the increasing worldwide usage of the Internet, electronic commerce (e-commerce) has been catching on fast in a lot of businesses. As e-commerce booms, there comes a demand for a better system to manage and carry out transactions. This has led to the development of agent-based e-commerce. In this new approach, agents are employed on behalf of users to carry out various e-commerce activities.

Although the tradeoff of employing mobile agents is still a contentious topic (Milojicic, 1999), using mobile agents in e-commerce attracts much research effort, as it may improve the potential of their applications in e-commerce. One advantage of using agents is that communication cost can be reduced. Agents traveling and transferring only the necessary information save the bandwidth and reduce the chances of network clogging. Also, users can let their agents travel asynchronously to their destinations and collect information or execute other applications while they can disconnect from the network (Wong, 1999).

Although agent-based technology offers such advantages, the major factor that is holding people back from employing agents is still the security issues involved. On the one hand, hosts cannot trust incoming agents belonging to unknown owners, because malicious agents may launch attacks on the hosts and other agents. On the other hand, agents may also have concerns on the reliability of hosts and will be reluctant to expose their secrets to distrustful hosts.

To build bilateral trust in an e-commerce environment, the authorization and authentication schemes for mobile agents should be well designed. Authentication checks the credentials of an agent before processing the agent's requests. If the agent is found to be suspicious, the host may decide to deny its service requests. Authorization refers to the permissions granted for the agent to access whichever resource it requested.

In our previous work, we have proposed a SAFER (Secure Agent Fabrication, Evolution & Roaming) architecture (Zhu, 2000), which aims to construct an open, dynamic and evolutionary agent system for e-commerce. We have already elaborated agent fabrication, evolution, and roaming in Guan (1999, 2001, 2002), Wang (2001), and Zhu (2001). This article gives an overview of the authentication and authorization issues on the basis of the SAFER architecture.

BACKGROUND

Many intelligent agent-based systems have been designed to support various aspects of e-commerce applications in recent years, for example: Kasbah (Chavez, 1998), Minnesota AGent Marketplace Architecture (MAGMA) (Tsvetovatyy, 1997), and MAgNet (Dasgupta, 1999). Unfortunately, most current agent-based systems such as Kasbah and MAGMA are serving only stationary agents. Although MAgNet employs mobile agents, it does not consider security issues in its architecture.

D'Agents (Gray, 1998) is a mobile agent system, which employs the PKI for authentication purposes, and uses the RSA (Rivest, Shamir, & Adleman, 1978) public key cryptography (Rivest et al., 1978) to generate the public-private key pair. After the identity of an agent is determined, the system decides what access rights to assign to the agent and sets up the appropriate execution environment for the agent.

IBM Aglets (Lange, 1998; Ono, 2002) are Java-based mobile agents. Each aglet has a globally unique name and a travel itinerary (wherein various places are defined as context in IBM Aglets). The context owner is responsible for keeping the underlying operating system secure, mainly protecting it from malicious aglets. Therefore, he or she will authenticate the aglet and restrict the aglet under the context's security policy.

Ajanta is also a Java-based mobile agent system (Karnik, 1999, 2001, 2002) employing a challenge-response based authentication protocol. Each entity in Ajanta registers its public key with Ajanta's name service. A client has to be authenticated by obtaining a ticket from the server. The Ajanta Security Manager grants agents permissions to resources based on an access control list, which is created using users' Uniform Resource Names (URNs).

iJADE (intelligent Java Agent Development Environment) (Lee, 2002) provides an intelligent agent-based platform in the e-commerce environment. This system can provide fully automatic, mobile and reliable user authentication.

Under the public key infrastructure (PKI), each entity may possess a public-private key pair. The public key is known to all, while the private key is only known to the key owner. Information encrypted with the public key can only be decrypted with the corresponding private key. In the same note, information signed by the private key can only be verified with the corresponding public key (Rivest, 1978; Simonds, 1996). The default algorithm that generates the key pairs is the digital signature algorithm (DSA), working in the same way as a signature on a contract. The signature is unique, so that the other party can be sure that you are the only person who can produce it.

MAIN THRUST OF THE ARTICLE

This article presents an overview of the architecture based on SAFER (Secure Agent Fabrication, Evolution & Roaming) (Zhu, 2000) to ensure a proper authentication and authorization of agent. Here, the public key infrastructure (PKI) is used as the underlying cryptographic scheme. Also, agents can authenticate the hosts to make sure that they are not heading to a wrong place. According to the level of authentication that the incoming agent has passed, the agent will be categorized and associated with a relevant security policy during the authorization phase. The corresponding security policy will be enforced on the agent to restrict its operations at the host. The prototype has been implemented with Java.

Design of Agent Authentication and Authorization

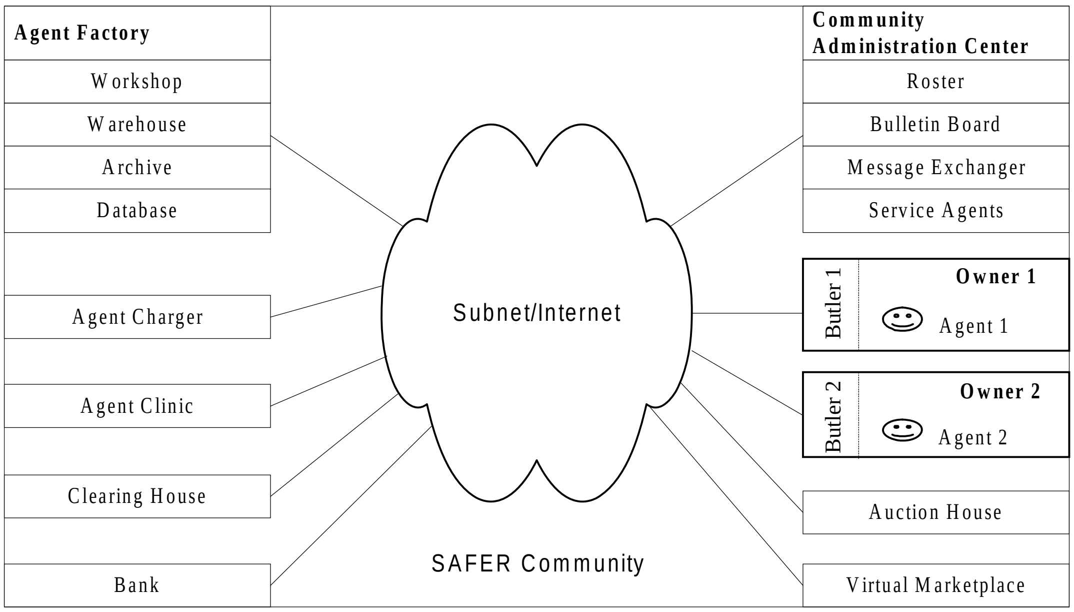
Overview of the SAFER Architecture

The SAFER architecture comprises various communities and each community consists of the following components (see Figure 1): Agent Owner, Agent Factory, Agent Butler, Community Administration Center, and so forth. The Agent Owner is the initiator in the SAFER environment, and requests the Agent Factory to fabricate the agents it requires. The Agent Butler is a representative of the Agent Owner authorized by the owner to coordinate the agents that are dispatched. Owner can go offline after dispatching his or her agents, and thereafter the butler can take over the coordination of the agents. The Agent Factory fabricates all the agents. This is the birthplace of agents and is thus considered a good source to check malicious agents. The Community Administration Center (CAC) is the administrative body, which has a roster that keeps the data of the agents that are in the community. It also collects information, such as addresses of new sites that agents can roam to.

Agent Structure and Cryptographic Schemes

In SAFER, mobile agents have a uniform structure. The agent credentials (hard-coded into the agent (Guan, 2000, 2001)) are the most important part of the agent body and are immutable. This part includes FactoryID, AgentID,

Figure 1. SAFER architecture



Expiry Date, and so forth. The Agent Factory then signs this immutable part. When the receiving host accepts an agent, it can verify with the Agent Factory's public key whether the agent's credentials have been modified. The mutable part of the agent includes the Host Trace, which stores a list of names of the hosts that the agent has visited so far. Upon checking, if any distrusted host is found, a host may decide not to trust this agent and impose a stricter security policy on it.

In SAFER, the main cryptographic technology used is the PKI. The public keys are stored in a common database located in CAC, where the public has read access, but no access to modify existing records.

Authentication Process

Authenticating Host

Before roaming to the next host, it is the duty of the agent to authenticate the next host to make sure that the host it is visiting is a genuine one. A hand-shaking method is devised to authenticate hosts. The agent sends its request to a host, asking for permission to visit. The host will sign on the agent's request message with its private key and send it back to the agent. The agent can then verify the host's identity by extracting the host's public key from the common database and authenticating the signature. If the authentication is successful, then the agent is communicating with the genuine host and starts to ship itself over to the host.

Authenticating Agent

Authentication of an agent involves two major steps: 1) to verify the agents' credentials, and 2) to verify the mutable part of the agent, checking whether it has been tampered with by anyone in its roaming process.
The authentication procedure is shown in Figure 2. Firstly, the agent will be checked for its expiry date. If it has not expired, its host trace will be examined to see if it has been to any distrusted host. If the agent passes these two tests, the final test is to check the trustworthiness of the factory that has manufactured it.

Authorization Process

After the host accepts an agent, it has to determine what resources the agent is allowed to access based on the level of authentication that the agent has passed. Four levels of authorization have been designed, with level 1 being the strictest and level 4 the most lenient. Level 1 authority is given to agents that the host does not have

Figure 2. Authentication & authorization procedure

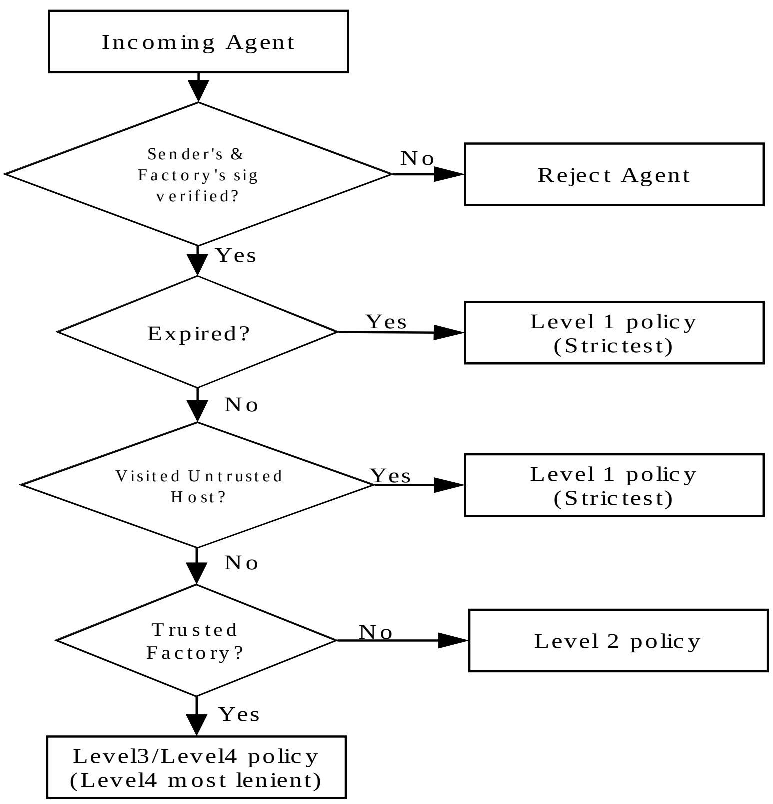


Table 1. Definition of the various security policies

Level of leniency	Policy name	Permissions
Level 4 (Most lenient)	Polfile.policy	FilePermission (Read, write)
		AWT Permission
		Socket Permission (Accept, Listen, Connect)
		Runtime Permission (create/set SecurityManager, queuePrintJob)
Level 3	Pol1.policy	FilePermission (Read, write)
		AWT Permission
		Socket Permission (Accept, Listen, Connect)
		Runtime Permission (create SecurityManager, queuePrintJob)
Level 2	Pol2.policy	FilePermission (Read only)
		AWT Permission
		Socket Permission (Accept, Connect)
		Runtime Permission (create SecurityManager)
Level 1 (Most Strict)	Pol3.policy	FilePermission (Read only)
		No AWT Permission
		No Socket Permission
		No Runtime Permission

much trust in. An agent that passes all levels of authentication and is deemed to be trusted may be awarded the level 4 authority. Table 1 shows the four policies and the restrictions imposed on each policy. The permissions can be customized to meet the requirements of different hosts. Here, AWT stands for Abstract Window Toolkit (AWT), which allows our programs to create a Graphical User Interface (GUI) to interact with the users.

Implementation

Implementation of agent authentication and authorization was done using the Java programming language. The Java Security API and the Java Cryptography Extension were widely used in the implementation. The graphical user interfaces were designed using the Java Swing components.

Discussions

We do not intend to compare our prototype with mobile agent systems such as D'agents and Aglets on detail benchmarks, as the focus of our approach is on the security issues in the context of e-commerce applications. Here, we present our features in comparison to related work, and discuss the advantages and limitations of our system in the following subsections.

Our approach has some features that are similar to the related systems discussed in the second section. For example, the authentication mechanism is based on PKI. The authorization mechanism is implemented using the Java security manager and some user-defined security policies. The major features of our approach lie in the method of authorization. Some agent systems authorize agents based on a role-based access control list and some are based on the identity of the agent. The SAFER system is different in that it allocates a different security policy based on the identity of the agent and the level of authentication it has passed.

Advantages of Our Infrastructure

Storage of Keys

One of the principal advantages of the prototype implemented is that there is no sending of keys over the network. This enhances the security of the system since it is impossible that keys can get intercepted and replaced.

The database storage of the public keys also allows an efficient method of retrieval of keys. This facilitates the verification of all previous signatures in the agent by the current host. For example, the owner may want to verify the signatures of all the previous hosts that the agent has visited. Instead of having all these hosts append their public keys to the agent (which may be compromised later), the owner can simply retrieve the keys from the database according to the hosts' ID.

Examining the Agent's Host Trace

Every host is required to sign on the agent's host trace before it is dispatched to the next destination. The IDs of the hosts visited are compared with the distrusted host list that each host would keep. If a distrusted host were found, the host would then take special precautions against these agents by imposing a stricter security policy on its operations.

Automation of the Authentication and Authorization Process

The beauty of this system is that it can be automated or run manually when the need arises. In the automatic configuration, when an agent is sent over, the host will do the authentication and assign an appropriate security policy to the agent. If the execution is successful, the host signs the agent and adds its identity on the host trace, before sending it out to the next host. In the manual configuration, all the authentication and authorization procedures need prompting from the host owner. The advantage is that the host has more control on what methods to authenticate and what authorization level and policy to enforce on the agent.

Limitations of Our Infrastructure

Pre-Determined Security Policies

In the current design, the agent is assigned to the security policy based on the authentication process. Having predetermined security policies may be stifling to the operations of an agent. It would be useless if the agent is denied the read access but instead granted other permissions that it does not need. The limitation here is an implementation choice because the mechanism to customize the permission for each agent has not been developed. Predetermined security policies are simpler to implement for large-scale systems.

Difficulty in Identifying a Malicious Host

The current implementation does not have a way of identifying the host that is causing the attacks on the agent. The agent owner can only detect that certain information has been tampered with, but does not know which host exactly caused the disparity.

FUTURE TRENDS

The implementation of the prototype has provided a basic infrastructure to authenticate and authorize agents. We are improving our approaches and implementation in two aspects. Firstly, to make the system more flexible in enforcing restrictions on agents, a possible improvement is to let the agent specify the security policy that it requires for its operation at the particular host. It is desirable to have a personalized system with the agent stating what it needs and the host deciding on whether to grant the permission or not. Secondly, the protection of agents against other agents can be another important issue. The authentication and authorization aspects between communicating agents are similar to that of host-to-agent and agent-to-host processes. We are designing certain mechanisms for this type of protection.

M

CONCLUSION

The advantages of employing mobile agents can only be manifested if there is a secure and robust system in place.

In this article, the design and implementation of agent authentication and authorization are elaborated. By combining the features of the Java security environment and the Java Cryptographic Extensions, a secure and robust infrastructure is built. PKI is the main technology used in the authentication module. To verify the integrity of the agent, digital signature is used. The receiving party would use the public keys of the relevant parties to verify that all the information on the agent is intact. In the authorization module, the agent is checked regarding its trustworthiness and a suitable user-defined security policy will be recommended based on the level of authentication the agent has passed. The agent will be run under the security manager and the prescribed security policy.

KEY TERMS

Agents: A piece of software, which acts to accomplish tasks on behalf of its user.

Authentication: The process of ensuring that an individual is who he or she claims to be.

Authorization: The process of giving access rights to an individual or entity.

Cryptography: The act of protecting data by encoding them, so that they can only be decoded by individuals who possess the key.

Digital Signature: Extra data appended to the message in order to authenticate the identity of the sender, and to ensure that the original content of the message or document that has been sent is unchanged.

Java: A high-level programming language similar to C++ developed by SUN Microsystems.

Private Key: That key (of a user's public-private key pair) known only to the user.

Public Key: The publicly distributed key that if combined with a private key (derived mathematically from the public key), can be used to effectively encrypt messages and digital signatures.

INTRODUCTION

With the introduction of the World Wide Web, electronic commerce has revolutionized traditional commerce and boosted sales and exchanges of merchandise and information. Recently, the emergence of wireless and mobile networks has made possible the admission of electronic commerce to a new application and research subject—mobile commerce, which is defined as the exchange or buying and selling of commodities, services, or information on the Internet through the use of mobile handheld devices. With services provided by mobile commerce, consumers may use the microbrowsers on their cellular phones or PDAs to buy tickets, order meals, locate and book local hotel rooms, even write contracts on the move.

In just a few years, mobile commerce has emerged from nowhere to become the hottest new trend in business transactions. NTT DoCoMo's i-mode (2003) is by far the most successful example of mobile commerce. Introduced in February 1999, i-mode has attracted over 36 million subscribers worldwide. With i-mode, cellular phone users can easily access more than 62,000 Internet sites, as well as specialized services such as e-mail, online shopping and banking, ticket reservations, and personalized ringing melodies that can be downloaded for their phones. The i-mode network structure not only provides access to i-mode and i-mode-compatible contents through the Internet, but also provides access through a dedicated leased-line circuit for added security. i-mode users are charged based on the volume of data transmitted, rather than the amount of time spent connected. In Spring 2001, NTT DoCoMo introduced its next-generation mobile system, based on wideband CDMA (W-CDMA), which can support speeds of 384Kbps or faster, allowing users to download videos and other bandwidth-intensive content with its high-speed packet data communications.

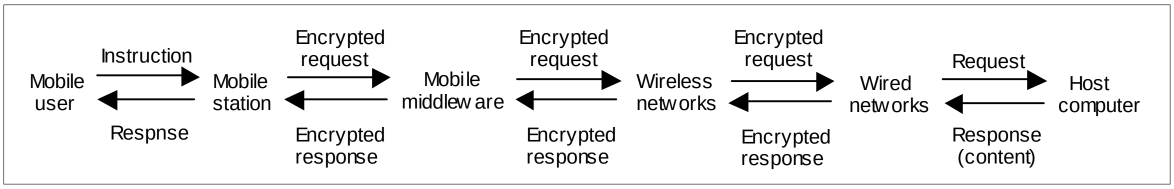
BACKGROUND

A mobile commerce system is very complex because it involves such a wide range of disciplines and technologies. In general, a mobile commerce system can be divided into six components: (1) mobile commerce applications, (2) mobile stations, (3 mobile middleware, (4) wireless networks, (5) wired networks, and (6) host computers.

To explain how these components work together, the following outline gives a brief description of a typical procedure that is initiated by a request submitted by a mobile user:

1. *Mobile commerce applications:* A content provider implements an application by providing two sets of programs: client-side programs, such as a user interface on a microbrowser, and server-side programs, such as database accesses and updating.
2. *Mobile stations:* Mobile stations present user interfaces to the end users, who specify their requests on the interfaces. The mobile stations then relay user requests to the other components and display the processing results later using the interfaces.
3. *Mobile middleware:* The major purpose of mobile middleware is to seamlessly and transparently map Internet contents to mobile stations that support a wide variety of operating systems, markup languages, microbrowsers, and protocols. Most mobile middleware also encrypts the communication in order to provide some level of security for transactions.
4. *Wireless networks:* Mobile commerce is possible mainly because of the availability of wireless networks. User requests are delivered to either the closest wireless access point (in a wireless local area network environment) or a base station (in a cellular network environment).

Figure 1. Flowchart of a user request processed in a mobile commerce system



5. *Wired networks:* This component is optional for a mobile commerce system. However, most computers (servers) usually reside on wired networks such as the Internet, so user requests are routed to these servers using transport and/or security mechanisms provided by wired networks.
6. *Host computers:* This component is similar to the one used in electronic commerce, which includes three kinds of software. User requests are generally acted upon in this component.

To better illustrate the above procedure, Figure 1 depicts a flowchart showing how a user request is processed by the components in a mobile commerce system (Leavitt, 2000).

MOBILE COMMERCE SYSTEMS

Since each component in a mobile commerce system is large enough to be a research area by itself, only elements in components that are specifically related to mobile commerce are explained in this article. Related research on mobile commerce systems can be found in the article by Varshney, Vetter, and Kalakota (2000).

Mobile Commerce Applications

The applications of electronic commerce are already widespread; mobile commerce applications not only cover these but also include new ones. For example, some tasks that are not feasible for electronic commerce, such as mobile inventory tracking and dispatching, are possible for mobile commerce. Table 1 lists some of the major mobile commerce applications (Gordon & Gebauer, 2001; Sadeh, 2002), along with details of each.

Mobile Stations

A mobile station or a mobile handheld device, such as a personal digital assistant (PDA) or Web-enabled cellular phone, may embrace many of the features of computers, telephone/fax, e-mails, and personal information managers (PIMs), such as calendars and address books, and networking features. A mobile station differs from a PC or notebook due to its limited network bandwidth, limited screen/body size, and mobility features. The limited network bandwidth prevents the display of most multimedia on a microbrowser, while the limited screen/body size restricts the mobile stations of today to either a stylus or keyboard version. Table 2 lists some major mobile station

Table 1. Major mobile commerce applications

Mobile Category	**Major Applications**	**Clients**
Commerce	Mobile transactions and payments	Businesses
Education	Mobile classrooms and labs	Schools and training centers
Enterprise resource planning	Resource management	All
Entertainment	Games/images/music/video downloads and online gaming	Entertainment industry
Health care	Accessing and updating patient records	Hospitals and nursing homes
Inventory tracking and dispatching	Product tracking and dispatching	Delivery services and transportation
Traffic	Global positioning, directions, and traffic advisories	Transportation and auto industries
Travel and ticketing	Travel management	Travel industry and ticket sales

Sony Ericsson Z1010			32MB	Keyboard	MP3, MMS, WAP2.0

specifications, although several table entries may be incomplete as some of the information is classified as confidential due to business considerations.

Mobile Middleware

The term middleware refers to the software layer between the operating system and the distributed applications that interact via the networks. The primary mission of a middleware layer is to hide the underlying networked environment's complexity by insulating applications from explicit protocol handling disjoint memories, data replication, network faults, and parallelism (Geihs, 2001). Mobile middleware translates requests from mobile stations to a host computer and adapts content from the host to the mobile station (Saha, Jamtgaard, & Villasenor, 2001). According to an article in *Eurotechnology* entitled Frequently asked questions about NTT-DoCoMo's i-mode (2000), 60%of the world's wireless Internet users use i-mode, 39% use WAP, and 1% use Palm middleware. Table 3 compares i-mode and WAP, the two major kinds of mobile middleware.

Wireless Networks

Network infrastructure provides essential voice and data communication capability for consumers and vendors in cyberspace. Evolving from electronic commerce (EC) to

Table 3. Comparisons of WAP and i-mode

Developer	WAP Forum	NTT DoCoMo
Function	A protocol	A complete mobile Internet service
Host Language	WML (Wireless Markup Language)	CHTML (Compact HTML)
Major Technology	WAP Gateway	TCP/IP modifications
Key Features	Widely adopted and flexible	Highest number of users and easy to use

mobile commerce (MC), it is necessary for a wired network infrastructure, such as the Internet, to be augmented by wireless networks that support mobility for end users. From the perspective of mobile commerce, wireless networks can be categorized into wireless local area networks (WLANs) and wireless cellular networks.

WLAN technologies are suitable for office networks, home networks, personal area networks (PANs), and ad hoc networks. In a one-hop WLAN environment, where an access point (AP) acting as a router or switch is a part of a wired network, mobile devices connect directly to the AP through radio channels. Data packets are relayed by the AP to the other end of a network connection. If no APs are available, mobile devices can form a wireless ad hoc network among themselves and exchange data packets or perform business transactions as necessary. Many WLAN products are available on the market. In general, Bluetooth technology supports very limited coverage range and throughput. Thus it is only suitable for applications in personal area networks. In many parts of the world, the IEEE 802.11b (Wi-Fi) system is now the most popular wireless network and is used in offices, homes, and public spaces such as airports, shopping malls, and restaurants. However, many experts predict that with much higher transmission speeds, 802.11g will replace 802.11b in the near future.

Cellular system users can conduct mobile commerce operations through their cellular phones. Under this scenario, a cellular phone connects directly to the closest base station, where communication is relayed to the service site through a radio access network (RAN) and other fixed networks. Originally designed for voice-only communication, cellular systems are evolving from analog to digital, and from circuit-switched to packet-switched networks, in order to accommodate mobile commerce (data) applications. Currently, most of the cellular wireless networks in the world follow 2G or 2.5G standards. However, there is no doubt that, in the near future, 3G systems with quality-of-service (QoS) capability will dominate wireless cellular services. The two main standards for 3G are Wideband CDMA (WCDMA), proposed by Ericsson, and CDMA2000, proposed by Qualcomm.

Host Computers

A host computer processes, produces, and stores all the information for mobile commerce applications. This component is similar to that used in an electronic commerce system because the host computers are usually not aware of differences among the targets, browsers or microbrowsers they serve. It is the application programs that are responsible for apprehending their clients and responding to them accordingly. Most of the mobile commerce application programs reside in this component, except for some client-side programs such as cookies. Usually this component contains three major elements: a Web server, a database server, and application programs and support software.

FUTURE TRENDS

It is estimated that 50 million wireless phone users in the United States will use their handheld devices to authorize payment for premium content and physical goods at some point during the year of 2006. This represents 17% of the projected total population and 26% of all wireless users (The Yankee Group, 2001). Mobile commerce is an effective and convenient way to deliver electronic commerce to consumers from anywhere and at anytime. Realizing the advantages to be gained from mobile commerce, many major companies have begun to offer mobile commerce options for their customers in addition to the electronic commerce they already provide (Over 50% of large U.S. enterprises plan to implement a wireless/mobile solution by 2003, 2001).

However, without secure commercial information exchange and safe electronic financial transactions over mobile networks, neither service providers nor potential customers will trust mobile commerce systems. Mobile security and payment are hence crucial issues for mobile commerce. Security issues span the whole mobile commerce system, from one end to the other, from the top to the bottom network protocol stack, from machines to humans. For example, in WAP, security is provided through the Wireless Transport Layer Security (WTLS) protocol (in WAP 1.0) and IETF standard Transport Layer Security (TLS) protocol (in WAP 2.0). They provide data integrity, privacy, and authentication. One security problem, known as the “WAP Gap” is caused by the inclusion of the WAP gateway in a security session. That is, encrypted messages sent by end systems might temporarily become clear text on the WAP gateway when messages are processed. One solution is to make the WAP gateway resident within the enterprise (server) network (Ashley, Hinton, & Vandenwauver, 2001), where heavyweight security mechanisms can be enforced.

In an IEEE 802.11 WLAN, security is provided by a data link level protocol called Wired Equivalent Privacy (WEP). When it is enabled, each mobile host has a secret key that is shared with the base station. The encryption algorithm used in WEP is a synchronous stream cipher based on RC4. The ciphertext is generated by XORing the plaintext with a RC4 generated keystream. However, recently published literature has discovered methods for breaking this approach (Borisov, Goldberg, & Wagner, 2001; Fluhrer, Martin, & Shamir, 2001; Stubblefield, Ioannidis, & Rubin, 2002). The next version, 802.11i, is expected to have better security.

Payment on mobile commerce systems is another issue. Although the Secure Electronic Transaction (SET) protocol (SET Secure Electronic Transaction Specification, Version 1.0, 1997) is likely to become the global standard in the domain of electronic commerce over the Internet, a WAP client device normally does not have sufficient processing and memory capability to utilize SET software. A "thin" SET wallet approach (Jin, Ren, Feng, & Hua, 2002) has thus been proposed to adapt the SET protocol for WAP clients. Under the "thin" SET wallet model, most of the functionality of current "fat" SET wallets is moved to the wallet server. To support a SET payment, a WAP client installed with only a "thin" wallet securely connects with a wallet server, which communicates with other SET entities. When SET purchase requests arrive from the "thin" wallet, the wallet server takes over the responsibility of routing requests and managing digital keys and certificates.

CONCLUSION

The emerging wireless and mobile networks have extended electronic commerce to another research and application subject: mobile commerce. A mobile commerce system involves a range of disciplines and technologies. This level of complexity makes understanding and constructing a mobile commerce system an arduous task. To facilitate this process, this article divided a mobile commerce system into six components, which can be summarized as follows:

- Mobile commerce applications: Electronic commerce applications are already broad. Mobile commerce applications not only cover the existing applications, but also include new applications, which can be performed at any time and from anywhere by using mobile computing technology.
- Mobile stations: Mobile stations are limited by their small screens, limited memory, limited processing power, and low battery power, and suffer from wireless network transmission problems. Numerous mobile stations, such as PDAs or Web-enabled cellular phones, are available on the market, but most use one of three major operating systems: Palm OS, Microsoft Pocket PC, and Symbian OS. At this moment, Palm OS leads the market, although it faces a serious challenge from Pocket PC.
- Mobile middleware: WAP and i-mode are the two major kinds of mobile middleware. WAP is widely adopted and flexible, while i-mode has the highest number of users and is easy to use. It is difficult to predict which middleware will be the eventual winner in the end; it is more likely that the two will be blended somehow at some point in the future.
- Wireless and wired networks: Wireless communication capability supports mobility for end users in mobile commerce systems. Wireless LANs and cellular networks are major components used to provide radio communication channels so that mobile service is possible. In the WLAN category, the Wi-Fi standard with 11 Mbps throughput dominates the current market. It is expected that standards with much higher transmission speeds, such as 802.11g, will replace Wi-Fi in the near future. Compared to WLANs, cellular systems can provide longer transmission distances and greater radio coverage, but suffer from the drawback of much lower bandwidth (less than 1 Mbps). In the latest trend for cellular systems, 3G standards supporting wireless multimedia and high-bandwidth services are beginning to be deployed. WCDMA and CDMA2000 are likely to dominate the market in the future.
- Host computers: Host computers process and store all the information needed for mobile commerce applications, and most application programs can be found here. They include three major components: Web servers, database servers, and application programs and support software.

An important trend for mobile commerce is enhancing mobile security mechanisms and payment methods. Mobile commerce systems can prosper only if information can be securely exchanged among end systems (consumers and vendors). Security issues (including payment) include data reliability, integrity, confidentiality, and authentication and are usually a crucial part of implementation in wireless protocols/systems. Solutions are updated frequently, due to the lack of a comprehensive wireless security infrastructure and standard. A unified approach has not yet emerged.

KEY TERMS

i-mode: the full-color, always-on, and packet-switched Internet service for cellular phone users offered by NTT DoCoMo.

Mobile Commerce: the exchange or buying and selling of commodities, services, or information on the Internet (wired or wireless) through the use of mobile handheld devices.

SET: the Secure Electronic Transaction (SET) protocol is a technical standard designed to provide security for payment transactions among cardholders, merchants, payment gateways, and certification authorities in Internet.

Third Generation (3G): wireless system that can provide fairly high-speed (384 Kbps) packet-switched wide-area wireless Internet access to support multimedia applications.

Wi-Fi: IEEE 802.11b (Wi-Fi) is a wireless local area network standard. It operates in an unlicensed radio frequency band at 2.4 GHz and provides data access at 11 Mbps.

Wired Equivalent Privacy (WEP): a data link-level protocol that provides security for the IEEE 802.11 WLAN standards. The encryption algorithm used in WEP is a stream cipher based on

Wireless Application Protocol (WAP): an open, global specification that allows users with mobile devices to easily access and interact with information and services instantly

Mobile Location Services

George M. Giaglis
Athens University of Economics and Business, Greece

INTRODUCTION

The term "mobile era" as a characterization of the 21st century can hardly be considered an exaggeration (Kalakota & Robinson, 2001). Mobile phones are the fastest penetrating technology in the history of mankind, and global mobile phone ownership has surpassed even the ownership of fixed phones. Mobile applications, despite potentially being very different in nature from each other, all share a common characteristic that distinguishes them from their wire-line counterparts: they allow their users to move around while remaining capable of accessing the network and its services. In the mobility era, *location identification* has naturally become a critical attribute, as it opens the door to a world of applications and services that were unthinkable only a few years ago (May, 2001).

The term "mobile location services" (MLS) [or "location-based services (LBS), as they are sometimes also referred to] has been coined to group together applications and services that utilize information related to the geographical position of their users to provide value-adding services to them (Rao & Minakakis, 2003). This article provides a concise introduction to the major types of MLS and also introduces the reader to the most important positioning technologies that render the provision of MLS possible. Finally, the article also introduces a number of issues that are critical for the future of MLS, including privacy protection, regulation, and standardization.

CATEGORIES OF MOBILE LOCATION SERVICES

Mobile networks are quickly becoming ubiquitous. The ability to reach mobile phone users regardless of their location and, even more importantly, the ability to reach mobile phone users *based* on their location has created a new world of exciting and promising applications. While the possibilities for providing innovative MLS are limited only by one's imagination, we will outline the most important categories of such services in this section.

Emergency Management

Perhaps the clearest market application of MLS is the ability to locate an individual who is either unaware of his or her exact location or is not able to reveal it because of an emergency situation (injury, criminal attack, and so on). MLS are even applicable as a means of overcoming one of the most common problems of motorists, namely, the fact that, most often than not, they are unaware of their exact location when their vehicle breaks down. The ability of a mobile user to call for assistance and at the same time automatically reveal his or her exact location to the automotive assistance agency is considered one of the prime motivators for signing up subscribers to MLS (Hargrave, 2000).

Navigation Services

Navigation services are based on mobile users' needs for directions within their current geographical locations. The ability of a mobile network to locate the exact position of a mobile user can be manifested in a series of navigation-based services:

1. By positioning a mobile phone, an operator can let users know exactly where they are as well as give them detailed *directions* about how to get to a desirable destination.
2. Coupled with the ability to monitor traffic conditions, navigation services can be extended to include destination directions that take account of current *traffic conditions* (for example, traffic congestion or a road-blocking accident) and suggest alternative routes to mobile users.
3. The possibility to provide detailed directions to mobile users can be extended to support *indoor routing* as well. For example, users can be assisted in their navigation in hypermarkets, warehouses, exhibitions, and other information-rich environments to locate products, exhibition stands, and other points of interest.
4. Similarly, *group management* applications can be provided to allow mobile users to locate friends, family, coworkers, or other members of a particular

group that are within close range and, thus, create *virtual communities* of people with similar interests.

Information Provision

Location-sensitive information services mostly refer to the digital distribution of content to mobile terminal devices based on their location, time specificity, and user behavior. The following types of services can be identified within this category:

1. *Travel services*, such as guided tours (either automated or operator-assisted), notification about nearby places of interest (for example, monuments), transportation assistance, and other services that can be provided to tourists moving around in unfamiliar surroundings.
2. *Mobile yellow pages* that provide a mobile user, upon request, with knowledge regarding nearby facilities.
3. *Infotainment services*, such as information about local events, location-specific multimedia content, and so on.

Advertising and Marketing

Mobile advertising is among the first trial applications of MLS, due to its promising revenue potential and its direct links to mobile-commerce activities. Furthermore, mobile advertising has gained significant attention because of the unique attributes, such as *personalization* (Kalakota & Robinson, 2001), that offer new opportunities to advertisers to place effective and efficient promotions on mobile environments. There are various mechanisms for implementing mobile advertising coupled with MLS. Examples of mobile advertising forms include *mobile banners*, *alerts* (usually dispatched as SMS messages), and *proximity-triggered advertisements*.

Tracking

Tracking services can be equally applicable to the consumer and the corporate markets. As far as consumers are concerned, tracking services can be utilized to monitor the exact whereabouts of, for example, children and elderly people. Similarly, tracking services can be effectively applied in corporate situations as well. One popular example refers to tracking vehicles so that companies know where their fleet and goods are at any time. A similar application allows companies to locate their field personnel (for example, salespeople and repair engineers) so that they are able, for example, to dispatch the nearest engineer and provide their customers with accurate personnel arrival times. Finally, the newfound opportunity to provide accurate product tracking within the supply chain offers new possibilities to mobile supply chain management (m-SCM) applications (Kalakota & Robinson, 2001).

Billing

Location-sensitive billing refers to the ability of a mobile service provider to dynamically charge users of a particular service depending on their location when using or accessing the service. For example, mobile network operators may price calls based on the knowledge of the location of the mobile phone when a call is made. Location-sensitive billing includes the ability to offer reduced call rates to subscribers who use their mobile phone when at their home, thereby allowing mobile operators to compete more effectively with their fixed telephony counterparts.

POSITIONING TECHNOLOGIES

The applications and services that were discussed in the previous section are based on underlying technological capabilities that enable the identification of the location of a mobile device, thereby making the provision of MLS possible. Positioning techniques can be implemented in two ways: *self-positioning* and *remote positioning* (Zeimpekis et al., 2003).

In the first approach (self-positioning), the mobile terminal uses signals, transmitted by the gateways/antennas (which can be either terrestrial or satellite) to calculate its own position. More specifically, the positioning receiver makes the appropriate signal measurements from geographically distributed transmitters and uses these measurements to determine its position. A self-positioning receiver, therefore, "knows" where it is, and applications collocated with the receiver can use this information to make position-based decisions, such as those required for vehicle navigation.

In the case of remote positioning, the mobile terminal can be located by measuring the signals travelling to and from a set of receivers. More specifically, the receivers, which can be installed at one or more locations, measure a signal originating from, or reflecting off, the object to be positioned. These signal measurements are used to determine the length and direction of the individual radio paths, and then the mobile terminal position is computed from geometric relationships.

Self-Positioning Techniques

Global Positioning System (GPS) and Assisted GPS (A-GPS): GPS is the worldwide satellite-based radio navigation system, consisting of 24 satellites, equally spaced in six orbital planes 20,200 kilometres above the Earth, that transmit two specially coded carrier signals: one for civilian use and one for military and government use (Djuknic & Richton, 2001). The system's satellites transmit navigation messages that a GPS receiver uses to determine its position. GPS receivers process the signals to compute position in three dimensions—latitude, longitude, and altitude—with an accuracy of 10 meters or less. The main advantage of this technique is that GPS is already in use for many years. However, in order to operate properly, GPS receivers need a clear view of the skies and signals from at least three or four (depending on the type of information needed) satellites, requirements that exclude operation in indoor environments. As far as the A-GPS method is concerned, the mobile network or a third-party service provider can assist the handset by directing it to look for specific satellites and also by collecting data from the handset to perform location identification calculations that the handset itself may be unable to perform due to limited processing power. The A-GPS method can be extremely accurate, ranging from 1 to 10 meters (Giaglis et al., 2002).

Indoor Global Positioning System (Indoor GPS): This system focuses on exploiting the advantages of GPS for developing a location-sensing system for indoor environments. It should be noted that the GPS signal does not typically work indoors, because the signal strength is too low to penetrate a building (Chen & Kotz, 2000). Indoor GPS solutions can be applicable to wide space areas where no significant barriers exist. Indoor GPS takes into account the low power consumption and small size requirements of wireless access devices, such as mobile phones and handheld computers. The navigation signal is generated by a number of pseudolites (pseudo-satellites). These are devices that generate a GPS-like navigation signal. The signal is designed to be similar to the GPS signal in order to allow pseudolite-compatible receivers to be built with minimal modifications to existing GPS receivers. As in GPS, at least four pseudolites have to be visible for navigation, unless additional means, such as altitude aiding, are used (Giaglis et al., 2002).

Remote Positioning Techniques

Cell Identification (Cell-ID): The Cell-ID (or *Cell of Origin, COO*) method is the most widely used technique to provide location services and applications in second-generation mobile communication networks. The method relies on the fact that mobile networks can identify the approximate position of a mobile handset by knowing which cell site the device is using at a given time. The main benefit of the technology is that it is already in use today and can be supported by all mobile handsets. However, the accuracy of the method is generally low (in the range of 200 meters in densely covered areas and much lower in rural environments) (Giaglis et al., 2002).

Angle of Arrival (AOA): The basic idea is to steer in space a directional antenna beam until the direction of maximum signal strength is detected. In terrestrial mobile systems, the directivity required to achieve accurate measurements is obtained by means of antenna arrays (Sakagami et al., 1994). Basically, a single measurement produces a straight-line locus from the base station to the mobile phone. Another AOA measurement will yield a second straight line, and the intersection of the two lines gives the position fix for this system.

Time of Arrival (TOA): Positioning information is derived from the absolute time for a wave to travel between a transmitter and a receiver or vice versa. This implies that the receiver knows the exact time of transmission. Alternatively, this approach might involve the measurement of the round-trip time of a signal transmitted from a source to a destination and then echoed back to the source, giving a result twice that of the one-way measurement. This does not imply synchronization between the transmitter and the receiver and is the most common means of measuring propagation time.

Differential Time of Arrival (DTOA): The problem of having precisely synchronized clocks at transmitter and receiver is solved by using several transmitters synchronized to a common time base and measuring the time difference of arrival at the receiver. More specifically, each DTOA measurement defines a hyperbolic locus on which the mobile terminal must lie. The intersection of the hyperbolic loci will define the position of the mobile device.

CRITICAL ISSUES RELATED TO MLS

Further to the business and technological aspects of mobile location services discussed above, a number of other critical factors will also ultimately determine their successful application in mobile communication networks. Such issues include the need to protect sensitive personal information of individuals, as well as the role of regulation and standardization initiatives in establishing the right climate for market rollout and healthy competition.

Privacy Protection

According to Nokia (2001), "of all the challenges facing mobile location service providers, privacy is undoubtedly the biggest single potential barrier to market take-up" (p. 9). For example, mobile advertising based on a user's location is a sensitive issue and has to be provided only with the explicit consent of the user.

However, even in such a case, the likely exchange of information between third parties (for example, network operators and advertising agencies) may hamper the privacy of user's personal data. To ensure commercial success of mobile location services, user trust must be ensured. A clear prerequisite of the trust-building mechanism is that the control over the use of location information is always on the hands of the user, not of the network operator or the service provider.

Regulation and Standardization

The role of regulatory and policy-making bodies is substantially enhanced in the case of mobile location services. It is not surprising that the initial boost to the market has come from such bodies (the US FCC mandate for emergency services) and that the European Commission has had a very active role in the development of the market on the other side of the Atlantic.

Standardization can also be a serious success or failure factor for any new technology, and mobile location services are not an exception to this rule. A number of bodies worldwide are working toward defining commonly accepted standards for the mobile industry, but prior experience has shown that standardization efforts may have a regional, rather than a global, scope. For example, the presence of incompatible standards for second-generation mobile telephony in Europe and the Americas has created considerable problems for users and the industry alike. Worldwide efforts to define universal standards for third-generation systems provide a more optimistic view of the future; however, the danger of incompatibility and technological "islands" remains. To this end, a number of standardization initiatives are underway, sometimes initiated by the industry. For example, Ericsson, Motorola, and Nokia, have joined forces to establish the *Location Interoperability Forum (LIF)*, with the purpose of developing and promoting common and ubiquitous solutions for mobile location services.

The importance of standardization becomes even more evident when we think of what can be termed as *the paradox of mobile location services*. Although these services are by definition local, any given user will most probably need them when in a nonlocal environment. We can envisage tourists outside the familiar surroundings of their local residences relying on MLS to obtain assistance and directions, and companies also utilizing MLS to track their goods in distant lands. To be useful to their users, mobile location services must, therefore, be provided in a location-independent and user-transparent fashion. From a standardization and technological point of view, this requirement poses a difficult problem: *service portability* and *roaming* issues have to be resolved in order for MLS to be compelling to users (UMTS, 2001).

KEY TERMS

Angle of arrival (AOA): A positioning technology in which the mobile network sends directional antenna beams to locate a mobile device at the intersection of the directions of maximum signal strength.

Assisted global positioning system (A-GPS): A variation of the *global positioning system (GPS)* in which the mobile network or a third-party service provider assists the mobile handset in determining its geographical position (either by directing it to look for specific satellites or by collecting data from the handset to perform location identification calculations that the handset itself may be unable to perform due to limited processing power).

Cell Identification (Cell-ID): The Cell-ID method is the basic technique to provide location services and applications in second-generation mobile communication networks. The method relies on the fact that mobile networks can identify the approximate position of a mobile handset by knowing which cell site the device is using at a given time.

Differential time of arrival (DTOA): A positioning technology in which several transmitters (synchronized to a common time base) are used to measure time differences of arrival at the receiver and, hence, determine the receiver's geographical position.

Global positioning system (GPS): GPS is the worldwide satellite-based radio navigation system. The system's satellites transmit messages that a receiver uses to determine its own geographical position.

Indoor global positioning system (Indoor GPS): A variation of the *global positioning system (GPS)* for use in indoor environments, where the normal GPS signal does not typically work, because the signal strength is too low to penetrate a building. Indoor GPS navigation signals are generated by a number of pseudolites (pseudo-satellites) and are sent to pseudolite-compatible receivers that use the information to determine their own geographical positions.

Location-based services (LBS): A synonym for *mobile location services (MLS)* denoting applications that utilize the knowledge of one's geographical position to provide added-value services.

Location identification: The ability of mobile hosts to determine the geographical location of wireless access devices.

Mobile location services (MLS): Applications provided over a mobile network that utilize information related to the geographical position of their users to provide added value to them.

Time of arrival (TOA): A positioning technology where information is derived from the absolute time for a wave to travel between a transmitter and a receiver or vice versa.

Mobile Transaction Models Framework

Eduardo Rodriguez
Universidad de Buenos Aires, Argentina

INTRODUCTION

Currently, mobile technology is undergoing a high growth stage, allowing for an increasing plethora of mobile devices (handheld PCs, handsets, etc.) and daily access to distributed resources and information.

This availability entails the requirement for transactional capabilities adapted to the specific characteristics of the mobile environment without losing the consistency and reliability guarantees of traditional online transactional processing (OLTP) systems.

One of the objectives of this work was the study of transactional models applied to mobile environments. After analyzing the state of the art, we observed that none of the models covers all the necessary characteristics for current requirements, and therefore, we propose a framework that allows us to capture and compare the main features to be taken into account in these models.

BACKGROUND

Transactional Systems' Requirements for Mobile Environments

Below we describe the requirements needed for a transactional system in order to be applied to a mobile environment (Tewari et al., 1995; Dunham et al., 1997; Lee et al., 1997):

- ***Ability to distribute the transaction's processing***: Due to memory, power processing, and battery limitations of the mobile hosts (MHs), it may be necessary to execute certain sections of the transaction in the mobile support station (MSS).
- ***Share the state and the partial results***: Because, as was stated in the previous item, parts of a transaction can be executed in the MH, while others run in the MSS, items must be shared.
- ***Capture the movement of mobile transactions***: Due to the physical movement of the MHs, it is necessary to transfer a transaction's control as it moves from cell to cell.
- ***Support long-lived transactions***: This is required, because some processes can take a considerable amount of time, and besides, the search for a computer that has physically moved from a cell can be a time-costly operation.
- ***Support long disconnection periods***: Recall that disconnections can be caused by physical problems, or simply by the MH's own decision. For an MH to continue operating despite being disconnected from the network, it may be necessary to maintain local copies of the data needed (*caching techniques*).
- ***Support partial failures and provide different recovery strategies***: These failures can be caused by battery problems, static electricity, accidental computer turnoffs, etc.

Mobile Transactional Models

The use of transactions in a mobile environment differs substantially from the use of transactions in centralized or distributed systems. The main differences are the high disconnection frequency and the mobility of the transactions. Therefore, transactional models and commit coordination protocols must be revised to take into account the mentioned differences (Dunham et al., 1997).

There are models that explicitly support mobility, such as Kangaroo Transactions (Dunham et al., 1997), which creates a subtransaction on every MSS that the user passes by, establishing a link between them so as to move the data as the user moves. It can use compensations, if necessary, in case of failures. Another example of this kind of model is Moflex (Ku et al., 1998), which allows for the definition of parameters that specify, in a flexible way, the behavior of the transactions. A transaction is made up of subtransactions that can be either compensatable or not. It is possible to define the behavior these transactions will follow, such as the success or failure dependencies they must maintain with other subtransactions, conditions regarding the geographic location, etc. When a transaction faces a handoff, it can behave as specified by the user through a series of rules. Other models, like reporting/cotransactions (Chrysanthis, 1993) allow explicit sharing of partial results between active transactions, while transactions migrate from MSS to MSS as the MH moves from cell to cell, in order to minimize communication costs. Finally, the prewrite model (Madria, 2001) incorporates a prewrite operation before a write operation and also supports mobility.

Another group of models supports disconnections. An example is isolation-only transactions (IOTs) (Lu et al., 1994, 1995), designed to allow disconnected operations in mobile computers, detecting read/write conflicts based in limitations of the serializability. When a transaction commits, results are published only if all the accessed data maintained a connection with the server; otherwise, results are only locally visible, and the transaction is validated at reconnection time. In the weak/strict transactional model (Pitoura et al., 1995), transactions can also execute in disconnected mode, but there are special versions of read and write operations (called *weak read* and *weak write*) that operate on local copies of data items, which must be checked and eventually published at reconnection time. Data clusters of computers are defined that enforce the locality and validity concepts. There is another model, called planned disconnection (Holliday et al., 2000), with the main innovation of planning the disconnections that the user will perform, so as to minimize disruption to the remaining sites. A *planned disconnection* is defined as a disconnection where the user informs the system of his or her intention to disconnect and reconnect in an orderly manner. Finally, it is important to note that the prewrite model (described in the previous paragraph) also supports disconnection.

For more information on these models, please read Coratella et al. (2003).

COMPARISON FRAMEWORK

The idea behind our comparison framework is to act as a guide that should allow us to capture and compare the main characteristics to be taken into account in mobile transaction models.

Definition

Here, we describe the main characteristics that must be taken into account in order to define a transactional model capable of being applied to a mobile environment, trying to take full advantage of its peculiarities.

Relating Physical Aspects

- ***Mobility support***: Maintain the transaction's execution, even though the computer moves from cell to cell.
- ***Disconnection support***: The ability to execute transactions even when the mobile computer is disconnected, using caching techniques.
- ***Replication support***: Support the replication of information to have a lower communication cost.

Relating Transaction Execution

- ***Place of execution***: Some models execute transactions at the MSS, while others execute them at the MHs.
- ***Compensable transactions***: Compensable transactions allow the system to partially commit changes, because they can be later reverted if the whole transaction aborts.
- ***Conditions of execution***: Conditions to be evaluated before, during, and after the execution of the transaction. These conditions can be based on time, etc.
- ***Efficient concurrency handling***: In mobile environments, there is a higher probability that a transaction will become a long-lived transaction (LLT), so the concurrency must be handled efficiently, in order not to lock an object for a long time (for example, Field Call).

Relating the Model's Adaptability

- ***Take advantage of the geographical localization of the mobile unit***: A transaction could specify location-dependent conditions in order to modify its behavior. Furthermore, a handoff may not be always a significant event for the execution of a transaction.

- ***Final states***: Specify acceptable final states for the transaction.

Relating Implementation Issues

- ***Take advantage of mobile techniques***: Use techniques that take into account the mobile environment's characteristics.
- ***Take into account physical limitations***: The limitations imposed by mobile devices, such as low power processing, small memory, etc., should be taken into account.
- ***Take advantage of the particular characteristics of a transaction***: For example, whether a transaction is read-only or not, interactive or not, etc., to increase the system's flexibility and performance.

Comparison of Transactional Models

The mobile transactional models are compared here, using the previously defined framework. For each section in the framework definition, a comparison table is presented, and then an analysis is carried out.

Because mobility is one of the main characteristics to take into account (see Table 1), it is important that transactional models can continue the execution of a transaction even if the user moves from one cell to another (handoff). Disconnection support is also an important issue, because it allows the user to continue working while the MH is disconnected. Another useful characteristic, which can lower communication costs, is the ability to access replicated data, because in this way, a subtransaction can use data located in the local machine, instead of in a possibly-far-away centralized database.

The Kangaroo, Moflex, reporting/cotransaction, and prewrite models all support mobility, because, during a handoff, the original base station must migrate the transaction's state to the target MSS in order to follow the physical movement of the MH. On the other hand, none of these models, except prewrite, allow the user to continue working while the mobile computer is not connected to the network.

In the following table, a comparison of the models is shown, taking into account characteristics related to the execution of transactions. These transactions can be executed either in the MH, MSS, or both (if the model allows this). The decision as to where a transaction should be executed depends on the processing capacity of the computer, if the transaction is interactive or not, etc.

Although nearly all the models allow the definition of compensable transactions and, therefore, the sharing of information before the commitment of the whole transaction, there are differences in the way this facility is provided. The *reporting/cotransactions* model allows a transaction to share its partial results in an explicit way, while this is not possible in the other models.

As can be seen from this table, the Moflex model is the only one that allows the specification of transaction execution conditions.

All the studied models provide facilities for concurrency management, though each one does it in different ways: IOT, prewrite, and planned disconnections allow for the publishing of partial results within the mobile computer; weak/strict allows this at a cluster level; reporting/cotransactions allows for the explicit publishing of these results; the rest of the models expose their changes globally.

In Table 3, we describe those characteristics related to the adaptability of transactional models.

Table 1. Characteristics related to physical aspects.

Transactional Model	Mobility Support	Disconnection Support	Replication Support
Kangaroo	√	×	×
Moflex	√	×	×
IOT	×	√	×
Weak/strict in data clusters	×	√	√
Reporting/cotransa ons	√	×	×
Prewrite	√	√	×
Planned disconnections	×	√	√

Table 2. Characteristics related to the execution of the transactions

Transactional Model	Place of Execution	Compensating Transactions	Execution Conditions	Concurrency Handling
Kangaroo	MSS	√	×	√
Moflex	MSS	√	√	√
IOT	MH	×	×	√
Weak/strict in data clusters	MH	√	×	√
Reporting/ cotransactions	MSS	√	×	√
Prewrite	MH	×	×	√
Planned disconnections	MH	×	×	√

Because, by definition, in a mobile environment, a MH can roam through different geographical regions, it is important for the model to be able to adapt a transaction's execution to the changing conditions generated by this roaming. The main characteristic to consider as regards adaptability is the one related to geographical location, that is, the ability of a transaction to change its behavior depending on the position of the MH.

Here, Moflex is the only model that supports preconditions related to the geographical localization of the mobile computer and the specification of final acceptable states.

Table 3. Characteristics related to adaptability

Transactional Model	Geographical Localization	Acceptable Final States
Kangaroo	×	×
Moflex	√	√
IOT	×	×
Weak/strict in data clusters	×	×
Reporting/cotransa ons	×	×
Prewrite	×	×
Planned disconnections	×	×

Classification of Mobile Models

From all the issues analyzed so far, a classification of mobile models arises based on the presence or not of specific features. This classification allows us to pinpoint the existing voids and to highlight the aspects that deserve further work to reach a more capable architecture (Figure 1).

According to how deep the mobility support, the models can be categorized as follows:

- ***Total mobility***, reflects the ideal model, with both hand-off and disconnection support.
- ***Hand-off support*** provides cell-switching detection but cannot function if disconnected.
- ***Disconnection support*** is only able to work if disconnected and does not take into account the switching of cells.

A second difference is established between those adaptable models that allow for the establishment of locality conditions or nonadaptable conditions. From a third point of view, models allow transactions to be executed only at MSSs, only at MHs, or at both.

All models should exhibit efficient handling of concurrency and LLT because of the specific nature of mobile environments.

From this classification, we observe the lack of models that support hand-offs and disconnections simultaneously. The prewrite model is a special case near total mobility, because it always supports hand-off, but disconnection is supported when it has pre-read all data. If it disconnects from the network before the pre-read phase, it cannot continue the transaction.

Moreover, no current model allows for adapting the site of execution (i.e., MH, MSS, or combined). This analysis shows that the state-of-the-art is not optimal and points out several promising areas for future research (for example, the extension of current models or the definition of new ones).

CONCLUSIONS

In this work, we defined a framework to be used as a tool for studying transactional models that take maximum advantage of the peculiarities of mobile computing environments. We consider it a valuable tool not only to compare existing models, but also to validate new transactional models to come.

As a practical demonstration of its usefulness, we studied some transactional models applied to mobile environments, comparing them with the help of this tool.

From this comparison and the classification made, we can say that none of the studied models covers all of the characteristics described in the framework. We consider that the essential items every transactional model should meet are *mobility support* and *disconnection support*. It can be seen that none of the models covers both characteristics (prewrite model supports a limited version of total mobility), which leads us to believe in the need to extend some of these models to support those items or to define a completely new mobile transactional model.

FUTURE TRENDS

We consider it necessary to create a flexible and dynamic simulator, so that arbitrary configurations can be easily defined and measured, in order to compare the different approaches of solving problems present in mobile environments. This will allow us, in a further step, to develop concrete implementations to be tested in real environments. To do this, existing implementations must be studied, this being a complex task given the recent definition and development of these systems.

Another possible future work is the definition of mobile models using ObjectZ, as proposed by Graeme (2004). This could lead to a more concrete and clear way of describing a model, rather than just writing a textual specification in a natural language. Besides, having a formal description could greatly enhance the study of these models before the actual simulation/implementation phase, including the possibility of applying model checking to foresee problems.

KEY TERMS

Handoff: Process that occurs after a cell change. The MH identifies itself at the MSS of the cell into which it has moved.

MH (Mobile Host): This is a mobile computer or device.

Mobile Computing: This is an environment made up of a set of devices that interact to give the user the possibility of staying connected while moving from one location to another.

Mobile Technique: This is an implementation technique used to support mobile transactional models, for example, techniques relating to geographic data usage, caching, concurrency handling, dissemination of information, etc.

MSS (Mobile Support Station): This refers to a computer with a wireless interface that offers information and services support to MHs.

Serializability: An execution is said to be serializable if its effect is the same as if the transactions were executed in serial order.

Transactional Model: This defines a way to handle transactions in a database environment, including using subtransactions, scope, limitations, etc.

Mobile Telecommunications and M-Commerce Applications

Clarence N.W. Tan
Bond University, Australia

Tiok-Woo Teo
Bond University, Australia

INTRODUCTION

This article presents an overview of prevailing trends and developments shaping mobile commerce (m-commerce) and the wireless economy. A review of wireless telecommunications infrastructure attempts to demystify the evolving technology landscape. Mobile Internet deployment and adoption demographics are highlighted, as are innovative wireless applications and current m-commerce issues.

BACKGROUND

The World Wide Web (WWW) and Web browser software brought mass market accessibility to the Internet. Riding on this ubiquity and reach is electronic commerce (e-commerce) in its many forms: inter-business dealing, intra-organization transactions and business-to-consumer trade, and so forth. E-commerce has witnessed impressive growth and continues to be a significant propellant of Internet progress. Participants have, however, hitherto been essentially tethered to fixed line connections. The development of novel wireless services and mobile adaptations of familiar applications (Ghini, 2000) is fueled by demand from increasingly nomadic users looking to access familiar online facilities, and the steady convergence of telecommunications and computing technologies (Messerschmitt, 1996).

Wireless telecommunications was conceived in the 1980s to carry voice, but has evolved to become data bearer, including Internet communications. The cellular telephone is now commonplace and more personal digital assistants (PDAs), hand-held computers and the like are sporting cellular radio connectivity. These devices form a sizable platform for deploying m-commerce applications. M-commerce refers to the ability to browse, interact with and make payment for goods and services directly from mobile terminals such as cell phones, PDAs and portable computers (Tan, 2002). Industry forecast statistics point to exponential growth in the sector:

- Worldwide shipment of Web-enabled wireless devices rose 796% in 2000 over 1999 and consumer transactions committed from such terminals will total US $1.8 trillion worldwide by 2005 (Source: Gartner Group).
- International wireless data market was expected to grow from 170 million to more than 1.3 billion subscribers between 2000–2004, equipping themselves with 1.5 billion wireless-capable handsets and other Internet appliances by end of 2004 (Source: Cahners In-Stat Group).
- Wireless Internet users in the Asia-Pacific region alone will rise 10-fold from 20 to 216.3 million between 2000–2007 (Source: Strategis Group).

As Internet and mobile communications converge, e-commerce evolves into m-commerce. The tremendous potential of “anytime” convenience and “anywhere” mobility in carrying out everyday online transactions will spur many unique mobile services yet.

TECHNOLOGY ROAD MAP

Early wireless telecommunications architecture in the late 1940s was modeled after television broadcasting. Tall, centralized transmitter towers provided radio coverage. Limitations like restricted user mobility and capacity, poor voice quality and high cost saw the introduction of new cellular technology in late 1970s—a superior architecture persisting to this day.

A cellular mobile communications system comprises a vast collective of low-power antenna subsystems, dispersed in small overlapping geographical units called cells. Individual cellular base stations provide local coverage and interconnect for a combined footprint that constitutes the wireless network. Modern implementations are typified by larger, sparse cells in rural areas and small, dense ones in metropolitan districts. The technology road map is demarcated by milestones corresponding to transmission bandwidth.

First Generation—1G: Analogue radio transmission characterized 1G cellular systems. The one-time de facto standard throughout the Americas and the Asia-Pacific was the Advanced Mobile Phone Service (AMPS) introduced in the United States in 1983. Despite technical imperfections such as limited growth capacity, poor data transport and deficient transmission security, 1G systems maintained their popularity till the early 1990s. Improved derivatives of AMPS are still deployed in the remaining analogue cellular networks around the world today.

Second Generation—2G: Digital radio transmission heralded the 2G era. Information is digitized into a stream of computer binary coded data packets for transmission and reassembly at the receiving end. Two competing digitization schemes are Time Division Multiple Access (TDMA) and Code Division Multiple Access (CDMA). Better bandwidth utilization boosts network capacity, enhances coverage and improves voice quality. New service features such as data encryption, short text messaging, fax and data transmission can also be offered.

Launched commercially in 1991, the European developed, TDMA-based Global System for Mobile Communications (GSM) is the de facto international 2G standard today, with 863.6 million subscribers in 174 countries at end of May 2003 (Source: GSM Association, *http://www.gsmworld.com*). An American adaptation of GSM called PCS 1900 was launched in late 1995. CDMA-based networks began commercial operation in 1995 and are now the predominant standard in the Americas, Korea and Japan, with 164.1 million subscribers in 60 countries as at June 2003 (Source: CDMA Development Group, *http://www.cdg.org*).

Conventional fixed line Internet connectivity offers varying data rates:

- Up to 56 kbps (kilobits per second): Analog modem
- 64–128 kbps: Integrated Services Digital Network (ISDN)
- 256 kbps–1.5 Mbps (megabits per second): Optical fiber and Digital Subscriber Line (DSL)

In comparison, 2G data service provides 9.6–57.6 kbps throughput, with most network operators supporting only speeds no more than 14.4 kbps. This makes for poor overall user experience for consumers increasingly accustomed to higher-speed, broadband Internet access through fixed connections. Real-time multimedia applications such as live video are also impracticable on 2G architecture. Solutions better optimized for wireless data transmission are clearly needed to meet growing demand for quality mobile Internet access.

Second-and-a-Half Generation—2.5G: 2.5G systems extend 2G infrastructures for upgraded data throughput. New handsets, however, are required to tap the improvements and other added functionalities. The enhancement to GSM is called the General Packet Radio Service (GPRS). Capable of a theoretical maximum 171.2 kbps transmission, the average is 40–80 kbps deployed in practice. Like the Internet, GPRS networks are also based on the Internet Protocol (IP) standard, so GPRS terminals function just like other wired Internet sub-nodes with seamless access to familiar applications such as the WWW, e-mail, Telnet and FTP (File Transfer Protocol), and so forth. The first commercial GPRS service was inaugurated in the United Kingdom in June 2000. 2.5G CDMA technology is known as the IS-95B standard and offers ISDN-like data rates. Its first commercial debut in Japan in early January 2000 beat GPRS to market by some 6 months, and the 64 kbps throughput was superior to prevailing 2G GSM offerings.

While data speed boost is useful in time-sensitive applications like online transactions and credit authorization, there remain technical idiosyncrasies and transmission latencies detrimental to time-critical multimedia functions such as video decoding and playback. Hence, 2.5G is still not the ideal platform for deploying high quality, real-time video conferencing.

"2.75G": When wireless data rates approach those of conventional fixed line broadband connectivity, user experience will improve significantly and truly mobile Internet access would be a reality. Some have termed this stage of the road map loosely as "2.75G".

The Enhanced Data rates for Global Evolution (EDGE) standard is engineered as an extension to GSM technology and leverages past investments in TDMA and GPRS. Throughput of 384–553.6 kbps is theoretically possible and early EDGE-compatible handsets support rates in excess of 100 kbps. The world's first commercial EDGE service was deployed in the United States in July 2003. The equivalent evolution in CDMA technology is the CDMA2000 standards, providing network speeds from 144–614 kbps. From the first commercial service in Korea in October 2000, CDMA2000 subscribers have grown to number 54.1 million by June 2003 (Source: CDMA Development Group).

Third Generation—3G: Wireless broadband connectivity and industry standards harmonization characterize 3G systems. New handsets are again necessary to exploit multimedia capabilities and applications enabled by high-performance wireless networking at unprecedented 384 kbps–2 Mbps speeds.

More importantly, the vision is for 3G devices to roam seamlessly on enabled networks within a country and across continents, creating truly borderless mobile services. To this end, the International Mobile Telecommunications 2000 (IMT-2000) recommendations were promulgated in late 1999 with international participation. IMT-2000 prescribes how mobile service providers should evolve existing cellular networks towards full inter-network compatibility independent of underlying radio technologies. Disparate TDMA, CDMA, GSM systems and their derivatives will be accommodated. For example, under IMT-2000, GSM will evolve into the Universal Mobile Telecommunications System (UMTS) and employ a new transmission technology called Wideband CDMA (W-CDMA). The first commercial UMTS 3G service was introduced in Japan in October 2001.

WIRELESS MESSAGING

SMS—Short Message Service: The Short Message Service is a wireless radio service for bidirectional transfer of alphanumeric messages of up to 160 characters each among mobile terminals in GSM and UMTS networks (European Telecommunications Standards Institute, 2002). Multiple text messages (up to 255) may be concatenated to form longer ones. Messaging is near instantaneous and operates on a store-and-forward scheme that guarantees delivery. Sent messages are routed to their destinations by an electronic intermediary in the cellular network called a Short Message Service Center, or SMSC (European Telecommunications Standards Institute, 2002). If the intended recipient is not immediately contactable, the message is stored for a stipulated time period to facilitate reattempted delivery. The SMSC can notify a message sender of the ultimate delivery success or failure via an SMS notice called a delivery report.

Introduced in 1991, SMS began as a supplement to voice calls, alerting subscribers to awaiting recorded messages. Its use has since grown to encompass notification services like paging alerts, new e-mail notice and calendar reminders; and information services like weather forecast, traffic watch, stock quotes, gaming results and horoscope readings, and so forth. Interpersonal communications still dominate SMS messaging volume by far today but SMS is also finding increasingly sophisticated uses in corporate applications such as job dispatch (Tan, 2002) and secure m-commerce transactions systems (Tan, 2003).

In 2002, an estimated 360 billion SMS messages were sent worldwide with some 30 billion sent monthly in December—double the rate 24 months ago (Source: GSM Association). The growth trend is expected to continue.

EMS—Enhanced Messaging Service: EMS is a minor extension to SMS whereby a mix of formatted text (e.g., bold, italics, etc.), simple animations, tiny pictures and short melodies can be included as message content. The specification provides for amalgamating multiple classic SMS messages to convey the increased EMS message complexity. Compatible handsets have been commercially available since 2001, but there has been a lack of full interoperability among different makes and models due to proprietary implementations of the EMS standard by manufacturers.

MMS—Multimedia Messaging Service: MMS is the latest generation wireless messaging standard that inherits the SMS store-and-forward schema and features improved security mechanisms for managing message encryption, authentication and privacy. MMS is devised to carry a full range of multimedia elements including text, audio clips, still pictures, animated images and full-motion video, all encoded using industry standard file formats (e.g., JPEG for photographs, MP3 for audio, MPEG for video, etc.). Such rich content increases message size and considerably more bandwidth is needed to deliver MMS messages expeditiously. Hence, the takeoff of MMS is only expected to dovetail on the rollout of 3G networks internationally. The world's first commercial MMS service was introduced in Hungary in April 2002.

INNOVATIVE APPLICATIONS

The sheer success of the mobile telephone as a consumer device is indisputable. Mobile phones have already outstripped conventional telephone subscriptions in many countries. As cellular telecommunications networks and the Internet converge, the spillover of Internet e-commerce will fuel m-commerce takeoff. Wireless broadband technology can be used to deploy not only mobile variants of existing Web-based applications, but also fundamentally new ones. This creates new value proposition for consumers and revenue streams for vendors. The true power of the mobile Internet lies in these innovative applications that will be spawned, some of which are listed next.

- **Location-based services (LBS):** LBS refers to the provisioning of value-added services to cellular subscribers based on the physical location of their mobile devices within the network. Potential applications: location-based call billing, emergency medical services, courier fleet tracking, proximity-based personalized marketing, locality information services like navigation and directory assistance, and so forth.
- **Mobile multimedia entertainment:** Higher bandwidth afforded by 2.5G and 3G networks creates new distribution channels for paid multimedia entertainment like computer games, music and video. For example, games can be downloaded wirelessly for play on enabled handsets or with other gamers on the network. Music and video vendors may stream

content wirelessly on demand to mobile devices for instantaneous preview playback and subsequent purchase.

- **Wireless telemetry:** The facility for gathering data or remotely controlling devices over the footprint of a cellular network through two-way communication between remote equipment and a central facility. Potential applications: security alarm monitoring, climate control, meter readings and inventory status polling, and so forth.
- **Wireless electronic payment systems:** Cellular phones become secure, self-contained tools for instantly authorizing payment for goods and services wirelessly over the network. One example is the use of SMS messages for making purchases at vending machines.
- **Telematics:** The integration of wireless telecommunications and in-vehicular monitoring and location systems will bring mobile Internet facilities, location-based services and multimedia entertainment to vehicle dashboards. Potential applications: online information services (e.g., traffic news, weather forecast, route assistance, etc.), target advertising based on vehicle locale and streaming media content, and so forth.
- **Wireless telemedicine:** Cellular telecommunications and wireless broadband multimedia technologies can deliver health care expertise and services remotely. Potential applications: remote monitoring of patients in ambulances and long-distant specialist teleconsultation for patients in remote regions.

CURRENT ISSUES

The realm of m-commerce is still in its infancy and to the extent that it bears roots in e-commerce, many technical, business, marketing and legal perspectives in m-commerce may be extrapolated from e-commerce ones. But as a fundamentally new business paradigm, m-commerce will elicit contentious issues of its own. A few have been highlighted as follows.

- **Wireless privacy:** Industry self-regulation and legislation are needed to guard against potential threat of undue surveillance and profiling, invasion to personal privacy and wireless spam resulting from abuse of location data gathered for provisioning LBS.
- **Wireless security:** Increased vigilance is necessary as computer viruses and like malicious attacks begin to target PDAs and mobile phones, as such devices gain more processing power and intelligence, and users become ever more reliant on them for voice and data services.
- **Wireless emission and public health**: Concerns persist on the long-term impact on public health from cellular emission, radiation and electromagnetic interference in the face of rapid consumer adoption of mobile phones. While no conclusive evidence exists to suggest significant risks, a more precautionary approach is prudent pending further research.

CONCLUSION

Mobile telecommunications have seen an evolution from a voice focus to data-centricity. For now, 3G networks present a viable channel for distributing practically any digital content. The future along the technology roadmap continues to emphasize quality multimedia delivery. Cellular devices are expected to improve in form and function, benefiting from advances in display, storage, imaging, processing and battery technologies. Historically, new handsets were required for each successive generation of wireless infrastructure and their timely volume availability at mass market prices remains crucial to the success of future networks.

The continued proliferation of mobile-enabled portable consumer electronics and the rising demand for ubiquitous computing will contribute to the volume and value of m-commerce, and begin to unleash the power of the mobile Internet.

Harold Webb
The University of Tampa, USA

INTRODUCTION

Many educators and industry leaders believe industry-academic collaboration can change learning processes and improve learning outcomes by providing opportunities and resources not otherwise attainable (Sikkel, Spil, & van de Weg, 1999; Wohlin & Regnell, 1999). In the case of deploying advanced information technologies (AITs; e.g., computer-aided software engineering tools, enterprise resource planning systems, and database tools) via industry-academic collaboration, each institution's culture and unique organizational objectives influence collaborative relationships. The challenge in these relationships is to facilitate mutual understanding and clarify distinctions in addressing each organization's goals. The aim of these relationships is the appropriation of AITs in a manner that enriches educational experiences while meeting industry needs.

There are many quandaries associated with this phenomenon. How does the deployment of AITs within the educational curriculum facilitate the educational process? To what degree should these resources be utilized in education? What tools and methods should be used to deploy these resources? What should the role of the AIT vendor or consultant be? Can academic independence be maintained within a strong industry collaborative relationship?

Without a framework that identifies relevant variables, it is daunting at best to begin to assess the impact of varying degrees of adoption, identify effective processes of deployment, and move toward assessing costs and benefits. Though some frameworks address industry-academic collaboration (Mead, Beckman, Lawrence, O'Mary, Parish, Unpingco, et al., 1999), none have considered the implications of AITs on the evolution of interinstitutional collaborative relationships. This exposition discusses a framework seeking to address this need. The framework proposes a theoretical model for understanding the forces at work when integrating AITs into educational settings (LeRouge & Webb, 2002).

We begin our discussion by introducing adaptive structuration theory as the foundation for the industry-academic AIT collaboration framework (DeSanctis & Poole, 1994). We then introduce constructs and relationships related to industry-academic collaboration within the context of enterprise resource planning (ERP) systems.

BACKGROUND: THEORETICAL FRAMEWORK - ADAPTIVE STRUCTURATION

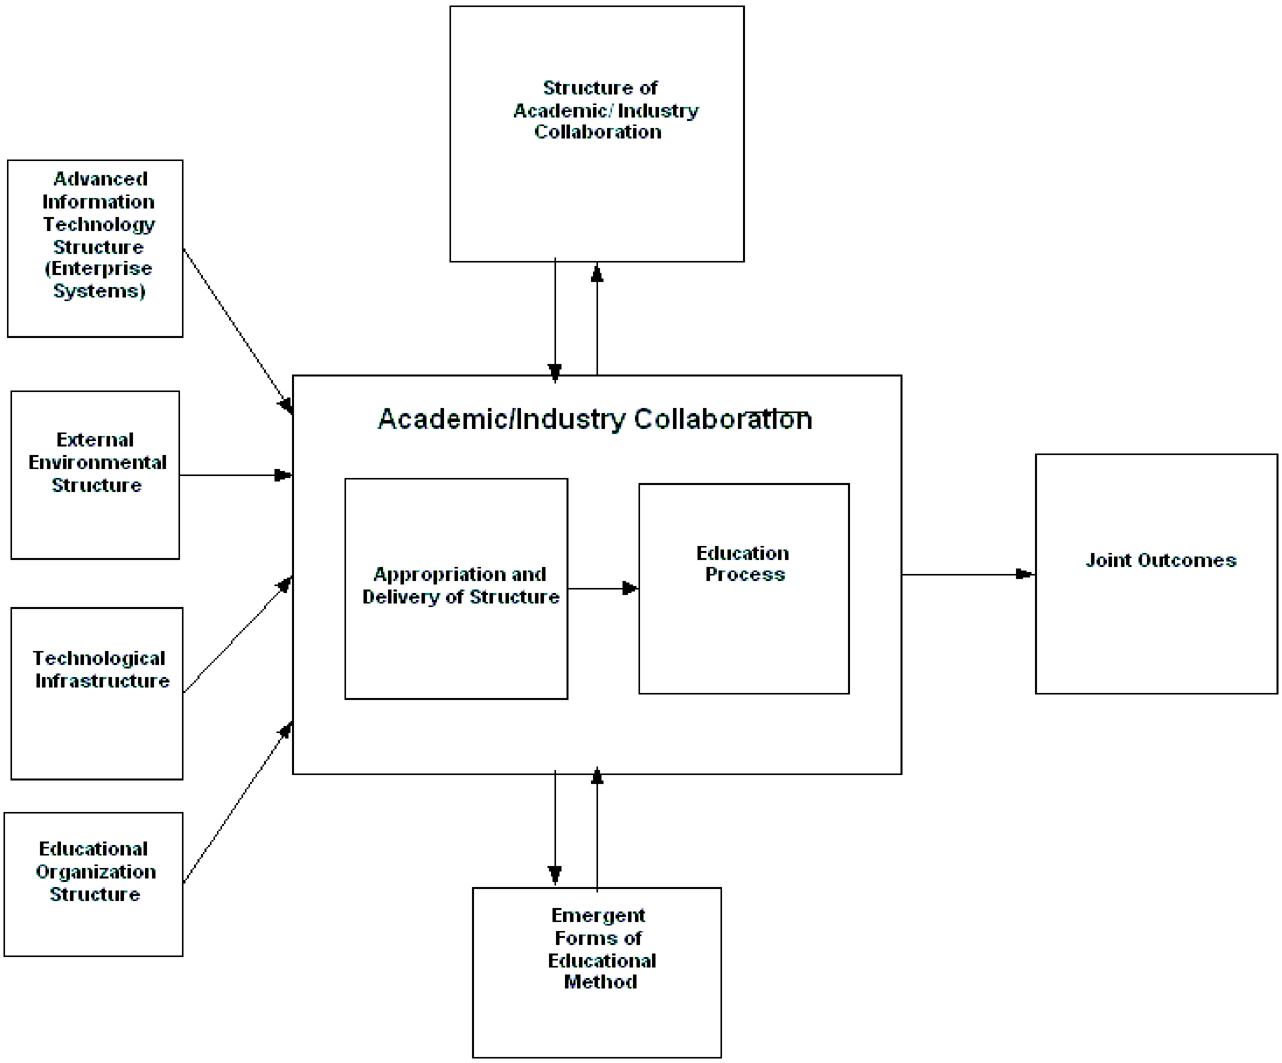
Adaptive structuration theory (AST), an extension of structuration theory, has been used as a framework to study organizational change processes when advanced technologies are adopted. Adaptive structuration is a sociotechnical perspective that introduces human actors and organizational context as moderators of the impacts of technology (Gopal, Bostrom, & Chin, 1993; Poole & DeSanctis, 1992). This perspective posits that the adoption of an advanced technology is a process of organizational change that results from the mutual influence of technology and social processes.

It is our premise that in an academic setting, human actors and organizational context are moderators of the collaborative process in which AITs are appropriated as each entity strives to fulfill its own needs. Such dynamic processes have an effect not only on the outcome of the appropriation, but also on the evolution of the relationship between industry and academia. As the number of academic institutions adopting AITs increase, we feel AITs will serve some groups better than others.

We introduce the framework's components in the context of ERP systems adoption in academe. We exemplify ERP systems within the specific context of colleges of business for a number of reasons: market demand, level of commitment required, interdisciplinary functionality, and level of system sophistication. The level of commitment and potential impact implied by the magnitude of ERP systems suggests that the study of ERP systems in business colleges may be associated with a considerable effect size detectable in future research efforts.

Our model of the constructs and relationships is represented in Figure 1. Model constructs and attributes are summarized in Table 1.

Figure 1. Adaptive structuration theory applied to industry-academic collaborations involving AITs (adapted from DeSanctis and Poole, 1994; LeRouge & Webb, 2002)



ADVANCED INFORMATION TECHNOLOGY STRUCTURE

Two ways have been suggested to describe the contributing social structures offered by an AIT. The first, "structural features," refers to the types of rules and resources offered by the system. The second, "spirit," can be thought of as the intended purpose and utilization of the system (DeSanctis & Poole, 1994).

With respect to technology spirit, there is a natural gap in appropriation between business use and academic use of ERP systems. The spirit of ERP systems can be described as information technology structures designed to integrate operational-level transaction processing, multilevel decision support, and strategic management of major corporations. However, the goals of ERP use in colleges of business are primarily educational and exploratory in nature, often focusing on discipline-related subsystems. This gap in system goals and values may have implications for academic-industry collaboration.

With regard to structural features, ERPs are a comprehensive suite of applications that support diverse organizational functions and processes. The suites developed by major ERP vendors commonly contain more than 15 modules, each of which is geared toward a different industry process and requires a significant training investment. For example, SAP offers some certification programs requiring over 40 days of classroom training. Accordingly, ERP systems challenge colleges with a level of sophistication that affords flexibility in feature set and appropriation, but requires substantial training to achieve acceptable performance.

Table 1. Constructs of interest (LeRouge & Webb, 2002)

Construct	Attributes
Advanced Information Technology Structure (Enterprise Systems)	♦ Structural features (restrictiveness, level of sophistication, comprehensiveness [suite of applications supporting diverse functions], learning curve) ♦ Spirit (enterprise-wide strategy, daily operations, management support system, strategic planning tool, convergence with educational goals)
External Environmental Structure	♦ Accreditation standards and curriculum studies ♦ Technology-vendor market position and status ♦ Industry standards and technology trends ♦ Technology market competition and end-user demands ♦ Technology-enabled labor supply
Technology Infrastructure	♦ Software and hardware ♦ Internal maintenance and software support ♦ Database creation and maintenance ♦ Computer lab facility and student remote access ♦ Industry donation or grants to support technology infrastructure
Educational Organization Structure	♦ Departmental structure ♦ Major program requirements ♦ Course objectives ♦ Instructor preferences
Appropriation and Delivery Structure	♦ Appropriation moves (direct use, relation to other structures, interpretation of structures, or judgment of features) ♦ Faithfulness ♦ Instrumental uses ♦ Attitude
Education Process	♦ Learning models (collaborative learning, hands-on experience, simulations, conceptual presentations, programmed instruction, real-world exposure, case studies) ♦ Supporting technologies (textbooks on technology, presentation tools, asynchronous communication tools, synchronous communication tools, computer-based training modules)
Emergent Forms of Educational Method	♦ Educators enrolling in corporate training programs ♦ Project- or task-specific internships ♦ Industry experts participating in classroom presentation ♦ Students and educators participating in AIT-specific list serves ♦ Credit for and/or increased access to technology training programs for students ♦ Industry development of targeted educational tools, databases, and exercises
Joint Outcomes	♦ Student learning and education in technology arena ♦ Increased work pool and employable students ♦ AIT market exposure ♦ Contribution to industrial research and development effort and academic research ♦ Continued and enhanced program attractiveness
Structure of Academic-Industry Collaboration	♦ Rules (industry participation in curriculum development studies, inclusion of AIT in curriculum development research, academic participation in industry development, educator participation in corporate training programs) ♦ Resources (technology alliance programs, opportunities and invitations for field research)

EXTERNAL SOURCES OF STRUCTURE

A report of the American Accounting Association determined that "the markets for accounting students will drive the 'models' of education, including delivery, content and pedagogy" (Lea, Berlin, Butterwick, Carpenter, Flaherty, Glazerman, et al., 1998). However, ERP systems have found new avenues of opportunity to continue past growth through such channels as e-commerce and service-firm-oriented modules (Stedman, 2000; Wilson, 2000). As such, the ERP market seems strong as is the demand for graduates to work with such systems (Watson & Schneider, 1999). Examples of sources of structure are detailed curriculum guides for computer science (Lidtke, Stokes, Haines, & Mulder, 1999) and information systems (Gorgone & Gray, 2000), as well as documented industry needs for trained graduates and focused ERP research that are driving vendor alliance programs (SAP, Inc., 2001).

TECHNOLOGY INFRASTRUCTURE

A practical component in any study of the appropriation of AITs is a basic cost-benefit analysis. Are the total costs and commitments in deploying these systems rewarded with an enriched educational experience and increased marketability?

Technology infrastructure can be a major cost consideration. ERP systems are large-scale AITs requiring a significant commitment of academic resources (Becerra-Fernandez , Murphy, & Simon, 2000; Watson & Schneider, 1999). These systems typically cannot be deployed or maintained without support from ERP vendors or consultants. Industry may facilitate appropriation through donated services; however, colleges may face additional costs. Hence, some form of collaborative relationship seems a precursor for the existence of these systems in academic settings.

EDUCATIONAL ORGANIZATION STRUCTURE

The philosophies of appropriating ERP systems among educational entities vary widely. The overall philosophic quandary involves balancing conceptual technology education and the development of technology skills. ERP exposure may be used to emphasize the informational aspects of various topics via conceptual illustration rather than dwelling on the technology. Conversely, ERP systems can be used to create the learning environment necessary for experiential learning where students work through business problems via scenarios using a system running training data. The degree of centralization and support in an academic department and the degree of coupling existing between courses included within the curriculum can affect the adoption of ERP systems.

This educational organization structure also impacts the appropriation of technology and the collaborative relationship. If constraints mandate deploying only one ERP system within the curriculum, could the college be transmitting a product endorsement message that constrains the scope of the curriculum? Are there positive or negative connotations, from a student or industry perspective, for a college of business known as an Oracle, SAP, or Sybase "shop"? Accordingly, do companies place any implicit or direct pressure on colleges to exclusively employ their software?

APPROPRIATION AND EDUCATION PROCESS

Structuration has at its core motivated and practical actions. Rules and resources embodied in social institutions are appropriated by participants and enter into the production and reproduction of the social system (Poole & DeSanctis, 1992). Industry-academic collaborative interaction is embodied in the appropriation of the AIT into the educational process.

Educators determine the curriculum strategy and the degree of appropriation for these mammoth ERP systems. The degree of appropriation has been addressed by academic institutions in a variety of ways ranging from inclusion of exemplary material within courses to new course creation, to establishing new degree programs.

The appropriation structure leads to choices regarding strategies for integrating the learning model(s) and supporting technologies within an instructional design. ERP systems are adaptable to many models of learning depending upon the educator's objectives. The model of learning chosen may affect the instructor's approach and utilization of these tools. To illustrate, conceptual presentation and demonstration may adequately support knowledge-level learning objectives, while experiential learning models may better support higher order learning objectives (Leidner & Jarvenpaa, 1995). One example of educational process is the case-based learning approach for ERP system development in undergraduate classes (Stewart & Rosemann, 2001), while another is the integration of vendor training materials into an existing college course (SAP, Inc., 2001).

EMERGENT FORMS OF EDUCATIONAL METHOD

Educational approaches discussed in the research on collaboration among software engineering programs and vendors that potentially influence collaboration with ERP system vendors include the following.

- Accelerated internship programs providing hands-on experiences (Powell, Diaz-Herrera, & Turner, 1997; Wohlin & Regnell, 1999)
- Independent study support by vendors and institutions
- Industrially experienced teachers (Wohlin & Regnell, 1999)
- Educational credit for vendor-sponsored training programs (Beckman, Coulter, & Mead, 1997)
- Jointly developed courses (Wohlin & Regnell, 1999).
- Participation in upgrade and maintenance efforts
- Case studies inspired by industry (Dawson & Newsham, 1997; Sikkel et al., 1999)
- Research within industry settings (Wohlin & Regnell, 1999)

An example of emergent forms of ERP-related education is the use of problem-based learning in which graduate students work with industry partners to design ERP solutions to solve a business problem. The completed solutions are then used as the basis for the development of teaching cases to support learning in undergraduate ERP-related courses (Stewart & Rosemann, 2001).

JOINT OUTCOMES

The purpose of ERP appropriation and industry-academic collaboration is to achieve mutually beneficial joint outcomes for both academia and industry (SAP, Inc., 2001; Stewart & Rosemann, 2001). The desired joint outcomes may include facilitating the educational mission, gaining competitive advantage, accessing educational resources, enhancing reputation, increasing revenue, and providing a staffing source (Mead et al., 1999). The academic institution, industry, or both may desire each of these goals. However, just as success is not guaranteed in implementing these systems in an industry setting, desired joint outcomes from academic appropriation are not guaranteed.

STRUCTURE OF ACADEMIC-INDUSTRY COLLABORATION

The collaborative system is not a recognized organization, but a structured social practice of interdependence that has broad spatial and temporal extension (Giddens, 1982). There are no global, formalized standards for the appropriation of ERP systems in educational settings or specifications for industry's participatory role in this phenomenon. Though some industry alliance programs may require agreements regarding the fees, donations, or support of AITs, educational methods and processes are guided by practice and choice (SAP, Inc., 2001). Certain practices, or implied dynamic rules, are embodied in the collaborative relationship created between industry and academia. The existence of ERP alliance programs may be considered a representation of social practices affecting the structure of academic-industry collaboration. Representations of the implied social practice may also be found in such documents as curriculum guides that encourage industry participation and the study of ERP system concepts in academic programs (Gorgone & Gray, 2000; Lidtke & Stokes, 1999; Lidtke et al. 1999).

Practices suggested for a successful collaboration based upon case study experience (Powell et al., 1997) include the following.

- Central coordination point
- Right mix of knowledge and experience
- Cooperative planning and scheduling
- Flexibility to change curriculum
- Communication to build teamwork
- Balance to maintain objectivity

Mead, Unpingco, Beckman, Walker, Parish, and O'Mary (2000) provide examples of how the academic-industry collaboration process could work. Based on a study of 21 collaborations, this article discusses four alternative collaboration models in use, varying governance structures observed, and the need to establish metrics to monitor and modify the collaborative process.

FUTURE TRENDS

The appropriation of AITs in colleges of business is a modern phenomenon that aspires to bridge the industry-academic gap while fulfilling educational goals. From a practical perspective, industry and consumers of academic education often desire opportune, practical training and education from academic institutions (SAP, Inc., 2001; Stewart & Rosemann, 2001). However, the costs of appropriation may be high and the impact of appropriation on educational processes and collaborative relationships may be either minor or dramatic. Thus, the joint outcomes of AIT appropriations and collaboration are uncertain. Stakeholders should recognize the potential influence of structure and social context on desired outcomes when embarking on the process of industry-academic collaboration. AIT appropriation and associated collaboration decisions may affect the educational foundation and career prospects of the technological workforce. These changes are already underway in both industry and academe (SAP Inc.; Stewart & Rosemann). As such, further research is needed to investigate relationships among the constructs and attributes identified in the framework and their effect on both academe and industry.

CONCLUSION

Adaptive structuration recognizes that technology appropriation may be a key factor in the evolution of affected social structures. Adaptive structuration theory gains predictive and descriptive power by identifying social complexities and relationships associated with the adoption of advanced information technologies. The major contribution of this exposition is the extension of adaptive structuration theory to better understand the dynamics of industry-academic collaboration as they evolve on campus and in the workplace.

KEY TERMS

Advanced Information Technology Structure: The rules and resources offered by systems such as computer-aided software engineering tools, enterprise resource planning systems, and database management systems that support the intended purposes and utilization of those systems.

Appropriation and Delivery Structure: The rules and resources that determine the choices made by educators regarding strategies for integrating the learning model(s) and supporting technologies within a selected instructional design.

External Environmental Structure: The rules and resources offered by outside interests including academic standards bodies, technology developers and vendors, industrial organizations, employers, and end users.

Educational Organization Structure: The rules and resources offered by the internal educational institution that are derived from how it is organized as well as program requirements, curriculum, and course objectives.

Education Process: The use of learning models and supporting learning technologies to deliver the learning experience and/or training with students.

Emergent Forms of Educational Method: New methods and techniques that may be employed or used in the education process related to the deployment of AIT in academe.

Joint Outcomes: The direct output and by-products of the education process including student learning, an employable work force, AIT market exposure, and contributions to industrial and academic research.

Structure of Academic-Industry Collaboration: The representation of social practices among the stakeholders affecting academic-industry collaboration that result in the establishment of rules of practice and the provision of resources.

Technology Infrastructure: The required supporting activities and facilities including network, hardware, software, development, and maintenance.

Modeling for E-Learning Systems

INTRODUCTION

Computer-based instruction is touted as an effective tool to support knowledge dissemination within predefined learning environments. Indeed, many see it as a way to overcome geographical or social barriers to knowledge transmission and educational institutions. However, its domain of application has traditionally been restricted to basic skills and educational contexts. Recently, dynamic and complex business environments shaped by technological changes and the downsizing trend of the '90s placed new constraints on the underlying assumptions (Fuglseth, 2003). Organizations are now pushing for skill flexibility, demanding specialized knowledge and requiring faster learning curves from employees. Many advocate Internet-based education materials as one way to meet those challenges (Bernardes & O'Donoghue, 2003; Karoulis et al., 2004; Storey et al., 2002; Strazzo & Wentling, 2001). However, this raises important questions concerning both effectiveness and efficiency of such tools and materials. Indeed, developing interactive multimedia-based courseware remains pretty much a black art, consuming enormous resources. So far, there is a lack of established models to predict the performance and evaluate how adequately courseware can meet user needs. In fact, developing courseware should take into account the target constituency requirements, organizational context, and the stated educational or training goals. Developing the wrong training materials can lead to costly investments in creating and maintaining content to match the increasing expectations on e-learning. Perhaps this can explain the recent rash of failed e-learning projects—current results do not measure up to business and individual expectations yet.

A better understanding of the many factors affecting e-learning performance would allow individuals and organizations to achieve the expected benefits. In so doing, development teams need methods, techniques, and tools to evaluate in advance which features are needed to achieve higher outcomes, namely, performance and satisfaction. Thus, the need to develop predictive models to improve learning effectiveness is in order.

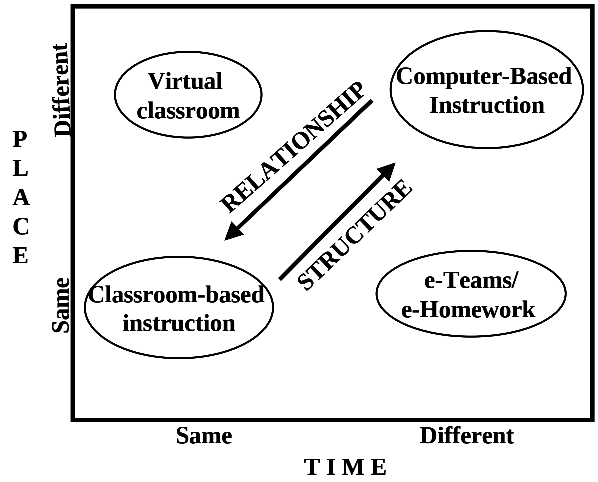
This overview includes four sections. "Background" presents a proposed e-learning theoretical framework to guide our analysis based upon the reviewed literature. "Key Issues" section describes main issues arising from the proposed e-learning conceptual framework. "Future Trends" describes our vision on how to approach e-learning initiatives and future trends. Finally, we present a general conclusion.

BACKGROUND

Organizational investment in e-learning strategies reflects strategic choices regarding skill development through e-learning. According to Wentling, Waight et al. (2000), e-learning involves acquiring and using distributed knowledge facilitated by electronic means in synchronous or asynchronous modes. As shown in Figure 1, knowledge could be distributed geographically within varying time frames.

Thus, the effective use of technology-based instruction would provide to organizations the ability to succeed at operational levels. This justifies the adoption of a holistic approach to courseware evaluation as a diagnos-

Figure 1. Proposed types of e-learning in terms of time and place



tic and managerial tool. We propose a framework, shown in Figure 2, which comprises three basic entities, business processes, people, and information systems, and three main relationships: (a) interaction between people and systems, (b) process-based roles played by people during this interaction, and (c) having the learning task be executed, as part of the e-learning experience, by people performing their process-based roles. This framework could lead to working techniques and approaches that assist development team members in designing work-related e-learning experiences within organizational contexts. To motivate a workable approach, we will now discuss each of these entities and relationships.

Reviewed literature strongly suggests that the external and internal fit among business strategies, culture, human resource practices, and leadership styles is critical to worker performance. Moreover, work contexts, for example, physical and technological conditions surrounding individual tasks, affect people's perceptions and, in turn, influence their motivation to engage into and perform learning tasks (Astleitner, 2001; Bandura, 2000; Chen, 2002; Dix et al., 1998; Kim, 2000; Liu & Dean, 1999; Reeves & Nass, 1996; Strazzo & Wentling, 2001; Vouk et al., 1999; Welbourne et al., 2000; Wentling et al., 2000).

Within the e-learning experience, business processes provide yardsticks to define educational or training goals and monitor outcomes. However, we need also to consider the roles people perform when interacting with courseware. Such process-based roles could be as diverse as e-learners, e-instructors, e-speakers, systems and courseware designers, supervisors, reviewers, human resource managers, and information technology officers among many others.

Human-computer interaction can model parts of the e-learning experience in accordance with Norman's extended model (Dix et al., 1998). Furthermore, the experience is also shaped by the way people relate to systems. This is supported by Reeves' and Nass' (1996) work, which suggests that people relate to media as they would relate to real people, treating them with affection and courtesy. Building on these findings, we argue that the more e-learning systems themselves are easy to use and learn and are "nicely behaved," the likelier e-learners will engage in the experience and profit from their outcomes.

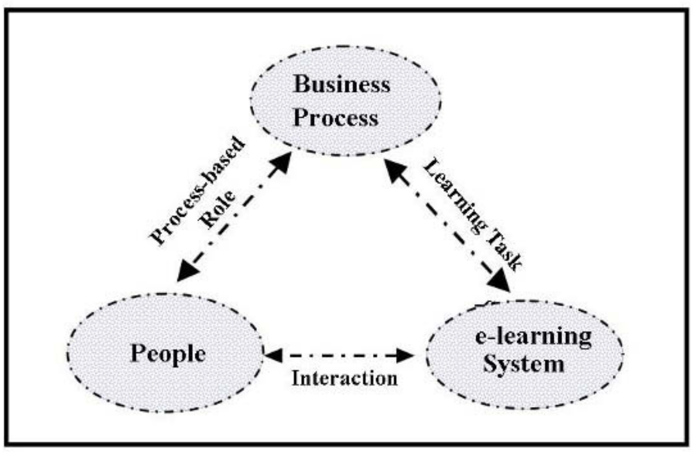
The interplay among these three relationships (process-based role, learning task, and interaction) relates to a just-in-time learning concept. Strategic knowledge acquisition should be enmeshed in current activities to support employees in learning new skills when performing day-to-day business tasks. We believe this concept can foster gradual alignment between learning outcomes, and technology with strategic aspects of business.

KEY ISSUES

We identify structure and relationship as the main issues within our framework as presented in the previous section. Figure 1 shows different modes of e-learning regarding the use of technology in education, both in terms of distance and time. As technology gets more extensively used for delivery, the need for course structure becomes higher and the relationship between instructor and e-learner turns increasingly weaker. Figure 1 also shows this relationship as defining three types of e-learning, which are set apart from conventional classroom instruction.

This shows that using technology to support learning requires higher course structure than traditional classroom-based instruction to be effective (Karoulis et al., 2004; Liu & Dean, 1999). However, current approaches take a one-size-fits-all method to provide courseware

Figure 2. Proposed e-learning framework



delivery regardless of differences in place and time. We cannot argue strongly enough that delivery needs to be tailored to context (space and time) to overcome the barriers imposed by structure and to improve the e-learning experience. This should be done differently for different students with diverse cognitive styles, roles, and tasks within organizational contexts. We will now discuss factors affecting structure and relationship.

As for structure, organizations identify training needs taking into account work context, business process dynamics, individual tasks, objectives, and areas for performance improvement. A business-process approach driving the design and the development of interactive course contents should focus on skill gaps to define instructional objectives in order to meet performance standards. In this way, setting up appropriate goals for training evaluation poses the same requirements both for electronic and traditional media. However, as courseware becomes available and distributed through the Internet, quality of service (QoS) becomes an increasingly important factor to e-learner satisfaction. Thus, technology becomes another structural issue.

From the technology standpoint, three aspects are critical to e-learner satisfaction. The first is courseware evaluation (Chen, 2002; Karoulis et al., 2004; Kim, 2000; Liu & Dean, 1999; Storey et al., 2002; Strazzo & Wentling, 2001; Wentling et al., 2000). Indeed, users' perceptions of mismatch between content and structure reduce their motivation to learn and perform (Astleitner, 2001). Usability is a second aspect affecting both engagement and acceptance. It measures the extent to which a computer system can be used to complete well-defined tasks or achieve specified goals productively and satisfactorily for the intended users in a given context (Dix et al., 1998). Last, but not the least, user modeling completes the set of key technological aspects for e-learners' satisfaction. User modeling is the knowledge a system has about the user's level of knowledge and intentions, processed as users interact with systems. Knowledge of both user and task domains should allow intelligent and adaptable systems to properly respond to the competence levels and needs of the tasks within contexts of use (Dix et al., 1998). This holistic understanding would help developers take into consideration users' expectations at the early stages of system design. In this way, expected learner performance would supplement the metrics suggested by the literature (Dix et al., 1998; Wentling et al., 2000) concerning the implementation of strategies and quality-of-service goals.

Regarding relationship issues, two factors are relevant for this overview: cognitive styles and motivation. Cognitive styles are individual characteristics that serve as stable indicators of how learners perceive, think of, remember, and solve problems (Kim, 2000; Liu & Dean, 1999). This characteristic is consistent with major dimensions of individual differences and explains stable individual performance across tasks over time. Thus, it is a key variable in designing effective systems for a particular user group, especially at early stages of the interaction. Indeed, results show that cognitive styles can help in explaining usability problems when browsing hypermedia documents (Chen, 2002; Kim, 2000; Liu & Dean, 1999). However, research results are numerous and mixed and give no consistent evidence about the relationship between cognitive styles and learners' performance in computer-based settings (Shih & Gamon, 2001; Wentling et al., 2000).

Motivation can be defined as the internal set of processes (both cognitive and behavioral) through which human energy becomes focused on the direction of effort (Welbourne et al., 2000). This definition is twofold. First, the internal set of processes by which human energy becomes focused describes the "agentic" nature of individuals in interaction with their environment (Bandura, 2000; Liu et al., 2002). A second relevant aspect of motivation is the direction of effort, which implies individual goal orientation assessed using defined internal success criteria. These two motivation-related aspects require that development teams actively involve different user roles at early stages of system design to get high usability, learnability, acceptance, and usage levels in order to likely match specific individual, task, and contextual characteristics. In this way, organizations could be more effective in creating the conditions to foster knowledge acquisition, transfer, and reutilization across different learner groups.

FUTURE TRENDS

Currently, people perceive learning as a product rather than a process. Adopting the latter view would require a holistic approach to analyze e-learner experience. This may lead to a paradigm shift in dealing with process, especially since learning, as an activity, is deeply enmeshed in interdependent and rapidly evolving organizational processes. Our vision is to pursue useful endeavors to effectively support learning by people within organizational contexts during their performance of work-related tasks. In this sense, e-learning systems would become tools for people to use, as often as needed, to acquire new knowledge related to current or future tasks. For this to happen, we need to develop a close people-process-system fit. To achieve that, cost-effective, integrated tools for courseware and competence-building evaluation within specific knowledge domains are in order. This requires coordination of efforts, information, and competencies among the key players, including

Table 1. Identified research topics

Issues	Proposed research topics
Learning task	How do e-learning initiatives relate to organizational knowledge management practices?
E-learner	In what conditions could e-learning be effective for everybody? Are there usability metrics universal across roles, levels of technology experience, cognitive styles, job levels, organizational contexts, and cultures? Does task complexity level mediate users' perception about usability? Would the initial role assigned by people to media hold steadily throughout the learning process, or does it change over time, motivated by learners' habits?
Interaction	To what extent is learners' trust and performance affected by perceived support for privacy, confidentiality, and security at the system level? Could software agents be the new "hidden persuaders" (Packard, 1957/1981) to get learners to go further into the skill-development cycle, overcoming obstacles along the way? Should such concerns be incorporated into a design discipline centered on ethical and deontological roles?

universities, companies, government, and research communities. Such coordination is fundamental to achieve skill development at individual, organizational, and societal levels, articulated with defined strategies. Table 1 summarizes the topics identified in our analysis and describes specific research goals toward the fulfillment of this vision.

CONCLUSION

We have discussed a holistic approach covering business processes, e-learners, and information systems fit, while stressing the need for quantitative models, especially in evaluation. The interplay among these entities defines the organizational space for the just-in-time learning concept. The expected benefits lie in aligning learning outcomes with business strategies.

KEY TERMS

Business Process: A set of organized work-related tasks and resources to pursue a specific organizational objective influencing learning experiences by defining two specific relationships: process-based roles (between business process and people) and learning tasks (between business process and information systems).

E-Learning Experience: A process by which people identify work-related learning needs, formulate related goals and the associated internal level-of-success criteria, search for feasible online options to achieve defined learning goals, select and acquire choices, and engage into and complete them successfully by achieving the related goals in a productive and satisfactory manner.

E-Learning Framework: A formal construct to diagnose and manage learning outcomes in terms of the operational dynamic of three basic entities: business process, information systems, and people.

Just-In-Time Learning: Strategic knowledge acquisition enmeshed in business activities to support employees in learning new skills when performing day-to-day tasks, while fostering the alignment between learning outcomes, technological and strategic business issues.

Learning Task: A set of steps with a defined learning goal addressing specific training needs identified within business processes driving the definition of proper instructional design and e-learning system requirements.

Motivation to E-Learn: An individual variable denoting an internal set of processes (both cognitive and behavioral) by which human energy becomes focused on learning particular work-related content (whether by actively interacting with courseware, participating in a virtual class, self-studying, doing e-homework alone or in group) to achieve specific learning goals.

Process-Based Role: The combination of a set of expected work-related behaviors, responsibilities, and the associated set of required competencies to perform within business settings in order to achieve organizational goals.

People-Process-System Fit: A degree of consistency among learner groups, business processes, and e-learning systems that (a) reflects the target constituency requirements, organizational context, and the stated educational or training goals, (b) applies the principles and approaches of constructivism, user-centeredness, participatory design, quality management, and organizational development to instructional design of courseware, and (c) translates into expected performance levels.

Modeling Information Systems in UML

Peter Rittgen
University College of Borås, Sweden

INTRODUCTION

The first approaches to object-oriented modeling appeared by the second half of the 1970s, but not much happened for more than a decade, so there were still barely more than a handful of modeling languages at the end of the 1980s. It was the early 1990s that witnessed an ever-growing market in competing object-oriented methods so that potential users found it increasingly difficult to identify any single method that suited their needs. This phenomenon came to be known as the "method wars." Towards the end of 1994 two of the "big" players, Grady Booch and Jim Rumbaugh, decided to join forces by integrating their respective approaches, the Booch method and OMT (Object Modeling Technique). In late 1995, Ivar Jacobson became a member of this team merging in his OOSE method (Object-Oriented Software Engineering). The efforts of the "three amigos" aimed at overcoming unnecessary differences between the individual approaches and also improving each of them by creating a common, standardized modeling language that could serve as an industry standard. The result was the release of the Unified Modeling Language (UML), version 0.9, in June 1996. The UML partners, an industry consortium, performed further work on UML. This led to the versions 1.0 and 1.1 being introduced in 1997. The latter was adopted by the OMG (Object Management Group) in the same year. The current version is 1.5 (OMG, 2003) but a major upgrade to 2.0 is in preparation (Björkander & Kobryn, 2003).

BACKGROUND

UML is a language to support the development of software systems. It features a common framework, which provides a set of diagram types covering different aspects of an information system. Here we will focus on the ones we deem to be most important: class diagram, use case diagram, and activity diagram. The first is the principal diagram for the static view on a system. The second is often put forward as the central diagram in communication with the user (see, e.g., Dobing & Parsons, 2000). The latter plays a central role in the information system (or business-oriented) perspective (see following sections). Elementary concepts of the UML are actor, activity (and state), object, and class.

An **actor** is a human being or a (computer) system who/which is able to perform activities on his/her/its own. The actor typically represents a group of similar human beings/systems and corresponds to the role the actor performs in the given context. *Teacher* is an example for such an actor. In UML actors are shown as stick figures.

An **activity** refers to a logically connected set of actions that are carried out as a unit in some order. These actions might be executed sequentially, alternatively, concurrently or in any combination thereof. *Grade exam* is an example for an activity.

*"An **object** is an abstraction of a set of real-world things such that:*

- *all of the real-world things in the set - the instances - have the same characteristics,*
- *all instances are subject to and conform to the same rules" (Shlaer & Mellor, 1988, p. 14).*

The structure (attributes) and behavior (operations) of similar objects are gathered in their common **class**. The values of the attributes at a certain point in time represent the state of the object. Classes are drawn as rectangles with the object identifier printed in bold face. Additional horizontal compartments can be introduced for the attributes and operations of the class. The object is depicted in the same way with the object identifier underlined (optionally followed by a colon and the respective class identifier). *Grade* is an example of a class, *F: Grade* that of an object.

Figure 1 shows how these concepts are related to each other: actors perform activities that involve objects. Each object is an instance of precisely one class. The class diagram shows classes and their relations (called associations). An activity diagram gives a detailed account of the order in which activities are executed. It can also show the relevant states of the involved objects. The use case diagram visualizes use cases (complex activities) and their relation to actors.

Figure 1. Language overview

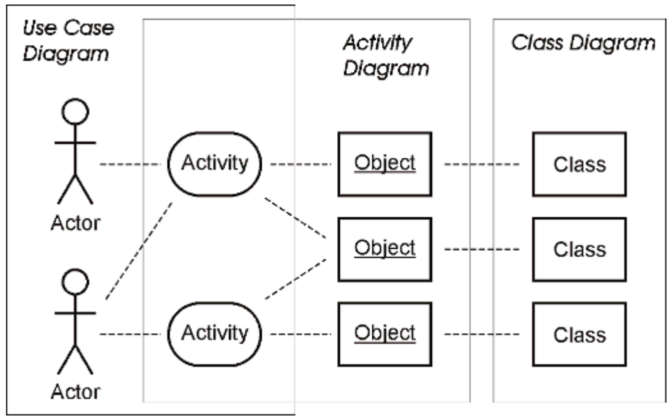

Figure 2. Use case diagram

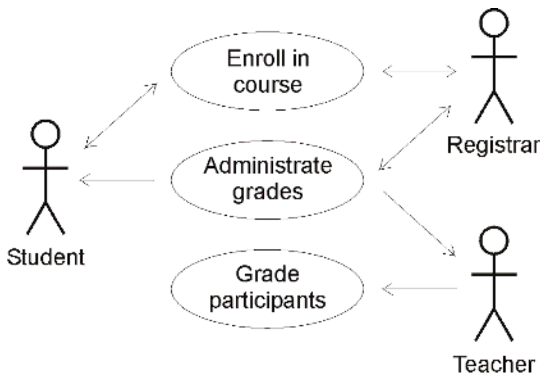

Use Case Diagram

Use cases were introduced in 1992 by Jacobson and his colleagues. Their book is now available in the 2nd edition (Christerson, Jonsson, & Övergaard, 2004). A use case describes a way in which an actor can interact with your organization. It forms part of a use case scenario, a business situation that is supposed to be supported by the information system in question. *Figure 2* gives an example of a use case diagram involving 3 use cases and 3 actors.

The arrows indicate the direction of the information flow. So the registrar can both read and enter/change grades, whereas teachers and students can only read them. Often the arrowheads are omitted to simplify modeling. Each use case is detailed by a description in structured English of the activities that make up this use case. The use case diagram and the use cases form the basis for the development of class diagrams and activity diagrams. The former specify the static structure of the information that is handled by the use cases, and the latter give a precise, formalized account of the process logic.

Activity Diagram

An activity diagram consists of the detailed activities that make up the use cases. *Figure 3* gives an example of such a diagram in relation to the use cases of *Figure 2*.

The use case *Enroll in course* comprises the activities *Apply for course* (performed by the student) and *Enroll student* (performed by the registrar). *Grade participants* maps to *Grade exam* assuming that the grade for the course is determined by a final exam only. The use case *Administrate grades* involves the activities *Enter grade*, *Check grade* and *Change grade*. Note that the activity diagram also contains activities that are not present in the use case diagram, such as *Deliver course* and *Write exam*. That is because, in our example, they are not supposed to be supported by the information system and hence do not constitute use cases of such a system. But they are still an important part of the overall business process.

The business process in *Figure 3* starts with the initial state (the black dot). The activities are in the boxes with round sides. The rectangles contain objects-in-state where the object identifier is underlined and the object's state is enclosed in square brackets. So after *Enter grade*, for example, the object *Grade* is in state *entered*. Alternative paths leaving an activity must be labeled by so-called guards that determine under which condition each path is taken. These guards are also enclosed in square brackets and should be mutually exclusive. The process terminates when the final state is reached (i.e., the circle containing the black dot). Actors are included in the form of so-called

Figure 3. Activity diagram

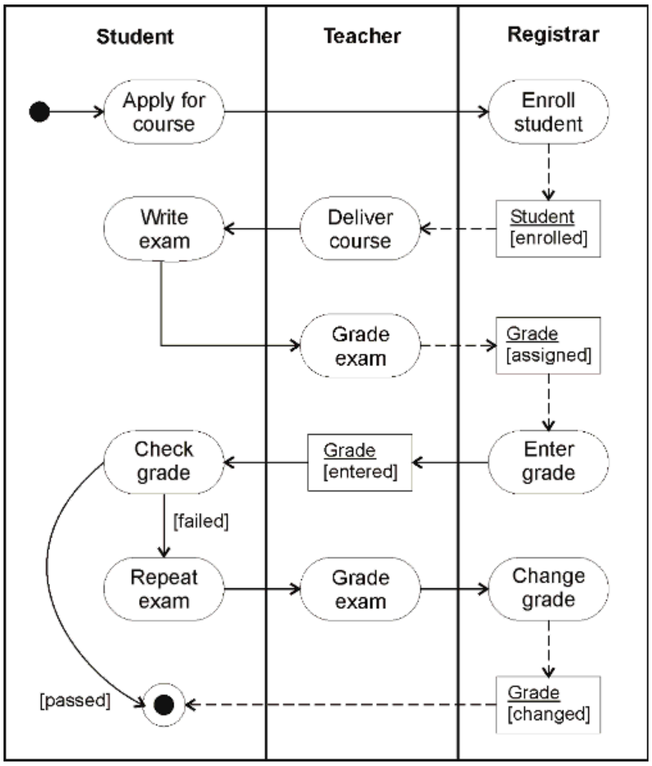

Figure 4. Class diagram

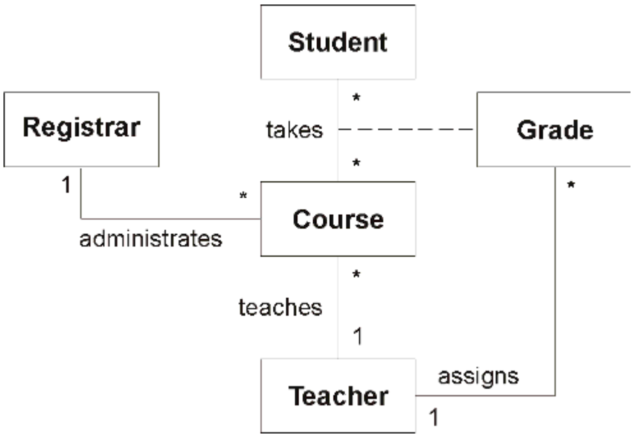

swim lanes. Concurrent execution is achieved by introducing synchronization bars. For more detailed information on activity diagrams we refer the reader to the OMG (2003, p. 3-155 ff).

Class Diagram

A typical approach to identifying classes is that of looking at the nouns contained in a textual specification of the system. Jacobson, Christerson, Jonsson, & Övergaard (2004) suggest that we should limit our attention to the nouns contained in the Use Case Diagram instead to avoid having to eliminate inappropriate class candidates. If we apply this to the use case diagram of *Figure 2* we arrive at the class diagram of *Figure 4* where all the nouns of the former map to a class of the latter. Observe that the noun *participants* maps to the class *Student*.

The class diagram also shows associations between the classes that indicate the way in which they are related to each other. A single line is drawn connecting the respective classes. It can be labeled with a verb that determines the nature of the association. In addition we can also specify the cardinality with the asterisk referring to an unlimited number. In the example a *Teacher teaches* a number of *Course*s but each *Course* is only taught by one *Teacher*. *Grade* is a so-called association class. It qualifies the relation between *Student* and *Course* and is therefore attached to the association path by a dashed line. For further details refer to the OMG (2003, pp. 3-34 ff).

MODELING INFORMATION SYSTEMS IN UML

UML has been designed primarily to support the development of software systems. In such systems the software artifact plays the central role and the role of human beings is restricted to the specification of requirements and, later on, the use of the system. An information system, on the other hand, is a human activity system (sometimes also called a socio-technical system) where some part of the system *might* be *supported* by software (Buckingham, Hirschheim, Land, & Tully, 1987).

The focus being on software systems, it is natural that UML does not emphasize the aspects of an information system that aim at the value and support it can provide to the business, such as strategy (e.g., value chains & strategic goals) and organization (e.g., organizational charts and business processes). These issues are dealt with in "business modeling" (also called enterprise modeling) but UML is beginning to advance into that field, too. The OMG (2003, pp. 1-9), for instance, claims that business processes can be represented in UML. This claim can, however, be challenged in a number of ways. First of all there is very little direct support for business processes in the basic UML diagrams (Bruno, Torchiano, & Agarwal, 2002). Instead many of the required concepts are "hidden" in extensions to UML, such as Enterprise Collaboration Architecture (ECA) (OMG, 2004). Another issue is whether UML models are indeed "understandable" enough to form a solid basis for the communication between "developers" and "users." An empirical study of UML's usability (Agarwal & Sinha, 2003) showed that UML diagrams score between 4.3 and 5.3 on a 7-point Likert scale,that is, the ease-of-use of UML is closer to indifference (4) than to the optimum (7). Understandability of UML is also weakened by construct redundancies, inconsistencies and ambiguities (Shen & Siau, 2003).

Candidate languages for business processes (in native UML) are use cases and activity diagrams. The former have been criticized for their conceptual flaws (Dobing & Parsons, 2000), such as fragmentation of objects, and for construct overload and ambiguity (Shen & Siau, 2003). In addition they restrict the specification of process logic to a textual form, which is neither rigorous nor expressive enough for typical flows of control. Activity diagrams come closer to fulfilling the requirements of a business-process language and are therefore often used in that way (see next section).

FUTURE TRENDS

So far, there is still an abundance of languages used for business modeling, for example, Architecture of Integrated Information Systems ARIS (Scheer, 1999), Open System Architecture for Computer-Integrated Manufacturing CIMOSA (AMICE, 1993), Integrated Definition IDEF* (Ang, Pheng, & Leng, 1999), Integrated Enterprise Modeling IEM (Spur, Mertins, & Jochem, 1995), Dynamic Essential Modeling of Organization DEMO (Reijswoud, Mulder, & Dietz, 1999), and GRAI Integrated Methodology GIM (Doumeingts, 1998). Often modelers also pick out particular model types from integrated methods or use "stand-alone" languages that were developed for specific purposes. In the area of business process modeling these include: Event-Driven Process Chains (EPC) (from ARIS), Business Process Modeling Language (Arkin, 2002), IDEF3 (Mayer et al., 1997), Tropos (Castro, Kolp, & Mylopoulos, 2002), and Petri Nets (Aalst, Desel, & Oberweis, 2000).

But how can we bridge the gap between these enterprise-modeling languages and UML? One approach consists of devising mechanisms that "translate" domain models into UML models. Such a translation is by no means straightforward but typically involves the reconstruction of the domain model as a UML diagram by a modeler who is experienced in both the domain language and UML. It usually involves the loss of information that was present in the domain model and the necessity to add information not yet represented. This implies also the risk of introducing errors, or more precisely inconsistencies between the original and the translated model. Examples of such an approach can be found in many of the languages mentioned due to the popularity of UML, for example, EPC to UML (Nüttgens, Feld & Zimmermann, 1998), IDEF and UML (Noran, 2000), Tropos and UML (Mylopoulos, Kolp, & Castro, 2001), DEMO and UML (Mallens, Dietz, & Hommes, 2001), or Petri Nets and UML (Gou, Huang, & Ren, 2000).

Another – and perhaps even more promising – approach is to equip UML itself with domain support. This can be done in at least two ways: extending existing concepts or introducing new ones (typically in the form of profiles). A major effort towards the latter is being made under the heading "Enterprise Distributed Object Computing (EDOC)" and was adopted by the OMG in February 2004 (version 1.0) but work is still ongoing. Its core is the Enterprise Collaboration Architecture ECA (OMG, 2004). The former approach is followed by several researchers independently. In the area of business processes and workflows they primarily investigate extensions of use cases and activity diagrams (see, for example, Rittgen, 2003; Dumas & Hofstede, 2001).

CONCLUSION

The UML is a widely used modeling language in the area of software systems modeling but it still has to gain ground in domain modeling, especially in business (or enterprise) modeling. Promising steps have already been taken that have so far led to results such as EDOC. But there is still a need for research that provides the core concepts and diagrams of the UML with domain-specific semantics to make them more useful for business modeling. On the other hand, add-on concepts such as EDOC processes require a tighter semantical integration with the existing models. Future research and development will show which of the paths towards integration is more promising and will hence be taken. But all approaches mentioned share a common goal: to improve the communication and understanding between the different people involved in shaping an information system and thereby also improving the system itself.

KEY TERMS

Activity: A logically connected set of actions that are carried out as a unit in some order. It is associated with a state (called action state) in which the system remains while the activity is performed.

Actor: A person or (computer) system that can perform an activity. The actor does not refer to a particular individual but rather to a role (e.g., *Teacher*).

Attribute: A property of an object/class. The class *Car*, for example, can have an attribute *Color*, its value for the object *MyCar: Car* might be *blue*.

Class: A template for similar objects defining attributes and operations.

Object: An abstraction of a set of real-world things that has state, behavior and identity. An instance of its class where the values of the attributes determine the state, and the operations the behavior.

Operation: A function or transformation that may be applied to or by objects in a class. The class *Account*, for example, might have the operations *Open*, *Close*, *PayIn* (*Amount*), and *Withdraw* (*Amount*).

State: A certain combination of attribute values of an object.

Modeling Technological Change in Small Business

Arthur Tatnall
Victoria University, Australia

INTRODUCTION

The introduction of a new information system into a small business, or upgrading an existing system, should be seen as an innovation and considered through the lens of innovation theory. The most widely accepted theory of how technological innovation takes place is provided by innovation diffusion, but most of the research based on this model involves studies of large organisations or societal groups. This article argues that another approach, innovation translation, has more to offer in the case of innovations that take place in smaller organisations (Burgess, Tatnall & Darbyshire, 1999; Tatnall, 2002; Tatnall & Burgess, 2004).

BACKGROUND

There are important differences in the processes by which small and large enterprises choose to adopt or reject computers (Burgess et al., 1999), and this article concerns itself only with issues related to small business. To begin, however, it is important to distinguish between invention and innovation. Whereas invention can be seen in the discovery or creation of new ideas, innovation involves putting these ideas into commercial or organisational practice (Maguire, Kazlauskas & Weir, 1994). Invention does not necessarily invoke innovation and it is fallacious to think that invention is necessary and sufficient for innovation to occur (Tatnall, 2004).

Changing the way things are done is a complex affair (Machiavelli, 1995, p. 19) and one that is difficult to achieve successfully. The dominant paradigm, by far, in innovation research is that of *innovation diffusion* and no discussion would be complete without consideration of this approach. Innovation diffusion has had success in describing how innovations diffuse through large populations (Rogers, 1995). There are occasions, however, when diffusion does not occur and the diffusion model finds these difficult to explain (Latour, 1996). The approach offered in *innovation translation*, informed by actor-network theory (ANT), is also worthy of consideration. In the translation model the key to innovation is creating a powerful enough consortium of actors to carry it through, and when an innovation fails this can be considered to reflect on the inability of those involved to construct the necessary network of alliances amongst the other actors. This article will compare these two models of technological innovation.

INNOVATION DIFFUSION

Rogers (1995), perhaps its most influential advocate, approaches the topic of innovation diffusion by considering a variety of case studies, the prime concern of which is the identification of factors that affect the speed with which an innovation is adopted, or that cause it not to be adopted at all.

In diffusion theory the existence of an innovation is seen to cause uncertainty in the minds of potential adopters, causing a lack of predictability and of information. Rogers (1995) asserts that a technological innovation embodies information, and that this has the potential to reduce uncertainty. Diffusion is thus considered to be an information exchange process amongst members of a communicating social network driven by the need to reduce uncertainty (Lepa & Tatnall, 2002). There are four main elements of the theory of innovation diffusion (Rogers, 1995):

Characteristics of the Innovation Itself

Rogers argues that the attributes and characteristics of the innovation are important in determining the manner of its diffusion and the rate of its adoption, and outlines five important characteristics of an innovation that affect its diffusion: relative advantage, compatibility, complexity, trialability and observability. The attributes of the potential adopter are also seen as an important consideration and Rogers maintains that these include social status, level of education, degree of cosmopolitanism and amount of innovativeness.

Nature of the Communications Channels

Acts of communication are a necessary part of any change process, and to reach a potential adopter the innovation must be diffused through some communications channel. Channels involving mass media are the most rapid and efficient means of spreading awareness of an innovation, but interpersonal channels are generally more effective in persuading someone to accept a new idea.

The Passage of Time

In common with earlier researchers, Rogers found that different individuals in a social system do not necessarily adopt an innovation at the same time. Borrowing from work by Deutschmann and Fals Borda (1962), he proposes that adopters can be classified in their degree of "innovativeness" into five categories: innovators, early adopters, early majority, late majority and laggards, and that if the number of individuals adopting a new idea is plotted over time it usually follows a normal curve.

The Social System

Diffusion occurs within a social system in which the structure constitutes a boundary inside which this diffuses. Rogers argues that the system's social structure affects diffusion through the action of social norms, the roles taken by opinion leaders and change agents, the types of innovation decisions that are taken, and the social consequences of the innovation.

INNOVATION TRANSLATION

An alternative view is that of innovation translation, which draws on the sociology of translations, more commonly known as actor-network theory (ANT). The core of the actor-network approach is translation (Law, 1992), which can be defined as: "... the means by which one entity gives a role to others" (Singleton & Michael, 1993, p. 229).

Essentialism

Diffusion theory asserts that a technological innovation embodies information: some essential capacity or essence instrumental in determining its rate of adoption. A significant problem with an essentialist paradigm like this arises if a researcher tries to reconcile the views of all parties involved in the innovation on what *particular* essences are significant. The difficulty is that people often see *different* essential attributes in any specific technological or human entity, making it hard to identify and settle on the ones that allegedly were responsible for the diffusion.

To illustrate this difficulty, consider the case of a small business deciding whether to purchase their first computer. Researchers using an innovation diffusion model would begin by looking for innate characteristics of the PC that would make a potential adopter more likely to accept it. They would consider the relative advantages of a PC over alternatives like a filing cabinet. An examination of the compatibility, trialability and observability of a PC with this older office technology would show good reasons for acceptance. An examination of the PC's complexity would, however, bring out some reasons for reluctance in its adoption. The researchers would then investigate characteristics of the potential adopters, considering factors like their educational background, innovativeness, and how they heard about the innovation. If, however, you *ask* small business people why they purchased their first PC, the answers often do not match with this view.

Actor-Network Theory: The Sociology of Translations

Rather than recognising in advance the essences of humans and of social organisations and distinguishing their actions from the inanimate behaviour of technological and natural objects, ANT adopts an anti-essentialist position in which it rejects there being some difference in essence between humans and non-humans. ANT considers both social and technical determinism to be flawed and proposes instead a socio-technical account (Latour, 1986) in which neither social nor technical positions are privileged. To address the need to properly consider the contributions of both human and non-human actors, actor-network theory attempts impartiality towards all actors in consideration, whether human or non-human, and makes no distinction in approach between the social, the natural and the technological (Callon 1986).

Mechanisms of Translation

The process of translation has four aspects or "moments" (Callon, 1986), the first of which is known as *problematisation*. In this stage, a group of one or more key actors attempts to define the nature of the problem and the roles of other actors so that these key actors are seen as having the answer, and as being indispensable to the solution of the problem. In other words, the problem is re-defined (translated) in terms of solutions offered by these actors (Bloomfield & Best, 1992). The second moment is *interessement* and is a series of processes that attempt to impose the identities and roles defined in the problematisation on the other actors. It means interesting and attracting an entity by coming between it and some other entity. Here the enrollers attempt to lock the other actors into the roles proposed for them (Callon, 1986) and to gradually dissolve existing networks, replacing them by a network created by the enrollers themselves.

If the interessement is successful then the third moment, *enrolment,* will follow through a process of coercion, seduction, or consent (Grint & Woolgar, 1997), leading to the establishment of a solid, stable network of alliances. Enrolment, however, involves more than just one set of actors imposing their will on others; it also requires these others to yield (Singleton & Michael, 1993). Finally, *mobilisation* occurs as the proposed solution gains wider acceptance and an even larger network of absent entities is created (Grint & Woolgar, 1997) through some actors acting as spokespersons for others (Tatnall, 2001).

FUTURE TRENDS: TRANSLATION VERSUS DIFFUSION

Many small businesses are family-related concerns with several members working in the business. Investigations (Tatnall, 2001, 2002; Tatnall & Burgess, 2002) suggest that a common reason why a small business first acquired a PC is that it was, at least partly, intended for family use. In this regard, one reason that the PC was obtained was in the belief that it would assist with their children's education. Once obtained, other uses almost always also found for the technology, but the question remains: Would the characteristics of the PC and of the people involved in its adoption have been identified by a diffusion model? Table 1 summarises difference in approaches between the diffusion and translation frameworks.

An Example: Adoption of a Slide Scanner by a Small Publishing Company

To illustrate the use of the two innovation models, consider the case of DP Pty Ltd – a small publishing company where four people work on the publication of information systems textbooks. DP is a very small business with a well-established market. Members of the company do much of the writing, and all of the work involved in publication of their books, but send the work off for printing and binding. Most of DP's print runs are small. All those involved in the work of the company are computer literate and make good use of IT. None of them, however, has much knowledge of computer graphics.

Several years ago, the company decided it needed to improve the appearance of the covers on its textbooks.

Table 1. Innovation diffusion versus innovation translation

	Innovation Diffusion	**Innovation Translation**
Innovation	A technology perceived to be new by the potential adopter.	A technology that has yet to be "black-boxed".
Communication	Communication channels can be categorised as cosmopolite or localite, and mass media or interpersonal. Innovations are transferred through these channels.	Translations are made by actors in enrolling the innovation.
Time	Speed of decision to innovate, earliness of adoption and rate of adoption are important.	Network dynamics in enrolment, control, and dissemination are what matter.
The Social System	Homophily versus heterophily. Sharing of interests of human actors.	Interessement between actants, both human and non-human, and goals. Black boxes form when interests move in the same direction.
The Technology	Changes are made to the form and content of the technology as a result of experiences during implementation (re-invention).	The technology is translated through being enrolled, regardless of whether its form or content is modified.
Socio-Technical Stance	The social system and the technology are separate. Diffusion is the adoption of technology by a social system. Technology transfer requires the bringing together of social and technical elements.	The social system and the technology are inseparable. Successful innovation and technology transfer gives the appearance of separation, but this is merely evidence that the actor-network has stabilised.

Adapted from McMaster et al. (1997)

Several options were considered until someone thought of using a photograph. The brother of one of the directors is a landscape photographer who was able to provide a suitable colour photograph. This was supplied in print form, and a problem arose in how to convert it (or its negative) into a suitable format to print on the cover along with the cover text. A digital image seemed to be the answer. The photograph was scanned (using a flat-bed scanner) and the digital image inserted into Microsoft Word so that text could easily be added. The final result was then converted into an Acrobat file and sent off to the printer. This process, however, proved to be quite a lot of bother. Today the company makes use of a Nikon slide and negative scanner, considerably improving the quality of the covers, but also making the process of producing them much simpler. This device is capable of producing digital images of slides and negatives at various resolutions. The question is: why did DP decide to adopt this *particular* item of technology?

Consider first the application of a diffusion model. Here the company would have been mainly influenced by attributes and characteristics of the technology itself. The directors would have considered the relative advantage, compatibility, complexity, trialability and observability of this technology compared with the alternatives. Two of the directors of the company certainly did see some relative advantage in using the slide scanner, particularly as they both had large numbers of colour slides that they had taken over the years. There was, however, one major disadvantage of this technology and that was its high cost: the slide scanner was around four times as expensive as a good flat-bed scanner. The slide scanner did not come out well on compatibility or complexity, as it was quite different and difficult to use. The company arranged trial use of the scanner, which was lucky as it proved difficult to find anyone else using one – its observability was low. On this basis, it is difficult to see why DP would have adopted the slide scanner at all.

When a translation model is applied, the situation is seen quite differently. The socio-technical network consisting of the publishing company personnel, their computers, and their books was destabilised by the need to find a new way of producing book covers. The addition of a new actor, the landscape photographer, introduced new possibilities that worked to further destabilise this network. The slide scanner (also seen as an actor seeking to enter the network) offered new possibilities in which existing (and future) slides and negatives could easily be turned into digital images. This included *any* of the directors' old slides, not just those required for book covers. As well as the main application of producing book covers, both directors quickly saw advantages in a device that could also easily convert the old slides and negatives they had each taken of their children and of their holidays into digital format. It was thus a combination of factors, some business-related and others rather more personal, that the translation modes suggests could be seen as leading to the adoption of this technology.

It should also be pointed out that a significant translation occurred from the slide scanner advertised by Nikon in the magazine article and on their Web page to the device adopted by the publishing company. DP was not interested in using the scanner in all the ways that Nikon offered. They wanted a device to digitise slides and negatives for two reasons: the easy creation of attractive book covers, and the conversion of their own colour slides into a format that could easily be displayed on a video monitor. They did not adopt the scanner advertised by Nikon, but a device for creating book covers and formatting their slides for video display.

CONCLUSION

The translation approach to innovation details the construction of networks and alliances to support and embed changes in order to make them durable. Innovation diffusion and innovation translation are based on quite different philosophies, one stressing the properties of the innovation and the change agent and routed in essentialism, and the other emphasising negotiations and network formation.

Innovation translation is more attuned to the human and political issues involved in small business decision making, and so offers a useful approach to modelling innovation in small business. Most current writings on technology uptake and innovation employ either no theoretical model at all, or else use a diffusion model. The author suggests that future research should further investigate the use of a translation model to explain the adoption of information technology in small business, and encourages future researchers to consider this approach.

KEY TERMS

Actor-Network Theory: An approach to research in which networks' associations and interactions between actors (both human and non-human) are the basis for investigation.

Innovation: The application, in any organisation, of ideas new to it, whether they are embodied in products, processes or services.

Innovation Diffusion: A theory of innovation in which the main elements are: characteristics of the innovation itself, the nature of the communication channels, the passage of time, and the social system through which the innovation diffuses.

Innovation Translation: A theory of innovation in which, instead of using an innovation in the form it is proposed, potential adopters *translate* into a form that suits their needs.

Invention: The discovery or creation of new ideas.

Sociology of Translations: Another term used to refer to actor-network theory.

Socio-Technical Research: Involving both social and technical interactions, occurring in such a way that it is not easily possible to disentangle them.

Technological Innovation: The introduction or alteration of some form of technology (often information technology) into an organisation.

Model–Supported Alignment of IS Architecture

Andreas L. Opdahl
University of Bergen, Norway

INTRODUCTION

An *information system (IS)* is a system that communicates, transforms, and preserves information for human users. An information system comprises one or more software applications and databases, and their relationships to their human users, operators, and maintainers.

A modern enterprise has many information systems that can be related in various ways. For example, information systems can be *related by exchange* because they exchange data through message passing or shared databases, or because they exchange functions through remote procedure calls or Web services. Information systems can also be *related by overlap* because they maintain the same data or provide the same functions. Information systems can be related in many other ways too, either *directly*, such as when one IS controls another, or *indirectly*, for example, because several ISs depend on the same run-time platforms or because they compete for their users' attention or for computer resources. In addition to being related to one another, information systems can be related to the *surrounding organization* in many ways. For example, organization units such as departments, individuals, or roles may be the *owners*, *users*, *operators*, or *maintainers* of ISs; organizational goals and strategies can be *realized by* ISs; organizational processes can be *supported* or *automated by* ISs; and so on.

The *information systems (IS) architecture* of an enterprise comprises its information systems, the relationships between those information systems, and their relationships to the surrounding organization. In addition to single enterprises, *alliances* of enterprises and *parts* of enterprises, such as divisions and departments, can have IS-architectures too. The above definition implies that *every* enterprise has an IS-architecture, even if that architecture is not explicitly talked about, described, or managed: 'IS-architecture' is a way to look at organizations and their information systems.[1]

IS-architecture alignment is the process of selecting an *IS-architecture vision* towards which the architecture should be incrementally but systematically evolved. This article will present a model-supported framework for aligning an IS-architecture with its surrounding organization (Opdahl, 2003a). The framework shows how an enterprise's *current* IS-architecture can be represented in an enterprise model, from which *candidate architecture visions* can then be generated, before one of them is selected as the enterprise's IS-architecture vision.

BACKGROUND

Zachman (1978) defines 'IS-architecture' as "the sum total of all information-related flows, structures, functions, and so on, both manual and automated, which are in place and/or required to support the relationships between the entities that make up the business." In the last few decades, several IS-architecture methods have been proposed in both industry and academia (Opdahl, 2003a).

A related term is *information architecture (IA)*, used by some authors (e.g., Periasamy & Feeny, 1997) as a synonym to 'IS-architecture', although IA can also be used to emphasize the information sharing and information management aspects of IS-architecture. Another related term is *enterprise architecture (EA)* (McGovern et al., 2004), sometimes called *enterprise information architecture (EIA)* (Cook, 1996), which, according to Chorafas (2002), "is to align the implementation of technology to the company's business strategy" and "to make technology serve innovation economics." 'EA'/'EIA' is sometimes used synonymously with 'IS-architecture', but can also be used to emphasize organizational aspects such as process structure and organizational roles.

IS-architecture alignment can also be understood as an intermediate step (or level) between ICT strategy and detailed IS planning (Brancheau & Wetherbe, 1986).

IS-ARCHITECTURE ALIGNMENT

A *good IS-architecture* should be *strategically* and *operationally fit* to the enterprise, *simple and well structured*, *well managed*, and *clearly and explicitly described*. These characteristics are explained as follows:

- *Strategically fit* means that the IS-architecture should support the enterprise in pursuit of its goals and strategies. This is of course the primary characteristic of a good IS-architecture.
- *Operationally fit* means that the IS-architecture should be integrated with the enterprise's *organi-*

zational structures, such as its *market structure*, *product structure*, *process structure*, *function structure*, *organization structure*, and so on. Although operational fitness may not be a goal in itself, some degree of operational fitness is necessary to achieve strategic fitness.

- *Simple and well structured* means that the IS-architecture should not be unnecessarily complex, because a complex IS-architecture will be difficult to comprehend and understand, and difficult to change without unanticipated consequences. It will therefore be hard to manage.
- *Well managed* means that the principles, activities, roles, and responsibilities for IS-architecture maintenance and evolution should be well-defined and properly taken care of. An IS-architecture that is not explicitly and properly taken care of may start to drift and quickly become unnecessarily complex and/or strategically and operationally unfit.
- *Clearly and explicitly described* means that the enterprise should always document both its *current* IS-architecture and its IS-architecture *vision*. Whereas the current architecture should be represented by a sketch or blueprint,[2] the vision should

Table 1. The core metatypes in the representation framework. For each metatype, a brief description is given, along with examples of possible sub-metatypes (from Opdahl, 2003a).

Metatype (Subtype examples)	*Description*
Goal (mission, vision, business objectives, etc.)	The motives/rationales for the **Activities** carried out by the **Organization Units** and for other **Phenomena**. ***Goals*** *can be either explicit statements or implicit ideas. They can be either shared or individual and either official or private.*
Strategy (business strategies, principles, plans and standards, etc.)	Guidelines for how **Organization Units** carry out **Activities**. *G**uidelines** can be either formal or informal.*
Organization Unit (divisions, business units, departments, work groups, employees, project groups, boards, committees, etc.)	One or more persons. *An **Organization Unit** can be either an individual or a group. It can be either permanent or temporary.* *Note that a **Role** is a subtype of **Organization Unit**, i.e., an individual unit at the type level. The **Role** subtype is so important in enterprise modeling that it should often have its own icon.*
Activity (functions, processes, tasks, some projects, etc.)	Actions or events that occur in the enterprise. ***Activities*** *can either be singular, continuous, or repeated.*
Information	A pattern of information or data that is used and/or produced in the enterprise. ***Information*** *can be on electronic or other formats, e.g., paper.*
Application	A software system that automates or supports an **Activity** in order to let an **Organization Unit** accomplish an **Goal**.
Database (electronic archives, libraries, etc.)	A collection of data or information in the enterprise. *A D**atabase** can be in electronic or other form.*
Basic Software (operating systems, protocols, etc.)	A group of cooperating programs that are used by Applications and Databases.
Computing Equipment (computers, peripherals, etc.)	A piece of hardware.
Network	A communication network that connects computers with other computers, peripherals, and/or networks.
Phenomenon	Any of the above, i.e., either an objective, a strategy, an organization unit, an activity, information, an application, a database, basic software, computing equipment, a network, or an instance of one of the extensional metatypes.

additionally be documented by a set of higher-level evolution principles.[3]

IS-architecture alignment is the process of selecting such a set of higher-level principles—expressed as an IS-architecture vision—towards which the IS-architecture is to be incrementally but systematically evolved.

Henderson and Venkatraman's (1993) *strategic alignment model* distinguishes between the external and internal domains of businesses on the one hand, and between the business domain and the ICT domain on the other hand. In consequence, their framework distinguishes between *strategic integration*, which is "the link between business strategy and I/T strategy," and *functional integration*, which is "the link between organizational infrastructure and processes and I/S infrastructure and processes" (Henderson & Venkatraman, 1993). Relative to Henderson and Venkatraman's model, IS-architecture alignment focuses on 'functional integration' and on the 'internal domain' of enterprises.

MODELING ORGANIZATIONS AND IS-ARCHITECTURES

The framework for model-supported alignment relies on a structured view of an *organization* (Opdahl, 2003a) as a collection of *organizational elements* with *organizational relationships* between them. There are different types of elements, such as *goals*, *organization units*, and *activities*. Table 1 lists the most important ones, with further details given in Opdahl (2003a). The terms used in Table 1 are only suggestions. In real projects, they should be refined into more organization-specific terms. For example, 'organization unit' could be replaced by terms such as 'division', 'department', 'project group', 'role', and 'position', and the term 'activity' could be refined into 'project', 'process group', 'process', 'process step', 'operation', 'business function', and so forth. The framework defines many types of organizational relationships too (not shown in Table 1), such as goals that are *realized-by* activities and organization units that *carry-out* activities and that are *responsible-for* goals.

According to the framework, a part of the organization forms an *IS-architecture*, which is correspondingly viewed as a collection of *IS-architecture elements* and *relationships*. Examples of IS-architectural element types are *applications* and *databases*, and an example of a relationship type between IS-architecture elements is that applications *manipulate* databases. There are also various types of relationships between IS-architecture elements and other organizational elements, such as databases that *store* information, and activities that are *supported-by* applications and that *manipulate* information.

IS-architecture elements form *IS-architecture areas*, which may comprise several different types of elements. A particularly important type of IS-architecture area is the enterprise's *information systems*, which are collections of tightly coupled applications and databases that are related to the rest of the organization. But the framework also allows for other types of IS-architecture areas that group other kinds of IS-architecture elements, for example *responsibility areas* that group information systems into larger clusters. IS-architecture areas are important because they can be used to make the IS-architecture simple and well structured, and thereby more manageable: in a good IS-architecture, the architecture areas support the enterprise's goals and strategies, and the elements in each architecture area are closely related to one another, whereas there are few relationships between elements that belong to distinct areas.

Figure 1 shows the most important organizational and IS-architectural element types in the framework. Goals and strategies are executed by the grey-shaded operational organization, whose three domains are shown as layers in Figure 1. The *organizational domain* comprises organization units, activities, and information; the *information systems domain* comprises IS-architecture areas, applications, and databases, whereas the *ICT-infrastructure domain* comprises basic software, computing equipment, and computer networks.

Importantly, many elements in the framework are *decomposable*. For example, an organization unit can have sub-units, and an information element can have sub-elements. Decomposable elements of the same type form *organizational structures*, similar to organizational *dimensions* (Armour, 2003). Examples of organizational structures are the hierarchy of organization units in an enterprise and its business function hierarchy.

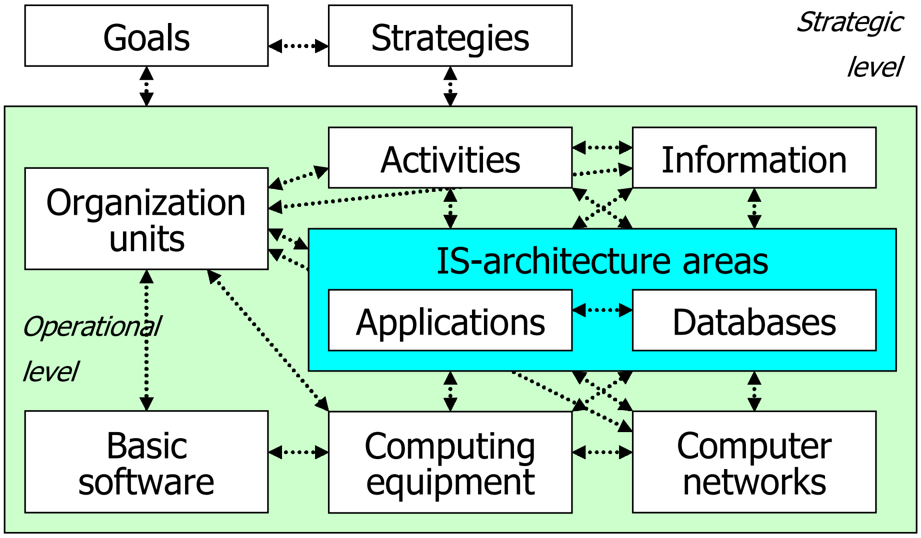
Figure 1 is also a sketch of a more detailed underlying *metamodel* (Opdahl, 2003a). The metamodel can be seen as a model of a modeling language for representing IS-architectures and the organizations that surround them. The metamodel has been implemented in a graphical enterprise-modeling tool, supported by the Computas-Metis modeling and metamodeling tool family. The framework and tool can be used to represent an enterprise's *current* IS-architecture, as well as *candidate* and *selected* IS-architecture *visions*.

ALIGNING ORGANIZATIONS AND IS-ARCHITECTURES

The framework for model-supported alignment centers on *operational* and *strategic fitness*, the two most important

M

Figure 1. The core of the IS-architecture representation framework. The core metamodel can be extended with metamodels that represent other metatypes, such as products and locations and IS architecture areas other than information systems (Opdahl, 2003a).



characteristics of a good IS-architecture. Firstly, the framework systematically investigates alternative ways to achieve operational fitness by generating a candidate architecture vision for each of them. Secondly, the generated candidate visions are evaluated and compared according to their strategic fitness, before one of them is selected as the enterprise's IS-architecture vision. In other words, the framework investigates different ways to achieve operational fitness and selects one of them according to strategic fitness.

In the first step, different ways to align the IS-architecture with the surrounding organization are investigated systematically, inspired by an approach outlined by Kiewiet and Stegwee (1991). Each candidate architecture vision is expressed as a set of *IS-architecture principles* used for grouping IS-architecture elements into IS-architecture areas. Each principle prescribes one way to group one type of IS-architecture element and, together, the set of principles prescribes one way to group all the element types in the architecture.

A principle for grouping IS-architecture elements (of a particular type) comprises (a) an organizational structure, (b) possibly a hierarchical level of decomposition of that structure, and (c) a relationship, possibly indirect through several intermediate relationships, between that structure (at that level of decomposition) and an IS-architecture element (of that type). According to the principle, two IS-architecture elements will belong to the same group if they have the same relationship (c) to an element at the appropriate level of decomposition (b) in the organizational structure (a). For example, applications (a type of element) may be grouped into information systems (a type of architecture area) according to the business function (an organizational structure) that they support (a particular relationship). Furthermore, applications can be grouped into a few large information systems according to high-level business functions or into many smaller information systems according to lower-level, more decomposed functions (decomposition levels in the hierarchy of business functions) (Opdahl, 2003a).

This structured view of IS-architecture alignment, along with the equally structured views of organizations and IS-architectures presented in the previous section, makes it possible to systematically investigate all possible sets of principles, either manually or automatically. If the current IS-architecture and its surrounding organization are represented in an IS-architecture model, it is even possible to automatically generate models of each candidate architecture vision.

The first step of the alignment framework ensures that the generated candidate visions will be both *operationally fit, simple and well structured*, and *clearly and explicitly described*. But it does nothing to satisfy the most important criterion of all, *strategic fitness*. In the second step, the candidate architectures are therefore evaluated and compared according to strategic fitness. The framework does *not* currently support automatic selection of optimal or satisficing architectures leaving this task for manual assessment according to, for example, the enterprise's goals and strategies. However, automatic generation of enterprise models for candidate architecture visions should make selection easier by making assessments of and comparisons between candidates more concrete. Developing heuristics for critiquing, shortlisting, prioritizing, and selecting candidate architectures remains a topic for further work.

FUTURE TRENDS

This article has outlined how enterprise models can be used to help enterprises align their IS-architectures with the surrounding organization. But model-supported alignment of IS-architectures is only one among many important ways in which future enterprises can benefit from enterprise models. For example, new ICT systems will gradually become adaptable and manageable through enterprise models, as when a new customer resource management (CRM) system is tailored by modifying associated models of information processes and markets. Later changes to the enterprise model can then be automatically reflected in the running CRM system, so that both initial adaptation and subsequent management can be done at the model level.

When the enterprise's ICT systems thus become controllable through enterprise models, there is a danger that enterprises become more rigid and uncoordinated as a result, because the models are expressed in many different and unrelated modeling languages. This danger can be avoided by *integrating* the modeling languages and technologies used to control different ICT systems. As a result, the enterprise can become better coordinated because its ICT systems become semantically integrated. The enterprise can also become more flexible because changing ICT systems through enterprise models is easier than changing them at the implementation level. There is therefore a need for theories and tools for tightly integrating a broad variety of enterprise models and modeling languages (Opdahl, 2003b; Opdahl & Sindre, 1997), including information and process models, actor and organization models, and goal and business-rule models. In this light, the alignment framework is only a partial contribution to developing theories and tools for tying together ICT systems in a flexible way through tightly integrated enterprise models.

CONCLUSION

The article has presented a model-supported framework for aligning an IS-architecture with the surrounding organization. One advantage of the framework is that it does not only derive blueprints of future architectures, but also generates *principles* for evolving the current IS-architecture towards the architecture vision. Another advantage is that the framework can in principle be supported by a tool, which can in the long run be developed into an *IS-architecture* (or *enterprise architecture*) *workbench*. The workbench could gradually be extended to supplement the framework with a variety of alternative approaches to ICT strategic alignment.

The framework needs to be developed further. When tool support becomes available, it must be validated by industrial case studies. Further research is also needed on how to compare candidate architectures and how to best represent and visualize IS-architectures. Also, the framework in its present form is *reactive* rather than *proactive*, because it takes the surrounding organization as a given. Although it should not be difficult to modify the framework to better support proactive use, this needs to be investigated.

Behind the alignment framework is a broader view of tomorrow's enterprises, whose ICT systems will be controlled by comprehensive enterprise models. As a result, *enterprise model integration* will become a prerequisite for ICT systems integration and thereby become the key to successful *enterprise integration*. In the enterprises of the future, the cost of establishing and maintaining large models will be shared by many different areas of use. For this to happen, new theories, technologies, and tools are needed to develop, maintain, and operate large models that integrate multiple perspectives on the enterprise and that are used for different purposes (Opdahl, 2003b; Opdahl & Sindre, 1997).

KEY TERMS

Enterprise Model: A diagrammatic representation of an enterprise or part of an enterprise. An enterprise usually focuses on certain aspects of the enterprise, such as its goals and strategies, its business processes, its organization structure, its information and knowledge, etc.

Information System (IS): A system that communicates, transforms, and preserves information for human users. An information system comprises one or more computerized data systems along with their human users, operators, and maintainers.

Information Systems Architecture, IS-Architecture: The set of information systems in an organization, the relationships between those information systems, and the relationships between the information systems and the rest of the organization.

IS-Architecture Alignment: The process of selecting an IS-architecture vision that is strategically and operationally fit for the enterprise, simple and well structured, well managed, and clearly and explicitly described.

IS-Architecture Model: An enterprise model that focuses on the enterprise's IS-architecture and that can be used to represent a current architecture or to illustrate a candidate or selected architecture vision. An IS-architecture sketch is a high-level model, whereas an architecture blueprint is more detailed.

IS-Architecture Principle: A high-level rule that can be used to make decisions about developing and/or evolving individual ICT systems.

IS-Architecture Vision: A coherent set of IS-architecture principles that together guide all the aspects of IS-architecture evolution that are considered important.

ENDNOTES

1. This contrasts authors who define 'IS-architecture' as a 'blueprint' or 'sketch' of how the enterprise's ISs *are* or *should be* organized. In the terminology of this article, although a blueprint or sketch can *represent* or *describe* an IS-architecture, the blueprint or sketch *is not* the architecture.
2. The difference between the two is that a *sketch* is a rough representation that is used to communicate central aspects of an IS-architecture, whereas a *blueprint* is intended as a complete description of the architecture.
3. Principles are preferable to blueprints because a blueprint is only valid for as long as the rest of the organization stays roughly the same, whereas a principle can be useful even after the organization has undergone changes, although the enterprise's principles must of course be re-evaluated from time to time as it evolves.

Moderator in Government-Initiated Online Discussions

Arthur R. Edwards
Erasmus University Rotterdam, The Netherlands

INTRODUCTION

In an older version of a Dutch Internet dictionary the moderator is defined as "a person who exercises censorship on a mailing list or newsgroup."[1] In the libertarian tradition of the Internet, moderation has often been viewed as conflicting with free speech and unrestrained communication (Tsagarousianou, 1998). However, as the history of the famous PEN-experiment (Public Electronic Network) in Santa Monica (1990-96) already showed, the free speech principle has to be weighed against other legitimate concerns, like the need to facilitate a genuine discussion and to counteract possible abuses of the medium (Docter & Dutton, 1998).

This article covers government-initiated online discussions between citizens, government officials, politicians, and social organizations. The importance of moderation of these discussions is now generally recognized (see, for instance, Coleman & Gøtze, 2001). Moderation is important to stimulate and regulate online discussions as purposeful social action. Some characteristics of online interaction, such as its virtuality or anonymity may diminish the psychological thresholds to participate in a discussion, but they may also inhibit the social cooperation that is needed to accomplish complex communicative tasks. From research on discussions in political newsgroups we know that discussions often serve more as a means for reinforcing preexisting views than to persuade others (Hill & Hughes, 1998; Davis, 1999; Wilhelm, 2000). These findings do not imply that the moderation of political newsgroups is imperative. As far as they can be characterized as online "free-for-all-discussions" that satisfy a social need to express opinions and concerns, this is an open question that can be left to the participants. Online discussions, however, that are initiated to involve citizens in dealing with public issues, do require moderation. In these settings, moderation is also necessary to realize some potential advantages of online discussions. Because of their asynchronous nature, there are more possibilities for structuring them. Various discussion lines can be opened and managed. Also, there is more flexibility possible in providing information. To reap these fruits, moderation is necessary.

BACKGROUND

A moderator can be defined as a person (or group of persons) who facilitates a discussion in view of its goals and agenda.

The moderator roles have been discussed since the inception of the Internet community. The Guide for Electronic Citizen Consultation, published by the Dutch Ministry of the Interior (1998), mentions three moderator roles. First, the moderator functions as a "host" so that the participants feel at ease. He shows them the way, so to speak, in the discussion, how it works, where information can be found, etc. Second, the moderator is seen as a "discussion leader." In this role, he furthers the progress of the discussion. Also, he makes sure that all participants actually take part in the discussion. Third, the moderator has a role as an "arbiter." He may designate certain postings as inappropriate and decide to remove them. Coleman and Gøtze (2001) have listed a number of metaphors to designate various moderator roles, based on work by White (2002) and others. These include the roles of "social host," "project manager," "community of practice facilitator," "'cybrarian," "help desk," "referee" and "janitor." These designations are useful, as they give an impression of the variety of moderator roles. White (2002) relates each role to specific types of communities and applications, and also indicates which key skills are required.

In this article, a more theoretical approach will be proposed by outlining a conceptual model of the "management" of Internet discussions. The underlying claim of this model is that it specifies all (main) tasks that have to be performed in the design and management of online policy exercises that should carry at least some weight in the political decision-making. A management approach suggests that certain general "management functions" have to be performed. I distinguish (1) the strategic function, (2) the conditioning function and (3) the process function (see figure 1).

The *strategic* function is to establish the boundaries of the discussion and to embed it in the political and organizational environment. This includes the following tasks:

- Establish the *goals* that the discussion is designed to achieve, both towards the citizenry and the institutional decision-making system;
- Establish and maintain the *substantive domain* of the discussion, i.e., the boundaries of the agenda within which themes and issues may be raised;
- Obtain *political and organizational support* for the discussion;
- Establish the *status* of the discussion in terms of influence on decision-making;
- Ensure that the *results* of the discussion will actually be carried over into the decision-making process and to give feedback on this to the participants.

The *conditioning* function refers to all kinds of conditions and provisions that have to be taken care of to further the discussion. This may include the following:

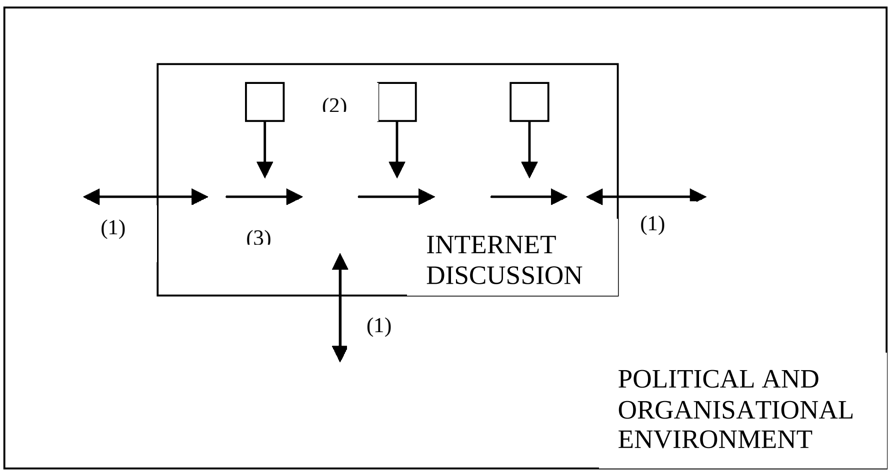
- *Solicit people* to join the discussion as *participants*;
- Provide *information to facilitate informed discussion*;
- Provide *supporting technologies*, such as moderation software, simulation models and visualization.

The *process* function includes all tasks that have to do with the discussion process as a cooperative, purposeful activity:

- Set the *interactional goal* of the discussion, i.e., the kind of results to be reached by the participants within the discussion, for instance, exploration of problem definitions or consensus about a proposal of policy measures;
- Specify the *agenda* of the discussion, within the substantive domain that has been established in the strategic function: the questions, propositions or themes to be discussed;
- Set the *schedule* of the discussion;
- Manage the *discussion process* in view of its interactional goal, its agenda, and its schedule, for example, assign messages to discussion lines or open new discussion lines;
- Facilitate the progress of the discussion by making *summaries* during the discussion;
- Stimulate the *interactivity* of the discussion, for instance, by stirring up participants to take part in the discussion and to give reactions to specific contributions;
- Set and maintain the *rules of the game.*

As an analytical tool, this model can be used in two ways. First, in an actor-oriented way, it can be used as an instrument to discover what moderators do (Edwards, 2002). Second, in a process-oriented way, it can be used to ascertain how the different management functions are performed and which actors are involved. Used in this way, the model allows for contributions to the manage-

Figure 1. The management of online discussions (Edwards, 2002; reprinted)



(1) strategic function: establish the boundaries of the discussion and embedding it in the political and organizational environment.
(2) conditioning function: take care of conditions and provisions.
(3) process function: further the progress of the discussion as a cooperative, purposeful activity.

ment of online discussions by other actors than the moderator (Edwards, 2004).

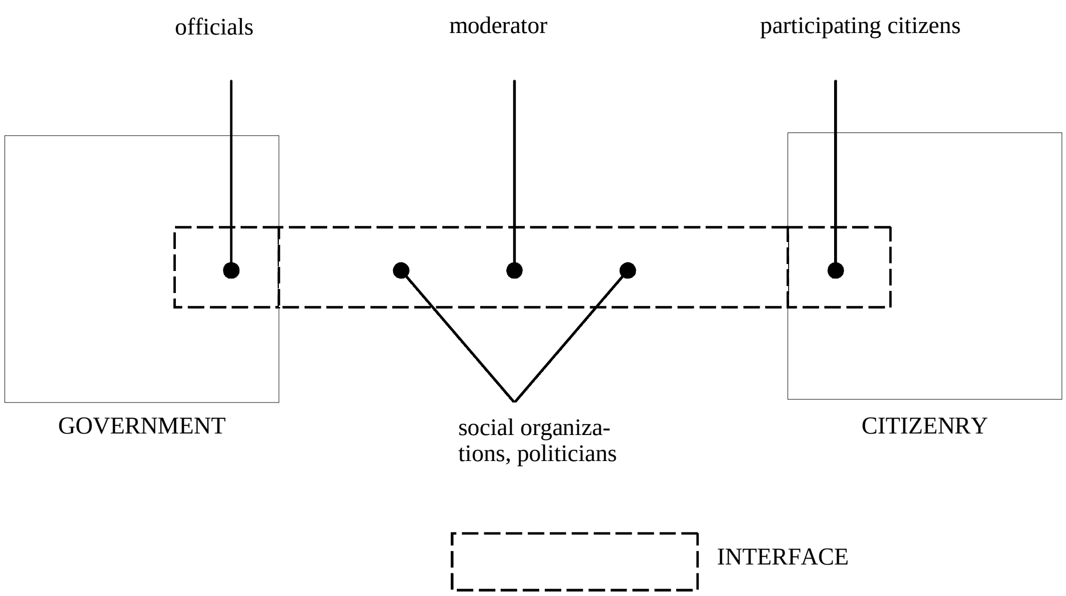
EMPIRICAL FINDINGS ON MODERATION

Case studies indicate that the moderator's primary involvement is in the process function (Edwards, 2002, 2004; Märker et al., 2002; Lührs et al., 2003). First of all, the moderators put a lot of effort into enhancing the interactivity of the discussion, for instance by stirring politicians and other institutional actors to react to contributions of citizens. Moderators are also involved in the formulation of the discussion themes (the agenda*)*. In most cases this takes place in cooperation with the staff of the initiating agency. Furthermore, to keep the discussion on track as a purposeful activity, moderators manage discussion lines and make summaries. Finally, moderators set and maintain some rules of the game, although their actual interventions as a filter are relatively seldom needed. As far as the conditioning function is concerned, moderators are often involved in the information provision. They may do this by inviting others, notably public agencies, interest groups, and political parties, to provide their views on the subject. With regard to the strategic function, moderators are involved in carrying over the results of the discussion to the policy makers. It seems plausible that other strategic tasks, such as establishing the strategic goals of the discussion, its status, as well as obtaining organizational and political support are accomplished by the initiators themselves. We conclude that moderators fulfill important intermediary roles between citizens and public administration.

The significance of this can be clarified further, when we relate our findings to the features of a *deliberative procedure*. In a deliberative democracy, citizens share a commitment to the resolution of problems of collective choice through free public deliberation, and regard their basic institutions as legitimate in so far as these institutions establish a framework for this (Cohen, 1989). We may take an approach to online discussions as providing forums for free public deliberation (Schalken, 1998; Tsagarousianou, 1998). From Benhabib (1994), three principles can be derived that constitute a deliberative procedure. The first principle states that the participation in deliberation is governed by the norms of equality and symmetry. This principle reflects Habermas's "ideal speech situation." It stipulates that all citizens should have equal opportunities to start or to enter a public discussion, as well as to advance stands or proposals and to oppose the stands or proposals of others. Furthermore, the participants are required to defend their proposals by arguments and to refrain from using power (Habermas, 1975). Benhabib's second principle states that all participants have the right to question the assigned topics of the discussion. The third principle is that all have the right to initiate reflexive arguments about the very rules of the discourse procedure and the way in which they are applied or carried out.

With regard to the first principle, the efforts of moderators to enhance the interactivity of the discussion and to create a forum on which politicians and other institutional actors probe the views of citizens and expose their

Figure 2. Actors involved in government-initiated online discussions (Edwards, 2004)



own points of view to critical discussion, can be seen as contributing to an ideal speech situation. Moderators see to it that participants refrain from using power during the discussion, so that only the "force of arguments" can settle the dispute. In addition, moderators can do a lot to ensure that participants defend their proposals by arguments. In particular, a moderator is legitimated to intervene if a participant does not react when a point of view that he advanced earlier in the discussion is attacked by another participant. Benhabib's second principle, the right of participants to question the assigned topics of conversation, implies that the agenda of the discussion (the specific questions or propositions) should be open to amendments, both at the start and during the discussion. Benhabib's last principle suggests that the moderation policy should be transparant and negotiable. Some discussion rules have to be formulated at the start of the discussion. Together with the agenda, they can be consolidated in a commonly agreed charter of the discussion group.

The empirical findings suggest that moderators can do a lot to enhance the interactivity and openness of the discussions as well as their relevance for public policy making. However, the performance of the moderator is dependent on several *institutional and organizational factors*. Moderators do not function in isolation—they have to cooperate with other actors. Figure 2 depicts the interface of actors that are involved in the discussions.

A government that initiates an online discussion with citizens, can recruit a moderator from its own staff, appoint an independent ("third party") moderator, or recruit a moderator from the citizenry. An independent moderator has an autonomous stand towards the various parties in the discussion. While acting as an intermediary, a moderator serves both as an agent of the initiating government, and as an agent of the participating citizens. Here lies a field of tension in which an independent moderator is in a better position to strike a balance. Nevertheless, an independent moderator might also be a source of bias in its own right. For instance, when the moderator is involved in information provision or in making summaries of the results of the discussion, he or she is always vulnerable to allegations of being partisan.

Moderation by civil servants is an acceptable option, if the moderation is transparant and negotiable and citizens have no reason to question the impartiality of the moderation. In many cases, it is an interesting option to involve citizens in the moderation. There are a few cases documented of online discussions, in which citizen-moderation took place. In an online discussion in 2001 in the German city of Bremen, the moderation was performed by a team consisting of four citizens, a civil servant and an expert. It came out that citizen moderators can take over an important feedback function, and can contribute to the success of the discussion by their knowledge of the local situation and relevant people (Westholm, 2003).[2] Citizen moderation and moderation by government staff are less appropriate, however, in cases where the issue is controversial.

In most cases the moderator's position is embedded in *organizational arrangements* in which the initiating government and sometimes also social organizations are represented. In the "project groups," "'supervisory teams," or "editorial groups," the moderator, public officials and representatives of other organizations work together in organizing and managing the discussion. These organizational arrangements are of strategic importance, because they embed the discussion in the organizational and political environments. On the one hand, they impose some limits on the autonomy of the moderator, but on the other hand they may enhance the relevance of the discussion, as to its impact on the regular policy process.

The position of *social organizations* deserves some special attention. The social organizations can figure in five roles: (a) as initiators of a discussion, (b) as partners of the initiating government to give legitimacy to the discussion and to participate in the formulation of its agenda, (c) as information providers, (d) as agencies for soliciting participants, and (e) as participants in the discussion. The involvement of social organizations in online discussions, their interaction with individual citizens, civil servants, and politicians, is an important subject for further research.

The participation of *politicians* is important, as they are the final decision makers in a representative democracy. Their commitment will be beneficial to the discussion's impact on political decision making. Politicians often show a reluctance to involve themselves in "interactive policy exercises" with citizens, whether face-to-face or online (Coleman & Gøtze, 2001). Moderators should encourage their participation, although a too dominant presence of politicians may thwart a free expression of citizens' points of views. Herein lies another example of the "sense of balance" that moderators have to show.

A possibility for strengthening the position of the *participating citizens*, and thereby enhancing the openness of the discussion, is to present the agenda and the moderation policy at the start of the discussion as proposals that are open to amendments. The outline of the discussion would then be consolidated in a commonly agreed upon charter. Also, procedural rules could be established for amendments or additions to the agenda during the discussion. Other provisions can be made to further the openness and negotiability of the moderation.[3] Furthermore, citizens can be invited to make suggestions as to relevant information or to forward information to be placed on the discussion site. Finally, the conclusions of the discussion could be consolidated in a collaboratively drafted summary.[4]

FUTURE TRENDS

A recent trend is the development of specific *discourse support systems*, i.e., systems of information and communication technologies for supporting a discussion. They provide a Web-based platform as well as a methodology and appropriate tools for enabling a fruitful dialogue. Generally, they also provide a set of features for moderating the discussion (Gordon & Richter, 2002; see also Coleman & Gøtze, 2001).5 Moderator tasks will be more and more embedded in such systems of both social and technical components. More and more, the technical components will enable cooperative work and design by the participants.

CONCLUSION

Moderators are emerging new intermediaries in forms of deliberative democracy that are supported by modern information and communication technologies (ICTs). In this article we focused on online discussions as one category of these new forms. Another category includes ICT-facilitated face-to-face discussions.6 Insofar as these forms will enter into the practice of democratic governance, moderators will establish themselves as elements of the information and communication infrastructure between the citizenry and public administration. Moderators enhance the quality of online discussions and their relevance for political decision-making.

Moderator tasks will be more and more embedded in systems of both social and technical components. In the organizational arrangements, procedures, and discussion rules, as well as in the design of the technological components, due attention has to be given to the openness of the discussion, and to the transparency and negotiableness of the moderation.

KEY TERMS

Deliberative democracy: a form of democracy in which citizens share a commitment to the resolution of problems of collective choice through free public deliberation, and in which the basic democratic institutions provide a framework for this.

Deliberative procedure: a discussion that is governed by the norms of equality and symmetry in participation and the right of the participants to question the agenda and the discussion rules, as well as the way in which the agenda and rules are applied.

Discourse support system: a system of information and communication technologies, providing a Web-based platform, a methodology, and appropriate tools for fruitful discussions.

Moderator: a person or group of persons who facilitates a discussion in view of its goals and agenda.

The conditioning function of the management of online discussions: take care of all kinds of conditions and provisions to further the discussion.

The process function of the management of online discussions: all tasks that have to do with the discussion process as a cooperative, purposeful activity.

The strategic function of the management of online discussions: establish the boundaries of the discussion and embed it in the political and organizational environment.

Monitoring Strategies for Internet Technologies

Andrew Urbaczewski
University of Michigan, Dearborn, USA

INTRODUCTION

Most large organizations that provide Internet access to employees also employ some means to monitor and/or control that usage (Reuters, 2002). This article provides a classification and description of various control mechanisms that an organization can use to curb or control personal Internet usage. Some of these solutions are technical, while others rely instead on interpersonal skills to curb cyberslacking.

After a review of goals for a monitoring program, a list of different activities to monitor and/or control will also be provided. Then a discussion of different techniques for monitoring and associated products will be explored, followed by a discussion of fit between corporate culture and monitoring.

BACKGROUND

The Worker's Perspective

In this age of cell phones, pagers, wireless PDAs, email, and home network links, many employees feel like the employer owns them not just during the workday, but perhaps constantly. Though tiresome, the worker may accept this as an unfortunate circumstance of 21st century knowledge work. However, in the tit-for-tat that this availability demands, the employee may feel that (s)he should be allowed to use the Internet at work to take care of quick business tasks, such as paying bills, sending an email, or checking that evening's movie listings. So long as it isn't excessive, the employee may wonder why the employer even cares. Employers can and do care for many reasons, some more profound than others.

Goals for Monitoring

Why do companies monitor their employees? Organizations monitor for many reasons, including simply "because they can." An electronic monitoring effort is often difficult to establish and maintain, so before an organization begins such an effort, there should be clear monitoring goals.

The popular press is filled with stories of employees frittering away time on the Internet (Swanson, 2002). In the beginning, employees were likely to spend unauthorized time on the Internet at pornography and gambling sites, but now news and online shopping are more likely outlets for cyberslacking (Reuters, 2002). This is quite the opposite of employers' expectations when they implemented Internet connections.

Responding to these challenges, employers created acceptable use policies (AUPs). Some organizations already had AUPs implemented to keep out electronic games, and they simply modified those policies. Other organizations created new AUPs, which directly addressed the Internet's productivity threat. AUPs are useless without enforcement, but in today's litigious society, it behooves accusers to be certain of transgressions before enforcing the policy. Monitoring tools create an irrefutable log of usage which can stand as legal evidence. Some employers hope the mere threat of punishment will keep employees from cyberslacking, often with some success (Urbaczewski & Jessup, 2002). Below are listed some possible goals of a monitoring effort.

Increase Employee Productivity

The Internet was introduced into many organizations as a tool to increase employees' efficiency. While traditional IT packages provided few opportunities for employees seeking to slouch on employer time, the Internet posed an entirely different situation. Computers now had the capability to be an electronic equivalent of a water cooler, break room, or smokers' perch. To curb the potential problem of employees wasting time while appearing to be busy, an organization could implement a monitoring program which completely blocks and/or records the amount of time spent at non-work-related Internet sites. An alternative could be limiting access to frivilous sites to non-production hours only, such as during lunchtime.

Bandwidth Preservation

In some organizations, concerns are not productivity-based but rather that network bandwidth is being dominated by applications and instances not directly work-related. An example might be listening to streaming audio or watching streaming video, both constant drains on bandwidth. People can also engage in excessive file transfers across networks which results in reduced network performance. Two possible solutions to this problem are to purchase more bandwidth or limit the usage of existing bandwidth, with monitoring programs aiding in the latter solution.

Legal Liability Reduction

Along with productivity and bandwidth usage, organizations are also concerned about Internet usage from the potential exposure it brings to legal liability. Consider the following fictitious scenarios:

"Organization X today was sued for negligence, as an employee was running a child pornography server inside the corporate network."

"ABC Corporation today was sued by a former employee who is now in treatment with Gambler's Anonymous. He is charging that ABC, by placing an unrestricted Internet terminal on his desktop, essentially gave him unfettered access to the virtual casinos thriving on the Internet."

"Company B is defending itself today against a privacy lawsuit. It is charged that when an employee downloaded a file-sharing program, that program was equipped with a backdoor which allowed malicious hackers entrance into Company B's networks. These hackers then took thousands of credit card numbers and personal data from the databases..."

Other possibilities like sexual harassment suits and industrial espionage make the legal risks mount. Organizations indeed may wish to monitor Internet connections to prevent any potential legal liabilities from allowing illegal activities to be conducted on their networks.

MAIN THRUST

Different Monitoring Strategies

Once an organization decides it will monitor, it needs to know what to monitor. While Web porn is probably the most reported off-topic use of the Internet in an organization, it is certainly not the only transgression that might come from an Ethernet card. Excessive personal e-mail, filesharing, instant messaging, multimedia streaming, and Usenet browsing and posting are among other ways that employees use the corporate Internet connection for personal enjoyment.

There are several different control mechanisms that an organization might use, generally grouped into one of two categories: managerial and technical. The managerial techniques for monitoring are similar to ways that monitoring of employees has been done for decades: walking around and keeping one's eyes open. When a manager starts to wonder about an employee's performance or collegiality, then the manager starts to pay more attention to that employee's work habits.

Overall, however, the most popular means of monitoring employees is through technology. In many ways, this makes sense – a technical solution to a technological problem. Electronic monitoring operates like "big brother" (Zuboff, 1988), keeping a constant watchful eye on the network and its connected systems (or whatever subset of those systems/hours that a manager may choose to watch). Records can then be kept and offered as later "proof" of an offender's cyberslacking or lack thereof.

Electronic Monitoring Techniques

Logging at the Gateway

Many logging technologies are designed to capture and record packets as they enter and leave the organization, or at least the header information that indicates the sender, recipient, and content of the message. Gateway logging is useful in that it provides a central point of network control. However, it is difficult to accurately gauge how long an employee stares at a particular page, and if all that time (s)he is actually staring at that page or if (s)he has actually gone to lunch and returned later. Moreover, gateway logging can be defeated by the use of encryption tools like PGP (www.pgp.com, see McCullagh, 2001, for a more detailed description of an FBI case with the Philadelphia organized crime ring), or even tools like Anonymizer.com that allows a person to surf the Web anonymously using their gateways and encryption tools. In cases where these technologies are used, a separate technology might also be needed.

Spying at the Client

When gateway logging is insufficient, one can monitor and record connections directly at the source. A keystroke logging program can record everything that a person types on a computer, and many even include technologies to take screenshots or use the Web camera on the desk to prove that it was the person actually sitting at the computer and not someone who just walked up to the terminal.

Client sniffing programs are excellent at recording exactly what the user is doing with the computer at any given time. Many will record all of the user's keystrokes, mouse movements, and active windows, allowing the reconstruction of the entire computing session. Moreover, they can capture other undesirable activity, such as playing games and typing job application letters. However, these programs are not without their own faults. First of all, the manager must install the program on the user's computer, which may not be as easy as it sounds, especially with laptop and other mobile computers. Second, the program must not be detectable (and thus deletable) by the monitored employees. Managers then must sift through mountains of captured data to determine if there is any untoward activity, or enough to warrant further investigation. However, products are available which meet the previously described concerns to varying degrees, and the next section will discuss some of those products.

Software Products for Controlling Internet Usage

As mentioned previously, there are various products available to serve as control mechanisms. They are grouped in the following into five categories. Note that software products come and go, and the availability of certain products and companies are subject to market forces. The categories themselves should remain stable for the time being, although who knows what the future may hold. For example, if this chapter was being written in 1999, there would likely be no section on file-sharing.

Web Monitoring Products

As the popular press articles have largely focused on employee cyberslacking as a problem with personal Web usage, a number of products have been created to help employers manage these problems. The software products are all customizable to some degree, but there are two main classifications of these products: those that *monitor* and record Web usage, and those that actively *block* access to certain Web sites deemed inappropriate. The listing to follow, which is not intended to be exhaustive, details several of these products.

Cybersitter (www.cybersitter.com) and *NetNanny* (www.netnanny.com) are two programs that are geared largely at individuals, as they are installed on the client and maintain logs of Web pages seen by the users. *Websense* (www.websense.com) however, is designed to monitor the Web usage of an entire network. It runs near the firewall and logs all Web requests leaving the network. All of these programs can be configured to block and/or record access to certain Websites. Some of these programs can be tailored to allow different access rules at different times of day. For example, an organization may wish to allow its employees to use the Internet for shopping and other personal entertainment before and after normal business hours and on the lunch hour but not during the work day.

E-Mail Monitoring Products

E-mail can easily be monitored by simply examining accounts for incoming mail or logging the actions of the simple mail transport protocol (SMTP) server for outgoing mail. These logs are often difficult to read, especially with large volumes of mail and users. A series of products can assist in parsing the logs or searching for users or keywords, like *MIMESweeper* (www.mimesweeper.com) and *Message Inspector* (http://www.zixcorp.com/compro/messageinspector.php). Encrypted e-mail can present its own challenges, and additional policies may be necessary regarding the use of strong encryption in an organization.

Monitoring e-mail sent through popular Web-based providers like Yahoo! or Hotmail can be difficult as well, because the message never passes through the SMTP servers for the organization, nor does the organization have direct control over users' mailboxes. Monitoring these types of mail services is usually done through a general monitoring tool, as listed in another section next.

File-Sharing Monitoring Products

File-sharing has a history of waxing and waning between one of the easiest applications to monitor to one of the toughest. Users of file-sharing services often try to devise ways to run their services around and through corporate attempts to halt them. Other problems were created by users demanding that they be allowed to use these programs, especially at high-profile universities like Yale and Indiana. In those cases, something had to be done to limit the amount of bandwidth these services could use, because other legitimate traffic was being delayed. A number of hardware and software solutions cropped up to aid network managers in their quest to reduce or eliminate file-sharing traffic.

On the software side, it was mentioned above that already existing firewalls can be configured to block traffic on certain TCP (OSI layer 4) ports. Other programs, like *DynaComm I:scan* (http://www.dciseries.com/products/iscan/), are designed to examine the packets at the application layer (OSI layer 7) to determine the type of packet and whether or not to block it. Hardware solutions like *Packeteer* (www.packeteer.com) plug into the network to control the amount of bandwidth available to certain applications. Packeteer has been most popular at colleges and universities, which in general do not want to be accused of censorship or limiting access to resources, but still have to deal with bandwidth concerns amongst thousands of users.

Instant Messaging (IM) Monitoring Products

IM's "fire-and forget" nature made it one of the toughest applications to monitor for a long time. The problem was exacerbated because the employers generally did not control the IM servers or the clients. In 2002, applications were created which successfully monitor IM applications and content, implemented largely to comply with certain US Securities and Exchange Commission (SEC) requirements on keeping logs of all transactions between brokerage houses and their customers. IM is usually not monitored to conserve bandwidth, but it can become a productivity drain similar to e-mail.

Facetime (www.facetime.com) is probably the leader in monitoring organizational IM. The Facetime product can record all IM activity, important in SEC-regulated businesses and government agencies with freedom of information requirements. *Vericept* (www.vericept.com) also has all-purpose monitoring capabilities, but focuses largely on monitoring, blocking and recording IM activity. Organizations looking to block and monitor IM and communicate securely using encryption might turn to *Compliancer Hub* (www.communicatorinc.com).

General Monitoring (Spying at the Client) Tools

There are a series of more powerful, less-specific tools available for almost total user monitoring, classified as general monitoring tools. These tools are installed at the client and can create a record of almost everything a user does with the computer. Records can be written to a network database or even e-mailed to another account.

TrueActive (www.winwhatwhere.com) is probably the original instantiation of this type of program, marketed largely to businesses for specific monitoring purposes. There are also many programs targeted at individuals, including *Spy Agent* (http://www.spytech-web.com/spyagent.shtml) and *eBlaster* (http://www.spectorsoft.com/products/eBlaster_Windows/index.html). Managers are often surprised at the sheer amount of data these programs provide, quite often more than a manager really wants to know. One should carefully consider the implications before implementing a general monitoring tool. Employees may react strongly to such total monitoring.

FUTURE TRENDS

Seeking the Recommended Fit between Goals and Monitoring Solutions

If productivity is a major concern, one might begin with a passive but comprehensive logging tool. Cyberslacking can be easily seen and measured, but it is done unobtrusively. When an employee's productivity falls, as observed traditionally, the technical data showing cyberslacking are available. This can be used for implementing positive disciplinary measures, or for supporting a termination. Periodically and when a situation occurs, employees should be reminded of the organization's policy about personal Internet usage and resulting enforcement actions. This is not to embarrass potential offending parties, but rather to keep the policy salient.

If legal liability is the major concern, minimally intrusive means can also be used for the monitoring and recording of transmitted data. In December 2002, five major Wall Street brokerage houses were fined $1.65 million for not keeping e-mails the required two years. An organization can avoid these types of penalties by simply logging and maintaining records of Internet traffic without any review, except on an as required basis. The RIAA and other entertainment industry groups in early 2003 began warning organizations to actively ensure that their employees were not using company networks to access copyrighted music and video files, lest the companies themselves be held liable. The RIAA has been supplying offenders' IP addresses and access times to companies and universities, identifying individuals who may have traded in music and video files. In the end, a company pursuing this strategy would be more concerned with record-keeping than record-reviewing.

An organization pursuing the third goal, bandwidth preservation, can likely use the least passive of all monitoring tools – simply observing bandwidth usage spikes where they occur, and witnessing their relationship to organizational goals. A firm that sees bandwidth constantly full with apparently work-related material may want to investigate adding additional bandwidth resources. At the same time, organizations that suddenly block or "throttle" access to popular Internet destinations known for non-work-related information will likely solve many problems. Employees are more likely to realize that they need to get to work or identify another means of entertainment than they are to complain and cause a ruckus over no longer being able to access these sites at all or at high speeds.

CONCLUSION

This article has detailed several types of control mechnisms. It has listed goals for monitoring, applications to monitor, and means of accomplishing the monitoring. Furthermore, it lists names of actual tools that can be used to accomplish the monitoring. What this article so far has not discussed is the viability and consequences of the monitoring.

In a series of studies, it was found (not surprisingly) that Internet monitoring indeed has a significant positive effect on keeping employees on task (Urbaczewski & Jessup, 2002). However, it was also found that monitored employees were more likely to turnover and less likely to participate in other organizational activities. Could this happen in all organizations? Possibly, but the key to remember when establishing monitoring is:

"Make the monitoring strategy fit the corporate culture"

Some organizations have a culture where monitoring of most (if not all) activities is simply expected. These industries generally include those handling cash or financially-related transactions (e.g., banks, casinos) or deal with physical and/or national security (CIA, FBI, R&D labs, etc.). In these cases, monitoring fits the culture, and if the organization is already monitoring employees in other ways, it also makes sense to monitor computer systems.

Other organizations have cultures which generally detest monitoring. Some industries, like publishing, academia, and other "civil liberties" organizations do not generally monitor their employees, as their foundations are centered on freedom of speech and the unfettered search for the truth. The introduction of monitoring in these industries will likely result in a culture clash between employees and management (Simmers, 2002).

The question then becomes "how does one then reap the benefits of monitoring without angering employees and creating unwanted stress in the organization?" Communication of the control mechanisms to the employees, with a clear understanding of how it supports corporate goals and principles, is key. Explicit statements of who will be monitored, what will be monitored, and when monitoring will occur should also be communicated to the employees, largely through AUPs.

KEY TERMS*

Acceptable Use Policy (AUP): A policy created in an organization to outline the permitted and restricted uses of the company's networks and computer systems.

Bandwidth: Colloquially, the amount of network capacity available for a connection.

Blocking: A means of disallowing access to Internet content and services by restricting access at the corporate gateway.

Cyberslacking: The process of using the Internet to waste time during a workday, similar to how an employee might spend time in a colleague's office or on the telephone.

Logging: Creating a record of all employee Internet usage.

OSI Layer 4: The Transport Layer of a network connection, which provides service differentiation and connection management. From the Open Systems Interconnect model.

OSI Layer 7: The Application Layer of a network connection. It describes how applications work with the network operating system. From the Open Systems Interconnect model.

*Definitions specific to their use in this chapter.

Motivation for Using Microcomputers

Donaldo de Souza Dias
Federal University of Rio de Janeiro, Brazil

INTRODUCTION

Information technology implementation is an intervention we make in order to improve the effectiveness and efficiency of a sociotechnical system. Using microcomputers to help individuals perform their jobs and tasks is one of the most important actions we take when implementing this technology effectively. Information systems effectiveness has been extensively studied using, mainly, user satisfaction and quality of information constructs to evaluate users' acceptability (Iivari & Ervasti, 1994; Ives et al., 1983; Neumann & Segev, 1979). However, sometimes, the result of this intervention is not successful and may even generate difficulties related to people participation in the process. This leaves us with a question: What motivates individuals to use microcomputer technology in their daily activities?

Theorists and empirical researchers have been trying to understand the relevant motivators for the implementation and use of computer technology based on the idea that people make an effort if an activity is enjoyable or offers external rewards (Igbaria et al., 1996; Schwartz, 1983). They have been aiming to find out how individuals feel motivated to work with computers, and what motivates them to use computers in their daily activities.

BACKGROUND

Computer and information technology usage is determined by intrinsic as well as extrinsic motivation (Deci, 1975; Igbaria et al., 1996). The main driving forces considered in the literature as motivators for computer and information technology adoption are perceived usefulness, perceived ease of use, and perceived enjoyment (Davis, 1986, 1989; Igbaria et al., 1996). However, it is known that some individuals create personal obstructions to using technology (Pirsig, 1981), particularly, microcomputer technology (Igbaria & Parasuraman, 1989; Martocchio, 1994). They resist microcomputers usage and experience anxiety when they have to deal with them. We present results found in previous studies for relations and comparisons among the motivational forces above (Dias, 1998a, 1998b, 2002; Dias et al., 2002). The results presented here, all statistically significant at $p < 0.05$, were based on constructs measured using the instrument developed in Dias (1998a) and presented in the Appendix.

MAIN MOTIVATIONAL FORCES

Figure 1 shows the results for the relationships among perceived enjoyment, perceived ease of use, and perceived usefulness found in Dias (1998a). The author focused on the motivators perceived usefulness, perceived ease of use, and perceived enjoyment. The aim was to find out how Brazilian operations managers felt about using computer technology in their workplaces, how the perceived usefulness of computers is affected by ease of use and users' enjoyment in working with them, and how to find opportunities to act according to this acquired knowledge, in order to increase the quality of microcomputer technology usage in organizations. In his study, the author emphasized the relationships among these perceived motivators for using microcomputer technology. The impact of the motivators on systems usage or microcomputer adoption was considered to be beyond the scope of his research.

The path analysis model used was based on the natural precedence of intrinsic motivational factors over extrinsic motivational factors, as proposed by the Freudian theory of psychoanalysis (Freud, 1976).

The data for that study were gathered using a questionnaire administered personally to 79 Executive MBA students at a Brazilian university. Respondents held managerial positions in 55 companies, ranging from small firms to large corporations, located in Rio de Janeiro. The average age of respondents was 36, and they had an average of 11 years working experience. All of the participants were college graduates. Managers said they used microcomputer technology mainly because they perceived it as a useful tool to increase the quality of their work, to accomplish tasks more quickly, and to increase the productivity of their jobs.

Figure 2 shows results of a model in which computer anxiety and enjoyment were considered as antecedent variables to ease of use and usefulness (Dias, 1998b). We found that managers who were more anxious about computer technology tended to find it more difficult to use. On the other hand, enjoyment had a positive direct effect on ease of use and usefulness, as stated before.

M

Figure 1. Relationships among enjoyment, ease of use, and usefulness.

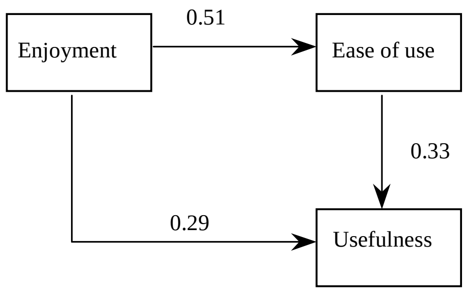

Figure 2. Anxiety and enjoyment as antecedent variables.

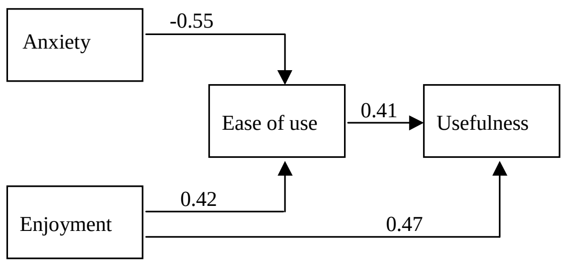

Figure 3. Motivation level for graduate, undergraduate, and elementary school students.

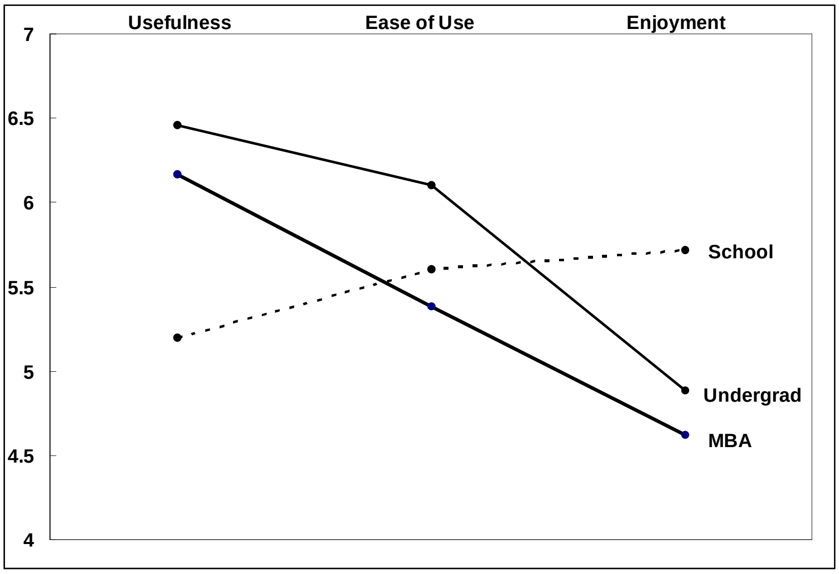

In a study made at a private university located in Rio de Janeiro, with data gathered from 336 undergraduate computer information systems students, Dias et al. (2002) tested the influence of some antecedent variables on enjoyment, ease of use, and usefulness. They found that (a) the fact that a student worked part-time in an area related to information technology positively influenced his or her perception of how easy it was to use microcomputers; (b) enjoyment with microcomputers seemed to decrease as students attained seniority in the university; and (c) older students perceived greater usefulness for microcomputers.

Level of education and age have shown influence on microcomputer attitudes (Igbaria & Parasuraman, 1989). Dias (2002) did a study on the motivation for using microcomputers among different classes of users. He aimed at finding out how graduate, undergraduate, and elementary school students, which represent very specific strata of educational level and age, would differ on the motivational factors examined here. The data for his study were gathered as follows:

- Fifty-three Executive MBA students of a leading Brazilian public university: The average age of respondents was 36, and they had an average of 11 years working experience, all participants were managers and had a college degree.
- Forty-six students aiming for degrees in Business Administration at a private university located in Rio de Janeiro: The average age of respondents was 22.
- Thirty-nine elementary schools students enrolled in the fourth to eighth grades of private (82%) and public schools located in the city of Rio de Janeiro: The students used microcomputers regularly at school, at home, or at relatives' homes.

Factor analysis confirmed that the statements for usefulness, ease of use, and enjoyment constituted three

Table 1. Actions for successful implementation of microcomputers.

Action	Motivational Forces
Develop friendly systems	Ease of use/enjoyment
Encourage user participation in systems development	Usefulness/ease of use
Implement intensive user training	Ease of use
Sell the system to users	Usefulness
Facilitate access to microcomputers	Ease of use
Respond to user needs	Usefulness
Use up-to-date technology	Usefulness/enjoyment
Align business and information technology	Usefulness

distinct perception constructs for the three classes of users. It confirmed the existence of three factors that accounted for 63.5% of the total variance in the 138 interviewees.

Figure 3 shows the motivational profile for graduate, undergraduate, and elementary school students on the usage of microcomputers.

Dias (2002) found that there was a statistically significant difference in the perceived enjoyment, perceived ease of use, and perceived usefulness of using microcomputers among MBA, undergraduate, and elementary school students. MBA and undergraduate students were most motivated by microcomputer technology usefulness. Elementary schools students mostly enjoyed the play aspect of microcomputers.

We did a study with managers in order to better understand these motivational forces and to generate recommendations for increasing the motivation for using microcomputers. Thirty-six managers were split into six working groups and asked to (1) discuss their experience in using microcomputers in their organizations (taking into account personal resistances for using computers in the workplace), situations in which this technology is used compulsively, motivators they thought were important for using computers for task execution, and organizational culture; and (2) propose actions they thought should be taken in the implementation of microcomputers in their workplaces that would lead to a more effective usage of this technology.

The main actions suggested and the corresponding motivational forces are presented in Table 1. We found that in order to attract adult users, information systems should be friendlier, use up-to-date interfaces, and be developed with user participation. In addition, it is important to offer intensive user training, to market the new systems to users heavily, and to fully meet the users' needs in the specification of the systems.

Although managers showed less unanimity on the motivating power of enjoying themselves while using microcomputers, this motivation factor clearly showed its significance. Enjoyment seems to serve more as self-motivation, while usefulness seems to be linked to a feeling of duty—something that the organization expects managers to do or to attain.

FUTURE TRENDS

According to the World Summit on the Information Society (WSIS, 2003):

The global Information Society is evolving at breakneck speed. The accelerating convergence between telecommunications, broadcasting multimedia and information and communication technologies is driving new products and services, as well as ways of conducting business and commerce. At the same time, commercial, social and professional opportunities are exploding as new markets open to competition and foreign investment and participation.

The modern world is undergoing a fundamental transformation as the Industrial Society that marked the 20th century rapidly gives way to the Information Society of the 21st century. This dynamic process promises a fundamental change in all aspects of our lives, including knowledge dissemination, social interaction, economic and business practices, political engagement, media, education, health, leisure and *entertainment. We are indeed in the midst of a revolution, perhaps the greatest that humanity has ever experienced.*

Several new concepts lay the foundation for prospering in the next form of information and communication technology. The future microcomputer usage will be based upon ubiquity, universality, uniqueness, and unison (Watson et al., 2002). The keys to managing network-driven firms will be based on this notion of ubiquitous networks. In addition, we have to consider the new generation of students entering business schools around the world. These students are quite different from the students of the last decades, and we have to consider the technological, social, and cultural changes that are developing. The implications for the next-generation organization and information systems based on the Internet and mobile microcomputer technology have to be considered, and the motivational forces discussed here will probably have to be readdressed.

CONCLUSION

The research described here on motivation for using microcomputers offers several contributions for theory and practice. It confirmed that there are three positively interrelated motivators for computer technology usage: perceived usefulness, perceived ease of use, and perceived enjoyment. It also found that perceiving microcomputers as easy to use is negatively related to people's anxiety toward using them.

The research also compared the perceived reasons for using microcomputers among different classes of users and showed that there are significant differences in the motivation for using them among graduate, undergraduate, and elementary school students. Elementary school students have greater enjoyment in using microcomputers than MBA and undergraduate students in Business Administration. MBA and undergraduate students in Business Administration perceive greater usefulness in the usage of microcomputers than elementary school students, and they said that they used microcomputers mainly because this increased the quality of their work and allowed them to accomplish tasks more easily and quickly. Undergraduate students in Business Administration think it is easier to use microcomputers than do MBA and elementary school students. MBA students think it is most difficult to use microcomputers in their daily tasks.

We should emphasize that the motivational forces studied here could not apply equally to different countries, cultures, or organizational environments. A study made by Straub et al. (1997) compared the technology acceptance model (TAM) (Davis, 1986) across three different countries: Japan, Switzerland, and the United States. The study was conducted by administering the same instrument to employees of three different airlines, all of whom had access to the same computer technology innovation—e-mail. They used perceived ease of use and perceived usefulness as independent variables. The results indicated that the model holds both for the United States and Switzerland, but not for Japan, suggesting that the model may not predict motivation for technology use across all cultures. Harris and Davidson (1999) examined microcomputer anxiety and involvement of groups of microcomputer-using students in six developing countries: China, Hong Kong, Malaysia, New Zealand, Tanzania, and Thailand. Differences in computer anxiety were found to exist between some of the groups, which were probably attributable to demographic factors. Differences

Appendix 1

	Fully disagree Fully agree
1. I do not see time go by when I am using a computer.	1 2 3 4 5 6 7
2. Using computers enables me to accomplish my tasks more quickly.	1 2 3 4 5 6 7
3. I feel motivated to perform activities using computers.	1 2 3 4 5 6 7
4. I find it is easy to use a computer to do my work.	1 2 3 4 5 6 7

KEY TERMS

Computer Anxiety: Degree to which an individual is nervous in his or her interaction with computers; the uneasiness some people feel when they have to use a microcomputer. Anxiety results from a danger or a danger threat. As a feeling, it has a clearly unpleasant character.

Computer Self-efficacy: A judgment of one's capability to use a computer. It incorporates judgments of an individual on his or her skills to perform tasks using a microcomputer.

Extrinsic Motivation: Motivation that derives from what you obtain from engaging in an activity. An example of extrinsic motivation for using microcomputers is using it because you think it is useful for your job.

Intrinsic Motivation: Motivation that derives from the activity itself. An example of intrinsic motivation for using microcomputers is using it because you enjoy it.

Microcomputers Ease of Use: User perception on how simple and easy it is to understand and use microcomputers; degree to which an individual believes that using a particular computer system would be free of physical or mental effort.

Microcomputers Enjoyment: The extent to which the activity of using microcomputers is perceived as being enjoyable in its own right, apart from any performance consequences. It encompasses the feelings of joy, elation, or pleasure associated by an individual to a particular act.

Microcomputers Usefulness: The degree to which an individual believes that using a particular computer system would enhance his or her job performance.

Sociotechnical System: One that focuses on the interaction between the technical and social subsystems that exists in any work situation. As there is always a social system operating along with any technological system, we need to jointly design these two interrelated systems to get the best results from any work system.

Multicast Routing Protocols, Algorithms and its QOS Extensions

INTRODUCTION

The advancement in optical fiber and switching technologies has resulted in a new generation of high-speed networks that can achieve speeds of up to a few gigabits per second. Also, the progress in audio, video and data storage technologies has given rise to new distributed real-time applications. These applications may involve multimedia, which require low end-to-end delay. The applications' requirements, such as the end-to-end delay, delay jitter, and loss rate, are expressed as QoS parameters, which must be guaranteed. In addition, many of these new applications involve multiple users, and hence the importance of multicast communication. Multimedia applications are becoming increasingly important, as networks are now capable of carrying continuous media traffic, such as voice and video, to the end user. When there is a lot of information to transmit to a subset of hosts, then multicast is the best possible way to facilitate it. This article addresses different multicast routing algorithms and protocols. We have also discussed about the QoS multicast routing and conclude this article with mobile multicasting.

BACKGROUND

Multicast consists of concurrently sending the same information to a group of destinations such that exactly one copy of the packet traverses each link in the delivery tree. Interactive multicast applications include video conferencing, computer-supported cooperative work, and virtual whiteboard applications. Other multicast applications such as remote education require a lesser amount of interaction. A third group of multicast applications are noninteractive, for example mailing lists and some real-time control applications.

In a true multicasting, the least-cost path from the source to each network that includes members of the multicast group is determined. This results in a spanning tree of the required configuration. This is not a full spanning tree, but includes at least those networks containing group members. The source transmits a single packet along the spanning tree. The packet is replicated by routers only at branch points of the spanning tree.

When the same data need to be sent to only a subset of the clients on the network, both broadcast and multiple unicast methods waste network bandwidth by sending multiple copies of the data. Broadcast wastes bandwidth by sending the data to the whole network, whether the data are wanted or not. Broadcast also needlessly slows the performance of client machines. Each client must process the broadcast data, whether the client is interested or not. Multicast falls between these two extremes. It is useful for building distributed pseudo-real-time applications such as videoconferencing and audioconferencing. However, its use is not restricted to these kinds of applications. Any application that involves sending copies of data to multiple places can benefit. For instance, one could distribute network routing tables to all routers in an enterprise, while not burdening all of the workstations with processing these messages. If one has to send audio and video, which needs a huge amount of bandwidth compared to Web applications, multicast is the best possible solution. Multicasting has three advantages over broadcasting, particularly when the recipient group size is significantly smaller than all the possible recipients in a network. First, by routing a message only where it needs to go, multicasting conserves network bandwidth, facilitating more efficient use of the network infrastructural resources. It can result in user toll charges that are lower than broadcast delivery. Second, data transmission can be restricted to only the paying subscribers for services such as video on demand. Third, the dissemination of sensitive information can be limited to a select group of recipients.

MULTICAST ROUTING PROTOCOLS

- Distance-Vector Multicast Routing Protocol (DVMRP) designed to deliver multicast datagrams to a group of hosts across the Internet. DVMRP constructs source-based multicast delivery trees using the reverse-path multicasting (RPM) algorithm. In DVMRP a datagram from a multicast source is initially propagated downstream by a designated multicast router to all other multicast routers, regardless of whether they have multicast group members or not. Multicast routers without downstream or local members send explicit prune messages upstream to remove themselves from the distribution tree. The net effect is a source-specific shortest path tree, with the members forming the leaves of the tree. Once the multicast tree is set up, multicast routers keep track of the reverse path to the multicast source. If an arriving datagram does not come through the interface that the router uses to send datagrams to the source of the multicast, then the arriving datagram is dropped.
- Core-Based Trees (CBT): The CBT protocol was first discussed in the research community and then standardized by the IETF (Ballardie, 1997). The CBT uses the basic sparse mode paradigm to create a single shared tree used by all sources. The tree is rooted at a core. All sources send their data to the core, and all receivers send explicit join messages to the core. CBT uses only a shared traffic tree, and is not designed to use shortest path trees. CBT uses bidirectional shared trees, but PIM-SM uses unidirectional shared trees. Bidirectional shared trees involve slightly more complexity, but are more efficient when packets are traveling from a source to the core across branches of the multicast tree. In this case, instead of only sending "up" to the core, packets can also be sent "down" the tree. While CBT has significant technical merits and is on par technically with PIM-SM, few routing vendors provide support for CBT.
- Protocol Independent Multicast – PIM: PIM provides both dense mode (PIM-DM) (Deering, 1998) and sparse mode (PIM-SM) (Estrin, 1998) group membership. As the name implies, the multicast architecture is independent of the protocol employed for unicast routing. PIM can scale to wide-area networks, and is particularly attractive for sparse multicast group. Essentially PIM can use either the shared tree approach of CBT or the shortest-path approach of DVMRP, with appropriate choice made on a per group or per host basis. The PIM architecture relies upon choosing a suitable rendezvous point (RP), similar to a core in CBT, when constructing the multicast delivery tree for a group. The RP provides a place for multicast sources to "meet" multicast recipients.
- Border Gateway Multicast Protocol (BGMP) (Thaler, Estrin & Meyer, 1998**):** is a new inter-domain multicast routing protocol that addresses many of the scaling problems of earlier protocols. BGMP attempts to bring together many of the ideas of previous protocols and adds features that make it more service provider friendly. BGMP is designed to be unified inter-domain multicast protocol in much the same way that Border Gateway Protocol (BGP) is used for unicast routing.

MULTICAST ROUTING ALGORITHMS

Different multicast routing algorithms are summarized in this section, both unconstrained and constrained. A taxonomy of these multicast routing algorithms is given in Table 1.

- Shortest Path Tree: A shortest path algorithm minimizes the sum of the weights on the links along each individual path from the source to a receiver in the multicast group. If unit weight is used per hop, the resulting tree is a least-hop tree. If the weight represents the link delay, the resulting tree is a least-delay tree. The Bellman-Ford and Dijkstra algorithms are the two best-known shortest path algorithms. Both are exact and run in polynomial time.
- Minimum Spanning Tree: A minimum spanning tree is a tree that spans all the group members and minimizes the total weight of the tree. The well-known centralized minimum spanning tree algorithm is Prim's algorithm. In Prim's algorithm the tree construction starts from an arbitrary root node and grows until the tree spans all the nodes in the network. Minimum spanning tree algorithms run in polynomial time and can be used to solve tree optimization problems.
- Steiner Tree: The Steiner tree aims to minimize the total cost of the multicast tree, and is known as NP-complete. If the multicast group includes all nodes in the network, the Steiner tree problem reduces to the minimum spanning tree problem. Unconstrained Steiner tree algorithms can be used to solve tree optimization problems. Tree cost optimization for a whole session duration for unconstrained routing algorithm is proposed in Chakraborty, Chakraborty, Pornavalai and Shiratori (1999). Salama et al. (Salama, Reeves & Viniotis, 1997) gave very good reviews on

Table 1. A taxonomy of multicast routing problems

	No optimization	**Link optimization**	**Tree optimization**
No constraints		Link optimization (polynomial time complexity)	Tree optimization (NP-complete complexity)
Link constraints	Link-constraints (Polynomial complexity) Multiple-link-constrained (Polynomial complexity)	Link-constrained link optimization (Polynomial time complexity)	Link-constrained tree optimization (NP-complete complexity)
Tree constraint	Tree-constrained (Polynomial time complexity) Multiple-tree-constrained (NP-complete complexity)	Tree-constrained link optimization (Polynomial time complexity)	Tree-constrained tree optimization (NP-complete complexity)
Link and tree constraints	Link and tree-constrained (Polynomial time complexity)		Link and tree-constrained tree optimization (NP-complete complexity)

algorithms on the Steiner tree problem. A summary can be found in Wang & Hou (2000).

Other than the these algorithms, it is worth mentioning four of the approaches that have been discussed in the Internet community:

- Addressable Internet Multicast (AIM) by Brian Levine et al. (Levine & Garcia-Lun-Aceves, 1997) attempts to provide explicit addressing of the multicast tree. The routers run an algorithm to label all the branch points uniquely, and then make these labels available to end systems. This allows numerous interesting services or refinement of multicast services to be built.
- Explicitly Requested Single-Source (Express) by Hugh Halbrook et al. (Holbrook & Cheriton, 1999), is aimed at optimizing multicast for a single source. The proposal includes additional features such as authentication and counting of receivers, which could be added to many other multicast protocols usefully. Express makes use of an extended address (channel + group) to provide routing without global agreement on address assignment.
- Connectionless Multicast (CM) (Oooms et al., 2002) is a proposal for small, very sparse groups to be implemented by carrying lists of IP unicast addresses in packets. The scheme may be well suited to IP telephony application where a user starts with a unicast call, but then adds a third or fourth participant.

REAL-TIME MULTICASTING AND QOS

Multicast applications have been consistently increasing on the Internet. Most of these applications such as video conferencing, video-on-demand and Webcasting are multimedia oriented, which usually require large bandwidth, stringent delay and delay jitter, while the multicast protocols running on today's Internet are for best-effort services that have no guarantee for these metrics. There is an urgent need to design and implement multicast protocols with QoS guarantee, and there have been considerable efforts made addressing this issue in recent years.

The basic task of multicast communication is to deliver traffic through a multicast tree. If the objective is to find the minimum cost tree and with QoS constraints added, the problem is usually termed as a Constrained Steiner Minimum Tree (CSMT) problem.

To solve the CSMT problem there are many heuristic solutions available. Although these heuristics give insights into how we can efficiently build multicast trees, they are more theoretical than practical, and may not be suitable for the Internet environment. Hence another group of researchers developed some practical QoS multicast protocols.

HEURISTIC FOR CSMT

The QoS constraints for real-time multicast applications usually include three metrics: delay, delay jitter and delay variation. Most of the heuristic algorithms are for constraints' SMT problem. We summarize them as follows:

- Constrained Shortest Path Tree (CSPT): The basic idea is to find an unconstrained shortest path tree (SPT) first. If the end-to-end delay to any group member violates the delay bound, the path from the source to that group member is replaced by the path with the least delay. A SPT can be constructed by merging the shortest paths from the source to each of the destinations. The worst case complexity of CSPT algorithm is $O(v^2)$, where v is the number of nodes in the network.
- Constrained Minimum Spanning Tree (CMST): Basically, this algorithm constructs the broadcast tree rooted at the source that does not violate the delay constraint using Prim's minimum spanning tree algorithm. This tree may not span all the nodes in the network. However, all the destinations should be in this tree if there exists a QoS satisfying tree. Then this tree is pruned beyond the multicast nodes. The worst-cast complexity is $O(v^2)$, and similarly CMST algorithm can always find a path when there exists one.
- KPP (Kompella, Pasquale & Polyzos, 1993)**:** This algorithm is based on KMB (Kou, Markowsky & Berman, 1981) algorithm. Similar to KMB algorithm, KPP algorithm first constructs a constrained distance network, and then follows the steps in KMB algorithm to find the CSMT. However, the delay constrained shortest path problem is proved to be NP-complete if the link delays and the delay bound are real values. The worst case complexity of KPP is $O(\Delta v^3)$, which is dominated by the calculation of the constrained distance network, where Δ is delay bound.
- Constrained Adaptive Ordering (CAO): This algorithm is based on shortest paths heuristic (SPH), which is another heuristic algorithm for SMT problem. It begins by arbitrarily choosing a group member node, and then adds the member node that is closest to the already built tree at each iteration, until all the group members attach to the tree. The CAO algorithm calculates the constrained shortest path to the tree at each iteration instead of the unconstrained shortest path. The constrained Bellman-Ford algorithm is used in the calculation. The CAO can also always find a QoS satisfying path if there exists one, but there are cases in which the running time of the algorithm grows exponentially.

Practical QoS Multicast Algorithms and Protocols

All these algorithms may not be deployable in practical networks. This is because these algorithms have excessive computation overhead, require knowledge about the global network state, and do not handle dynamic group membership. Hence, some QoS multicast algorithms and protocols with practical use are developed.

For source-based trees, Guerin et al. (Guerin et al., 1998) proposed a QoS extension of OSPF, with the minimum bandwidth requirement as the QoS parameter. Although the extension focuses on unicast flows, it can be extended with moderate modification to multicast flows as well.

Calberg et al. (Carlberg & Crowcroft, 1997) proposed the Yet Another Multicast (YAM) protocol. In this protocol, a new router that intends to join a multicast tree does a *bid-order* broadcast with limited scope using the TTL field. Banerjea et al. (Yan, Faloutsos & Banerjea, 2002) extended YAM and proposed the QoSMIC protocol. In this protocol, both local search with bidding and multicast tree search are used to locate routes. Specifically, a joining router broadcasts *bid-order* messages and at the same time sends a multicast-join message to a manager router. If the manager router has sufficient knowledge of the tree and the network topology, it sends bid-order messages to a set of selected candidates on-tree routers; otherwise, the manager router joins the multicast group and multicasts a bid-order message on the tree. On-tree routers that receive bid-order messages from either the manager router or the requesting router then respond by unicasting bid messages to the joining router. Bid messages collect dynamic QoS information on their way to the requesting router. QMRP (Chen, Nahrstedt & Shavitt, 2000) is new Qos-aware Multicast Routing Protocol. QMRP achieves scalability by significantly reducing the communication overhead of constructing a multicast tree; yet it retains a high chance of success. This is achieved by switching between single-path routing and multiple-path routing according to the current network conditions. MQDMR (Chakraborty, Chakraborty & Shiratori, 2003) is a modified Bellman-Ford algorithm based on Weighted Fair Queuing (WFQ). It utilizes the time duration of the participating nodes to find a path that satisfies multiple QoS constrains, if there exists one.

Having said that, it also should be mentioned that the Internet community is sharply divided into two groups on the issue of the need of QoS-sensitive routing. To some, the need for QoS sensitive routing is self-evident. However, a significant section of the community doubts the importance of QoS-sensitive routing. Some of the objections are technical: a QoS-sensitive network may be unstable; or it may not scale well enough to be applicable to the Internet. But the most fundamental objections are related to the very need for QoS-sensitive routing.

FUTURE TRENDS

A recent development is dynamically reconfigurable wireless ad hoc networks to interconnect mobile users for applications ranging from disaster recovery to distributed collaborative computing. In a mobile environment, the network not only must manage multicast group membership and establish the necessary routes, but also must contend with the fact that the established routes are themselves transient in nature. Regardless of the network environment, multicast communication is a very useful and efficient means of supporting group-oriented applications. This is especially the case in mobile/wireless environments where bandwidth is scarce and hosts have limited power. Another important application of ad hoc network is in critical situations such as disaster recovery or battlefield scenario. The fact that the network must deal not only with the dynamic group membership, but also with the dynamic location characteristics of mobile hosts, makes multicast in a mobile environment a challenging problem.

CONCLUSIONS

The aim of this article is to give an overview of multicasting and its different routing schemes over communication network and possible applications. We introduced the concept of multicasting and how it works. Then we discussed its routing protocols and algorithms. The advantages of multicasting have also been described, which is the main reason for the recent increase in interests in multicasting. It seems that multicast is the answer for the future multimedia data-transfer and various other real-time and nonreal-time applications as well. When multicast trees are considered, it is inclined towards graph-theory problems. To maintain optimal tree-cost in multicasting is an NP-complete problem, known as Steiner Tree problem. With respect to the existing networks infrastructure, there are different interesting solutions and related algorithms. These problems become more complicated when we consider the dynamic situation of the group membership. Most of the existing algorithms discussed are unconstrained routing algorithms. To find an optimal solution considering more than one link metric is an NP-complete problem. We also briefly discussed the mobile and ad hoc multicast, which has recently become an important topic for research.

KEY TERMS

Greedy Algorithm: An algorithm that always takes the best immediate, or local, solution while finding an answer. Greedy algorithms find the overall, or globally, optimal solution for some *optimization problems* but may find less-than-optimal solutions for some instances of other problems.

IGMP: The Internet Group Management Protocol (IGMP) is implemented within the IP module of a host and extends the host's IP implementation to support multicasting.

ODMRP: On-Demand Multicast Routing Protocol for mobile ad hoc networks. ODMRM is a mesh-based, rather than conventional tree-based, multicast scheme and uses a forwarding group concept.

PGM: An extreme example of maintaining state information is the Pragmatic General Multicast (PGM) protocol, formerly known as Pretty Good Multicast, which is implemented by Cisco, where routers maintain state information on a per-packet basis.

RMTP II: Reliable Multicast Transport Protocol II is a transport protocol for IP multicast, designed to reliably and efficiently send data from a few senders to large groups of simultaneous recipients.

RP: PIM-SM constructs a multicast distribution tree around a router called a rendezvous point (RP). This rendezvous point plays the same role as the core in the CBT protocol; receivers "meet" new sources at this rendezvous point.

RPF: In multicast, the router forwards the packet *away* from the source to make progress along the distribution tree and prevent routing loops. The router's multicast forwarding state runs more logically by organizing tables based on the reverse path, from the receiver back to the root of the distribution tree. This process is known as *reverse-path forwarding (RPF)*.

Multilingual Electronic Commerce in a Global Economy

INTRODUCTION

One of the major challenges facing organizations involved in electronic commerce (e-commerce) today is to organize and summarize information in such a way that end users can effectively and efficiently search for and analyze relevant information. Users can look for both structured as well as unstructured information in a system designed for electronic commerce. An example of structured information is the price of a specified product. Unstructured information, on the other hand, is information that is not well specified or that has multiple specifications. For example, the user may be looking for spices for cooking a shrimp dish where they can choose from a number of options. The user may have individual preferences1 for the selection of spices and may not know exactly how the information can be found in the system.

The problem of finding relevant information is exacerbated in global information management, especially in global electronic commerce. While globalization is presenting new opportunities for people and businesses worldwide, several challenges must be addressed in order to realize its full potential. Examples of these challenges include differences in culture and language, which can be an obstacle to unrestricted and free access of information, as well as the disorganization of the potentially precious knowledge asset. While language technology (Nirenburg, 1992; Onyshkevych & Nirenburg, 1995; Sheremetyeva & Nirenburg, 1996) is making rapid progress, much research is needed in managing and accessing multilingual information in order to reach the full potential of global electronic commerce (e.g., Malhotra, 1997, 1998). In Gangopadhyay and Huang (2000), the issue of knowledge requirements for building information systems that operate in multiple languages has been studied. Specifically, the focus was on studying user behavior in performing various tasks in a multilingual system. In order to study user behavior and performance in a multilingual electronic-commerce setting, a bilingual electronic catalog was designed and tested by online retailers selling products and/or services to customers interacting either in English or Chinese.

BACKGROUND

An electronic catalog is a graphical user interface that presents product and/or service information to users, typically using the World Wide Web. An electronic catalog is a key component of electronic commerce that has been used for business-to-consumer commerce as well as business-to-business commerce (Adam, Dogramaci, Gangopadhyay, & Yesha, 1998; Gangopadhyay, 2002). Although the term electronic catalog might sound like an electronic extension of paper catalogs, it offers features that are far beyond those found in paper catalogs. Such features include computational services such as efficient browsing and searching, online order processing such as checking out products using shopping carts and secure payment mechanisms, and back-end processing such as integration with company databases (Segev, Wan, & Beam, 1995). These features have extended the role of electronic catalogs to the point of being used as electronic storefronts.

With the rapid proliferation of electronic commerce both in local and global markets, there is an increasing need to provide support for internationalization such as foreign currencies, different date and time formats, sort order, and multiple languages (Broin, 1999). The need for providing multilingual support is echoed by the rapid increase of non-English-speaking users on the Internet. For example, it is reported that 75% of Internet users may be non-English speaking by 2005 (Thomason, n.d.). A side effect of the increasing number of non-English users of the Internet is the "contamination" of other languages with English terms (Voiskounsky, 1998). Intercultural class differences can also lead to differences in perceptions of abstractions and generalizations. These differences should be taken into account in designing the graphical user interfaces of e-commerce sites (e.g., Stander, 1998). An example of a multilingual electronic catalog is shown in Figure 1a and 1b, taken from Gangopadhyay & Huang (2000).

Empirical investigations in this field (e.g., Gangopadhyay & Huang, 2000) show that users prefer to use their ethnic language when conducting tasks that are

Figure 1a. Three modes of search in English

Figure 1b. Three modes of search in Chinese

unstructured or semistructured. However, language preferences diminish when the tasks become more structured. Also, nonethnic terms, such as computer, are difficult to express in an ethnic language where others, such as kung pao, are difficult to express in a nonnative language such as English. Hence, e-commerce Web sites designed for structured tasks dealing with nonethnic products should use international languages such as English. On the other hand, if the tasks performed by the users are likely to be unstructured and the products or services are ethnic in nature, ethnic languages should be used for designing the Web site.

FUTURE TRENDS

From the research results described above, we can surmise several implications for future research and practice in global electronic commerce. First, it is quite clear that users prefer to use their ethnic language when searching for ethnic products because it is difficult to translate them into another language, such as English. Some researchers (e.g., Doherty, 1999) assert that the *unified content model* is easier to implement in a global electronic commerce system. However, the unified content model may not be good from a user-interface standpoint for all product categories since users may prefer to use their own ethnic language.

Another closely related issue is the level of understanding of the information presented for bilingual users. The previous studies indicate that the language preference is not a major issue when dealing with structured information. However, when dealing with unstructured information, there is a significant preference toward using one's native language. While it takes more research to establish a relationship between language preference and information complexity, such research can render significant insights into the design of multilingual interfaces for global electronic commerce.

In multilingual systems that depend on word-for-word translation from one language to another, a lot of information may be lost during the translation process. For example, it is hard to tell the differences between *table* and *desk* in Chinese. In these cases, images may be helpful to present product information. It is also worthwhile to study the effect of multimedia information on user performance and satisfaction in global electronic commerce.

CONCLUSION
