KEY TERMS

Component-Based Web Engineering: The application of systematic, disciplined and quantifiable component-based and reuse-oriented approaches to the understanding, construction, operation and evolution of Web-based applications and systems.

Compositional Design and Reuse: The design or composition of components from a collection of generic building-block components.

Controlled Indexing: Objects may be indexed using controlled vocabularies, hierarchies or classifications.

DRM: Digital Rights Management (DRM) refers to methods and technologies designed to control access to or use of copyrighted data.

Federated Web Services: Usually, problems like authorization are handled on a network-by-network basis – a given login may only be valid to a single network or site. Federation provides a means to transcend this limitation. In our example, groups could federate by declaring trust in each other, thus permitting authorization across multiple organizations.

Software Contracts: A means of negotiating obligations to which a service donator and client may agree. This may include information about several levels, from the technical (available communications protocol) to the non-functional (quality of service).

UDDI: The Universal Description, Discovery and Integration specification provides a platform-independent way of describing and discovering services and service providers.

Uncontrolled Indexing: The indexing of objects using uncontrolled vocabularies, such as descriptions or semi-structured metadata.

UUID: Universally Unique IDs (UUID) are typically machine-generated, and are used as world-wide unique labels. Their uniqueness is assured through such means as encoding of timestamps and hardware identifiers.

Software Requirements Risk and Maintainability

Norman F. Schneidewind
Naval Postgraduate School, USA

INTRODUCTION

In order to continue to make progress in software measurement, as it pertains to reliability and maintainability, there must be a shift in emphasis from design and code metrics to metrics that characterize the risk of making requirements changes. By doing so, the quality of delivered software can be improved because defects related to problems in requirements specifications will be identified early in the life cycle. An approach is described for identifying requirements change risk factors as predictors of reliability and maintainability problems. This approach can be generalized to other applications with numerical results that would vary according to application. An example is provided that consists of 24 space shuttle change requests, 19 risk factors, and the associated failures and software metrics.

In addition to the relationship between requirements and reliability and maintainability, there are the intermediate relationships between requirements and software metrics (e.g., size, complexity) and between metrics and reliability and maintainability. These relationships may interact to put the reliability and maintainability of the software at risk because the requirements changes may result in increases in the size and complexity of the software that may adversely affect reliability and maintainability.

BACKGROUND

Several projects have demonstrated the validity and applicability of applying metrics to identify fault prone software at the code level (Khoshgoftaar & Allen, 1998; Khoshgoftaar et al., 1996a, 1996b; Schneidewind, 2000). This approach is applied at the requirements level to allow for early detection of reliability and maintainability problems. Once high-risk areas of the software have been identified, they would be subject to detailed tracking throughout the development and maintenance process (Schneidewind, 1999).

Much of the research and literature in software metrics concerns the measurement of code characteristics (Nikora et al., 1998). This is satisfactory for evaluating product quality and process effectiveness once the code is written. However, if organizations use measurement plans that are limited to measuring code, the plans will be deficient in the following ways: incomplete, lack coverage (e.g., no requirements analysis and design), and start too late in the process. For a measurement plan to be effective, it must start with requirements and continue through to operation and maintenance. Since requirements characteristics directly affect code characteristics and hence reliability and maintainability, it is important to assess their impact on reliability and maintainability when requirements are specified. As will be shown, it is feasible to quantify the risks to reliability and maintainability of requirements changes — either new requirements or changes to existing requirements.

Once requirements attributes that portend high risk for the operational reliability and maintainability of the software are identified, it is possible to suggest changes in the development and maintenance process of the organization. To illustrate, a possible recommendation is that any requirements change to mission critical software — either new requirements or changes to existing requirements — would be subjected to a *quantitative* risk analysis. In addition to stating that a risk analysis would be performed, the policy would specify the risk factors to be analyzed (e.g., number of modifications of a requirement or *mod level*) and their threshold or critical values. The validity and applicability of identifying critical values of metrics to identify fault prone software at the code level have been demonstrated (Schneidewind, 2000). For example, on the space shuttle, rigorous inspections of requirements, design documentation, and code have contributed more to achieving high reliability and maintainability than any other process factor. The objective of these policy changes is to prevent the propagation of high-risk requirements through the various phases of software development and maintenance. The payoff to the organization would be to reduce the risk of mission critical software *not* meeting its reliability and maintainability goals during operation.

APPROACH TO ANALYZING REQUIREMENTS RISK

By retrospectively analyzing the relationship between requirements and reliability and maintainability, it is possible to identify those risk factors that are associated with

S

Table 1. Change request hierarchy

Change Requests (CRs)
1. No Discrepancy Reports (i.e., CRs with no DRs)
2. (Discrepancy Reports) or (Discrepancy Reports and Failures)
   - 2.1 No failures (i.e., CRs with DRs only)
   - 2.2 Failures (i.e., CRs with DRs and Failures)
     - 2.2.1 Pre-release failures
     - 2.2.2 Post-release failures

reliability and maintainability. In addition, risk factors are prioritized based on the degree to which the relationship is statistically significant. In order to quantify the effect of a requirements change, various risk factors were used, which are defined as the attribute of a requirement change that can induce adverse effects on reliability (e.g., failure incidence), maintainability (e.g., size and complexity of the code), and project management (e.g., personnel resources).

Table 1 shows the Change Request Hierarchy of the space shuttle, involving change requests (i.e., a request for a new requirement or modification of an existing requirement), discrepancy reports (i.e., DRs: reports that document deviations between specified and observed software behavior), and failures. In Table 1, Category 1 versus Category 2 was analyzed with respect to risk factors as discriminants of the categories.

Categorical Data Analysis

Using the null hypothesis, Ho: A risk factor is not a discriminator of reliability and maintainability versus the alternate hypothesis H_1: A risk factor is a discriminator of reliability and maintainability, categorical data analysis is used to test the hypothesis. A similar hypothesis was used to assess whether risk factors can serve as discriminators of metrics characteristics. Requirements, requirements risk factors, reliability, and metrics data from the space shuttle *"Three Engine Out"* software (abort sequence invoked when three engines are lost) were used to test the hypotheses.

Table 2. Definition of samples

Sample	Size
Total CRs	24
CRs with no DRs	14
CRs with (DRs only) or (DRs and Failures)	10
CRs with modules that caused failures	6
CRs can have multiple DRs, failures, and modules that caused failures. CR: Change Request. DR: Discrepancy Report.	

Table 2 shows the definition of the change request samples that were used in the analysis. Sample sizes are small due to the high reliability of the space shuttle software. However, sample size is one of the parameters accounted for in the statistical tests that produced statistically significant results in certain cases.

To minimize the effects of a large number of variables that interact in some cases, a statistical categorical data analysis was performed incrementally. Only one category of risk factor at a time was used to observe the effect of adding an additional risk factor on the ability to correctly classify change requests that have *No Discrepancy Reports* versus change requests that have ((*Discrepancy Reports Only*) *or* (*Discrepancy Reports and Failures*)). The Mann-Whitney test for difference in medians between categories was used because no assumption need be made about statistical distribution. In addition, some risk factors are ordinal scale quantities (e.g., modification level); thus, the median is an appropriate statistic to use.

RISK FACTORS

One of the software process problems of the NASA Space Shuttle Flight Software organization is to evaluate the risk of implementing requirements changes. These changes can affect the reliability and maintainability of the software. To assess the risk of change, the software development contractor uses a number of risk factors. The following are the definitions of the 4 out of 19 risk factors that were found to have a statistically significant relationship with reliability and maintainability. The names of the risk factors used in the analysis are given in quotation marks.

Table 3. Statistically significant results (alpha ≤ .05). CRs with no DRs vs. ((DRs only) or (DRs and Failures)). Mann-Whitney Test

Risk Factor	**Alpha**	**Median Value** CRs with no DRs	**Median Value** (DRs only) or (DRs and Failures)
issues	.0076	1	14
space	.0186	6	123
mods	.0401	0	4
sloc	.0465	10	88.5

Table 4. Selected risk factor module characteristics

Change Request	**Failed Module**	**Metric**	**Metric Critical Value**	**Metric Value**
A	1	change history line count in module listing	63	558
A	2	non-commented loc count	29	408
B	3	executable statement count	27	419
C	4	unique operand count	45	83
D	5	unique operator count	9	33
E	6	node count (in control graph)	17	66
All of the above metrics exceeded the critical values for all of the above change requests.				

- Complexity Factor
  o Number of modifications or iterations on the proposed change; “mods”.
  - How many times must the change be modified or presented to the Change Control Board (CCB) before it is approved?
- Size Factor
  o Number of source lines of code affected by the change; “sloc”.
  - How many source lines of code must be changed to implement the change request?
- Requirements Issue Factor
  o Number of possible conflicts among requirements (requirements issues); “issues”
  - Will this change conflict with other requirements changes (e.g., lead to conflicting operational scenarios)?
- Performance Factor
  o Amount of memory space required to implement the change; “space”
  - Will the change use memory to the extent that other functions will not have sufficient memory to operate effectively?

RISK ANALYSIS EXAMPLE

This section provides a risk analysis example, using the space shuttle data and performing the statistical analyses in a. and b., as shown in Tables 3 and 4, respectively. Only those risk factors where there was sufficient data and the results were statistically significant are shown.

a. Categorical data analysis on the relationship between (CRs with no DRs) versus ((DRs only) or (DRs and Failures)), using the Mann-Whitney Test.
b. Identification of modules that caused failures as a result of the CR, and their metric values.

Categorical Data Analysis

Of the original 19 risk factors, only 4 survived as being statistically significant (alpha ≤ .05); 7 were not significant; and 8 had insufficient data to make the analysis. As Table 3 shows, there are statistically significant results for (CRs with no DRs) versus ((DRs only) or (DRs and Failures)) for the risk factors “mods,” “sloc,” “issues,” and "space". The value of alpha in Table 3 is used to prioritize the use of risk factors, with low values meaning high priority. The priority order is: "issues," "space," "mods," and "sloc".

The significant risk factors would be used to predict reliability and maintainability problems for this set of data and this version of the software. The finding regarding "mods" does confirm the software developer's view that this is an important risk factor. This is the case because if there are many iterations of the change request, it implies that it is complex and difficult to understand. Therefore, the change is likely to lead to reliability and maintainability problems. It is not surprising that the size of the change "sloc" is significant because previous studies of space shuttle metrics have shown it to be an important determinant of software quality (Schneidewind, 2000). Conflicting requirements "issues" could result in reliability and maintainability problems when the change is implemented. The on-board computer memory required to implement the change "space" is critical to reliability and maintainability because unlike commercial systems, the space shuttle does not have the luxury of large physical memory, virtual memory, and disk memory to hold its programs and data. Any increased requirement on its small memory to implement a requirements change comes at the price of demands from competing functions.

Identification of Modules that Caused Failures

Table 4 shows modules that caused failures, as the result of the CRs had metric values that far exceed the critical values. The latter were computed in Schneidewind (2000). A critical value is a discriminant that distinguishes high quality from low quality software (Schneidewind, 2000). A module with metric values exceeding the critical values is predicted to cause failures and maintainability problems. Although the sample sizes are small, due to the high reliability of the space shuttle software, the results consistently show that modules with excessive size and complexity lead to failures. Not only will the reliability be low, but this software will also be difficult to maintain. The application of this information is that there is a high degree of risk when changes are made to software that has the metric characteristics shown in the table. Thus, these characteristics should be considered when making the risk analysis.

FUTURE TRENDS

Reliability predictions that are made in the test phase, when failure data are available, are useful, but it would be much more useful to predict at an earlier phase – preferably during requirements analysis—when the cost of error correction is relatively low. Thus, there is great interest in the software reliability and metrics field in using static attributes of software in reliability and maintainability modeling and prediction. Presently, the software engineering field does not have the capability to make early predictions of reliability and maintainability problems. Early predictions would allow errors to be discovered and corrected when the cost of correction is relatively low. In addition, early detection would prevent poor quality software from getting into the hands of the user. As a future trend, the focus in research and practice will be to identify the attributes of software requirements that cause the software to be unreliable and difficult to maintain.

CONCLUSION

Risk factors that are statistically significant can be used to make decisions about the risk of making changes. These changes affect the reliability and maintainability of the software. Risk factors that are not statistically significant should not be used; they do not provide useful information for decision-making and cost money and time to collect and process. Metric characteristics of modules should be considered when making the risk analysis because metric values that exceed the critical values are likely to result in unreliable and non-maintainable software. This methodology can be generalized to other risk assessment domains, but the specific risk factors, their numerical values, and statistical results may vary.

KEY TERMS

Failure: The inability of a system or component to perform its required functions within specified performance requirements.

Maintainability: The ease with which a software system or component can be modified to correct faults, improve performance or other attributes, or adapt to a changed environment

Metric: A quantitative measure of the degree to which a system, component, or process possesses a given attribute.

Quality: The degree to which a system, component, or process meets specified requirements.

Reliability: The ability of a system or component to perform its required functions under stated conditions for a specified period of time.

Requirement: A condition or capability needed by a user to solve a problem or achieve an objective.

Risk: The chance of injury, damage, or loss.

Software Reuse in Hypermedia Applications

Roberto Paiano
University of Lecce, Italy

INTRODUCTION

Hypermedia applications were, at the beginning, hand-coded pages with "ad-hoc" links. This production method was acceptable until a few pages had to be produced, but it became rapidly unmanageable when several hundreds of pages with complex interactive objects had to be considered. In particular, two interwoven problems rapidly became relevant: how to ensure the "usability" of modern large hypermedia-applications (Garzotto, Matera & Paolini, 1999), and how to improve the efficiency of its production/maintenance process.

In good hypermedia applications, in fact, the reader should be able to effectively exploit the information contained in the application: that is, he or she should be able to quickly locate the objects of interest, to understand the inner structure of the objects and to easily navigate from one object to another. Several factors concur to the achievement of usability: one of the most important is to have a good structuring of the information objects and a good structuring of the navigation patterns.

BACKGROUND

Several authors have recently proposed the adoption of design models (Garzotto, Mainetti & Paolini, 1995; Isakowitz, Stohr & Balasubramanian, 1995; Schwabe & Rossi, 1995)and design patterns (Rossi, Schwabe & Lyardet, 1999), in order to improve the quality of hypermedia applications, at least for those aspects concerning structure and navigation. Other authors (Conallen, 1999; Schwabe & Rossi, 2000) have proposed the use of object oriented paradigm to model this kind of application, but the navigation structures are more simple. Design models provide, in fact, the primitives that allow structuring the information objects and the corresponding navigation patterns along regular and systematic features, improving consistency, predictability (for the user), robustness of the design, and therefore improving usability. The ancestor of these models can be traced to HDM (Garzotto, Paolini & Schwabe, 1993) and its evolution: W2000 Model (Baresi, Garzotto & Paolini, 2000).

The adoption of W2000 to design the internal structure and the navigational features of hypermedia applications is desirable for three reasons:

- resulting applications are usable;
- the production process can be decomposed into sub-problems easy to manage;
- the application model can be "executed" by a suitable "interpreter" to create the application pages in a way that is independent from the specific application.

Furthermore, in several real-life projects we encountered the problem of dealing with application families. An application family is a set of applications sharing (part of) the content and also (part of the) conceptual design. The problem of application families is the typical situation where the application owner, after a successful first application, needs a second one very similar to the first one. At first it seems a simple problem of "reuse" of content: use the same pictures, use the same texts, use the same data, and so forth (Garzotto, Mainetti & Paolini, 1996). After a while it becomes apparent that not only content, but also (pieces of the) conceptual structure must be "reused". Then comes a third "similar" application, and so on. So, the truth emerges: the designer should have started from the beginning having in mind a family of applications, knowing that several specific applications could have resulted from it. In other words the designer should have optimized the activity of "carving out," from a family, a specific application, for a specific need.

Therefore it became clear that the design process, the design model and the design support system should adopt the notion of family of applications. Such kind of activity is made easily using a structured model.

BRIEF DESCRIPTION OF W2000 METHODOLOGY

The methodology was developed by the UWA Consortium (UWA), and specifically by Polytechnic of Milan.

W2000 methodology assumes that it is essential to make a clear distinction between the different aspects of the application that need to be observed during the design phase, in order to make the design itself a structured and easily controllable process, and to obtain clear modeling, suitable for different users and delivery devices.

After the Requirements Analysis phase, guided by a goal-oriented approach, the methodology suggests a sequence of steps that may be briefly summarized as follows:

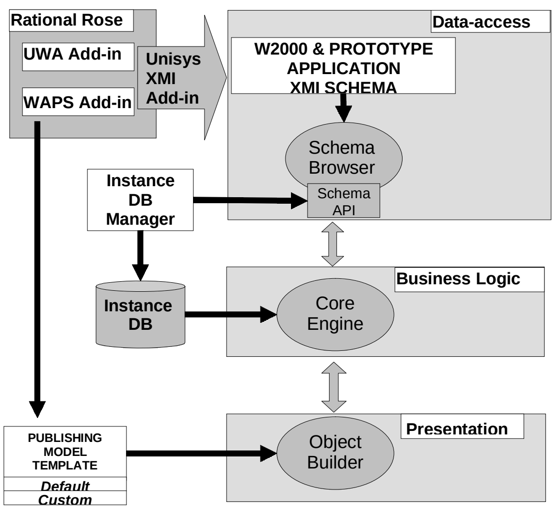
- Information Design: the goal is to describe the information that the application is going to deal with, giving it a structured organization from the user's point of view.
- Navigation Design: this reconsiders the information and its organization from the viewpoint of its fruition, defining the navigational paths the user can follow.
- Publishing Design: the results of the previous steps must be complemented with considerations on presentation and organized into "pages" and "fruition units".

According to the previous description, a database can store the application components described by the model, and then a run-time engine can extract those components from the database to display it to the reader. This kind of engine, named WAPS, is application independent, so it is really reusable and it may be defined as a W2000 methodology Interpreter. It is the last evolution of a family of navigation engines according to the evolution both of methodology (Bochicchio & Paiano, 2000; Paiano & Pandurino, 2003) and available technology (Bochicchio & Paolini, 1998; Bochicchio, Paiano & Paolini, 1999).

A REUSABLE INTERPRETER

The run-time environment, the WAPS core, has the main task of creating a mock-up application starting from the W2000 model in XMI format.

Figure 1. WAPS architecture



In accordance with the modular structure of the W2000 methodology and the various aspects of WA, as shown in Figure 1, it is possible to identify a clear n-tier architecture for the WAPS run-time environment. This choice was highly suitable for the W2000 methodology: in order to manage the complexity, each architecture layer manages a single aspect and provides services to the other levels. All the data managed in the modules are in XML format; furthermore, all interaction between modules is in the same format according to the market trend and standard.

It allows the use of transformation parsing techniques like XSL in the visualization and processing phases, also allowing the following of the evolution of methodology.

- Rational Rose Add-in: Rose helps to design the WA in graphic format using standard UML notation, in accordance with W2000 methodology, in order to obtain a "machine readable" description. Another rational rose add-in: "Unisys Rose XML Tools," produced by Unisys, exports the UML diagram into a standard XMI output.
- Schema Browser: This module allows a unique entry point to the WA schema, hiding the complexity in order to manage the XMI in raw mode. The module provides a set of schema APIs (S-API) to navigate through the WA model via W2000 primitives, bypassing the UML MOF used by XMI.
- Core Engine: This module corresponds to the business level for a three-tier application. This module has the task of understanding the requests from the Object Builder, using the S-API of the schema browser to compose the reply schema that will contain the application data taken from the Instance DB. Since this module creates the reply schema, all design customizations take effect at this stage.
- Object Builder: This module is the door to WAPS systems: the user request comes in, the prototyped page goes out. The module moves the request to the Core Engine and receives the response in XML-like format. Its main task is to apply a template to make the page visible. WAPS uses the XSLT transformation to obtain HTML or WML pages.
- Instance DB: It is an E-R database that contains the data that will be shown to the user. The E-R schema is derived from the W2000 model; thus the schema is fixed and does not change with the domain of the WA being prototyped.
- Publishing Model Template: It is an E-R database that contains the references to the visualization template to create the page.

FUTURE TRENDS

We are now assisting the revival of MVC (Model View Controller) architecture applied to the Web. There are several frameworks oriented to the prototyping of Web applications, based on the MVC paradigm, but the Model site is not fully specified.

The next step of research in this area is to join the W2000 Model definitions with the Model site of these frameworks.

To achieve this goal, the SET Lab of University of Lecce is developing this kind of interface between W2000 model and Struts framework developed by Apache software Foundation, obtaining very interesting results.

CONCLUSION

The adoption of structured approaches and conceptual models, such as W2000, is an important step in the direction to improve the quality and the reusability of hypermedia applications, reducing at the same time the costs and the time required for their development.

The construction of a reusable engine for hypermedia application, based on the W2000 model, is the logical extension to the model-based approach. The reusable engine, in fact, is able to implement the needed hypermedia software in an application-independent way. The effectiveness of this approach is based on the ability of the model to describe a wide range of complex hypermedia applications.

KEY TERMS

HDM: Hypermedia Design Methodology, developed by Polytechnic of Milan (Italy). It is a methodology to design hypermedia applications.

Interpreter: The traditional definition in computer science is a program that translates and executes source language statements one line at a time. The meaning in this article is: a program that accesses the model to understand the requested navigation one user action at a time.

W2000: A methodology to conceptually design Web applications, developed by Polytechnic of Milan (Italy) in the UWA project.

WAPS: A reusable W2000 interpreter to prototype Web applications.

Web Application: An application that presents the characteristics and the issues of both hypermedia applications and traditional applications. In other words, this kind of application has the navigational issues of Web sites joint to the traditional operation issues.

XMI: XML Metadata Interchange is a widely used interchange format for sharing objects using XML. It is defined by OMG.

XML: EXtensible Markup Language is a mark-up language much like HTML designed to describe data using your own tags. It is a recommendation of W3C Consortium.

Space Opera–GIS Basics

Paul H.J. Hendriks
Radboud University Nijmegen, The Netherlands

INTRODUCTION

The term "Geographical Information Systems", commonly abbreviated to GIS, is an umbrella term covering a class of computer based information systems that are typified by their focus on geographical or spatial data and information. The basic notion underlying a GIS is that every object present on the earth can be "geo-referenced", which refers to defining the spatial location of objects by referencing systems (e.g. latitude/longitude or postal zones). The key to specific GIS functionality is that GIS allow connection of geo-referenced data to attribute or non-spatial data of geographical objects. In varying ways and to varying degrees GIS facilitate the steps necessary for acquiring both classes of data and turning them into geographical information, including input (e.g. via GPS or scanning of maps), data processing and analysis (e.g. overlay analysis or shortest path calculation) and display (e.g., on maps).

The history of GIS spans roughly four decades, bringing a story that springs from many origins, and mingles many disciplines. GIS finds its roots in public administration domains and military applications, but has fanned out to many commercial, non-profit and academic areas. From its origins in the nineteen sixties, GIS has grown in size and stature, building on diverse influences concerning concepts and principles, data and issues of spatial infrastructure, software and software vendors, application areas, etc. The GIS landscape contains a multitude of proprietary and public domain GIS software packages (most notably Autodesk's AutoCAD Map, Erdas's Imagine, ESRI's Arc/Info, Intergraph's GeoMedia, Maplnfo and Smallworld). From its ongoing development history GIS emerges not as one sharply delineated concept or class of computer systems. The GIS landscape is as diverse as the multitude of roots from which it originated and the throng of influences that shaped its development.

BACKGROUND

GIS as an umbrella term covers various types of technology, ranging from relatively simple mapping facilities to advanced environments supporting spatial analysis. What combines different manifestations of GIS is that they all draw their operability from functionalities around spatial information, or geoinformation (Goodchild, 2003; Konecny, 2003). Developing an understanding of what distinguishes GIS from other information systems can be achieved by looking at GIS through four windows. Firstly, GIS can be defined through a *database window*, which involves exploring the alternative data models used in GIS and the principles and technical issues involved in defining and linking spatial and attribute data (including temporal data) based on these models. Secondly, an important distinction between different GIS refers to the types of spatial and non-spatial analysis they support, which involves looking at these systems through a *geographical analysis window*. Thirdly, applying a *visualization window* allows to assess the functionality of GIS for making the contents of their database and analysis outcomes visible, in which maps and computer cartography play an important role. Fourthly, GIS can be looked at through a *relevance window*. This fourth perspective, which involves looking at the context of system usage, is crucial for understanding GIS as information systems instead of data systems, as it should allow to understand how and when geographical analysis may make geographical data meaningful, how and when their presentation on maps will be useful, and how and when specific functionalities of GIS are necessary elements for defining GIS.

A DATABASE WINDOW ON GIS

Looking at GIS through a *spatial database* window shows GIS as a dedicated system for acquiring, storing and processing data with a spatial component (Haining, 2003; Shekhar & Chawla, 2003). Building a spatial database requires spatial data modeling and processing. Spatial modeling involves several steps. Firstly, it concerns developing a spatial understanding by distinguishing and relating the elements that define "spatiality", such as "location" or "distance". Secondly, it involves building a *conceptual spatial data model* by translating the spatial perspective into formalized data elements. Thirdly, a *logical spatial data model* must be built, which involves representing and formalizing the elements of the conceptual model in a univocal manner so that these can be entered into an automated system. Fourthly, the logical spatial data model has to be translated into the actual data storage, which refers to choosing a *physical data model*.

As the first two steps most specifically enter the spatial perspective in data modeling, we will focus on these.

Building a conceptual spatial data model consists of identifying spatial objects and characterizing these. Five aspects describe spatial objects:

1. These are objects that are in a certain place or location (aspect: *where* or *absolute location*),
2. with a certain spatial size, appearance, etc. (aspect: *spatial form*),
3. at a certain distance from other spatial objects and in a certain relationship with these (aspect: *spatial relationships* or *relative location*),
4. at a certain moment in time or during a certain period, and possibly subject to change (aspect: *when*), and
5. with other characteristics than spatial and temporal (aspect: *what*).

A basic distinction between conceptual spatial data models is whether they represent spatial objects in 2D or 3D. Commonly, four basic types of two-dimensional spatial objects are distinguished: points, lines (or specific collections of points), areas (objects identified by lines beginning and ending in the same point) and surfaces. Combinations of these basic classes and their characteristics may produce new types of spatial objects, such as spatial patterns, spatial structures, or spatial networks. For instance, a spatial network such as a road network or a network of pipelines, results from understanding points as nodes and lines as connections between nodes, and may be expanded to include areas and surfaces as well. Data models for representing these objects can be distinguished into raster models (based on fixed units of space) and vector models (based on combinations of points and lines). Three-dimensional spatial data models or geomorphometrical models, which are less common in GIS, aim to represent the height dimension of space in a more sophisticated form than by using contour lines. The most commonly used models are the triangulated network (TIN) and the digital elevation model (DEM).

Connecting the five aspects specified above with spatial objects involves three issues: firstly, defining the spatial data (aspects 1, 2, 3); secondly, defining the non-spatial data (aspects 4 and 5); and thirdly, linking spatial and non-spatial data. The non-spatial are typically called the attribute data in GIS, which include temporal data (see Christakos, Bogaert, & Serre, 2001). Describing absolute location (aspect 2) is called georeferencing. A basis distinction is between continuous (e.g., LATLONG) and discrete (e.g., postal zones) georeferencing.

Working with spatial data in GIS presumes a choice of spatial data model, facilities for getting data into the system based on that data model, and functions for processing data. Some GIS have chosen one spatial data model as the basis of their functionality for handling spatial (e.g., leading to a distinction between raster and vector GIS); others offer combinations of models and facilities for linking these. As to data input GIS users no longer need to collect all data themselves because many commercial datasets are available (e.g., based on postal zones or road networks), as well as spatial data sets built in academic or other public domain projects (see Rigaux, Scholl, & Voisard, 2002; Walford, 2002). Data input has been revolutionized by the Global Positioning System (GPS), which allows inputting both 2D and 3D spatial data from satellite data (e.g., Konecny, 2003). GIS typically contain functions for additional processing of data input from external data sets or from input devices (GPS, digitizers, etc.), such as geometric transformation (translating among methods of map projection), edge matching (ensuring that features crossing adjacent map sheets have the same edge locations, attribute descriptions and feature classes), and standard attribute editing functions (e.g., reclassifying objects based on their attribute data).

A GEOVISUALIZATION WINDOW ON GIS

The window of *visualizing spatial information* shows GIS as a system to present spatial data and information, e.g. via maps (Cartwright & Hunter, 2001). Geovisualization, and therefore also the use of maps in GIS, can refer to GIS output or input. Geovisualization as input refers to taking the visual form as the starting point for communication with GIS or further analysis steps within or outside of GIS (Maceachren & Brewer, 2004). For instance, maps can be used as interactive devices for defining queries for showing and exploring the contents of the database, e.g., to detect errors (Andrienko, Andrienko, & Gitis, 2003), or for starting a new geographical analysis. Using maps in GIS in an interactive sense presumes that the map is linked with a set of controls (e.g., it can be made clickable) allowing to change the content of the map or to take the content of the map as a step toward building a new map (e.g., Cartwright & Hunter, 2001).

Geovisualization as output refers to showing the GIS's contents, such as the data contained in the spatial databank, or the outcomes of spatial analysis. GIS can be used for producing, showing and interpreting maps and other visualizations. Producing maps involves generating data with a spatial footprint, and showing these in a new or updated map. Producers of atlases and road maps use GIS to facilitate updating the frequent changes in the location of objects (e.g., changes in the street networks, or the usually less frequent changes in the boundaries between administrative units). Geographical analysts that perform their analysis in analysis modules linked to GIS and show the analysis outcomes in GIS are another class of GIS map producers.

AN ANALYSIS WINDOW ON GIS

Through a *spatial analysis window* GIS appears as a system that offers possibilities for processing spatial and non-spatial data so that new spatial and non-spatial data and information can be inferred. GIS are best understood as toolboxes of operations that may be combined in multiple ways, guided by specific analysis needs. Additionally some GIS offer a (mostly modestly filled) spatial model base coupled to standard spatial analysis functions or offer functions for linking to external model bases (DeMers, 2002; Haining, 2003).

Typical analysis-related functions in GIS include retrieval, classification, overlay, neighborhood and connectivity operations. Such GIS functions may lead to GIS-based spatial analysis when applied and combined in different ways. Firstly, the analysis may involve generating new attribute data from existing attribute data of known spatial objects, while not affecting the location data of these objects. An example that fits within this class of spatial analysis is the overlay of two maps (e.g., private-public ownership and land use classes of lots) to produce a characterization of the areal units on the map in a third map (e.g., conveying an insight into the connections between ownership and land use of lots).

Secondly, GIS may support forms of analysis that deduce attribute properties from location data of known spatial objects. As an example consider combining network and aspect operations to assess whether a particular location is likely to run the risk of pollution in the case of a toxic spillover, because of how the downhill path runs from the spillover location (e.g., Rodriguez-Bachiller & Glasson, 2004).

Thirdly, analyzing attribute data of spatial phenomena may form the basis of the detection and subsequent characterization of new spatial objects. As an example consider a shop that is interested in what typifies its service area, to assess possibilities for adapting its range of goods. GIS allows to establish this neighborhood if customer trip data are available and to analyze prevailing demographic properties of residents within the window by connecting the spatial object with external attribute data as are available for postcode zones (e.g., Kidner & Higgs, 2003; Miller & Shaw, 2001).

Fourthly, spatial analysis may involve detecting new spatial characteristics of objects, by examining their spatial properties alone or in conjunction with associated attribute data. A GIS analyst may, for instance, perform a combined contiguity and network analysis based on address and routing information to determine how close residents are to a service such as an ambulance post or community service, to define the catchment areas of these services (e.g., Kidner & Higgs, 2003; Miller & Shaw, 2001).

A RELEVANCE WINDOW ON GIS

The *relevance window* concerns the objective for which the information stored in GIS and generated by GIS is used. A GIS is more than a collection of hardware and software. It is a specific aspect system of a larger system, namely the organization within which GIS data is managed and processed.

A view through this fourth window shows the classes of GIS applications and users (individuals, groups, departments, organizations, networks, etc.). Looking at typical GIS applications reveals a broad spectrum of uses and users (e.g., see Geertman & Stillwell, 2003; Grimshaw, 2000; Kidner & Higgs, 2003). Important business users of GIS include owners of large physical distribution networks, such as utility companies, for example gas, phone, electric, water, cable TV companies, the telecommunication industry, the transportation sector (including government transportation departments who use GIS, for instance, to store information on the state of pavement on the highway network, maintain an inventory of all highway signs, and analyze data on accidents). This sector also includes delivery companies that use GIS technology to keep track of shipments, know where they are, and plan efficient delivery routes (e.g., Miller & Shaw, 2001). GIS is also being used for siting facilities such as retail shops and warehouses, by analyzing demographic data of customer populations, access routes for customers, delivery routes for suppliers, etc. Large-scale GIS users also include farmers and foresters who increasingly use detailed maps for planning, analyzing and evaluating land use.

If we try to define GIS through a relevance window in more general terms their multicolored nature becomes even more apparent. GIS can be defined as dedicated spatial object and spatial network management tools as is customary in the AM/FM (automated mapping/facilities management) domains. GIS can be looked at as spatial decision support systems, when we see them as tools for supporting decision makers making choices that involve spatial elements, such as solving routing problems, connected location-allocation problems, or problems of service area development (e.g., Clarke & Madden, 2001; Grimshaw, 2000). GIS appear as organizational learning systems when their presence in organizations and functionalities are assessed from the perspective as to whether and when using spatial categories supported through GIS makes the organization smarter

(Hendriks, 2000, 2004). GIS can be tools in the hands of spatial scientists, including geographers, physical planners, forestry students, environmental students, and geologists, that support them in their research activities.

FUTURE TRENDS

In recent decades several developments have resulted in moving GIS from the outskirts of eclectic computing by geographical pioneers to mainstream data and information processing in private and public companies, in academia and even in private households (e.g., car navigation systems or route planners on the Internet). Many trends have supported this move. More data is available for GIS, via commercial datasets with spatial footprints and via new data collection techniques. Among these, Global Positioning System (GPS) has become a major source of new GIS data, and new GIS data comes increasingly from integrated GPS/GIS systems. The mobility of portable GIS and GPS systems has revolutionized GIS use. As GIS have been recognized for their integration facilities for databases of different kinds, GIS has quickly incorporated distributed systems and databases. Improvements in the software installation facilities user interface, improved interoperability of proprietary GIS packages, etc. have substantially altered how GIS “look and feel”. National geographical data infrastructures are being built and expanded, combining the datasets and knowledge of various agencies involved in spatial data handling (e.g., land register offices, spatial planning departments). GIS education has done its part in lowering some thresholds for recognizing the potential value of GIS, and in raising the critical awareness using GIS without profound geographical insight has limited value.

It can be expected that new developments will build on such existing trends. In the short run the further integration with GPS technology, and the development of national and transnational spatial infrastructures may be expected. In the longer run we may anticipate an increasing integration of scientific visualization and computer graphics with GIS capabilities. An increased integration of GIS with advanced modules for geographical analysis can also be foreseen. The use of animated and interactive maps, whether delivered via the Internet or not, holds much promise for enhancing the approachability of such spatial analysis modules.

CONCLUSION

Combining the four windows specified above – or adopting a more GIS-like terminology: overlaying these windows – allows drawing the contours of what GIS are. The four windows show Geographical Information Systems as sets of software tools and associated guidance principles that are based on insights as to how using spatial categories can further our understanding of phenomena and that allow the further development of such a spatial understanding through instantiations of combined spatial data, analysis and visualization models. History has moved GIS from the backwaters of pioneering academics and some individual public institutions into the floodlights. The story of GIS is an ongoing story of success, notwithstanding the critical comments GIS has received and is receiving (e.g., Sheppard, Couclelis, Graham, Harrington, & Onsrud, 1999). It presents GIS viewers with a space opera in which the acts they have seen so far have done everything to arouse the attention of what the future will hold for GIS and its users.

KEY TERMS

Geographical Analysis Model: A model to derive new spatial information by combining existing spatial and attribute data sources as appears useful for a given research goal (e.g., route selection, service area definition).

Geographical Information System (GIS): Computer system for acquiring, storing, processing, analyzing and displaying combined spatial and non-spatial data for academic, societal or organizational purposes.

Georeferencing: Identifying the geographic location of features and their boundaries on the Earth surface, e.g., derived from GPS, remote sensing, mapping, and surveying technologies.

Geovisualization: Data representation using more than one dimension to convey meaning, including animation and dynamic cartography, and spatialization (using geographic metaphors to generate georeferenced displays of nonspatial data such as text, image or sound archives).

Global Positioning System (GPS): A system of determining the absolute location of features by calculating x, y, z coordinates of ground locations from the signal of satellites orbiting the Earth.

Spatial Data Model: Set of principles and concepts for describing spatial objects and associated characteristics in a formal, univocal way, at the conceptual, logical or physical level.

Spatial Decision Support System: System built on the integration of spatial database management systems, geo-analytical models, geovisualization models, and the expert knowledge of individuals and organizations facing spatial decision problems.

Spatial Analysis in a Public Health Setting

INTRODUCTION

Spatial methods are an increasingly important tool in understanding public health issues. Spatial analysis addresses an often forgotten or misunderstood aspect of public health, namely, studying the dynamics of people in places. As advances in computer technology have continued apace, spatial methods have become an appealing way to understand the manner in which the individual relates to larger frameworks that compose the human community and the physical nature of human environments (streets with intersections, dense vs. sparse neighborhoods, high or low densities of liquor stores or restaurants, etc.). Spatial methods are extremely data-intensive, often pulling together information from disparate sources that have been collected for other purposes, such as research, business practice, governmental policy, and law enforcement. Although initially more demanding in regard to data manipulation compared to typical population level methods, the ability to compile and compare data in a spatial framework provides much additional information about human populations that lies beyond typical survey or census research. We will discuss general methods of spatial analysis and mapping which will help to elucidate when and how spatial analysis might be used in a public health setting. Further, we will discuss a practical research example focusing on the relationship between alcohol and violence.

BACKGROUND: GIS CAPABILITIES AND PREVENTION

A basic understanding of the capabilities of geographic information systems (GIS) is critical to the development of prevention activities because alcohol-related problems are not evenly distributed across space. GIS can be defined as a combination of computer hardware, software, spatial data (digital maps), and data with a geographic reference (e.g., alcohol outlets, crime locations) that facilitates spatial analysis. The key functions of GIS provide access to the broad spectrum of potential spatial analyses that can support the simple targeting of resources as well as the development of more complex models of spatial interactions. Both simple maps of problem rates or clusters and spatial interaction models may be useful for targeting traditional individual-based prevention programs or environmental interventions. Spatial interaction models, however, may be more appropriate for identifying the locations of events (e.g., assaults or crashes) that may be most amenable to environmental or regulatory prevention. In addition, GIS capabilities promote the development of a basic spatial/geographic epidemiology of alcohol use and related consequences, which is critical to the development of prevention programs (see Wieczorek, 2000, and Wieczorek & Hanson, 1997, for more details).

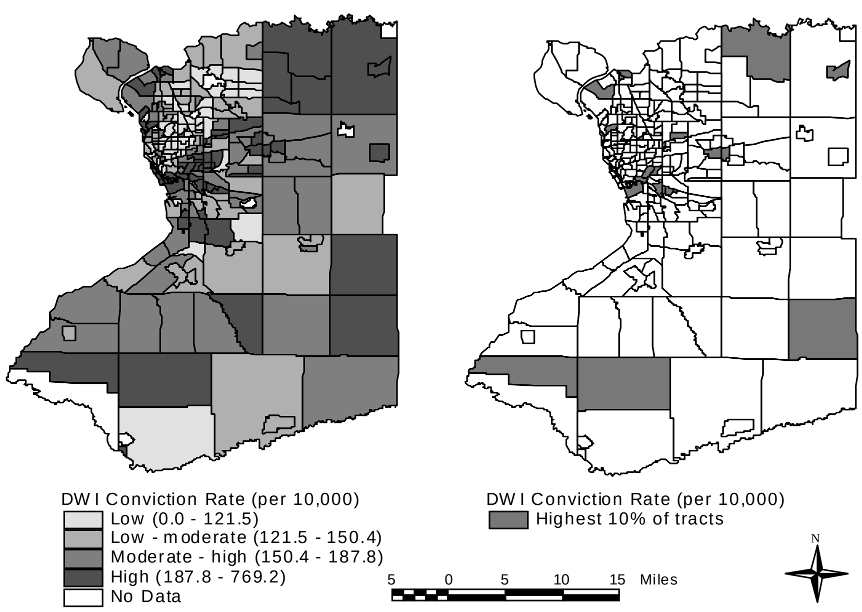
The key functions of GIS include: geocoding, data overlays, reclassification functions, and distance/adjacency measures. Geocoding is a generic term used to describe the GIS function of providing a specific location to descriptive data. Geocoding applies to point data (e.g., alcohol outlet) as well as to area data (e.g., number of assaults in a census tract). Sometimes geocoding is known as address matching because the process of matching points to addresses is very common. The advent of the Census Bureau's TIGER system has made geocoding a relatively low cost and widely available GIS function. However, professional geocoding services have developed to assist persons who are not comfortable in geocoding their own data or because of the high cost of updating digital maps based on TIGER in areas of changing population. Geocoding is the most basic of GIS functions because it transforms descriptive information into a format suitable for spatial analysis.

A GIS-based map may consist of multiple sources of data. The ability to combine multiple layers of information is known as the overlay function. An example of an overlay function is to place geographic boundaries (such as the outline of a town) on top of individual points (such as residences of DWI offenders). The points within each area can then be automatically counted to create rate-based maps such as those shown in Figure 1. To create rate-based maps from relevant point information, at least three layers of data are necessary (i.e., map of the points, a map with relevant boundaries, and census data on population). The ability to perform an intersection between separate maps, to aggregate data into meaningful geographic areas, and to link data to standard sources, such as census data, highlights some of the processing capabilities of GIS overlay functions, processes nearly impossible to accomplish by non-automated methods (see Wieczorek & Hanson, 2000, for an example using regions and mortality data).

One major contribution of GIS to prevention is its ability to provide useful visualizations of spatial data. The reclassification function of GIS allows the user to easily manipulate the number of categories or select specific information (e.g., crashes by time of day or day of the week) for display. Figure 1 shows how the reclassification function can assist in the targeting of prevention by reclassifying the same data to emphasize highest rate areas.

A second major contribution of GIS to prevention is that the technology enables the development of models of spatial patterns and interactions within and between populations and environments. These models require accurate information on the distance between individual objects (e.g., bars and traffic crashes) and their spatial relationships to one another. Distance and adjacency functions of GIS allow assessments of these relationships. Data generated from these assessments of spatial relationships can be exported from the GIS and used in spatial modeling software. Information about adjacencies of different geographic objects can be used to assess contributions of environmental features (e.g., bars) to problematic public health outcomes in surrounding areas (e.g., assaults) (Gruenewald et al., 1996; Lipton & Gruenewald, 2002). Other important GIS functions are based upon the assessment of distance relationships: neighborhood functions calculate the number of a specific characteristic (e.g., assaults) within a specific radial distance (e.g., 300 yards) of point features (e.g., bars). Buffer functions use the distance function on a complex feature such as the road network to identify points within a set distance of the feature (e.g., homes of DWI offenders within 400 yards of a bus line). These GIS functions can also be combined in complex ways to provide new insights for targeting prevention activities to areas with the greatest need (see Harding & Wittman, 1995, for additional applications in support of prevention).

Figure 1. Reclassification and targeting prevention



Spatial Clusters

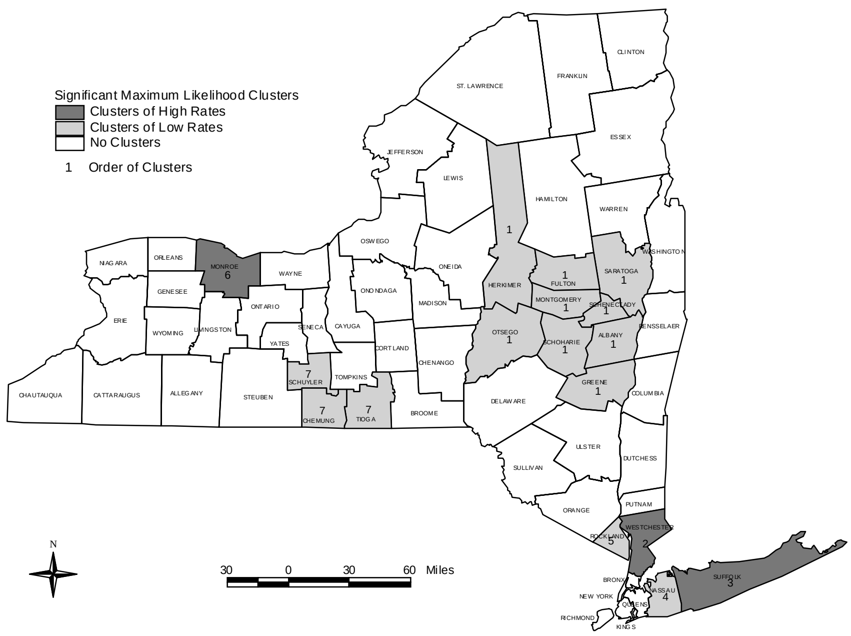
Spatial clusters are a greater than expected geographically close group of occurrences or events (e.g., deaths, crashes, alcohol outlets). Spatial clusters are a natural result of spatial dependencies in the data; by definition, spatially dependent data will have an uneven geographic distribution. The use of spatial cluster analysis was pioneered for finding cancer clusters, especially for rare cancers (Aldrich, 1990; Rickett, Savitz, Gesler, & Osborne, 1994). Specific spatial clustering techniques can be used with point or geographic area data and may also be used for space-time cluster analysis to examine temporal trends (Jacquez, 1994). Spatial cluster analysis is useful for identifying areas with significantly high or low rates of alcohol problems where services can be targeted, to identify new research questions (e.g, why are rates highest in certain areas), to empirically identify the appropriate scale of analysis in small area studies, and to examine the impact of interventions on communities over time (e.g., do the clusters change or disappear in response to interventions).

It is important to note that low rate clusters are as important to identify for prevention purposes as high rate clusters. High rate clusters clearly have problems that require prevention/intervention; however, low rate clusters may be areas at high risk of developing problems, especially if the low rate area is embedded in surrounding high rate areas. Characteristics of low rate areas may also provide important insights into factors important for prevention application in high problem locations. Figure 2 shows a map of spatial scan clusters of alcohol-related mortality in New York. Note that both high and low rate clusters are identified. The analysis of county-level data also shows the potential for regional level prevention approaches.

Other Spatial Analytic Techniques

Two additional approaches deserve mention in the context of spatial analysis for prevention. The first technique is a relatively simple method to control spatial autocorrelation in multiple regression analysis. Spatial autocorrelation, correlated measurement error between spatially adjacent units, is a substantial source of statistical bias in these analyses. The method is to use a GIS to calculate a generalized spatial potential for the dependent variable used in multiple regression of geographic area data (e.g., census tracts or zip code areas). Wieczorek and Coyle (1998) provide an example of this technique in the context of targeting the neighborhoods of DWI offenders. A generalized spatial potential (GSP) for the DWI rate was calculated for each tract by summing the ratio of DWI rates (V) and distances (D) to every other tract ($GSP_i = V_1/D_1 + V_2/D_2 + \ldots V_n/D_n$). By including the GSP as an independent variable in multiple regression, some aspects of biases due to spatial autocorrelation can be controlled (allowing more appropriate interpretations of model coef-

Figure 2. Significant spacial scan clusters of alcohol-explicit mortality



ficients and statistical tests). This approach is not as statistically complete as direct methods for assessing and controlling spatial autocorrelation (see Gruenewald et al., 1996), but it is a substantial improvement that may be implemented relatively easily.

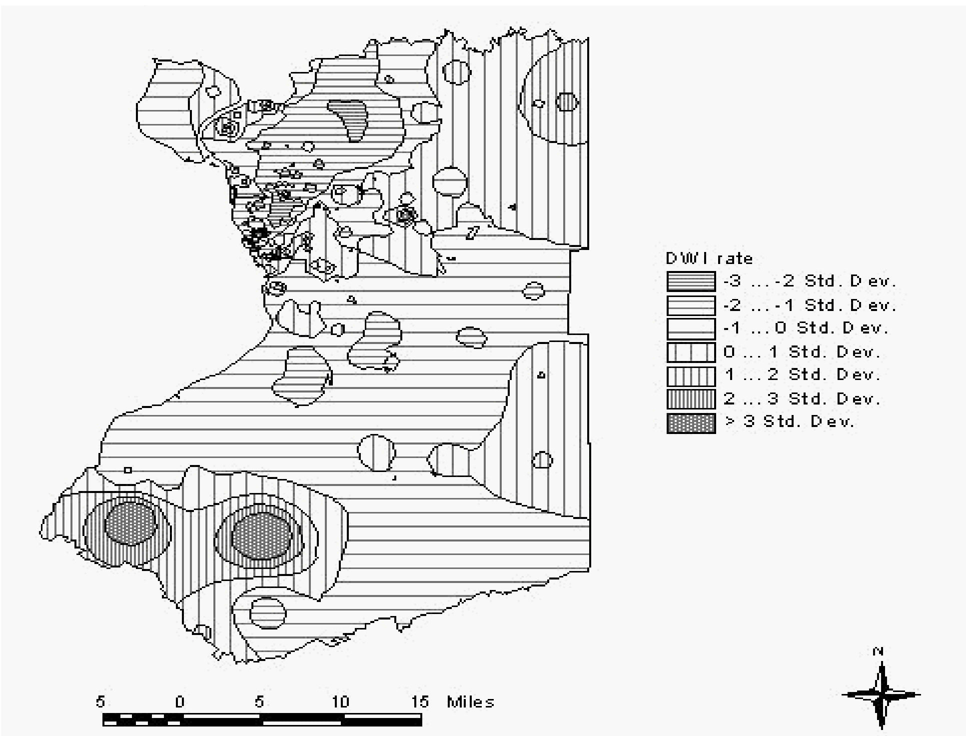
The second technique is the development of continuous surface models, or "kriging." Kriging is a modeling technique for spatial data that can be used to develop contour maps (e.g., maps that show lines of equal value such as DWI rates) from a limited number of assessment points or areas (Isaaks & Srivastava, 1989). These continuous surface models overcome a central limitation of area data; that actual rates within the geographic areas are unlikely to be as uniform as suggested in area maps. Kriging creates a continuous surface model by overlaying a grid of cells over the entire areas and calculating a weighted value for each cell based on the distance to surrounding centroids. The values calculated for the grid are then used to create a contour map. An example of kriging is provided in Wieczorek and Hanson (1997). Figure 3 shows a continuous surface model created by applying kriging to the specific tract rates used to generate Figure 1. A continuous surface model may provide a more realistic version of geographic variation that can be used to target prevention and assist in the overall planning of alcohol-related services.

SPATIAL ANALYSIS: AN EXAMPLE FROM VIOLENCE PREVENTION

Knowing where problem events take place is different from knowing why they take place where they do. And understanding the etiology of public health problems in different geographic areas requires knowing all the spatial technologies discussed to this point and their suitable application in spatial statistical analysis; the use of spatial data for the purpose of explicating the etiological dynamics of public health problems. This section will provide an example of one such application; a first approach to understanding the environmental correlates of violence.

Much of the criminology and public health literature is concerned about the determinants of violence in different community areas. A particular focus has been upon the role of alcohol outlets in violence. Similar to the work of Morenoff, Sampson, and Raudenbush (2001) and Baller, Anselin, Messner, Deane, and Hawkins (2001) our analysis includes demographic and socio-economic data so as to capture violence related to population characteristics (i.e., high unemployment, low rates of high school graduates, etc.). These population characteristics are analyzed in relation to the moderating effects of alcohol outlets on the production of violence. Moderation can simply be

Figure 3. DWI conviction rate continuous surface model



thought of as interaction of outlets with people (with a mix of characteristics). This outlet interaction could serve to increase or decrease violence, depending on the composition of population characteristics and outlet presence and type. Further, we examine spatial components of these moderating effects. Rates of violence may be affected by characteristics of populations living in adjacent areas (Gorman, Speer, Gruenewald, and Labouvie , 2001).

Our analysis assesses whether such spatial relationships exist and controls for spatial autocorrelations that may obscure the relationship between population characteristics and the production of violence. The sample comprised 766 zipcodes from four selected areas of California: Los Angeles, the Bay Area, Sacramento, and the northern section of the state. The first three areas are heavily urbanized while the last is quite rural. The three urban areas are heterogeneous with regard to ethnic, age and socio-economic composition, particularly in relation to the rural area that is more homogeneous in most population level measures. In this research, data are taken from three different sources: census data (1990), using a three-item scale representing concentrated disadvantage, immigrant concentration and residential stability, based on the work of Sampson, Raudenbush, and Earls (1997). Hospital discharge data for 1991, using patient home address contained information on assaults. California state data on alcohol outlets (1991) gave type and address of outlet.

The graphic presented in Figure 4 outlines the general conceptual framework that guides the analysis. We hypothesize that populations of people produce assaults at a given rate that is moderated by population characteristics (e.g., greater in places where there are more young people) and environmental characteristics (e.g., where there are more alcohol outlets). This adjusted rate may be further modified by the numbers and characteristics of nearby populations (not shown). It is assumed that errors in estimation are not independent, but rather are spatially autocorrelated, ρ_s.

In Figure 5, assaults per roadway mile are presented for each of the four regions. The difference in concentrations of assaults is apparent in this map, with greater densities occurring where there are greater densities of population. This is not, however, universally the case. For example, the western region of the Los Angeles basin appears to exhibit relatively greater assaults than expected from the population distribution observed. Overlays of zipcodes are represented on this particular map.

Table 1 and Figure 4 (note numbers in the figure) present the results of an analysis that includes the direct effects of population variables, alcohol outlets, and adjacent population density. Many, but not all, of the estimated coefficients from the model are significant. A direct interpretation of the coefficients of the model suggests that as population density increases, there is a reduction of approximately 2.16 assaults for every 10,000 persons in each zip code area. This rate, however, is that expected for an isolated population living in an area with no bars, restaurants or off-premise alcohol establishments (and rather unrealistically, with values of zero for the measures of population characteristics). This rate is moderated, however, by the presence of large populations in adjacent areas, the densities of restaurants, bars, and off-premise establishments, and local population characteristics. This rate is greater in areas where bar densities are greater and restaurant densities are less. This rate is further greater in areas where social disadvantage is greater, immigrant presence less, and residential stability greater. Finally, the rate at which local population density produces assaults is greater in areas surrounded by larger populations.

The results of this analysis indicate that it is possible to construct a conceptually well-framed spatial analysis of assault rates that explains to a substantial degree

Figure 4. Conceptual model and outline of model 3

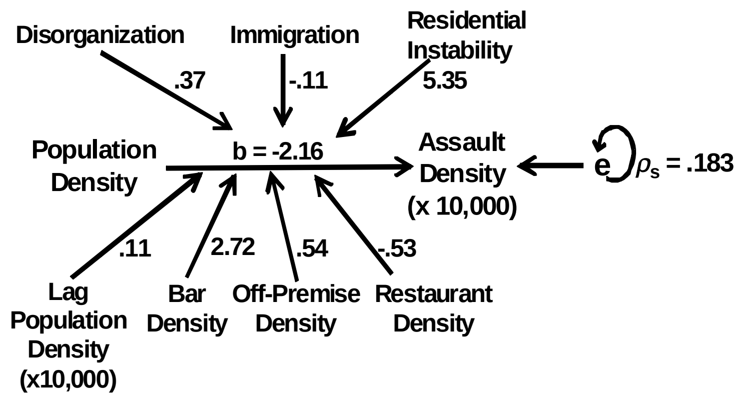


Figure 5. Assaults per mile of roadway

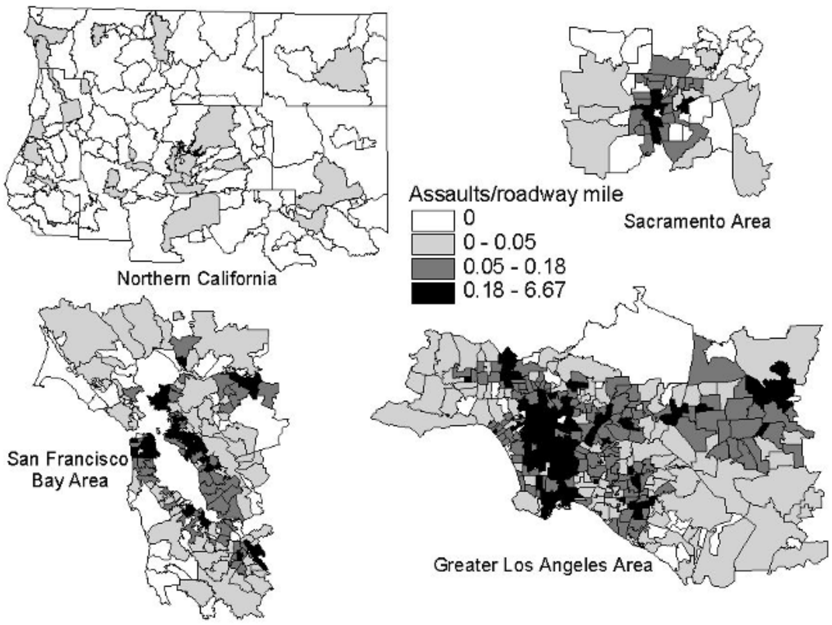

variation in rates of assault between places in California. Shifting from a representation that suggests that outlets on their own create violence to one that presents outlets as providing contexts for violence, the usual pattern of relationships of violence to environmental densities of alcohol outlets continue to be observed. The current analysis suggests, however, that alcohol outlets moderate rates at which violence is produced within areas and that these effects persist when controlling for spatial effects and other covariates related to the production of violence in local populations (Table 1). Notably, positive relationships continue to exist between bar and off-premise outlet densities and assaults, with no relationship to densities found for restaurants (Table 1 and Figure 4). At the geographic scale of the current study (zip codes), greater rates of violence are observed in stable non-immigrant areas with greater concentrated disadvantage. Bar densities, when controlling for other environmental or socio-demographic measures, are clearly connected to an increase in assaults. Thus, in this spatial example, beyond the obvious finding that denser populations have more assaults, we are able to observe important environmental effects that may be actionable in terms of prevention policy.

FUTURE TRENDS

Spatial analysis in public health is in its infancy. This is due to the rapid increase in computing power that has only in the last few years allowed for a more comprehensive development of mapping and spatial statistical techniques. There are two general areas of development that are interrelated: 1) GIS will become more intuitive and popular with more data becoming accessible (e.g., through geo-coding techniques that will become more consistent and "industry standard" through time); 2) Spatial statistical methods will become more available and more user friendly with statistical software companies offering spatial statistical solutions. As the comfort level grows with both mapping and spatial statistics, there will be an increasing demand for data and software that more capably handles research needs. This trend will only accelerate. The ability to add a spatial component to typical population level data opens up an entirely new approach toward thinking about public health issues. The individual will no longer be considered the sole unit of analysis, place will start to constitute its own unit of analysis or as complexly interacting with the individual. Further, as spatial methods improve we will be able to model the dynamic relationship between a target area and areas around the target. The above example is one of the first public health examples of such an approach. In the future, this dynamic modeling will become much more routine and essential to characterizing people in places. In addition, although not given in the above example, we will also have the ability to see how such dynamic spatial systems change over time. There is no methodological or theoretical obstacle to being able to, for example, analyze

Table 1. Associations of outlet densities with rates of assault hospitalizations (x 10.000)

how characteristics in one area, such as density of liquor stores, affects violence in an adjacent area and to see how this relationship changes through time.

SUMMARY AND CONCLUSIONS

In this chapter, we have described how spatial methods may be applied in a specific public health area, namely alcohol and alcohol-related problems. Although, an important area of research, it is by no means unique in allowing for spatial/ecological analysis. There are several important factors that should be considered when contemplating public health spatial analysis: 1) are there specific environmental features (such as the presence of bars or liquor stores) that might help explain an outcome (such as violence)? 2) Is there a dynamic relationship between individual behavior and environmental (area) setting? 3) Do environmental factors, such as alcohol outlets modify the relationship between socio-demographic factors and the outcome of interest (e.g., violence)? 4) Is there data available to support a spatial analysis? 5) Is the effect of adjacent areas likely to obscure relationships between exposures and outcomes (spatial autocorrelation)?

When studying alcohol-related problems, spatial analysis allows for the integration of disparate types of information into a meaningful story from both a public health and criminological point of view. The ability to put people in places in more than a purely descriptive framework signals a new generation in research that transcends traditional proscriptions against the use of ecological data. Further, measures of community health such as social cohesion take on a more fully realized form in a spatial analytical context. Indeed, given that most public health and criminological data is collected at a population level, spatial analysis allows researchers to more clearly observe population level effects for whatever measures chosen.

KEY TERMS

Geocoding: A generic term used to describe the GIS function of providing a specific location to descriptive data. Geocoding applies to point data (e.g., alcohol outlet) as well as to area data (e.g., assaults in a census tract).

Geographical Information Systems (GIS): The geographic use of data to develop maps and statistical relationships that help describe processes like the relationship between alcohol outlets and violence or vehicle crashes and alcohol outlets.

GIS Distance and Adjacency Function: The distance between individual objects (e.g., bars and crashes) and whether areas are adjacent to one another.

Kriging: A technique that can be used to develop contour maps (e.g., maps that show lines of equal value such as DWI rates) from a limited number of points or areas (which can be given a value at the centroid).

Overlay Function: The ability to combine multiple layers of information.

Spatial Analysis: Using geographic data to mathematically model the relationship between measures such those mentioned above, that is, alcohol outlets and violence.

Spatial Autocorrelation: The measure of similarity between values (for a given variable, e.g., income) located in space. Similarity of values in spatial proximity may indicate some underlying mechanism that is spatial in nature and contributes to the spatial pattern of the predictor variable. Controlling for spatial autocorrelation reduces statistical bias in parametric modeling.

Spatial Clusters: A greater than expected geographically close group of occurrences or events (e.g., deaths, crashes, alcohol outlets).

Spatial Modeling of Risk Factors for Gender-Specific Child Mortality

INTRODUCTION AND BACKGROUND

The global reduction of child mortality has been a priority of international and national organizations for the last few decades. Despite widespread global efforts to improve child survival, the latest UNICEF report on the *State of the World's Children 2000* (UNICEF, 2000) indicates that child mortality rates continue to remain higher in lesser developed countries (LDCs), and in some areas, girls continue to die at a greater rate than boys.

Matlab, a rural area of Bangladesh, shows child mortality has declined greatly in the last two decades (Figure 1). The rates have also declined in other rural areas across the country, though a lesser extent than in Matlab. The gender mortality differential that was notoriously high in Matlab in the 1980s virtually disappeared by the mid-1990s. Despite the large decline and elimination of gender disparity in child mortality, spatial variations in mortality continue to exist in Matlab (Ali et al., 2001). This variation most likely exists in the rest of Bangladesh, as well as in other less developed countries.

A multitude of social, demographic, economic, and environmental factors has been identified as global factors for contributing to the gender differential of child mortality in Bangladesh (Bairagi et al., 1999; Basu, 1989; Bhuiya & Streatfield, 1991; Chen et al., 1980; Fauveau et al., 1991; Islam & Ataharul, 1989; Koenig & D'Souza, 1986; Muhuri, 1995; Muhuri & Menken, 1997; Salway & Nasim, 1994). Measuring these social environments at a local geographic scale is important for identifying the environments that have a link with higher child mortality. The knowledge would eventually help in directing our effort towards the areas where it is essentially needed for child survival. Using a geographic information system (GIS), we attempted to define local level social environments, and to identify the environments that are influencing local level geographic variation of gender specific mortality in Matlab.

DATA AND METHODS

Child (one to four years) mortality for the periods 1984-86 and 1994-96 were chosen from Matlab demographic surveillance systems to examine the changes in local level spatial variation of mortality over a decade. The three-year periods were chosen to avoid temporal bias in the data.

The Matlab GIS (Figure 2) provided 7691 geographically referenced points of *baris* (a group of patrilineally households living in a geographic space). The mortality rates were smoothed at the point of *baris* by a spatially adaptive filtering that counted population (child) size close to 35. The choice of the specific population size is a trade- off between very low and very high smoothed data. Then, by using *kriging* (a method that is used to extrapolate the data at a regular spaced interval (Oliver &Webstar, 1990)) and contour mapping, gender specific surface maps of higher mortality were created for the two time periods. The temporal surface maps of each gender group were cross-classified, and an output map of each gender group was created (Figures 3 and 4) with the changes shown in: risk area remains risk area (R-R), risk

area changed to non-risk area (R-N), non-risk area changed to risk area (N-R), and non-risk area remains non-risk area (N-N). These maps were used as the dependant variable in a spatial regression model.

The data on social environment were smoothed using a fixed filtering of size 210 square meters. Here, our notion is that social environment beyond that distance has little influence on an individual's health outcome. The filtered data were used to create surface maps of the environment using the same kriging and contour mapping techniques. The social environment maps include educational status, population density, fertility rate, major occupations such as agriculture, fishing, and business, and Hindu (minority religious group) predominant areas. All of these maps were described in binary category: the dominant surface got the value "1"; else get the value "0". Finally, distance surfaces were created from the dominant surface of each of these maps; the closer a point to the dominated surface, the smaller the value of the point.

A distance map was created for embankment as an input variable of the model. The study site consists of two programmatic areas: non-intervention and intervention. The attribute of the former one was denoted by "1" and the latter one was denoted by "0". The map of accessibility to nearest health care was determined by cost (in time) distance. In computing the cost distance, rivers and canals were treated as barriers, and assigned their cost five times higher than that of the ground, which is based on waiting time and speed of movement through bodies of water.

Analytical Methods

Logistic regression was employed to determine predictive risk factors for gender-specific child mortality. The regression model takes the form:

$$\text{logit}(p)=\ln(p/1-p)=a+b_1x_1+b_2x_2+\ldots\ldots+b_nx_n$$

where p is the dependent variable expressing the probability of the outcomes.

RESULTS

The thresholds to define higher mortality areas for boys and girls are given in Table 1. The results of the multiple logistic regression show that the combined effects of the factors explain 11% of the total variations in predicting N-R for male children (Table 2). Being in an area outside an embankment is the most important factor in predicting risk for male child mortality, followed by areas of multiple groups of professionals. A high fertility rate also predicts spatial risk for male child mortality. Areas of higher population density show the lowest spatial risk among the factors. On the other hand, the same factors do not predict much (only 3% of total variations) in explaining N-N.

The results of the analysis for predicting R-R and R-N of male children are presented in Table 3. In the table, the model R-R shows that the comparison area predicts higher spatial risk for male child mortality. The effect of an

Models: Risk area remains risk area (R-R) and risk area changed to non-risk area (R-N).

embankment in predicting spatial risk is also significant. The distance to treatment centers, and areas dominated by multiple groups of professionals also influence risk areas to remain risk areas. Overall, the combined effect of the variables explains 16% of the total variation for male child mortality. Table 3 also shows that the factors included in predicting R-R do not predict R-N.

The results of regression analysis for N-R and N-N of female child mortality are given in Table 4. In this case, the combined effect of the factors explains 10% of the total variations in predicting N-R. The comparison area predicts the highest risk among all factors of mortality included in the model, followed by embankment and then cost distance to health care. However, modeling N-N with

Figure 1. Temporal pattern of gender-specific mortality in Matlab, Bangladesh

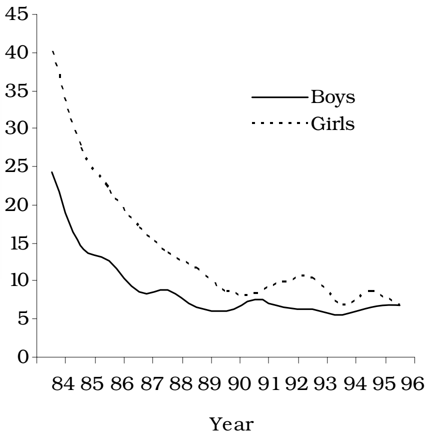

Figure 2. Matlab study area, Bangladesh

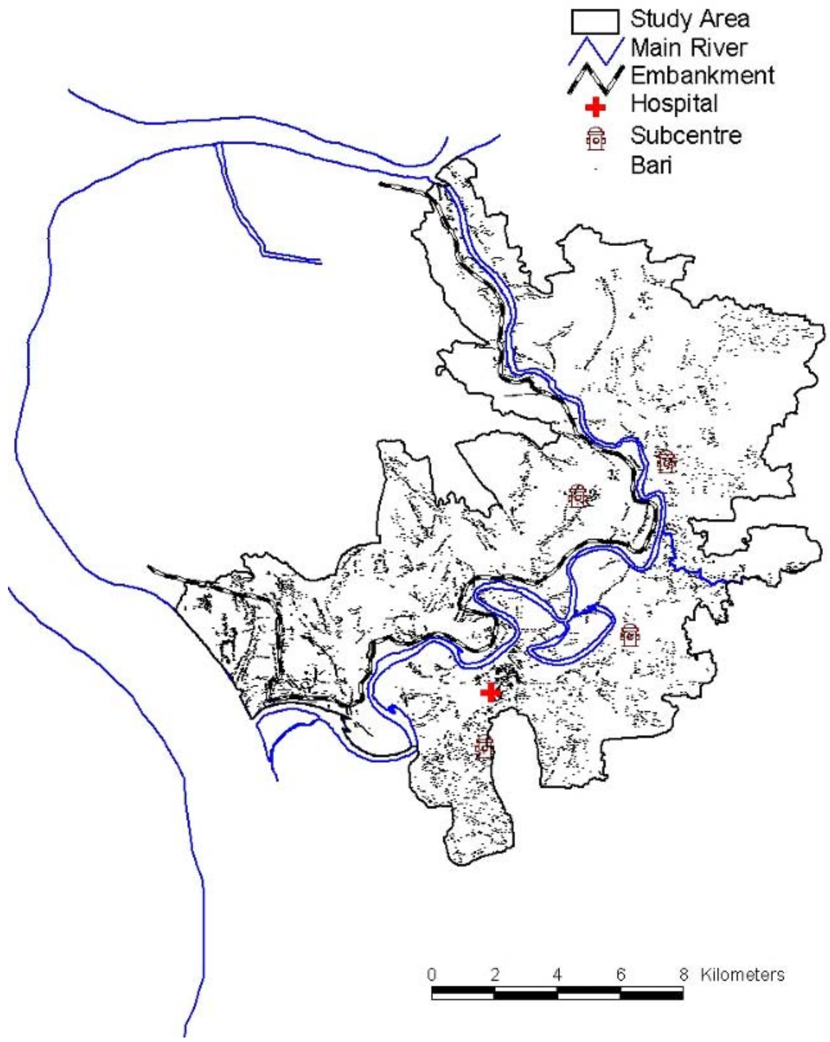


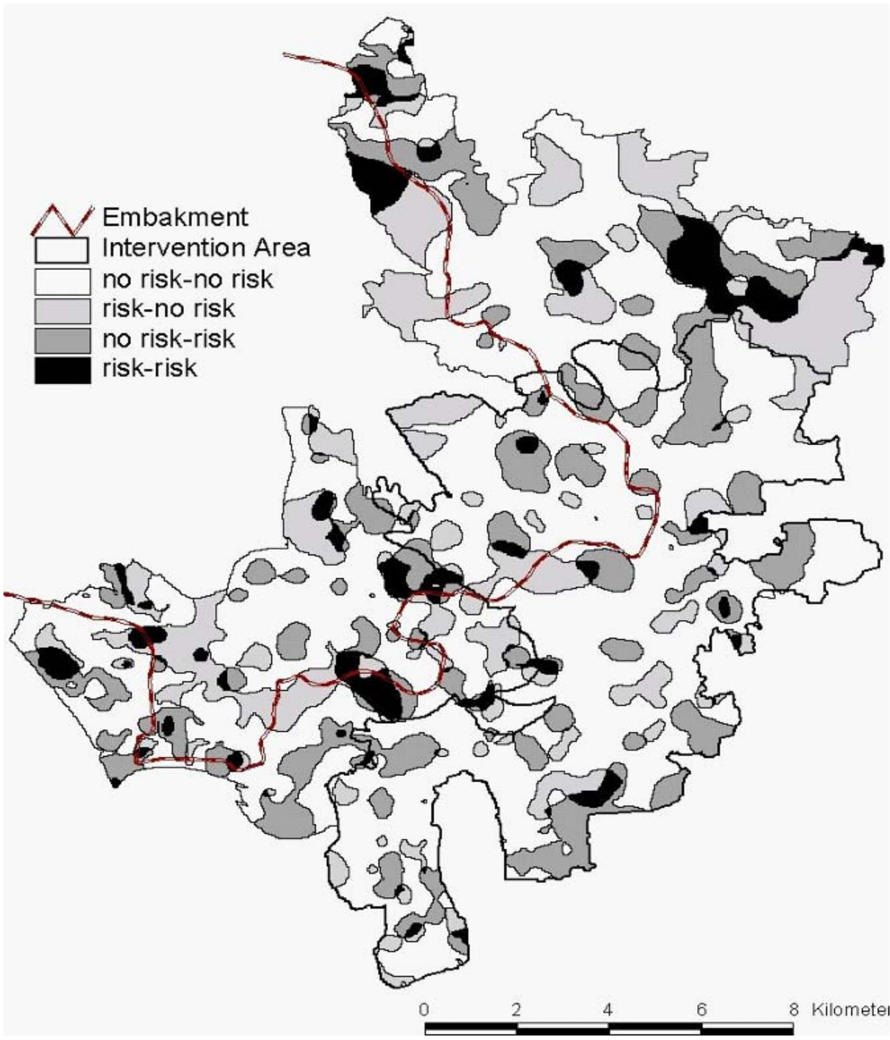
these factors has little impact on the outcome.

Table 5 presents the results of the analysis of R-R and R-N for female children. Of the factors, the comparison area influences the highest mortality, followed by multiple groups of professionals and embankment in predicting R-R. Educational status, distance to health care, and Hindu community explains 19% of the total variations in predicting R-R for girls. However, these factors did not show any influence in predicting R-N.

DISCUSSION AND CONCLUSION

The cross-classification analysis of temporal maps on higher mortality areas shows that although the mortality

Figure 3. Temporal change in risk for higher mortality of boys in Matlab, Bangladesh

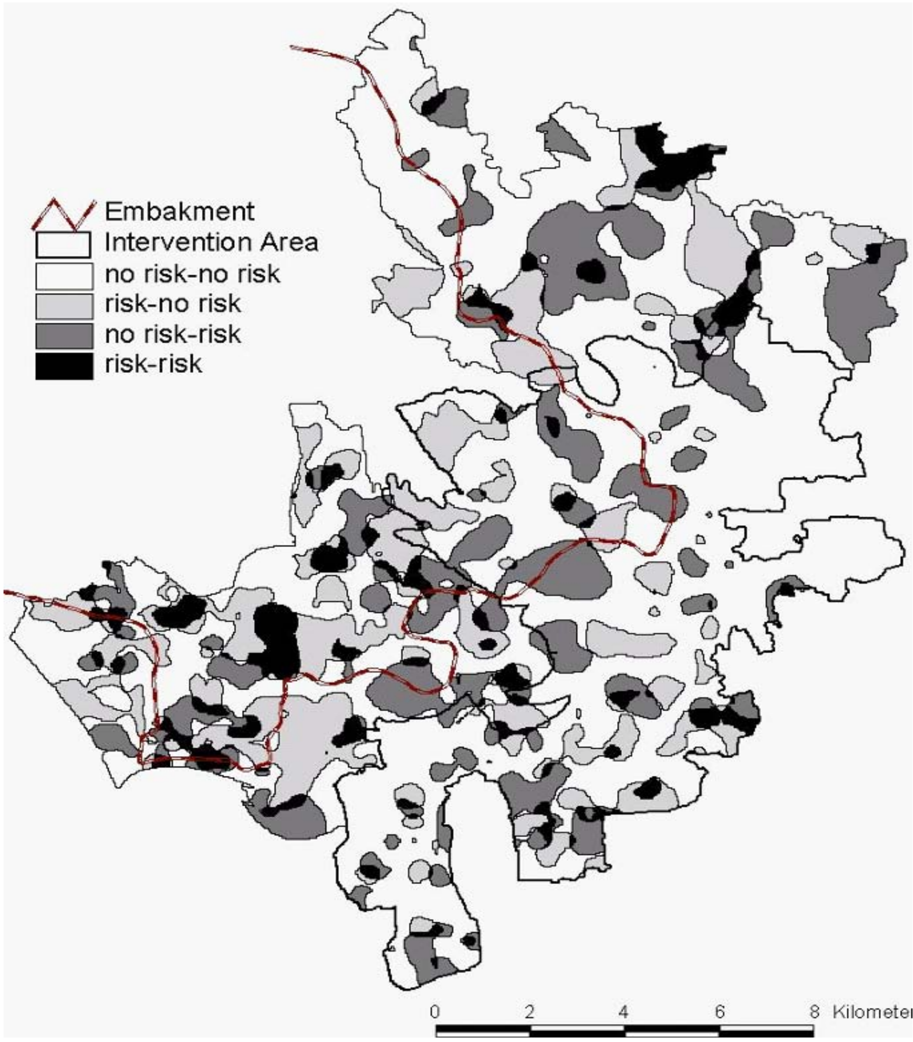


rates have declined over time, they have not declined consistently over the entire study area. About 25% of the areas that experienced lower child mortality in the 1980s shifted to higher mortality areas in the 1990s. On the other hand, a major part of the higher mortality area of the 1980s became lower mortality areas in the 1990s. The shift of one type to another type of mortality area resulted in the wide geographical variation of mortality in Matlab. The cross-classification of gender-specific mortality maps also indicates significant spatial variability in mortality between boys and girls. The variability implies that socioenvironmental processes of mortality for boys and girls are not the same.

The comparison areas where no intensive intervention was carried out, areas outside an embankment, areas distant from a treatment center, and the areas predominated by multiple groups of professionals predict a higher risk for male child mortality for both the models (N-R and R-R). The results are somewhat similar to previous studies (Myaux et al., 1997; Rahman et al., 1982). Areas of higher educational status, lower fertility level, lower population density, and non-Hindu areas predict spatial risk for male child mortality when modeling N-R.

The positive association of the areas of higher educational status with higher male child mortality indicates that neighbors' education status did not play any role in declining mortality to the extent that was anticipated. It suggests that education may not be a good predictor of mortality reduction, as it did not influence the outcome when modeling mortality with R-R. Similarly, areas of higher fertility show a negative association with higher mortality when modeling N-R, but do not show any signifi-

Figure 4. Temporal change in risk for higher mortality of girls in Matlab, Bangladesh



cant influence on mortality when modeling R-R for male children. The lower mortality in Hindu-dominant areas is perhaps related to their settlement pattern near the main river, which facilitates year-round easy access to treatment centers by their own boats. However, further study is required for a better understanding of the relationships between distance to treatment centers and mortality rates.

When predicting R-R and N-R for female children, areas of higher educational status, the comparison area of no intensive intervention, being outside an embankment, and greater distance to a TC were the common factors for higher mortality. Areas with multiple groups of professionals show a contrasting picture in predicting mortality when modeling the data with N-R and R-R for female. Predicting areas of mortality with the N-R model, the Hindu community shows a negative association for males and a positive association for female child mortality, indicating a gender bias in seeking health care services. According to Hindu laws, the daughters cannot inherit their father's property—this causes dowry systems existing during marriage. In many instances, the parents of a bride have to sell their assets to get the dowry demanded by the groom's family. Thus, a female child is not desirable in this society, and receives less attention by her parents.

Geographical analysis of health variation and its determinants have an important role in the design of equitable health programs. By modeling spatial risk, we identified several socioenvironmental predictors for gender-specific child mortality of this rural area of Bangladesh. A large amount of variation is left unexplained, modeling social environment for addressing gender-specific child mortality. This was anticipated, as we know that health is influenced by many factors (Wilkinson et al., 1998).

In conclusion, although this article describes the fact of the Matlab study area in Bangladesh, the findings of this study may provide insight into the socioenvironmental barriers of child survival elsewhere in the country and the region.

Contour Map: A line connecting points of equal elevation on topographic surface. The contour map depicts continuous distribution of the phenomena on earth surface.

Cross-Classification of Maps: A method that overlays two thematic maps of binary attributes to come up with an output theme containing attributes of both the themes.

Kriging: A geostatistical gridding method that produces visually appealing maps from irregularly spaced data. The estimates of kriging are unbiased and have minimum variance. The method is based on the assumption of spatial autocorrelation of data, and the autocorrelation structure (spatial distribution of the data) is addressed through variogram modeling. The underlying assumption of the variogram is that two observations close together are more similar than those further apart.

Matlab Demographic Surveillance Systems: A demographic surveillance system of about a size 200,000 population in a rural area of Bangladesh that has been maintained since 1966. The surveillance systems collect vital demographic data of the study population in a routine basis.

Social Environment: The environment created by human beings with their knowledge, attitude and behavior in a close neighborhood.

Spatial Filter: Spatial filtering is commonly used to enhance satellite imagery for visual interpretation. It involves applying a mathematical formula such as a mean or median to a group of pixels in a raster image using a moving window. It is also being used to create smoothed maps. The method can also be used to remove random noise caused by inaccurate records or mislocated cases.

Spatial Risk: The risk that is linked to locations in geographic space, usually from physical or social environment.

Surface Map: A three-dimensional portrait of the earth surface. Here, the third dimension is the spatial processes of social environment of the study area.

Speech and Audio Signal Applications

INTRODUCTION

With the development of the VLSI technology the performance of signal processing devices have greatly improved making possible the implementation of more efficient systems to storage, transmission enhancement and reproduction of speech and audio signals. Some of these successful applications are shown in Table 1.

BACKGROUND

The signal processing has played a very important role in the development of many speech and audio systems. This section presents a review of some of these successful applications.

Echo Cancellation for Long Distance Transmission

A very successful speech signal processing application is the adaptive echo cancellation used to reduce a common but undesirable phenomenon in most telecommunications systems, called echo. Here when mismatch impedance is present in any telecommunications system, a portion of the transmitted signal is reflected to the transmitter as an echo, which represents an impairment that degrades the system quality (Messershmitt). In most telecommunications systems, such as a telephone circuit, the echo is generated when the long distant portion consisting of two one-directional channel (four wires) is connected with a bidirectional channel (two wires) by means of a hybrid transformer. If the hybrid impedance is perfectly balanced, the two one-directional channels are uncoupled and no signal returns to the transmitter side (Messershmitt). However, in general the bridge is not perfectly balanced because the required impedance to properly balance the hybrid depends on the overall impedance network. In this situation, part of the signal is reflected, producing an echo. To avoid this problem an adaptive filter is used to generate an echo replica that is then subtracted from the signal to be transmitted. Subsequently the adaptive filter coefficients are updated to minimize, usually, the mean square value of the residual echo (Madisetti & Williams, 1998). To obtain an appropriate operation, the echo canceller impulse response must be larger than the longer echo path to be estimated. Thus assuming a sampling frequency of 8kHz and an echo delay of about 60ms, an echo canceller with 256 or more taps is required (Haykin, 1991). Besides the echo path estimation, another important problem is how to handle the double talk, that is, the simultaneous presence of the echo and the near speech signal (Messershmitt).

Table 1. Main audio and speech signal processing applications

- Echo cancellation in telecommunication systems
- Acoustic echo cancellation
- Noise canceling
- Active noise cancellation
- Adaptive equalization
- Narrowband speech coding
- Broadband audio and speech coding

Acoustic Echo Cancellation

A critical problem affecting speech communication in teleconferencing system is the acoustic echo. When a bidirectional line links two rooms, the acoustic coupling between loudspeaker and microphones in each room causes an acoustic echo perceivable to the users in the other room. The best way to handle it appears to be the adaptive echo cancellation. An acoustic echo canceller generates an echo replica and subtracts it from the signal picked up by the microphones. The residual echo is then used to update the filter coefficients such that the mean square value of approximation error is kept to a minimum (Perez- Meana et al., 2002).

Adaptive Noise Cancellation

The adaptive noise canceller is a generalization of the echo canceller in which a signal corrupted with additive noise must be restored or enhanced. When a reference

Table 2. Digital speech coding standards

Rate Kb/s	Application	Type of Coder	Year
64	Public Switched Telephone Network	Pulse Code Modulation (PCM)	1972
2.4	U.S. Government Federal Standard	Linear Predictive Coding	1977
32	Public Switched Telephone Network	Adaptive Differential PCM	1984
9.6	Skyphone	Multi-Pulse Linear Predictive Coding (MPLPC)	1990
13	Pan-European Digital Mobile Radio (DMR) Cellular System (GSM)	Regular Pulse Excitation Linear Prediction Coding (RPE-LPC)	1991
4.8	U.S. Government Federal Standard	Codebook Excited Linear Prediction Coding (CELP).	1991
16	Public Switched Telephone Network	Low Delay CELP (LD-CELP)	1992
6.7	Japanese Digital Mobile Radio (DMR)	Vector Sum Excited Linear Prediction Coding (VSELP)	1977

signal correlated with the noise signal but uncorrelated with the desired one is available, the noise cancellation can be achieved by using an adaptive filter to minimize the total power of the output of the difference between the corrupted signal and the estimated noise, such that the resulting signal becomes the best estimate, in the mean square sense, of the desired signal. This system works fairly well when the reference and the desired signal are uncorrelated among them. However, appropriate reference signals are not always available. To solve this problem several noise canceling algorithms have been proposed that are resistant to crosstalk situations. A different approach, developed by Dolby Laboratories, is used in the Dolby noise reduction systems in which the dynamic range of the sound is reduced during recording and expanded during the playback (Davis, 2002). Several types of Dolby noise reduction systems have been developed, including the A, B, C, and HXpro. Most widely used is the Dolby B, which allows acceptable playback even on devices without noise reduction. The Dolby B noise reduction system uses a preemphasis that allows masking the background hiss of a tape with a stronger audio signal, especially at higher frequencies. This effect is called psychoacoustic masking (Davis, 2002).

Active Noise Cancellation

A related problem to noise cancellation is the active noise cancellation that is intended to reduce the noise produced in automotive equipment, home appliances, industrial equipment, airplane cabins, and so forth. Active noise is achieved by introducing a canceling antinoise wave through an appropriate array of secondary sources, which are interconnected through an electronic system using adaptive systems with a particular cancellation configuration. Here, the adaptive filter generates an antinoise that is acoustically subtracted from the incoming noise wave. The resulting wave is captured by an error microphone and used to update the adaptive filter coefficients, such that the total error power is minimized. Some successful applications of this technology are the earphone, electronic mufflers, noise canceling in airplane cabins, and so forth (Davis, 2002; Kuo & Morgan, 1996).

Adaptive Equalization

Digital information transmitted through physical communication channels is often distorted due to the intersymbol interference (ISI), which is mainly caused by multipath propagation of the transmitted symbols and by the no ideal characteristics of the communication channels (Proakis, 1985). To overcome this problem, several methods have been reported in the literature such as transversal equalizers (TE), decision feedback equalizers (DFE), maximum likelihood sequence estimation (MLSE), and so forth (Proakis, 1985). Most of them perform fairly well with near stationary communication channels. However, they still present difficulties with mobile communication channels that fluctuate markedly with the motion of a vehicle, ground irregularities and changing environments, because in these situations the communication channels can be assumed to be stationary only within fractions of a wavelength, that is, over 4-5m in the 900-MHz band (Madisetti & Williams, 1998).

Table 3. Some of the most used wideband speech and audio coders

Coder	Bitrate	Application
• CCITT G.722	64 kbits/s, 56 kbits/s, 48 kbits/s	Speech
• Low Delay CELP	32 kbits/s	Speech
• Compact Disc	1.41 Mbits/s	Audio
• Perceptual Audio Coder	128 kbits/s	Audio
• MP3 (MPEG-1 layer III)	96 kbits/s	Audio
• Windows Media Audio	64 kbits/s	Audio
• VQF	80 kbits/s	Audio
• Mp3PRO	64 kbits/s	Audio
• OGG Vorbis	96 kbits/s	Audio
• WAV	10 MB/min	Audio

Speech and Audio Coding

Besides interference cancellation, speech and audio signal coding are another very important signal processing applications. This is because low bit rate coding is required to minimize the transmission costs or to provide a cost efficient storage. Here we can distinguish two different groups. The narrowband speech coders are used in telephone and some video telephone systems in which the quality of telephone-bandwidth speech is acceptable, and the wideband coders are used in audio applications that require a bandwidth of at least 20kHz for high fidelity (Madisetti & Williams, 1998).

Narrowband Speech Coding

The most efficient speech coding systems for narrow band applications use analysis-synthesis based method in which the speech signal is analyzed during the coding process to estimate the main parameters of speech that allow its synthesis during the decoding process. Two sets of speech parameters are usually estimated: The linear filter system parameters, which model the vocal track, estimated using the linear prediction method, and the excitation sequence. Most speech coders estimate the linear filter in a similar way, although there have been proposed several methods to estimate the excitation sequence that determines synthesized speech quality and compression rates. Among these speech coding systems we have the multipulse and regular pulse linear predictive coding and the codebook exited linear predictive coding (CELP) and so forth that achieve bit rates among 9.6 Kb/s and 2.4 kb/s, with reasonably good speech quality (Madisetti & Williams, 1998). Table 2 shows the main characteristics of some of the most successful speech coders.

Wideband Audio and Speech Coding

Higher bandwidths than that of the telephone bandwidth results in major subjective improvements. Thus a bandwidth of 50 to 20 kHz not only improves the intelligibility and naturalness of audio and speech, but also adds a feeling of transparent communication and eases speaker recognition. However, this will result in the necessity to store and transmit a much larger amount of data, unless efficient wideband coding schemes are used. Wideband speech and audio coding intend to minimize the storage and transmission costs while providing an audio and speech signal with no audible differences between the compressed and the actual signals with 20kHz or higher bandwidth and a dynamic range equal to or above 90 dB. Four key technology aspects play a very important role in achieving this goal: the perceptual coding, frequency domain coding, window switching and dynamic bit allocation. Using these features, the speech signal is divided into a set of non-uniform subbands to encode with more precision the components that are perceptually more significant and with fewer bits the perceptually less significant frequency components. The subband approach also allows the use of the masking effect, in which the frequency components close to those with larger amplitude are masked and then they can be discharged without audible degradation. These features, together with a dynamic bit allocation, allow significant reduction of the total bits required for encoding the audio signal without perceptible degradation of the audio signal quality. Some of the most representative coders of this type are listed in Table 3 (Madisetti & Williams, 1998).

Table 4. Other successful audio and speech applications

- Signal processing for hearing aids
- Virtual musical instruments synthesis
- Alaryngeal speech enhancement
- Cross-language voice conversion
- Speech and speaker recognition

FUTURE TRENDS

The audio and speech processing have achieved an important development during the last three decades; however, there still remain several problems that must be solved, such as to develop more efficient echo canceller structures with improved the double talk control systems. In adaptive noise canceling a very important issue that remains unsolved is the crosstalk problem. To get efficient active noise cancellation systems it is necessary to cancel the antinoise wave that inside into the reference microphone that distorts the reference signal to reduce the computational complexity of ANC systems, as well as to develop more accurate secondary path estimation. Another important issue is to develop low distortion speech coders for bit rates below of 4.8 kBits/s. Another important issue is to increase the convergence speed of adaptive equalizers, to allow the tracking of fast time varying communication channels. Finally, the speech and audio processing systems will also contribute to improve the performance of medical equipments such as hearing aids and alaryngeal speech enhancement systems, as well in security through the development of efficient and accurate speaker recognition and verification systems.

CONCLUSION

Audio and speech signal processing have been fields of intensive research during the last three decades, becoming an essential component for interference cancellation and speech compression and enhancement in telephone and data communication systems, high fidelity broadband coding in audio and digital TV systems, speech enhancement for speech and speaker recognition systems, and so forth. However, despite the development that speech and audio systems have achieved, the research in those fields is increasing in order to provide new and more efficient solutions in the previously mentioned fields, and several others such as the acoustic noise reduction to improve the environmental conditions of people working in the airports, in factories, and so forth. For example, research could be used to improve the security of restricted places through speaker verification systems, and improve the speech quality of alaryngeal people through more efficient speech enhancement methods. Thus it can be predicted that the speech and audio processing will contribute to more comfortable living conditions during the following years.

KEY TERMS

Adaptive Algorithm: Method used to modify the filter coefficients, online, in order to minimize the power of an adaptive filter output error.

Adaptive Filter: Linear system that modifies its parameters, minimizing some given criterion of the difference between its output and a given reference signal. Widely used in echo and noise canceling, equalization of communication channels, antenna arrays, and so forth.

Antinoise: Estimated replica of acoustic noise generated by an active noise canceller system, which is used to cancel an environmental noise.

Crosstalk: Interference present in a signal propagating through a communication produced by other signals present at an adjacent channel.

Double Talk: An interference produced when the speakers in both ends of a telephone line simultaneously speak. This phenomenon greatly disturbs the echo canceller performance.

Hybrid Transformer: Device used to connect two one-directional with a bi-directional channel, keeping uncoupled among them the two one-directional channels.

Narrowband Speech Signal: Speech signal with a frequency band equal to that of the telephone channel, that is, with a bandwidth of 300 to 3300 kHz.

Signal Compression: Signal coding that allows a reduction of the total number of bits required to represent a given signal without distortion or with negligible distortion.

Speaker Verification: Signal processing required for verifying the speaker identity by using his/her speech features.

Speech Enhancement: Signal processing performed in a given speech signal to improve its intelligibility and signal-to-noise-ratio.

Wideband Signal: Signal with a bandwidth wider than that of the telephone channel, usually between 50Hz to 20 kHz. This fact results in major subjective improvements.

Sponsorship in IT Project Management

David Bryde

INTRODUCTION

Since the 1970s academics and practitioners in the discipline of project management have sought answers to two inter-related questions: How is project success defined and measured? What are the influences on project success? To answer the first question people have studied project success criteria/key performance indicators. To answer the second, studies have focused on project critical success factors. Daniel (1961) introduced the concept of "success factors," stating that "in most industries there are usually three to six factors that determine success; these key jobs must be done exceedingly well for a company to be successful" (p.116). Approaches to the management of information have been established using Daniel's concept. For example, Rockart (1979) developed a Critical Success Factor (CSF) method for meeting the information needs of top executives. This method focused on understanding the objectives and goals of the company and the factors (CSFs) critical to their achievement, and establishing information systems to report on performance in these two areas. A key challenge has been to integrate the definitions and measures of success with CSFs, and in this respect work has been carried out to develop frameworks linking models of success criteria (the measures of success) with CSFs (see, for example, van Veen-Dirks & Wijn, 2002). The concept of CSFs has also been applied to project environments, with project CSFs being "those inputs to the management system that lead directly or indirectly to the success of the project" (Cooke-Davies, 2002, p. 185). Project management theory has also looked for a holistic answer to the questions of "How is project success defined and measured?" and "What are the influences on project success?", through the development of models linking project success criteria and project CSFs (Westerveld, 2002; Bryde, 2003).

BACKGROUND

Sponsorship as a Project Critical Success Factor

In respect of individual project CSFs, the importance of project sponsorship to achieving successful project outcomes has long been recognized. In a review of previous studies of CSFs, the sponsorship of projects by top management was highlighted as one of 8 major influences on success (Pinto & Slevin, 1987) and confirmed in a later study by the same authors as one of 10 influences (Pinto & Slevin, 1989). The importance of sponsorship is recognized through the distinction made between Macro CSFs, which involves activities in the realm of the sponsoring organisation and Micro CSFs, which are carried out in the domain of the project team (DeWitt, 1988). This crucial role of sponsorship has been identified in various manufacturing and service-related business environments, such as defence (Tishler et al., 1996), construction (Black et al., 2000), research & development (Pinto & Slevin, 1989) and management consultancy (Jang & Lee, 1998). Studies of project CSFs in IT environments have confirmed the pivotal influence of project sponsorship (see, for example, Bytheway, 1999; Fui-Hoon Nah et al., 2001; Procacinno et al., 2002).

ROLES OF PROJECT SPONSOR AND PROJECT MANAGER

A key step to delivering successful outcomes is gaining an understanding of the perspectives of all stakeholders to the project, including the sponsor and other stakeholders (Wright, 1998; Wateridge, 1995). In IT environments a lack of understanding has contributed to projects being unsuccessful. A failure by project managers to understand that users emphasized longer-term criteria relating to delivering workable systems, rather than short-term

Table 1. Role of the project sponsor

- Define the business benefit/requirements
- Understand the risks to benefit realisation
- Agree the project definition, including project objectives
- Develop the project strategy, including priorities
- Help define the project success criteria
- Specify any constraints
- Determine the relative priorities of cost, time and quality
- Monitor the project's business environment
- If necessary, re-define or cancel the project
- Monitor project performance
- Take delivery at project completion
- Monitor benefit realization
- Champion the project, including making resources availab
- Support the project manager in their role

Table 2. Role of the project manager

- Develop an effective working relationship with sponsor
- Deliver the project to time and cost, quality objectives
- Evaluate the risk profile and advise the sponsor
- Meet the defined project success criteria
- Manage the sponsor's and other stakeholders' expectations
- Define the project
- Build and lead the project team
- Monitor and control project progress
- Keep sponsor informed of progress and problems
- If necessary, recommend redefining or canceling of the project
- Hand over to the sponsor on completion

criteria linked to meeting time and cost objectives was a characteristic of IT projects perceived to be unsuccessful (Wateridge, 1998). A necessary step in achieving understanding is defining and delineating the roles and responsibilities of the project sponsor and project manager (Belassi & Tukel, 1996). *Table 1* summarizes the role of the project sponsor, drawing from the following extant literature: Snowdon (1976), Kliem & Ludin (1992, pp.163-169), Morris (1994, pp.188-189, 258-259), Briner et al. (1999, pp.65-67), Turner (1999, pp.50-53), and Hall et al. (2003).

The role of the project manager is summarized in *Table 2*. This table was constructed with reference to Gaddis (1959), Middleton (1967), Mantel et al. (2001, pp. 27-34), Anderson & Merna (2003), and Kendra & Taplin (2004).

FUTURE TRENDS

Although the importance of the sponsor to achieving project success is now well established (see earlier section "Background - Sponsorship as a Project Critical Success Factor"), and the roles of the sponsor and project manager are fairly well defined in theory, there are a number of critical issues that still need to be addressed in the future.

Awareness Among Project Sponsors of Their Role in Benefit Realization

Firstly, in some project organizations the role of the sponsor, especially in relation to their relationship with the project manager, is not clearly understood. This can lead to problems. For example, the responsibility for monitoring benefit realization (a sponsor role shown in *Table 1*) is often abdicated (without any corresponding authority) to project managers. However, it must be remembered that project managers only deliver products. A failure by the sponsor to fulfill their role in relation to benefit realization will lead to sub-optimal performance from the strategic perspective of the organisation.

Integration of Project Sponsor and Project Manager Perspectives

Secondly, there is the practical difficulty of integrating the perspectives of the sponsor and the project manager. The sponsor should be focused on the benefits of an IT system, its impacts on the organisation and its contribution to the company vision. However the project manager should be focused on delivering products, IS/IT functionality and how it will be used operationally. The need for such a strategic and tactical integration underpins work on the development of new models for the delivery of successful IT projects (for example, Byers & Blume, 1994; Ward & Elvin, 1999). Project managers, by their very nature, are backward looking and tend to focus on what has been done, what has been spent and the problems they have delivering the product. Sponsors, on the other hand, must be forward looking, trying to ensure that the benefits will be delivered and that nothing gets in the way of this.

Distinction Between "Executive" Project Sponsorship and the Sponsorship of Individual Projects

Finally there is the question of what is meant by executive sponsorship? There is a difference between the sponsorship provided by one person to an individual project and the sponsorship given by the organisation to enable a strategic vision to be linked with effective delivery of an IT system. This second type of sponsorship, which is a potentially new paradigm, involves company directors, senior executives and middle managers understanding how to lead and manage change. It focuses on ensuring the organisation is ready for a project to be undertaken. For example, an exploratory study showed that the greatest influence on achieving successful outcomes from business process re-engineering initiatives was the innovative capacity of the organisation (Teng et al., 1998). In a similar fashion, in the new paradigm, the sponsors of projects must ensure that organizational competency issues linked to project management, in such areas as programme management, benefits management, sponsoring individual projects, long-term planning and governance, training and support, are properly addressed.

To ensure success, most organizations intuitively restrict projects to a particular department or area, with little or no cross-functional interaction. This is purely a competency issue, largely relating to executive sponsorship rather than project management competencies. The line of least resistance is to manage work packages or small projects with limited impact on other areas of the business. However, successful organizations are able to manage complex and inter-related projects through effective sponsorship. It is not hard to appreciate that decisions made regarding a particular initiative will have ramifications in other parts of the business. These elements need to be managed by individuals who have the interests of the organisation as a whole at heart, rather than a specific initiative. Effective executive sponsorship achieves this. Project managers cannot be expected to manage these aspects as well as deliver the projects on time, to the right quality and at the right cost.

This executive sponsorship equates to demonstrating effective leadership and being a good corporate citizen. A real test of this is when projects get cancelled because the benefits cannot be realized or the risk profile is too great.

CONCLUSION

Over the last 30 years there has been much work carried out in establishing the importance of project sponsorship to achieving successful outcomes and in defining the theoretical roles of the project sponsor and the project manager. This has resulted in a "traditional" view of the project sponsor and project manager roles, which in the case of the sponsor tends to focus on the sponsorship of individual projects. A further element, which was discussed earlier, is that of "executive" sponsorship, which focuses on organizational competency issues linked to project management. Further study is needed to establish the extent to which the two types of sponsorship, "traditional" and "executive," are undertaken in practice and to explore the relationship between different types of sponsorship and project success. This will require the taking of a holistic view of "project success," that is, incorporating project management-related criteria (meeting cost, time and quality objectives), satisfaction-related criteria (for the customer, project team and user) and benefits-related criteria (tangible and intangible). From this holistic perspective it will be possible to investigate how variations in the nature of project sponsorship impacts on the different success criteria, with the most effective sponsorship being that which meets all three.

Another focus for future work in this area needs to be on how project sponsors and project managers work together to ensure that IT project performance is optimized and benefits are realized. To achieve such optimization it may also be necessary to redefine the sponsorship paradigm to focus on addressing organizational competency in project management. For this to be useful in terms of project management practice there will need to be accompanying education, training and awareness-raising activities of the broader sponsorship role.

KEY TERMS

Organisational Competency in Project Management: Ensuring that the organisation is in a ready state in order for projects to be able to deliver benefits.

Project Critical Success Factors: The influences on the success, or otherwise, of a project. A distinction can be made between the underlying factors, or causes of success or failure and the symptoms of an ineffective project management process. The lack of top management support is a typical project critical success factor, which can lead to a variety of symptoms, such as adequate resources not being made available to the project.

Project Manager: An individual with the responsibility of ensuring the project objectives are delivered.

Project Performance: The degree to which the project meets its overall objectives. This compares with *project management performance*, which is the degree to which the traditional objectives of cost, time and quality are met.

Project Sponsor: An individual or group with the responsibility and authority to ensure that the project benefits are realised.

Project Stakeholder: Any person or group that has an interest in the project. The interest could be in the project outcome, outputs or the project management process.

Project Success Criteria/Key Performance Indicators: The measures of success. The terms project success criteria and project key performance indicators are used interchangeably. Traditional measures are meeting cost, time and quality objectives. Other measures are linked to the attributes used by a stakeholder to judge whether their expectations have been met.

Standards for Web-Based Integration Adapters

Bill Karakostas
City University, London, UK

INTRODUCTION

EAI (enterprise application integration) refers to the plans, methods, and tools aimed at modernizing, consolidating, and coordinating the computer applications in an enterprise. Typically, an enterprise has existing legacy applications and databases and wants to continue to use them while adding or migrating to a new set of applications that exploit the Web, e-commerce, extranet, business-to-business (B2B) commerce, and other new technologies. Enterprise application integration is difficult mainly because there is no standard infrastructure for communication between heterogeneous systems. The four types of B2B and A2A integration challenges that most organizations encounter today are user-interface integration, application integration, business-to-business integration, and data integration.

- ***User-Interface Integration:*** Employees, suppliers, and other trading partners need fast access to relevant and up-to-date information without having to search through a variety of inconsistent Web sites, navigate dissimilar user interfaces, and enter multiple passwords. To access this information, users enter their chosen realm via a *portal* that presents a consistent interface to different applications.
- ***Application Integration:*** Business processes involving multiple applications require integration of application logic and functions or tasks. To facilitate this integration, applications must communicate to exchange important business information. If a business is interested in selling goods over the Web, then its Web store must be integrated with its payment server. Although these are two separate pieces of software, they are components of the same order-taking business process.
- ***B2B Integration:*** B2B integration is imperative for businesses to participate in a marketplace or other B2B-exchange environment. These environments bring together buyers and suppliers. When properly architected, a B2B-exchange platform can integrate catalog sources such as supplier-hosted catalogs, specialized vertical exchanges, and other online information.
- ***Data Integration:*** In most B2B e-commerce environments, data integration is essential, especially when data comes from many different sources. Data integration allows applications to work with data from different computing platforms, databases, and operating systems.

BACKGROUND

Distributed Web and component-based architectures will remain strategic for most organizations for the foreseeable future. Typical enterprise systems include ERP systems, mainframe transaction-processing systems, other technology legacy applications, or big hierarchical databases. For all these strategic systems, the challenge remains the same, that is, to make them full participants in Web-based e-commerce and business-to-business transactions.

To allow such systems to connect and interoperate on the Web, a number of protocols and languages such as XML (extensible markup language) and Java and software such as application adapters have been proposed. The section below discusses their role in application integration on the Web.

XML

Using XML to represent the data being exchanged between applications presents significant advantages from an integration viewpoint because it lets the receiving application obtain the data and metadata simultaneously. The application can more easily understand the data it receives as such data are *self-describing*. Once a system is given the metadata and data, a clear and fairly automated approach can be implemented for mapping the original data into the native format of existing applications using technologies such as the extensible style sheet language (XSLT). Implementing such automated mapping requires companies to provide dictionaries of their business terms. This can help a tool analyze new input document formats and try to associate elements to an existing internal system representation. Several current integration initiatives include XML, for example, OAG, Microsoft's BizTalk, and RossettaNet, which are attempting to establish business semantics and process standards on top of XML technology.

Integration Adapters

An integration adapter is a software component used to connect an application (called *target*) to another application (called *source*) in enterprise application integration so that data from the target application can be interfaced with and transmitted to and from the source application.

Application adapters serve to transform data back and forth from the native format of the target application to that of the source application. To establish a communication line between the two applications, the adapter acts as an agent on the source machine to send and receive requests from and to the target. The purpose of the adapter is to monitor the requests that are performed from a source application and is responsible by selecting an appropriate communication mechanism to send the data to the target for further processing. Adapters can be set to send notifications when an applications data has changed, publish data to one or many other applications, and subscribe to data topics from other applications. Adaptors hide the complexity of the application's programming interface. Traditionally, this task has been completed by bespoken in-house utility software that is costly to write and maintain.

Web-Based Integration Adapters

Web-based adapters link applications in one computing environment with information or logic in another computing environment using Web-based protocols for data and communications. Adapters typically consist of run-time components that reside on each end of the communication pipe between the platforms being integrated. An application that invokes an adapter to get access to required resources is often called the source, while the target is the remote data store or application logic the application accesses. Adapters use an application programming interface (API) that shields the application (and its developer) from the complexities involved in accessing data or resources. Historically, APIs have been proprietary, such as Microsoft's component object model (COM). Other common APIs are based on industry standards such as Java database connectivity (JDBC), J2EE (Java 2 Enterprise Edition) connector, simple object access protocol (SOAP), or open database connectivity (ODBC). Transmission control protocol/Internet protocol (TCP/IP) has become the de facto transport for Web-based adapters.

Requirements for Web-Based Adapters

Web-based integration adapters must fulfill certain requirements; that is, they need to be as follows.

- **Lightweight:** small-in-size components that use a simple XML-described API and contain no application logic
- **Standards based:** adapters need to implement open ubiquitous protocols such as XML-based protocols (e.g., SOAP) over HTTP (hypertext transfer protocol)
- **Scalable and reliable:** Adapters need to use XML document handling and interpretation, connector replication, standard exception handling, and management agents with logging and performance instrumentation.
- **Intelligent:** Intelligent adapters minimize message volume and overhead by being able to be interrogated and remotely, dynamically configured to work in the most appropriate way.
- **Supporting transactional integrity:** Adapters can deal with distributed transactions in either synchronous, two-phase commit mode, or asynchronous transaction-messaging mode.
- **Supporting event-driven functionality:** Adapters have historically been unidirectional and request driven. They can facilitate the execution of a database query, detect the presence of a message on a queue for processing, or initiate some remote application logic. However, emerging adapters are bidirectional and event driven by the target system.
- **Handling multiple protocols and data conversions:** Adapters must hide the mundane conversion routines required for information exchange between two disparate platforms. This includes conversion of data types and character sets, as well as network protocols.
- **Supporting schema and metadata support:** Adapters expose schema and metadata information through the source-side API to help ensure ease of use for developers and dynamic processing, especially with updating their configuration when changes occur in the data schema of the target system, without the need for manual intervention.
- **Easy to use for developers and management:** High-quality adapters provide considerable additional value by easing implementation and providing support for system management.

FUTURE TRENDS

An emerging standard, the J2EE connector architecture (JCA), defines an architecture and adapter behavior. JCA provides the ability to create an adapter once, then use it anywhere, including in most integration and application servers. The J2EE connector architecture specifies a standard architecture for integrating Java applications with existing enterprise information systems. The JCA standard proposed by Sun and its Java Community Process partners is part of Version 1.3 of the J2EE specification. JCA defines system-level contracts for connection management, and security and transactions between an application server and a connector. The connector implements these contracts in a way that is specific for the given application. The application server implements a standard connector API, referred to as the common client interface (CCI).

CONCLUSION

The lack of common business and technical architectures makes application integration across enterprises over the Web complex. It is not just the differences in data formats or interfaces, but the lack of common definition of the business concepts that underlies the different sources to be integrated. XML-based standard vocabularies aim to overcome the problem of semantic incompatibility by standardizing the definitions of business concepts, documents, and message exchanges in business-to-business exchanges. Application integration adapters simplify the integration process to the extent that it is almost automatic or requires as little development effort to implement as the off-the-shelf application packages that they can integrate. Adapters therefore minimize the need to deal with the interface details involved in communications between a variety of different source and target systems. Adapters are becoming more important as new service-oriented paradigms and technologies such as Web services are emerging. Ultimately, a greater number of existing Web applications will become service-based, leveraging service-oriented access standards such as the Web services description language (WSDL), SOAP, and other target systems. To convert such existing legacy applications to Web services, adapters will be required to translate Web services semantics into the proprietary calls the target legacy-system supports.

Emerging standards such as JCA, discussed in this article, have the potential to make adapters reusable across applications as well as across vendors. In addition, the JCA standard is likely to evolve, accounting for needs such as metadata and scalable communications.

KEY TERMS

Application Integration: Application integration is the process of bringing data or a function from one application program together with that of another application program.

Enterprise Application Integration: EAI (enterprise application integration) refers to the plans, methods, and tools aimed at modernizing, consolidating, and coordinating the computer applications in an enterprise. Typically, an enterprise has existing legacy applications and databases and wants to continue to use them while adding or migrating to a new set of applications that exploit the Internet, e-commerce, extranet, and other new technologies.

Integration Adapter: Data and application adapters (also known as data interfaces or data drivers) are native software objects that allow integration tools to retrieve data efficiently from complex, sometimes proprietary stores of information.

Integration Hub: A hub is a messaging server that exchanges important information between different applications so that the applications can interact in a meaningful way.

Messaging: In the context of an enterprise integration environment, messaging represents a communications system whereby important packets of information or messages are sent to and from queues by a software-based system known as a messaging server.

S

Staying Up-to-Date with Changes in IT

Tanya McGill
Murdoch University, Australia

Michael Dixon
Murdoch University, Australia

INTRODUCTION

Information and communications technology (ICT) has been changing rapidly over a long period, and this rate of change is likely to continue or increase (Benamati & Lederer, 2001a; Fordham, 2001). This rapid rate of change has produced many opportunities for organizations but has also brought with it many challenges (Benamati & Lederer, 2001b; Lederer & Mendelow, 1990). Among these challenges is the struggle for organizations to obtain personnel with the appropriate knowledge and skills in order to meet their ICT needs (Byrd & Turner, 2001; Doke, 1999). This is mirrored by the continual requirement for information technology (IT) professionals to keep up-to-date with the skills required by organizations (Benamati & Lederer, 2001a; Klobas & McGill, 1993).

Previous research has investigated the importance employers place on various skills and perceived deficiencies in these skills (e.g., Doke, 1999; Leitheiser, 1992; Nelson, 1991). While the call for improved communication and social skills has been consistent, the technical skills in demand have varied dramatically over time (Van Slyke, Kittner, & Cheney, 1998). Less has been written about students' perceptions of the importance of various ICT skills, though this was addressed in a study that compared Australian and American students' perceptions of ICT job skills (von Hellens, Van Slyke, & Kittner, 2000). This chapter provides an overview of a project that investigated the channels of information that ICT students use to keep up-to-date with employers' needs.

BACKGROUND

Given that the skills required by IT professionals change over time, IT professionals need effective methods to keep up-to-date. The methods used by IT professionals to keep up-to-date were studied by Klobas and McGill (1993). They identified the existence of a variety of information-gathering strategies and noted that while IT professionals tended to be diligent in their efforts to keep up-to-date, a majority found it difficult to do so. In a more recent study, Benamati and Lederer (2001a) investigated the coping mechanisms adopted by IT professionals and noted that many mechanisms were not successful.

If it is difficult for experienced IT professionals to keep up-to-date, it is likely that it is even more difficult for ICT students to do so. New graduates require marketable skills in order to gain good employment, but the skills most in demand change regularly. Little is known about how ICT students keep informed of employers' requirements or about how they ensure that they can meet those requirements. Yet, this knowledge would be of use to both educational institutions aiming to facilitate this process and to potential employers hoping to recruit students with the required skills.

Information about ICT skill requirements is available from a variety of sources in a variety of formats. Information sources include ICT suppliers, publishing companies, and universities. Formats include different types of publications, presentations, and personal contacts. The term "information channel" can be used to describe the various combinations of sources and formats of information.

HOW DO STUDENTS KEEP UP-TO-DATE?

Eighty-five information technology students at an Australian university were surveyed to investigate the channels of information that they use to keep up-to-date with employers' needs. Participants were recruited during class and completed a questionnaire on the spot.

The questionnaire listed information channels that may be used to keep up-to-date and asked participants whether they had used each channel within the last 3 months, and also asked them to rate the importance of each channel to them as a means of knowing what skills are in demand. Importance was measured on a 5-point scale ranging from (1) "Not important" to (5) "Vital." The initial list of channels of information was drawn from Klobas and McGill's (1993) report of the methods used by IT professionals to keep up-to-date with developments in

ICT. Several additional channels were included after consultation with industry contacts. Table 1 lists the information channels included in the questionnaire.

Overall, the students appeared to be diligent in their efforts to keep up-to-date with employers' skill requirements. The average number of channels used by the students during the previous 3 months was 3.8 (and the most common number used was 5). Thirteen students (15.3%) had not made any attempt to keep up-to-date during this period, and four (4.7%) had made use of all nine listed channels.

The information channels are ranked by frequency of use in Table 1. The most frequently consulted channels were newspaper employment and IT sections and Internet sources. University instructors had been consulted by about half of the participants during the previous 3 months. Other students had also been used as sources of information by a number of students (40%). This high level of use of other students to provide information about employers' skill requirements is understandable given the easy accessibility of other students (Klobas & McGill, 1993). Work colleagues were ranked seventh overall, but as only around a third of the participants had ICT work experience, this means that most of those with prior experience had consulted their colleagues (75% of those with prior ICT work experience had consulted their colleagues). The least used channels were books and vendor presentations. It is likely that students were conscious that information about employer skill requirements derived from books was not going to be sufficiently up-to-date to meet their needs.

Table 2 shows the importance rankings of the individual information channels. The most highly ranked information channel was Internet sources, such as the Cisco and Lucent sites. As well as being frequently used, newspaper ICT sections and employment pages were also considered very important (ranked two and three). University instructors were ranked fourth in importance, which was consistent with their frequency of consultation by students. Although other students were consulted by many students, they were not considered an important channel of information (ranked seventh). This suggests that students recognize that although other students are easily accessible sources of information, they are not necessarily accurate or reliable sources. Both books and vendor presentations were considered of low importance. In future research, it would be interesting to determine how well student perceptions match those of employers.

In addition to the items about methods used to keep up-to-date, participants were also asked several questions that addressed whether they believed they were, in fact, obtaining the skills employers required. A majority of participants believed that their degree would provide the skills employers require (67.1% "yes," 5.9% "no," and 27.1% "not sure"). This high level of confidence suggests that although only around 50% of students had consulted their instructors about employer skill requirements during the previous 3 months (and instructors were only given a medium ranking of importance), students implicitly accept that instructors know what skills students require. Industry certification was also seen as a very important means to ensure that students obtain the necessary skills (mean importance score was 4.18/5 for those students not yet working in the ICT industry). This is consistent with the results of a recent study on IT certification that found that students undertaking certification believe that the most important benefit of certification is that it provides "real-world" experience (McGill & Dixon, 2004).

Table 1. Information channels ranked by frequency of use

Rank	Information channel	Number	Percentage
1	Newspaper employment pages	56	65.9
2	Newspaper ICT sections	52	61.2
3	Internet sources (e.g., Cisco, Lucent)	47	55.3
4	University instructors	43	50.6
5	Other students	34	40.0
6	ICT magazines (e.g., *Packet Magazine*)	29	34.1
7	Work colleagues	24	28.2
8	Books	20	23.5
9	Vendor presentations	17	20.0

Table 2. Information channels ranked by importance

Rank	Information channel	Mean	Standard deviation
1	Internet sources (e.g., Cisco, Lucent)	3.55	1.40
2	Newspaper IT sections	3.38	1.44
3	Newspaper employment pages	3.30	1.30
4	University instructors	2.88	1.42
5	ICT magazines	2.62	1.43
6	Work colleagues	2.54	1.43
7	Other students	2.41	1.13
8	Books	2.24	1.34
9	Vendor presentations	2.13	1.32

Are There Demographic Differences in Use and Importance?

Patterns of use and perceptions of importance were further examined to determine whether gender, level of study, or previous ICT work experience had influence. Differences in use were explored using c^2 tests, and differences in importance were explored using independent sample *t*-tests. These factors had surprisingly little influence on patterns of use and perceived importance of information channels.

The first demographic factor considered was gender. No significant difference was found between the number of information channels used by male and female students. The only significant gender difference was for the levels of use and perceived importance of Internet sources. Male students used Internet sources more frequently and perceived them to be more important for keeping up-to-date with the skill requirements of employers.

The possible impact of previous ICT work experience was considered next. No significant difference was found between the number of information channels used by those with and those without previous ICT work experience. The only significant difference in usage of information channels was related to consultation with work colleagues and with other students. Those with previous work experience, not surprisingly, consulted with work colleagues more frequently, and they appeared to consider work colleagues a more important channel of information. Presumably, those with previous ICT experience would have received better quality information from their work colleagues than would those without ICT work experience who would have been receiving information from a pool of people with perhaps limited direct ICT experience.

Those without ICT work experience consulted other students more frequently, but there was no difference in perceptions of the importance of other students between those with and those without previous ICT work experience. As previously mentioned, this suggests that other students are consulted because of their accessibility rather than their credibility as sources of information. Those with previous ICT experience have other accessible sources of more credible information and, hence, do not rely so heavily upon other students.

The differences between undergraduate and postgraduate students were similar to those between students with previous ICT work experience and those without. This is consistent with postgraduate students being more likely to have previous ICT work experience than are undergraduates. (A total of 54.5% of postgraduates versus 22% of undergraduates had previous ICT work experience.) Undergraduate students consulted other students more frequently but did not value their information more highly. Postgraduate students also consulted work colleagues more frequently, but they did not value their input more highly. This finding differs from the added importance given to work colleagues by those with previous ICT experience, but the means are in the same direction, and the result may reflect the fact that 45.5% of the postgraduates did not have previous ICT work experience.

FUTURE TRENDS

The rapid rate of change in ICT is likely to continue (Benamati & Lederer, 2001b), and in fact, some authors believe that the rate of change is accelerating (Horn, 1999). This means that ICT students will continue to require access to up-to-date information about employers' ICT skill requirements. Given the increased role of electronic means of information dissemination (Bertot, 2003; Williams & Nicholas, 2001), it is likely that Internet sources of information will continue to be seen as the most important sources, and that their frequency of use will increase rapidly so that Internet sources will soon be the most frequently used. Greater broadband access will enable delivery of richer content and greater interactivity. Convergence of information technologies, such as notebooks, phones, and television, and the development of pervasive computing will provide even greater flexibility to students who wish to keep up-to-date with employer skill requirements.

CONCLUSION

New graduates require marketable skills in order to gain good employment, but as the ICT industry is subject to rapid change, the skills most in demand change regularly. The study described in this chapter investigated the approaches that a group of ICT students used to keep up-to-date with employers' skill needs. Overall, they appeared to be diligent in their efforts to keep up-to-date with skill requirements. The most commonly used channels were newspaper employment and IT sections and Internet sources. The same three channels were also rated most highly in terms of importance, with Internet sources being seen as most important.

Instructors were ranked relatively high in terms of both frequency of consultation and importance, and the results suggest an implicit confidence that the knowledge of instructors is up-to-date. While students have a wide variety of information channels available to them and do make use of them, instructors have a major role to play in providing up-to-date information about employers' needs. They need to be highly accessible and to ensure that their knowledge of employers' skill requirements remains current. Instructors should use studies of employers' requirements to assess their course offerings and to help guide their students.

KEY TERMS

Industry Certification: Certification involves passing a recognized standardized test (or set of tests) within particular subject areas. It intends to establish a standard of competency in defined areas. ICT industry certifications are designed to provide targeted skills that have immediate applicability in the workplace.

Information Channel: A term used to describe the various combinations of sources and formats of information.

Information Format: The arrangement and appearance of information. Format includes both the media used and the style of presentation.

Information-Gathering Strategies: The approaches and processes used by information seekers. Information-seeking behavior is influenced by previous experience, mental models, and preferences of information seekers.

Information Source: An organization or person from which information is obtained.

Information Technology Professionals: This is a term used to describe people for whom development and support of IT systems and related activities is their primary employment. The group includes people who design hardware, who develop and support information systems, and who train end users. It does not include people who use ICT in the course of pursuing other professions.

Information Technology Skills: All IT professionals require some computer skills; these may include particular programming languages or database skills or networking skills.

Stickiness and Web-Based Customer Loyalty

Guisseppi Forgionne
University of Maryland, USA

Supawadee Ingsriswang
BIOTEC and NSTDA, Thailand

INTRODUCTION

Between 1997-2003, Internet hosts grew from 16 million to over 233 million worldwide (www.isc.org, 2004). Of all Internet hosts, the number of commercial domain names (.com) is about 20.9%, which increased from 3.9 million in January 1997 to 48.6 million in January 2004.

Despite continued market growth, a number of Web sites have been unprofitable. From 2000 to 2003, at least 962 Internet companies ran out of money, shut down their operation and sold their businesses, with 63 5 of these enterprises operating in the business-to-consumer (B2C) sector (www.webmergers.com, 2004). Some notable failures were eToys.com, boo.com, bluefly.com, buy.com and valueamerica.com. An examination of the companies' IPO filings suggests that the collapses were caused by cut-price strategies, over-investment, incorrect expectations, and non-profitability. The surviving dot com companies in the new economy also have experienced financial difficulties. Amazon, a member of the Internet hall of fame, is still unable to generate a profit (www.webmergers.com (2004) REPORT). Surviving in the digital market has become a critical challenge for Web managers.

To face the business challenge, Web managers and marketers demand information about Web site design and investment effectiveness (Ghosh, 1998). Further, as the rate and diversity of product/service innovation declines and competition intensifies, Web managers must increase their efforts to improve their product/service and stabilize market shares. In this context, Donath (1999) and Hoffman (2000) noted the lack of, and the need for, research on Internet-related investment decisions. Web managers and marketers would benefit from reliable and consistent measuring tools for their investment decisions, and such tools are the focus of this article.

BACKGROUND

Since online consumers can switch to other Web sites or competitive URLs in seconds with minimal financial costs, most Web sites invest heavily in programs to attract and retain customers. The Web site's ability to capture consumers' attention is known widely as "stickiness".

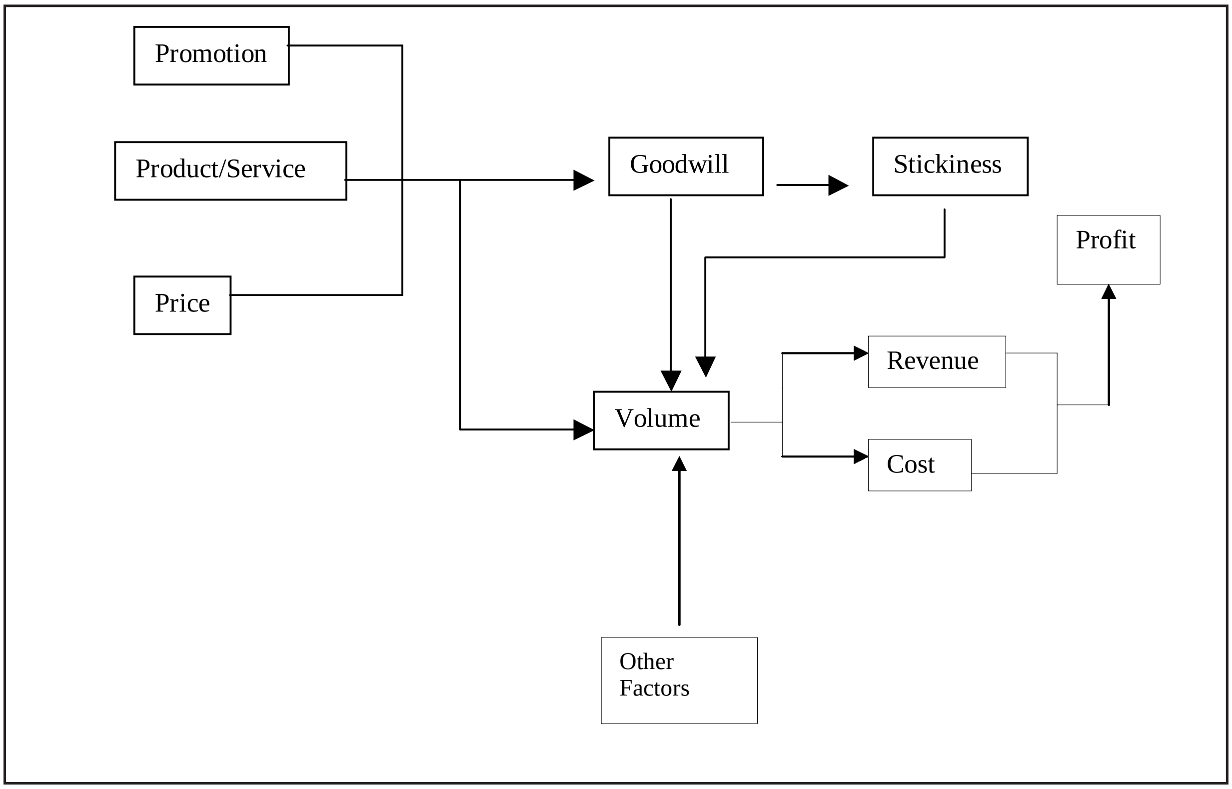
From one perspective (Rubric, 1999, p. 5), "The sticky factor refers to the ability of a web site to capture and keep a visitor's attention for a period of time." Likewise, stickiness can be described as the ability of the site in attracting longer and more frequent repeat visits or the ability of the site to retain customers (Anders, 1999; Davenport, 2000; Hanson, 2000; Murphy, 1999; O'Brien, 1999; Pappas, 1999). The various perspectives suggest that stickiness is similar to, if not the same concept as, customer loyalty.

On the other hand, Demers and Lev (2000) distinguished stickiness from customer loyalty. In their research, stickiness is represented by the average time spent at the site per visit, and customer loyalty refers to the frequency of visits. In fact, both the time duration and frequency of visits are mutually inclusive. The extension of the duration of relationships with customers is driven by retention (Reichheld, 1996). Loyal customers would visit the Web site frequently and remain with the site for a longer time period. In the process, these customers are generating not only traffic but revenue as well. Therefore, the goal of any Web site stickiness program must be to make customers loyal.

Customer loyalty has been a core element of marketing since the early eighties (Morgan & Hunt, 1994). The idea is to develop and maintain long-term relationships with customers by creating superior customer value and satisfaction. Enhanced customer satisfaction results in customer loyalty and increased profit (Anderson, Fornell & Lehmann, 1994; Reichheld & Sasser, 1990). Loyal customers, who return again and again over a period of time, also are valuable assets of the Web site. The ability to create customer loyalty has been a major driver of success in e-commerce (Reichheld & Schefter, 2000; Reichheld et al., 2000) since enhanced customer loyalty results in increased long-term profitability.

From marketing theory, then, stickiness can be viewed as the ability of a Web site to create both customer attraction and customer retention for the purpose of maximizing revenue and profit. Customer attraction is the ability to attract customers at the Web site, whereas customer retention is the ability to retain customer loyalty.

Figure 1. Stickiness conceptual model



MAIN THRUST

E-commerce customer loyalty, or stickiness, results from goodwill created by the organization's marketing efforts (Reichheld, 1996; Reichheld & Sasser, 1990), or

Stickiness = f(Goodwill) (1)
and Goodwill = f(Marketing Mix) (2)

By encouraging current and return visits, stickiness will influence the organizations' volume. Marketing theory also suggests that the mix of price (including switching costs to consumers), product/service (including site characteristics), and promotion (including banner and other Web site ads), as well as other factors (including consumer characteristics), will influence this volume (Page et al., 1996; Storbacka et al., 1994). Hence,

Volume = f(Stickiness, Promotion, Product, Price, Other Factors) (3)

Such volume will determine revenue, cost, and thereby profit for the Web site.

According to standard accounting practice and economic theory, profit is defined as the excess of revenue over cost, or

Profit = Revenue - Cost (4)

while revenue will equal volume multiplied by price, or

Revenue = Volume $\times$ Price (5)

According to standard accounting and economic theory, an organization's costs will have fixed and variable components, or

Total Cost = Fixed Cost + Variable Cost (6)

and variable cost will equal volume multiplied by unit cost, or

Variable Cost = Volume $\times$ Unit Cost (7)
with volume as defined in equation (3).

These marketing-economic-accounting-theory-based relationships are illustrated in Figure 1. This figure and equations (1) – (7) provide a conceptual model that specifies the manner in which the stickiness investment can contribute to an e-business organization's effectiveness by generating volume, revenue and profit. As such, the model identifies the information that must be collected to effectively evaluate investments in an e-commerce customer loyalty plan. These equations also provide a framework to objectively evaluate these plans and their impact on organizational operations and activities.

In practice, the model can be applied in a variety of ways. The general relationships can be used for strategy formulation at the macro-organizational level. In addition, the equations can be decomposed into detailed micro-level blocks with many variables and interrelationships. At this micro level, tactical policies to implement the macro strategies can be specified and evaluated.

EMPIRICAL TESTING

Much of the required model information is financial in nature. Such data are largely proprietary and therefore not readily available.

Summarized financial information is available from some Internet companies' quarterly (10-Q) and annual reports and other public sources. In particular, data were obtained from the 10-Q and 10-K reports for 20 Internet companies over the period 1999-2000. This pooled cross-section, time series data provided values for the revenue and marketing mix variables found in equations (1) - (7). Customer characteristics were proxied through demographic variables, and data for these variables were obtained from U.S. Census Bureau, Statistical Abstract of the United States for the period 1999-2000. The quarterly and annual report and Census data provided 120 observations to operationalize the model embodied in equations (1) – (7).

Goodwill, as defined in the economic literature (repeat business based on happy customers), is also not available from the annual and quarterly reports. However, an accounting measure of goodwill, amortization of goodwill and other intangible assets is available from the reports. Although not strictly the same concept as marketing goodwill, the accounting measure is likely to be correlated with economic goodwill and is thereby used as a proxy for economic goodwill (Chauvin & Hirschey, 1994; Jennings et al., 1996; McCarthy & Schneider, 1995).

No other data were provided by the available sources on a consistent and reliable basis. These data limitations reduced the variable list that could be used to operationalize the stickiness model specified in equations (1) – (7) to the list summarized in Table 1. To test the theory, then, it was necessary to use a truncated form of Figure 1's stickiness model.

Since, equations (4)-(7) in Figure 1's stickiness model are identities, only equations (1)-(3) must be estimated statistically from the available data. Prior research has shown that marketing investments in one period can continue to affect volume in subsequent periods (Hanson, 2000). Marketers call this phenomenon the carryover, lagged, or holdover effect. Stickiness investments and the marketing mix can be expected to create such an effect from new customers who remain with the Web site for many subsequent periods. Because of the data limitations, this important lagged effect had to be measured quarterly, and the carryover had to be restricted to one period. From the relationships in Figure 1, it seems reason-

$$\log(V_t) = \log(a_0) + a_1 \log(S_t) + a_2 \log(A_t) + a_3 \log(AI_t) + a_4 \log(GW_{t-1}) + z_1 \quad (8)$$

$$\log(S_t) = \log(b_0) + b_1 \log(GW_t) + z_2 \quad (9)$$

$$\log(GW_t) = \log(c_0) + c_1 \log(Q_t) + z_3 \quad (10)$$

Table 1. Variables with data

VARIABLE	DEFINITION
Volume **V**	total sales volume of the Internet company
Goodwill **GW**	amortization of goodwill and other intangible assets
Promotion **A**	sales and marketing expenditures
Product Quality **Q**	product development costs, which include research and development and other product development costs
Average Income **AI**	average consumer income
Stickiness **S**	number of unique visitors at the firm's Web site

Table 2. Results of the SUR estimation

Equation	MSE	R-Square	Adj. R-Square
Volume (equation 8)	0.3894	0.7408	0.7299
Stickiness (equation 9)	0.2190	0.1944	0.1862
Goodwill (equation 10)	3.5312	0.1296	0.1208

Table 3. SUR-estimated log-linear result

Variable	Volume (V_t)		Stickiness(S_t)		Goodwill (GW_t)	
	Est.	Prob>|T|	Est.	Prob>|T|	Est.	Prob>|T|
Constant	-5.09	.8282	8.74	<.0001	1.19	.0037
Stickiness	0.58	.0002				
Promotion	0.95	<.0001				
Income	0.09	.9885				
Lagged Goodwill	0.05	.1739				
Goodwill			0.17	<.0001		
Product Quality					0.77	<.0001

able to assume that the holdover will be expressed through the goodwill variable. Namely, goodwill in the previous quarter is assumed to affect revenue in the current quarter.

At time period *t*, the inputs may have joint, rather than independent, effects on volume. Moreover, elasticities (the percentage change in an output generated by a 1% change in an input) can provide useful information for policy making and analysis. To account for the nonlinearities, to facilitate the computation of elasticities, and to account for the carryover effect, equations (1) – (3) can be specified with the popular Cobb-Douglas production function, or in log-linear form in equations (8) – (10).

In equations (8) – (10), *t* denotes the considered time period (quarter), the a, b, c, and z labels denote parameters to be estimated, and the other variables are defined in Table 1. Price is excluded from the volume equation because data for the price variable are unavailable from the annual and quarterly reports.

Equations (8) – (10) below, form a simultaneous system of equations. Hence, simultaneous equation estimation techniques should be used to separate the effects of the marketing instruments and stickiness on volume. Otherwise, there will be a statistical identification problem.

There are several simultaneous estimation techniques that can be used to estimate the operational stickiness model (equations (8)-(10)). Using coefficients of determination, theoretical correctness of the estimated parameters, and forecasting errors as guidelines, the best results were generated by seemingly unrelated regressors (SUR). These results are summarized in Table 2 and Table 3.

Table 2 shows that the volume equation (8) has an R^2 = 0.74 and thereby accounts for about 74% of the variation in this variable. More importantly, Table 3 shows that the estimated coefficient of the stickiness variable in equation (9) is significant at the a = .05 level, suggesting that volume is significantly influenced by the stickiness of the Web site.

Table 2 shows that the operational stickiness model accounts for a relatively small percentage of the variation in stickiness and goodwill. Nevertheless, Table 3 indicates that goodwill has positive and significant effects on the stickiness of the Web site, while marketing instruments, such as product quality, also create positive effects on goodwill.

In short, the operational stickiness model provides reasonable statistical results. These results validate the theory that stickiness is an investment that, along with the marketing mix, will influence organizational performance. The results also indicate that volume will have inelastic responses to stickiness and promotion investments. That is, a 1% increase in such investments will lead to a less than 1% increase in volume. There are similar inelastic responses of stickiness to goodwill and goodwill to product quality.

FUTURE TRENDS

The analysis also suggests future research directions. First, it is useful to determine whether there are significant carryover effects from goodwill. If significant carryover effects are discovered, research should examine how long the investment in stickiness would contribute to the firm's short-term or long-term financial success. Second, research should evaluate what role competition plays in stickiness analysis. For example, additional research may examine how competitors' stickiness investments impact the firm.

Empirical e-commerce evaluations, then, will require the collection, capture, and retrieval of pertinent and consistent operational financial and other data for evaluation purposes. Appropriate statistical methodologies will be needed to estimate the proffered model's parameters from the collected data. Information systems will be required to focus the data, assist managers in the estimation process, and help such users to evaluate experimental customer loyalty plans. These tasks and activities offer new, and potentially very productive, areas for future research.

CONCLUSION

Figure 1's stickiness model shows how to measure the impact of online stickiness on revenue and profit, and the model also shows how stickiness and goodwill are related. The operational model can demonstrate and forecast the long-term revenue, profit, and return on investment from a Web site's products/services. In addition, the operational model: (a) provides a mechanism to evaluate Web redesign strategies, (b) helps Web managers evaluate market changes on custom loyalty plans, and (c) provides a framework to determine the "best" stickiness and other marketing policies.

In sum, in the e-commerce world, marketing still provides leadership in identifying consumer needs, the market to be served, and the strategy to be launched. Web managers must realize that desirable financial outcomes depend on their marketing effectiveness. With Figure 1's conceptual stickiness model, Web managers and marketers have a tool to evaluate their investment decisions.

KEY TERMS

Customer Attraction: The ability to attract customers at the Web site.

Customer Loyalty: The ability to develop and maintain long-term relationships with customers by creating superior customer value and satisfaction.

Customer Loyalty Plan: A strategy for improving financial performance through activities that increase stickiness.

Customer Retention: The ability to retain customers and their allegiance to the Web site.

Goodwill: The amount of repeat business resulting from happy and loyal customers.

Stickiness: The ability of a Web site to create both customer attraction and customer retention for the purpose of maximizing revenue or profit.

Stickiness Model: A series of interdependent equations linking stickiness to an organization's financial performance.

Storage and Access Control Policies for XML Documents

George Pallis
Aristotle University of Thessaloniki, Greece

Konstantina Stoupa
Aristotle University of Thessaloniki, Greece

Athena Vakali
Aristotle University of Thessaloniki, Greece

INTRODUCTION

The Internet (and networks overall) are currently the core media for data and knowledge exchange. XML is currently the most popular standardization for Web document representation and is rapidly becoming a standard for data representation and exchange over the Internet. One of the main issues is XML documents and in particular, storage and accessing. Among data management issues, storage and security techniques have a particular importance, since the performance of the overall XML-based Web information system relies on them. Storage issues mainly rely on the usage of typical database management systems (DBMSs), whereas XML documents can also be stored in other storage environments (such as file systems and LDAP directories) (Amer-Yahia & Fernandez, 2002; Kanne & Moerkotte, 2000; Silberschatz, Korth & Sudarshan, 2002). Additionally, in order to guarantee the security of the XML data, which are located in a variety of the above storage topologies, the majority of implementations also provide an appropriate access control. Most storage systems cooperate with access control modules implementing various models (Joshi, Aref, Ghafoor & Spafford, 2001), whereas there are few commercial access control products available. However, there are some standardized XML-based access control languages that can be adopted by most tools.

This article focuses on presenting an overview related to both storing and securing XML documents. Such an overview will contribute to identifying the most important policies for storage and access in Web-based information systems (which extensively use the XML as the data representation format). In addition, the most well-known related implementations are presented. A more integrated survey on these issues is presented in Pallis, Stoupa, and Vakali (2004).

BACKGROUND

Storage Policies

Several solutions for storing XML data have been proposed both in the scientific literature and in commercial products. In particular, storage approaches can be classified with respect to the type of system on which they rely and on the used XML document representation model. In this framework, they can be categorized as follows:

- Relational DBMS: Uses a collection of tables to represent both data and relationships among these data. More specifically, in order to represent XML data by using tables, it is necessary to break down the XML documents into rows and columns. The tree-like structure of XML facilitates both their decomposition and storage in relational tables. However, this process is expected to cause some performance overhead mainly due to the continuous translation of trees to tables (and vice versa). Due to its popularity, several models have been proposed to store XML documents in relational DBMSs (e.g., Bohannon, Freire, Roy & Simeon, 2002; Khan & Rao, 2001; Schmidt, Kersten, Windhouwer & Waas, 2000; Tian, DeWitt, Chen & Zhang, 2000; Zhu & Lu, 2001).
- Object-Oriented (O-O) DBMS: XML documents are stored as collections of object instances, using relationships based on the O-O idea (McHugh, Abiteboul, Goldman, Quass & Widom, 1997). O-O DBMSs have been designed to work well with object programming languages such as C++, C#, and Java. Inheritance and object-identity are their basic characteristics. However, O-O DBMSs cannot easily handle data with a dynamic structure since a new

class definition for a new XML document is needed, and the use of O-O DBMSs for XML document storage is not as efficient and flexible.

- Object-Relational (O-R) DBMS: The XML documents are stored in a nested table, in which each tag name in DTD (or XML schema) corresponds to an attribute name in the nested table. Currently, researchers have showed a steadily increasing interest in O-R DBMSs, since they combine both the benefit of the relational maturity and the richness of O-O modeling (Pardede, Rahayu & Taniar, 2004). In O-R DBMSs, the procedure for storing XML data to relation mapping is modeled by an O-R model. In this context, a number of transformation steps from the XML schema to an O-R model are presented (Widjaya, Taniar & Rahayu, 2004). More specifically, each nested XML element is mapped into an object reference of the appropriate type. Then, several mapping rules are indirectly embedded in the underlying model.
- Native XML DBMS: In this case, the XML document is the fundamental unit of storage (Kanne & Moerkotte, 2000). Therefore, a native XML database defines a (logical) model for an XML document, and stores and retrieves documents according to that model. In particular, two basic steps are involved for storing the XML documents on a native XML DBMS: (1) the data are described by its structure (DTD or XML schema), and (2) a native database XML schema (or a data map) is defined. However, the native XML DBMSs have not yet become very popular, since these systems must be built from scratch.
- LDAP Directories: XML documents are stored in LDAP directories which can be considered as a specialized database (Marron & Lausen, 2001). Therefore, the internal storage model of this database system is defined in terms of LDAP classes and attributes. More details about the architecture of the LDAP model and protocol are discussed by Howes, Smith, and Good (1999). Comparing the LDAP directories with the typical DBMSs, they are more widely distributed, more easily extended, and replicated on a higher scale.
- File Systems: Since an XML document is a file, a typical storage approach is to store it simply as a flat file. In particular, this approach uses a typical file-processing system, supported by a conventional operating system (as a basis for database applications). The wide availability of XML tools for data files results in a relatively easy accessing and querying of XML data (which are stored in files). By using a flat file for XML data, we have faster storing (or retrieving) of whole documents. However, this storage format has many disadvantages, such as difficulty in accessing and updating data, since the only way to accomplish this is to overwrite the whole file (Silberschatz et al., 2002).

Access Control Policies

In order to protect XML files, we need to design authorizations defining which client (subject) can access which protected resource (object) and under which mode. Since XML files are organized according to DTDs or XML schemas, protected resources can be both XML files, DTDs, or schemas, or parts of them, such as a specific element or even attribute.

The basic access control models are:

- Discretionary Access Control (DAC): Every subject and object is enumerated, and there are authorizations connecting each subject and object. The owner is responsible for defining policies in order to protect his/her resources, and (s)he can also define who is going to be assigned some access privileges. It is the most flexible and simple access control model. However, it does not provide high levels of protection, and it cannot be used in case multiple security levels are required.
- Mandatory Access Control (MAC): This is based on the existence of one central administrator responsible for the definition of policies and authorizations. It is expressed with the use of security labels associated with both subjects and objects. Every object has a classification label defining its sensitivity, and each subject is assigned a clearance label defining its trustworthiness. This model is more secure than DAC, but it cannot be used in wide distributed Internet-based environments. Therefore, their usage is gradually decreased.
- Role-Based Access Control (RBAC): The most widely used access control model in modern environments (Sandhu, Coyne & Feinstein, 1996). Subjects are assigned roles that are categorizations of subjects according to their duties in an organization. Thus, every subject is assigned roles that in their part have some authorizations. Therefore, the number of the needed policies is highly decreased. RBAC model is a super set, since it can also express DAC and MAC policies. It is appropriate for distributed heterogeneous networks offering Internet access. Moreover, it is recommended to protect hypertext documents (HTML or XML files). Lately, a generalized RBAC model has been proposed where objects and environmental conditions are assigned roles (Moyer & Ahamad, 2001).

FUTURE TRENDS

Implementations

Some of the most popular database vendors (like IBM, Microsoft, and Oracle) have developed (mainly) database tools for the storage of XML documents, and several storage techniques have been adopted in order to maximize functionality and performance. Furthermore, for reasons of integrity, the majority of the DBMSs are supported by access control mechanisms.

In general, the most well-known software tools that employ XML document storage and access control can be categorized in the following types of databases:

- XML-Enabled DBMSs: These provide various interfaces for extracting structured data from XML documents and then to be stored in DBMSs (according to their model). Table 1 presents the basic products of such an approach.
- Native XML DBMSs: XML documents are stored in XML internally in the database. Table 2 shows some of the most popular DBMSs.

Currently, the most widely adopted technology to enforce the security guarantees of the XML-based databases is the Microsoft (MS) .NET platform. MS .NET has been recently proposed and has been adjusted to support XML Web Services. Its security mechanism is adopted by MS SQL Server 2000 (Rys, 2001), Oracle 9i, and DB2, which have been designed to cooperate with Microsoft .NET technology.

All of the above storage systems can be supported by access control modules. Most of them support the Microsoft .NET access control framework. The idea of protecting XML files is quite new, and therefore most of the implemented systems still belong to the scientific literature and they have not stepped into the market.

The core of every access control mechanism is a language used for expressing all of the various components of access control policies, such as subjects, objects, constraints, and so forth. To date several languages have been proposed. Since XML is a structured language, it can be used in the definition of access control issues, such as roles, policies, and authorizations. Therefore, the most well-known general-purpose XML-based access control languages are:

- XACML (eXtensible Access Control Markup Language): This is an OASIS standard that defines both a policy language and an access control decision request/response language (both written in XML) (www.oasis-open.org/committees/xacml/repository). The policy language is used to describe general access control requirements, and has standard extension points for defining new functions, data types, combining logic, and so forth. The request/response language permits forming a query in order to ask whether a given action should be allowed (or not), and to interpret the result that defines the response.
- XrML (eXtensible rights Markup Language): This is a language for digital rights management (Wang et al.). By using XrML, the owner of a digital resource can specify who can use the resource (principal) and under what circumstances (constraints). The owner thus produces licenses containing such information that are then given to the appropriate principal. Since XrML is mainly used for protecting digital media, it contains schemas defining the metadata of such resources, such as audio or video files. Of course, it can be easily extended for controlling access to any other type of resource.

Table 1. Storage in XML-enabled databases

Product	DBMS Model	Storage
Oracle 9i *technet.oracle.com*	Object-Relational	XML documents are stored as relational tables.
MS SQL Server 2000 *www.microsoft.com*	Object-Relational	Each XML document is stored as a relational table, and an element is created for each row.
IBM's DB2 *www-4.ibm.com*	Object-Relational	XML documents are stored as relational tables.
XIS *www.exceloncorp.com/xis/*	Object-Oriented	XML documents are stored in a B-tree-like structure.
Lore (McHugh et. al., 1997)	Object-Oriented	XML documents are stored using an Object Exchange Model (OEM).
SHORE (Hess, Schulz & Brossler, 2000)	Object-Oriented	This stores information extracted from XML documents using a variant of R-trees and B-trees structure.

S

Table 2. Storage in native XML databases

Product	Storage Model
NATIX (Kanne & Moerkotte, 2000)	Tree structure: XML documents are split into sub-trees (basic storage and query units) based on certain criteria.
SODA *www.cse.unsw.edu.au/~soda/*	Tree structure: XML documents are stored in a single tree, which preserves all XML information.
Xyleme *www.xyleme.com*	Tree structure: XML documents are stored as trees until a certain depth where byte streams are used.
Ipedo *www.ipedo.com/html/products.html*	Collection structure: XML documents are organized into collections (like directories), which can be typed or un-typed.
eXist *exist.sourceforge.net*	Collection structure: XML documents are stored using a DOM-tree (built from SAX-events) and are organized into hierarchical collections, similar to storing files in a file system.
Tamino (Schoning, 2001)	Collection structure: Each XML document is stored in exactly one collection.
Xindice *www.dbxml.org*	Collection structure: Each XML document is stored in at least one collection (a collection can be created either consisting of documents of the same type, or a single collection can be created to store all documents together).

Table 3. Examples of access control tools

Product	Type	Access Control
XENA (Tan & Zhao, 2000)	Non XML-Based	Centralized tool protecting XML repositories using relational database technology.
Author-X (Bertino, Castano & Ferrari, 2001)	XML-Based	Java-implemented tool, supporting varying security granularity levels. PULL and PUSH dissemination technology.
ACP (Access Control Processor) (Damiani, De Capitani di Vimercati, Paraboschi & Samarati, 2000)	XML-Based	Decentralized system supporting distributed XML repositories by using both local and global authorizations.
ProvAuth (Kudo & Hada, 2000)	XML-Based	Access control environment where access is allowed with some provisions. It uses XACL.

- ODRL (Open Digital Rights Management): This is a language used for Digital Rights Management (DRM) in open environments (odrl.net/1.1/). It can express rights for protecting any digital content, like electronic publications, digital images, audio and movies, learning objects, computer software, and so forth.

Except for the languages, research has to present several access control tools protecting XML files. Those can be categorized into non XML-based and XML-based. Table 3 contains some of the tools belonging to both categories.[1] The only tool using a standardized access control language is ProvAuth (Provisional Authorizations) (Kudo & Hada, 2000). As its name suggests, access is allowed to users only after (or before) the execution of some provisional actions, like logging the session, encrypting the view of a protected document, and so forth. To support such functionality, a specific-scope XML access control language (XACL) has been introduced which is part of the IBM XML Security Suite. Due to its extensibility and flexibility, the model can be integrated into a conventional Web application consisting of clients and servers.

CONCLUSION

This article has presented an overview for storage and access control of XML documents. It is important to indicate that no definite guidelines have yet been proposed for selecting an optimal solution when storing and securing XML documents. In order to improve the management of XML documents, some issues should require further research. In particular, the storage of XML documents may be improved by using some data mining techniques (e.g., specific clustering algorithms). Furthermore, the XML management techniques should further extend existing access control policies, in order to improve the security in XML documents accessing. Finally, the commercial DBMSs should be extended to support more sophisticated storage and access control techniques such as integrated methods for locating and accessing dynamic XML documents.

KEY TERMS

Database Management System (DBMS): A collection of interrelated data that is called a database, and a variety of software tools for accessing those data. The three leading commercial DBMSs are: Oracle 9i, IBM DB2, and Microsoft SQL Server.

Discretionary Access Control (DAC): A model where the owner is responsible for defining policies in order to protect his/her resources and (s)he can also define who is going to be assigned some access privileges.

DTD: A set of rules defining the element types that are allowed within an XML document, and specifying the allowed content and attributes of each element type. Also defines all the external entities referenced within the documents and the notations that can be used.

Lightweight Directory Access Protocol (LDAP): A protocol definition for accessing specialized databases called directories. An LDAP directory is organized by a simple "tree" hierarchy.

Mandatory Access Control (MAC): A model expressed with the use of security labels associated with both subjects and objects.

Native XML Database: A database that defines a model for an XML document (as opposed to the data in that document), and stores and retrieves documents according to that model. At a minimum, the model must include elements, attributes, PCDATA, and document order. Examples of such models are the XPath data model, the XML Infoset, and the models implied by the DOM and the events in SAX.

Role-Based Access Control (RBAC): An access control model where subjects are organized into roles defining their duties in an organization or environment.

XML Document: A document consisting of an (optional) XML declaration, followed by either an (optional) DTD or XML schema, and then followed by a document element.

XML Schema: An alternative to DTDs; a schema language that assesses the validity of a well-formed element and attribute information items within an XML document. There are two major schema models: W3C XML Schema and Microsoft Schema.

Strategic Alignment of Organizational Strategies

Sam Lubbe
University of KwaZulu-Natal, South Africa

INTRODUCTION

Alignment is important to all organizations. This is confirmed by King (1995) but it is not yet clear how to achieve harmony between business strategy, information technology (IT) and e-commerce and what the impact of this alignment would be on an organization. In the past, the IT department was responsible for planning, development and management of information systems (IS). With the convergence of e-commerce, gaining an understanding of how e-commerce and IT may be jointly employed to support organizational strategies is important for managers (it is acknowledged that some organizations place e-commerce in the IT department, while others have it as a separate department). Good practice will ensure that the organization will find the best place for it. It is, however, good policy to split e-commerce and IT staff while aligning strategies. It is necessary to align the strategy for the e-commerce department as well. This alignment could be either "lawful" (wishes to create and protect) or chaotic (wishes to destroy).

Strategic alignment is defined by Papp and Fox (2002) as the use of IT in the integration and development of business strategies and corporate goals. Alignment is a dynamic process that requires close, continual assessment (because the goals keep on moving) and cooperation between achieving competitive advantage and surviving.

This article therefore discusses the changing environment of the organization in terms of strategic planning. Managers of tomorrow must understand what e-commerce is, how the approach to this concept will be, and how it will affect the leverage of the organization. The article will briefly provide a discussion of the topic and a perspective on the issues and problems as they relate to alignment. It will also briefly look at future trends and will end with a definition of some terms.

BACKGROUND

The establishment of alignment between IT and organizational objectives has consistently been reported as one of the key concerns of IS managers (Lubbe, 2001; Reich & Benbasat, 2000; Rodgers, 1997). Findings by authors (e.g., Dhillon & Orton, 2001; Hamilton & Chervany, 1981; Henderson & Sifonis, 1988; Moad, 1994; Papp, 1997; Reich & Benbasat, 2000) suggest that both practitioners and researchers should direct their efforts toward understanding of domain knowledge. On the other hand, Venkatraman (2000) argues that managers must also align their vision to dotcom to ensure that the leaders of the Industrial Age do not become the dinosaurs of the dotcom era.

Alignment should be based on different levels; that is, it can be based on the shared domain knowledge between business and IT executives, IT implementation success, communication between business and IT executives and connections between business, IT and e-commerce planning processes (Reich & Benbasat, 2000; Papp et al., 1996). Venkatraman (2000) argues that the Internet changes everything – particularly for brick and mortar organizations, branded products and services, and traditional supplier and customer relationships.

Papp (1997) argues that executives rarely agree and that they normally oppose each other while meeting to discuss alignment. These executives, however, acknowledge that there are different approaches to alignment, but are not willing to give any leeway. Each industry will also have a different type of dimension to its alignment that impacts its architecture through changes in e-commerce, IT and the business infrastructure. Therefore, with the advent of e-commerce another level had been added that impacts on effective planning of strategies.

Amadi (1998) and Cerpa and Verner (1998) state that strategic alignment and all its dimensions give value to the business on all levels of the business. Bildfell (2003) also noted that many planes or dimensions should be kept in mind while aligning strategies. These dimensions could be architectural alignment, cultural alignment, customer alignment, and so forth. Dhillon and Orton (2001) argue that strategic options such as cost leadership, differentiation, strategic alliances and globalization could further add on dimensions to the strategic alignment of the organization. They added that there will be some schizoid incoherence and that management should pay attention.

The relationship between peers inside the organization helps management visualize how alignment has been achieved within the organization. Enns et al. (2003) argue that the relationship between CIOs and their peers should successfully affect the visualization. The degree of mutual understanding of current objectives (short-term alignment) and the congruence of IT and e-commerce vision (long-term alignment) between IT, e-commerce and IT executives affects alignment as well. Alignment as a key should maximize the value and impact of the organization's IT and e-commerce investments and be flexible enough to allow the organization to act quickly to ensure that changes are taken into account.

Chan (2000) also argues that communication and understanding are factors that should be kept in mind on a business level. There should also be linked executive commitment to IS and e-commerce issues and initiatives. These links contribute to missions and dimensions for e-commerce, IT and the organization.

FUNCTIONAL INTEGRATION

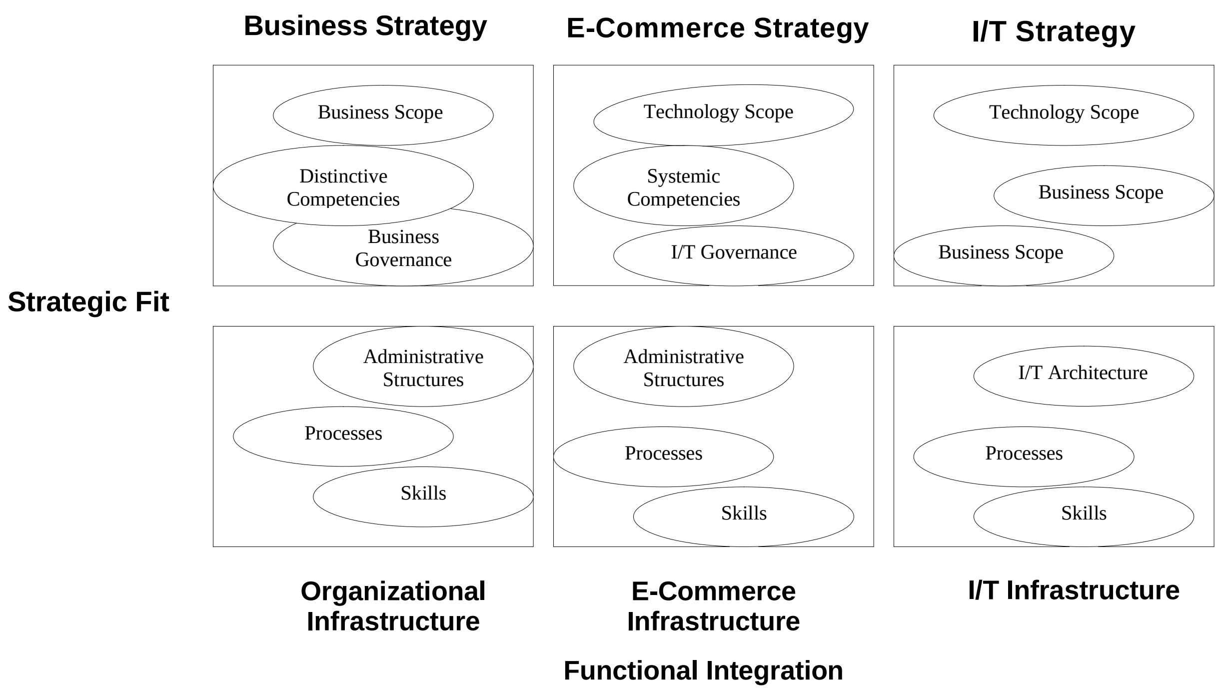
Some of the functions that should be paid attention to while attempting to align strategies are the shared domain knowledge between business, IT and e-commerce executives; IT and e-commerce implementation success; communication between business, e-commerce and IT planning process; and connections between business, e-commerce and the IT planning process. All the factors mentioned in this instance were found to influence short-term alignment, while only shared domain knowledge was found to influence long-term alignment. Reich and Benbasat (2000) established that a new factor, strategic business plans, affects both short-term and long-term alignment (supported by Dhillon & Orton, 2001).

All management functions must be aligned – especially for organizations that run e-commerce operations. If there is no alignment, then the dotcom strategy may be "hijacked" by staff members for their own purpose (Venkatraman, 2000). The functional areas will influence the ranking of enablers and inhibitors of strategic planning (Papp & Fox, 2002). The type of business (brick-and-mortar and/or e-commerce) will have a bearing on the alignment perspective of the organization. Bildfell (2003), on the other hand, argues that there are three functional areas that should be kept in mind while aligning strategies. These are relationships that accelerate the strategy; relationships that help penetrate new markets and relationships that improve competitiveness and solution capabilities.

INSTRUMENTS TO MEASURE ALIGNMENT

The Gartner Group had designed an instrument that could be used for measurement of assignment called Alignment

Figure 1. The strategic alignment model (Adapted from Papp & Fox, 2002)



Strategy Assessment (Business Wire, 1998). The instrument analyzes five key areas: IT application alignment with business goals; IT application alignment with business operations; IT infrastructure alignment with business goals; IT infrastructure alignment with business operations; and IT infrastructure alignment with IT applications. There are also other instruments (e.g., questionnaires, spreadsheets, etc.) as explained by Lubbe (2001). The instrument by the Gartner Group enables the CIOs to assess the effectiveness of IT support for key areas of business and to prioritize IT resources and applications so that they are in alignment with the organization's business goals and operations. The problem is to align e-commerce goals with IT and the organization still a concern for CIOs.

Amadi (1997) states that BPAR is a tool that can help with the visualization of alignment. Segars and Grover (1999) argue that instruments measuring alignment should take into account the different dimensions of alignment. These dimensions, according to them, include comprehensiveness, leverage, formalization, focus, and consistency. Any e-commerce or IT person needs to understand the leverage points of the industry, the history and current issues of the leverage effect, and to learn to apply "common sense" of the business units in the application of technology to business problems. Venkatraman (2000) argues that organizations should enter into alliances to explore a wide range of opportunities and leverage those that succeed. This is confirmed by Lubbe (2001). Papp and Fox (2002) support the importance of the strategic alignment by asking: Are the business strategies and plans leveraging IT?

ISSUES TO BE KEPT IN MIND

Organizations should identify strengths and weaknesses that affect alignment. Some organizations do believe that their strategies are aligned (50%) and 42% said that they were not aligned. This is a problem and could affect the flashes of commercial insight (gut feeling) that some managers exhibit. Some of the enablers and inhibitors of alignment are listed next. These were also listed and demonstrated by Moad (1994). Bildfell (2003) argues that successful alignment, keeping problems and success stories in mind, ensures that organizations will be competitive. Some enablers to alignment are important.

FUTURE TRENDS

Because e-commerce is evolving rapidly, organizations must continuously expand current business models (e.g., improve marketing) while experimenting to create new ones (Venkatraman, 2000). These new business modules will ensure that the goal posts for competitors keep on changing and ensure that the organizations stay competi-

Table 1. A summary of enablers and inhibitors of alignment of strategies

Some Enablers to Alignment
Executive support for IT and e-commerce
Strategy developed in tandem
Leadership shown by IT and e-commerce
E-commerce and firm's resources are shared
Close relationship between firm, e-commerce and IT
Some Inhibitors to Alignment
Prioritize work poorly
No close relationship with e-commerce and IT
IT and e-commerce do not know their customers
No executive support for IT and e-commerce
Strategic goals not achieved by IT and e-commerce
No communication

tive. Papp and Fox (2002) argue that there could be differences between the strategies of brick-and-mortar operations and normal business operations but that it has not been defined as yet.

CONCLUSION

IT and e-commerce groups have to earn the right to play a meaningful role in management forums. One important factor that the theory suggested is that IT and e-commerce people should devote the time necessary to develop shared domain knowledge, and thereby be able to provide some input on alignment. The organization should try to be "lawful" and not chaotic and will survive. Managers should remember that there could be alignment but still be problems preventing proper alignment.

KEY TERMS

Alignment: A dynamic process that requires close, continual assessment (because the goals keep on moving) and cooperation between achieving competitive advantage and surviving.

Competitive Advantage: Usually refers to characteristics that permit a firm to compete effectively with other firms due to low cost or superior technology, perhaps internationally.

Enablers: A factor that makes something possible (e.g., Alignment is an enabler for organizations to cut production costs by half).

Inhibitors: A factor that can stop an activity.

Leverage: Investing with borrowed money as a way to amplify potential gains (at the risk of greater losses).

Strategic Alignment: As the appropriate use of IT in the integration and development of business strategies and corporate goals.

Strategy: A detailed plan for achieving success in situations such as war, politics, business, industry or sport, or the skill of planning for such situations.

S

Strategic Experimentation and Knowledge Management

V.K. Narayanan
Drexel University, USA

INTRODUCTION

Historically, the focus of IT infrastructure has been to capture the knowledge of experts in a centralized repository (Davenport & Prusak, 1998; Grover & Davenport, 2001). These centralized databases contained knowledge that was explicit and historical (e.g., competitor pricing, market share), and the IT infrastructure served to facilitate functional decision-making or to automate routine tasks (i.e., in re-engineering). The users of technology approached the repository to obtain data in a narrowly defined domain (Broadbent et al. 1999). Consequently, IT originally played a significant yet ultimately limited role in the strategy creation process. Management information systems (MIS) arguably generated information that was less applicable to strategy creation, as noted in early writings on the linkage between MIS and strategic planning (Holmes, 1985; Lientz & Chen, 1981; Shank et al., 1985).

The active management of knowledge was similarly underdeveloped. Despite the fact that strategic decision makers had always emphasized the role of tacit knowledge, the actual importance of knowledge was not *explicitly* recognized. Formalized knowledge management (KM) (Davenport & Prusak, 1998), with its associated terminology and tools, is a recent development and, as such, did not inform the strategic planning process.

However, the shifts that have taken place in IT infrastructures over the last decade and the recent developments in knowledge management have brought them closer to the creators of strategy. Indeed, both IT and knowledge management are increasingly enablers in the contemporary strategic management practice.

1. IT infrastructure is transitioning in its focus from the functional work unit to a process orientation. Whereas computer systems were once the focal point, the new infrastructure is network-centric, with an emphasis on business knowledge (Broadbent et al., 1999). For example, traditional search engines utilized rule-based reasoning to identify elements matching specific search criteria; the "state-of-the-art" knowledge management systems employ case-based search techniques to identify all relevant knowledge components meeting the user's request (Grover & Davenport, 2001).
2. IT now takes into account contexts that include cross-functional experts that are knowledgeable in a wide variety of potentially relevant issues. Additionally, there is a greater emphasis on the integration of infrastructure with organization, structure, culture (Gold et al., 2001), and organizational roles (Davenport & Prusak, 1998). In many ways, the newer IT infrastructures have enabled the garnering of explicit knowledge throughout the organization improving the speed of strategy creation.

The objective of this article is to outline how the developments in IT and KM are facilitating the evolution of strategic management to strategic experimentation in order to create quantum improvements in strategy creation and unprecedented developmental opportunities for the field of IT.

BACKGROUND

Information Technology (IT)

For the purposes of this chapter, IT is defined as physical equipment (hardware), software, and telecommunications technology, including data and image and voice networks employed to support business processes (Whitten & Bentley, 1998). The overarching plan for IT deployment within an organization is called the *IT architecture*. Technology infrastructure refers to the architecture as including the physical facilities, the services, and the management that support all computing resources in an organization (Turban et al., 1996).

Knowledge Management (KM)

As used in this chapter, data are objective, explicit pieces or units; information is data with meaning attached; and knowledge is information with an implied element of action.

Knowledge is the fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers. In organizations, it often becomes embedded not only in documents or repositories but also in organizational routines, processes, practices, and norms (Davenport & Prusak, 1998, p. 5).

KM is "a set of business practices and technologies used to assist an organization to obtain maximum advantage from one of its most important assets—knowledge" (Duffy, 2000, p. 62). In other words, it is actively capturing, sharing, and making use of what is known, both tacitly, informally, and explicitly, within the organization. IT often facilitates knowledge management initiatives by integrating repositories (e.g., databases), indexing applications (e.g., search engines), and user interfaces. Davenport and Prusak (1998) note that KM also incorporates traditional management functions: building trust among individuals, allocating resources to KM, and monitoring progress.

Strategic Management

The concept of "strategy" explicated in strategic management is one of marketplace strategy (i.e., winning in the marketplace against competitors, entrenched or incipient). The underlying premise is that "to enjoy continued strategy success, a firm must commit itself to outwitting its rivals" (Fahey & Randall, 2001, p. 30). A large body of literature on strategic management has persuasively argued that effective strategy creation and execution are central to a firm's performance (Covin et al., 1994).

Strategy creation involves both goal formulation—defined in terms of external stakeholders rather than operational milestones—and crafting of the strategic means by which to accomplish these goals (Hofer & Schendel, 1978). The means typically include business scope, competitive posture, strategic intent, and the organizational mechanisms for implementation. In practice, the process of strategy creation has often taken the form of strategic planning. Comprehensive strategic planning (Gluck et al., 1978) has historically been practiced in large corporations. A celebrated example is the use of scenarios by Royal-Dutch Shell. Planning usually consisted of several sequential stages of decision-making involving diagnosis, alternative development, evaluation and choice, and implementation. In each step, the strategic planners emphasized deliberate juxtaposition of "objective data" and careful analysis with top management judgment, thus highlighting the role of tacit knowledge.

Strategic planning has evolved over the years. Writing in the 1970s, Gluck et al. (1978) identified four phases of evolution: budgeting, long-range planning, strategic planning, and strategic management. Each phase of evolution incorporated the lessons from the earlier phases, but also took into account the emerging realities faced by corporations. Gluck et al. (1978) noted that during the 1980s the "strategic management" phase would represent the cutting edge of practice in the world.

TOWARD STRATEGIC EXPERIMENTATION

The 1990s witnessed a revolution in organizational environments often characterized as "hypercompetition" (D'Aveni, 1994). These environments have created three major imperatives for organizations: time compression, globalization, and technology integration (Narayanan, 2001). The increased environmental dynamism also contributes to an increase in the degree of uncertainty confronted by strategic managers, calling into question traditional planning practices. Consequently, a new type of strategy creation process is evolving, which is termed "strategic experimentation." With this evolution, the relationship between strategy creation, knowledge management, and IT is undergoing a profound shift.

All four phases of strategic planning documented by Gluck et al. (1978) incorporated a sequential approach to strategy creation and execution, leading to the identification of one winning strategy that has the highest probability of success. Consequently, firms found it logical to commit the maximum available resources to the implementation of one wining strategy. The goal was to obtain a sustainable competitive advantage vis à vis the firm's rivals, and to reduce uncertainty ex ante using analytical forecasting techniques as well as market research. This approach to planning seems to have been effective during the 1980s when the environment was moderately dynamic.

In hypercompetitive environments, market participants frequently confront great uncertainty over technological possibilities, consumer preferences, and viable business models. This high level of ambiguity often results in a situation where (a) traditional methods of ex ante uncertainty reduction (e.g., market research) fail, and (b) the costs and risks of the traditional "big bet" strategic management approach outweigh the advantages in terms of focus, decisiveness, and concentrated resource commitment. It is in this situation that the emerging strategic experimentation approach holds significant promise.

Strategic experimentation (Brown & Eisenhardt, 1998; McGrath, 1998; McGrath & MacMillan, 2000) draws on real-options reasoning (McGrath, 1997), discussions of exploration vs. exploitation, and trial-and-error learning (Van de Ven & Polley, 1992).

1. Companies engaging in strategic experimentation continually start, select, pursue, and drop strategic initiatives before launching aggressively those initiatives whose values are finally revealed (McGrath & MacMillan, 2000).
2. Strategic initiatives serve as low-cost probes (Brown & Eisenhardt, 1998) that enable the discovery of product technology and market preferences. They also serve as a stepping stone option for future competitive activity in that particular product-market domain.
3. The role of the strategic manager is to administer a portfolio of strategic initiatives that represent an appropriate mix of high and low uncertainty projects, and to maximize the learning from these real options (McGrath & MacMillan, 2000).

Strategic experimentation represents a fundamentally different view of the practice of strategic planning and the path to competitive advantage. Movement is emphasized over position in this approach. Thus, competitive advantage is viewed as temporary at best, and hence, innovation and learning are considered crucial to success. Strategic experimentation is especially appropriate for high velocity environments such as emerging product markets with high uncertainty surrounding both technology and customer preferences (e.g., the early Personal Digital Assistant, Internet appliance, and satellite-based telephony markets). Here, low-cost probes can be very effective in gaining knowledge and reducing uncertainty while minimizing exposure to the results of faulty assumptions.

THE ROLE OF IT AND KNOWLEDGE MANAGEMENT IN THE ERA OF STRATEGIC EXPERIMENTATION

Since strategic experimentation represents the cutting edge of ideas in strategic management, we should expect significant advances in tool development and utilization in the next few years that will enable us to move the idea towards normal organizational practice.

Strategic experimentation necessitates several major functions that should be performed by an organization. KM is critical in strategic experimentation; therefore, it is not surprising that many of the tools currently moving into practice have emerged from KM. Following are the four major strategic experimentation functions and the associated KM tools.

Rapid Decision-Making

The ability to *quickly* garner tacit knowledge in all phases of decision-making is a central requirement in strategic experimentation. Current KM tools to support this include visualization and prototyping, group decision facilitation, and knowledge representation. Each method attempts to reduce the time needed for a group to progress from problem identification to solution implementation. These tools help to coordinate the use of data, systems, tools, and techniques to interpret relevant information in order to take action (Little, Mohan, & Hatoun, 1982).

Integration of Learning from Experiments

Organizational learning, another core concept in strategic experimentation, requires that appropriate learning be distilled from each experiment. This orientation combines decision-making and learning. Initiatives judged to be failures are not merely weeded out; they become occasions for discovery of root causes. Nor are successes simply alternatives to back financially; successes often generate potential best practices. Current KM tools in use for this purpose include learning histories (Roth & Kleiner, 1998), group brainstorming, and shared communication platforms.

Diffusion of Learning

Organizational learning has to be diffused throughout the organization. Since formal organizational channels may stifle transmission of tacit knowledge, diffusion may require interactions among “communities of practice” (Grover & Davenport, 2001; Davenport & Prusak, 1998). An organizational architecture incorporating relevant tools and IT infrastructure has to be designed to support theses interactions. KM tools such as knowledge maps identifying the experts in specific areas and repositories of case histories, are evolving to include dynamic updating of repositories and focused search tools to reduce information overload.

Managing a Portfolio of Strategic Experiments

Finally, unlike in previous eras, strategic experimentation requires maintenance and management of a portfolio of initiatives (Narayanan et al., 2001). This has three major implications. First, the knowledge base for decisions has to be broader and richer, simply due to the increase in the number of initiatives. Second, the knowledge base becomes much more complex, since the initiatives themselves differ in terms of the mix of tacit and explicit knowledge. Thus, newer initiatives are likely to be more dependent on tacit knowledge, whereas mature ones can be augmented by explicit knowledge. Finally, the sheer number of people involved in the process will be larger, given specialized pockets of tacit knowledge that would have grown up around specific strategic initiatives. DSS and other rich data applications, including cognitive mapping, can be used to capture the knowledge and feedback.

IT can accelerate the development of strategic experimentation by designing infrastructures that accommodate the new KM demands imposed by this new mode of planning. Consider how each of the following functions can be enhanced by IT infrastructure development.

1. Future developments can significantly reduce the time expended in solution development through real time displays, and expand opportunities for geographically dispersed collaboration. Also, advanced multimedia and communication capabilities increase the benefits of GSS and DSS tools.
2. Learning from experiments can be enriched by qualitative database construction, multimedia enhancements to communication applications, and open platforms to permit the sharing of knowledge over various communication channels, including wireless media.
3. Today, diffusion is hampered by information overload that has intensified competition for the user's attention (Hansen & Haas, 2001). To solve the problem, search tools should include separate parameters for content, rationale, and purpose of the query in order to isolate salient responses. Additionally, knowledge repositories must be maintained to ensure the contents are accurate and of high quality. Maintenance, currently provided by intermediaries (Markus, 2001), might be performed by faster automated systems.
4. Expert systems or neural networks may be developed to manage and track portfolios, promoting reuse of the knowledge captured.

The significant implication for IT infrastructure from our discussion is the need for *technology integration* (Narayanan, 2001) with both hard and soft technologies. IT infrastructure should exploit the potential for integration with other *hard* technologies such as telecommunications to enhance the organizational capacity for speed and the carrying capacity for *tacit* knowledge. Similarly, IT should seek to interface with *decision sciences* to embed AI-based processing tools, and with *cognitive theorists* to capture the tacit knowledge pervasive in organizations.

CONCLUSIONS AND IMPLICATIONS

We have argued that the technological changes of the 1990s have ushered in the need for strategic experimentation as the metaphor for planning practice. Strategic experimentation involves (a) maintaining a portfolio of strategic thrusts, (b) rapid decision-making so that successful experiments are backed and failures are weeded out quickly, (c) learning from both successes and failures, and (d) diffusion of both explicit and tacit knowledge throughout the relevant segments of an organization. This phase requires fundamental shifts in our view of knowledge management—its significance, use, and tools. Finally, we have argued that the shift to strategic experimentation requires fundamental shifts in the development of IT infrastructure. Instead of developing in relative isolation to other disciplines, IT should focus on technology integration by working in close collaboration with the telecommunication technologies, artificial intelligence community, and managerial cognition scholars.

KEY TERMS

Exploration and Exploitation: Exploration refers to the process of discovery of knowledge, whereas exploitation refers to utilizing the knowledge. Similar to basic and applied research.

Information Technology (IT): Refers to the physical equipment (hardware), software, and telecommunications technology, including data, image, and voice networks, employed to support business processes.

Knowledge Management (KM): A set of business practices and technologies used to assist an organization to obtain maximum advantage of its knowledge.

Options: A financial option owes the holder the right, but not the obligation, to trade in securities at prices fixed earlier. Options in the sense used here confer to a firm the rights, but not the obligations, to choose a strategic alternative.

Strategic Experimentation: A form of strategic management in which firms continually start, select, pursue, and drop strategic initiatives before launching aggressively those initiatives whose values are finally revealed.

Strategic Management: The process of strategy creation and implementation. The concept of "strategy" as used here is one of marketplace strategy (i.e., winning in the marketplace against competitors, entrenched or incipient). Strategy creation involves both goal formulation—defined in terms of external stakeholders rather than operational milestones—and crafting of the strategic means by which to accomplish these goals. Implementation refers to the means of executing the created strategy.

Strategic Knowledge Management in Public Organizations

Ari-Veikko Anttiroiko
University of Tampere, Finland

INTRODUCTION

New public management and the more recent concept of new public governance have become the dominant management doctrines in the public sector. Public organizations have become increasingly network-like units with various governance relations with actors from the public, business, and voluntary sectors. Their organization is based more on networks than on traditional hierarchies, accompanied by a transition from the command-and-control type of management to initiate-and-coordinate type of governance.

Among the most critical factors in this transformation is knowledge, for most of what has happened has increased the overall demand to create and process knowledge and to utilize it in the performance of governmental functions. The success of public organizations depends increasingly on how efficiently they utilize their knowledge assets and manage their knowledge processes in adjusting to local and contextual changes, as illustrated in Figure 1 (cf. Fletcher, 2003, pp. 82-83; Gupta et al., 2004, p. 3; Skyrme, 1999, p. 34). This requires that special attention be paid to strategic knowledge management.

Figure 1. The public organization as an institutional mediator (Adopted from Anttiroiko, 2002, p. 272)

In the early organization theories of public administration, knowledge was predominantly conceptualized within the internal administrative processes, thus to be conceived of as bureaucratic procedures, rationalization of work processes, identification of administrative functions, and selected aspects of formal decision-making. New perspectives emerged after World War II in the form of strategic planning and new management doctrines. The lesson learned from strategic thinking is that we need information on the external environment and changes therein in order to be able to adapt to and create new opportunities from these changes (see Ansoff, 1979; Bryson, 1995). As the complexity in societal life and related organizational interdependency has increased due to globalization and other trends, new challenges of managing organization-environment interaction also emerged (cf. Skyrme, 1999, p. 3).

BACKGROUND

The branch of management doctrine that became known as knowledge management (KM) reflected actual changes and new ideas in the business world. Classic works that inspired later developments included Polanyi (1966) and Drucker (1969). During the 1980s knowledge became widely recognized as a source of competitiveness, and by the end of the 1990s, knowledge management had become a buzzword. Among the best known thinkers who contributed to the rise of this field are Peter Senge (1990), Ikujiro Nonaka and Hirotaka Takeuchi (1995), Karl-Erik Sveiby (1997), and Thomas A. Stewart (1997). (On the evolution of knowledge management see Barclay & Murray, 1997; Gupta et al., 2004, pp. 8-10). It is becoming common understanding that in essence *knowledge management* is about governing the creation, dissemination, and utilization of knowledge in organizations (Gupta et al., 2004, p. 4; Lehaney et al., 2004, p. 13).

Knowledge cannot be managed in the traditional sense of management. The processing and distribution of information can surely be managed, but it is only one part of the picture. The other concerns knowledge and especially managers' ability to create conditions that stimulate active and dynamic knowledge creation, learning, and knowledge sharing within the organization (e.g., Nonaka, Toyama & Konno, 2000). To systematize this picture we may say that knowledge management includes four core areas (cf. Gupta et al., 2004; Lehaney et al., 2004):

- Information management: managing data and information, and designing information and knowledge systems
- Intellectual capital management: creating and utilizing knowledge assets, innovations, and intellectual capital
- Knowledge process management: organizing, facilitating, and utilizing sense-making and other knowledge processes
- Organizational learning: creating learning and knowledge sharing environments and practices

Traditionally the most widely applied areas of knowledge management in public organizations used to be data and transaction processing systems and management information systems serving mainly internal administrative functions. Yet, since the 1980s authorities started to facilitate the exchange of information by local area networks, followed by the Internet revolution of the 1990s. In the early 2000s the knowledge management agenda has focused increasingly on knowledge sharing and learning, and in inter-organizational network and partnership relations (see e.g., Wright & Taylor, 2003). As reported by OECD (2003, p. 4), knowledge management ranks high on the management agenda of the great majority of central government organizations across OECD member countries, followed with some time lag by regional and local authorities. Many public organizations have even developed their own KM strategies. The leading countries in this respect include France, Sweden, Finland, and Canada (OECD, 2003, pp. 28-29).

As to more operational actions, there has been a wave of intranet projects at all levels of public administration since the late 1990s. The result is that some 90% of state agencies surveyed by OECD in the early 2000s had their intranets in place. Sectors that really stand out as being well above the OECD average include organizations in charge of finance and budget, of justice, and of trade and industry (OECD, 2003, pp. 20-30). To give a concrete example from local level, New York City's Office of Technology set up extranet and intranet projects – the Human Services Extranet Project, to link the city agencies with human service contractors and the NYC Share Project, a citywide intranet that intended to improve the exchange of information among agencies – to facilitate external and internal knowledge processes. Such projects are typical in the public sector in the early 2000s. They indicate a transition from information management towards genuine knowledge management.

FOCUSING ON THE STRATEGIC ASPECT

Combining strategic thinking with knowledge management brings us to the very core of the life of organizations. *Strategic knowledge management* is a set of theories and guidelines that provides tools for managing an organization's knowledge assets and processes of strategic importance for the purpose of achieving organizational goals. The basic idea of strategic knowledge management in the public sector is to ensure that public organizations are capable of high performance by utilizing knowledge assets and knowledge processes when interacting with their environment.

What is essential in strategic knowledge management is that it needs to be strategic in the true sense of the word, as opposed to operational. Public employees have sometimes a tendency to view their knowledge requirements from the point of view of their current work practices. At an organizational level, too, there is sometimes a temptation to map out the future on the basis of current strengths and well-defined short-term challenges. The strategic approach to knowledge aims to overcome such inertia and narrow perspectives by creative knowledge processes, which help to transform views from introspective to outward-looking, from resources to outcomes, and from formal duties to actual impacts and customer satisfaction.

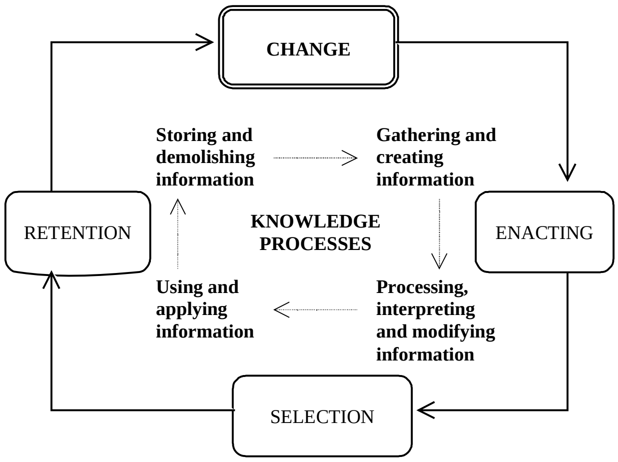
In the knowledge management literature, knowledge has primarily been approached either as an object or a process (cf. Sveiby, 2001). The main focus of public organizations is on knowledge processes framed by certain institutional arrangements. Among the most important of these are the political dimension and democratic control and legally defined functions, competencies and procedures within territorially defined jurisdictions. This theme will be discussed next.

FACILITATING STRATEGIC KNOWLEDGE PROCESSES

Public organizations possess and process a huge amount of information in their internal operations and external exchange relations. This is why the most important function of their knowledge management practice is to manage knowledge processes and to support knowledge-sharing practices.

Nonaka (1994) considers an organization's ability to accomplish the task of acquiring, creating, exploiting, and

Figure 2. Strategic sense-making and related knowledge process of the organization

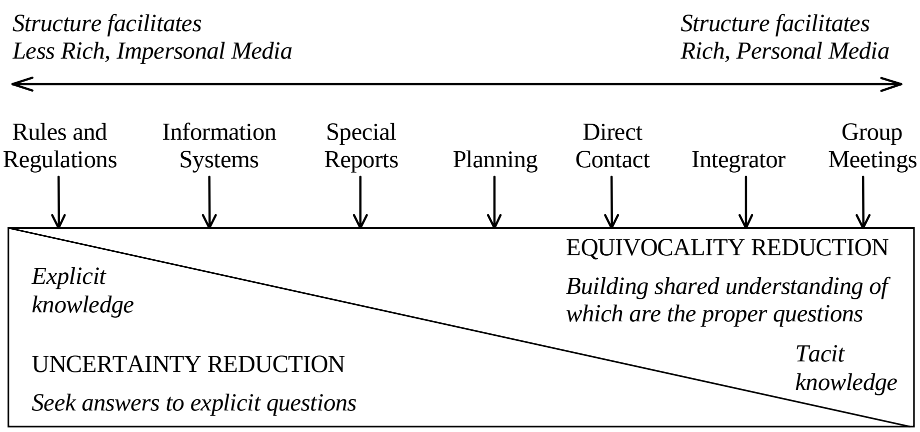


accumulating new knowledge. This formulation takes us very close to how the knowledge process can be operationalized. The *knowledge process* can be defined as an organizational process in which information is gathered, created, processed, used and dissolved in order to form an enriched orientation base for taking care of organization's basic functions (cf. Gupta et al., 2004, p. 3; Mendes et al., 2004, p. 153).

It is important to note that in the actual knowledge process it is more or less meaningless to make a clear-cut distinction between knowledge and information, for both are processed in such a process. For example, knowledge is not simply extracted from information, for knowledge is possessed by human beings and serves as a background and in-built epistemic frame to deal with complexity, novelty, and the requirements of innovativeness (cf. Wiig, 2000). Thus, genuine aspects of the category of *knowledge* are in question when we deal with statements, assumptions, and understandings and such learning and communicative processes in which these knowledge assets can be shared, assessed, and enriched. Many theorists consider that it is tacit knowledge in particular that is the most challenging and important form of knowledge in organizations (Nonaka, 1994; Polanyi, 1966). It also needs to be stressed that it is not knowledge as something abstract but a "generative dance" or interplay between (a) *knowledge* we possess and (b) *knowing* as an epistemic aspect of the interaction with the world that generates organizational innovation and strategic understanding (Cook & Brown, 1999).

Strategic knowledge processes are those aspects of knowledge processes that have the most profound and far-reaching impact on an organization's adjustment to contextual changes and on its core competencies. A paradigmatic form of a strategic knowledge process is the *sense-making or strategy process* in which an organization devotes effort to analyzing its internal attributes and external conditions and decides on that basis about the action lines in order to achieve its overall goals (cf. Weick, 1995). In such a strategic knowledge process the organization seeks information on environmental changes and utilizes this in strategy formulation, in which such tools as SWOT analysis have traditionally been used. A basic model of the organizational knowledge-based adaptation process is presented in Figure 2 (Anttiroiko, 2002). This model serves as a heuristic tool to conceptualize knowledge processes. Yet, it is important to keep in mind that this is only a starting point. When taking this idea further, clear-cut sequential stages or phases of the KM life cycle need to be "recontextualized" as a set of continuous interdependent sub-processes (cf. Mendes et al., 2004, p. 165). Thus, context-related and situational aspects of knowledge need to be integrated with all essential connections to their environments into the key functions and operations of an organization in order to assess their meaning as a part of actual strategic adaptation and sense-making processes.

Figure 3. Continuum of knowledge facilitation mechanisms (Daft & Lengel, 1986)



Applying Daft and Lengel (1986), we may ask how organization structures and systems should be designed in order to meet the need to manage knowledge processes. Well designed systems help to decrease the uncertainty and ambiguity faced by an organization by ordering the amount of relevant information and by enabling clarification of problems and challenges. Daft and Lengel propose seven structural mechanisms that can be used to deal with uncertainty and ambiguity in varying degrees, as illustrated in Figure 3. This model resembles the continuum of communication that has explicit knowledge and tacit knowledge as its extremities (Lehaney et al., 2004, p. 21).

The idea is that these mechanisms form a continuum starting from tools to be used to tackle well defined problems and thus to reduce uncertainty, and proceeding towards more communicative mechanisms designed to facilitate sense-making processes that aim at reducing equivocality or ambiguity (Anttiroiko, 2002).

As stated, a paradigmatic case for strategic knowledge management is the strategy process of an organization (on strategy and information resources, see Fletcher, 2003, pp. 82-84). What is of utmost importance is that managers ensure that people feel involved in the strategy formulation process. The staff also needs to understand the meaning of strategy in their own situations. This would help to make strategy documents living guidance that is owned by all in the organization, as concluded by Wright and Taylor (2003, p. 198).

Another important premise relates to organization culture and work practices that often impede the development of knowledge management. For example, employees may resist a new knowledge management initiative if they perceive it only as extra work. Similarly, employees may be reluctant to share their knowledge if there are no rewards or tangible benefits for themselves or their organizations. In all, the human factor is essential for improving KM practices, for most of the positive outcomes are the result of the commitment of all employees, successful structural changes in the organization, and the development of the organizational culture and climate (OECD, 2003, p. 4).

THE ROLE OF TECHNOLOGY

Information technology (IT) provides a range of new tools that can be effectively used in knowledge management. Relevant applications can support decision making, executive functions, planning, communication, and group work.

Tools and technologies available for knowledge management include generic communication tools (e.g., e-mail), computer-based information and decision support systems, document management systems, intranets and extranets, groupware, geographic information systems, help desk technology, and a range of knowledge representation tools. (Grafton & Permaloff, 2003; Gupta et al., 2004, pp. 17-24).In general, the Internet may be suggested as the KM infrastructure due to its widespread availability, open architecture, and developed interfaces (Jennex, 2003, p. 138).

In real life most of the tools applied in knowledge management are more or less conventional, such as training, seminars, meetings, and the like. Various KM-specific organizational arrangements had been adopted by about half of the organizations studied in the OECD survey on ministries, departments, and agencies of central government in the early 2000s. These measures include central coordination units for KM, quality groups, knowledge networks, and chief knowledge officers. Another important application area is the classification of information, referring to new filing mechanisms, e-archives, and new types of databases. In internal knowledge sharing Intranet projects form the mainstream, combined with wide access to the Internet and having e-mail addresses for the staff. The external knowledge sharing goes largely hand in hand with the emergence of new practices of e-governance. These practices have increased the knowledge sharing in both local and wider governance processes (Anttiroiko, 2004; OECD, 2003, pp. 17-20).

FUTURE TRENDS

The future challenge for public organizations is to increase their responsiveness to stakeholders, especially to citizens. At the same time they need to be capable of strategic institutional mediation in the increasingly turbulent environment, thus bringing an element of continuity and stability to social life and guaranteeing democratic and civic rights at different institutional levels. All this requires increasing capacity to manage knowledge of strategic importance.

CONCLUSION

Strategic knowledge management refers to the theory and practice of managing knowledge assets and processes of strategic importance. Public organizations need to create favorable organization structures and environments for knowledge sharing, organizational learning, and other aspects of knowledge management in order to create all the knowledge they require in their adjustment and trend-setting processes.

A main return of strategic knowledge management is better capability to adjust to contextual changes. This is difficult to measure, even if such tools as Balanced Scorecard (BSC), the Intangible Assets Monitor (IAM), and Intellectual Capital Index (ICI) are available. This is because they provide only a partial picture of KM performance, as claimed by Chaudhry (2003, p. 63). What seems to be needed is more process-focused assessments that are able to analyze the steps of KM processes, thus highlighting the actual changes in organizational knowledge base, capacities, and processes. As usual, there is no measurement system that fits all organizations in all situations. Rather, measurement should be tailored to the actual needs of the organization.

KEY TERMS

Intellectual Capital (IC): Knowledge and know-how possessed by an individual or an organization that can be converted into value in markets. Roughly the same as the concept of intangible assets.

Intellectual Capital Management (ICM): A management of value creation through intangible assets. Close to the concept of knowledge management.

Intellectual Property (IP): Any product of the human intellect that is unique and has some value in the marketplace. It may be an idea, composition, invention, method, formula, computer software or something similar. In practice, special attention is paid to such intellectual property that can be protected by the law (e.g., patent and copyright).

Knowledge Assets (KAs): Statements, assumptions, abstract models and other forms of knowledge regarding the organization itself and its environment (markets, customers, etc.) that an organization possesses. These assets provide economic or other value to an organization when interacting within it or with its environment.

Knowledge Management (KM): Management theory and practice on managing intellectual capital and knowledge assets and also the processes that act upon them. In practical sense KM is about governing the creation, dissemination, and utilization of knowledge in organizations.

Knowledge Management System (KMS): Set of tools and processes used by knowledge workers to identify and transmit knowledge to the knowledge base contained in the organizational memory.

Organizational Learning (OL): An organizational process in which the intentional and unintentional processing of knowledge within a variety of structural arrangements is used to create an enriched knowledge and orientation base and a better organizational capacity for the purpose of improving organizational action.

Strategic Utilization of Data Mining

Chandra S. Amaravadi
Western Illinois University, USA

INTRODUCTION

In the past decade, a new and exciting technology has unfolded on the shores of the information systems area. Based on a combination of statistical and artificial intelligence techniques, data mining has emerged from relational databases and Online Analytical Processing as a powerful tool for organizational decision support (Shim et al., 2002).

A number of techniques are available to analyze warehouse data, including descriptive techniques such as data summarization; data visualization; clustering and classification; and predictive techniques such as regression, association, and dependency analyses (Jackson, 2002; Mackinnon & Glick, 1999). The technology is being extended to mine semi-structured data as well (Hui & Jha, 2000).

Applications of data mining have ranged from predicting ingredient usage in fast-food restaurants (Liu, Bhattacharyya, Sclove, Chen & Lattyak, 2001) to predicting the length of stay for hospital patients (Hogl, Muller, Stoyan & Stuhlinger, 2001). See Table 1 for other representative examples. Some of the important findings are:

1) Bankruptcies can be predicted from variables such as the “ratio of cash flow to total assets” and “return on assets” (Sung, Chang & Lee, 1999).
2) Gas station transactions in the UK average £20, with a tendency for customers to round the purchase to the nearest £5 (Hand & Blunt, 2001).
3) Sixty-nine percent (69%) of dissatisfied airline customers did not contact the airline about their problem (Marple & Zimmerman, 1999).
4) Sales in fast-food restaurants are seasonal and tend to peak during holidays and special events (Liu et al., 2001).
5) Patients in the age group > 75 are 100% likely to exceed the standard upper limit for hospital stay (Hogl et al., 2001).

BACKGROUND

A majority of data mining (DM) applications serve a managerial purpose. They are useful in finding information such as identifying loyal customers or patients who are likely to stay longer at hospitals. This usage can be extended to strategic decision making as well. According to Sabherwal and King (1991), a *strategic application* is one that has a profound influence on a firm’s success, by either influencing or shaping the organization’s strategy or by playing a direct role in the implementation or support of it. If DM could be utilized in shaping the firm’s strategy, it could have a strategic impact. Let us then consider the process of strategic decision making (SDM). An interpretive view of this process involves *scanning* the environment for important events or information, *interpreting* these events as threats or opportunities, and *formulating* a response (Daft & Weick, 1984).

The interpretation stage involves some form of consensual validation, with managers comparing notes with subordinates or with peers (Daft & Weick, 1984). It is of particular interest since it involves modifying the *belief systems*, the summary of perceptions, observations, and experiences concerning the organization’s resources, markets, and customers. For instance, an organization

Table 1. Examples of data mining applications

- Predicting supplies in fast food restaurants (Liu, Bhattacharyya, Sclove, Chen and Lattyak 2001).
- Quality of health care (Hogl, Muller, Stoyan and Stuhlinger 2001).
- Analyzing Franchisee sales (Chen, Justis and Chong 2003).
- Predicting customer loyalty (Ng and Liu 2001).
- Job shop scheduling (Koonce, Fang and Tsai 1997).
- Mining credit card data (Hand and Blunt 2001).
- Bankruptcy prediction (Sung, Chang and Lee 1999).

might have a perception that its product lines are aging. Customers switching to competitors' products could confirm this observation. There is empirical evidence that belief systems influence strategic decision making (Lorsch, 1989). In a study of 12 firms, Lorsch (1989) found that major strategic decisions were influenced by core beliefs that included financial goals, acceptable types of risks, and distinctive competence, among other things. Thus decisions regarding product lines, customers, and suppliers are influenced by perceptions concerning adequacy of product lines, type of customers, reliability of suppliers, and so forth. We will alternatively use the term *micro-theories* (MTs) to refer to these beliefs and will regard each as a strategic assumption to be tested by data mining.

The mining process, often labeled as "KDD" (Knowledge Discovery in Databases) can be "data driven" or "hypothesis driven" ("question driven"). *Data-driven* methods attempt to identify all possible patterns from the data, while *hypothesis-driven* methods attempt to verify whether or not a particular pattern exists (Hogl et al., 2001). Usually, organizations have more data than they can analyze. Question-driven approaches are computationally more tractable, especially when large data sets are involved, since the solution space is bounded. In this mode, KDD commences with a set of MTs that management is keen on verifying. The remainder of the process is the same for both approaches (Mackinnon & Glick, 1999). The next step is to select suitable data (see Figure 1). This is greatly facilitated if the analyst already has hypotheses to verify. Otherwise, data selection will involve an iterative process of selection followed by testing. The required data needs to be carefully selected from the warehouse or organizational databases. It is then cleaned and transformed by filling in missing values, changing "look up codes" (i.e., standardizing codes from numeric values to text or vice-versa: "1"–married; "2"–single), and ignoring outliers if necessary. Calculations such as totals, cost/item, and discount are also performed during this stage. The next step is testing and analysis where each MT is examined using the "selected" and "cleaned" data. The last step is the sharing of results with management, usually through formal reports or presentations or via an intranet.

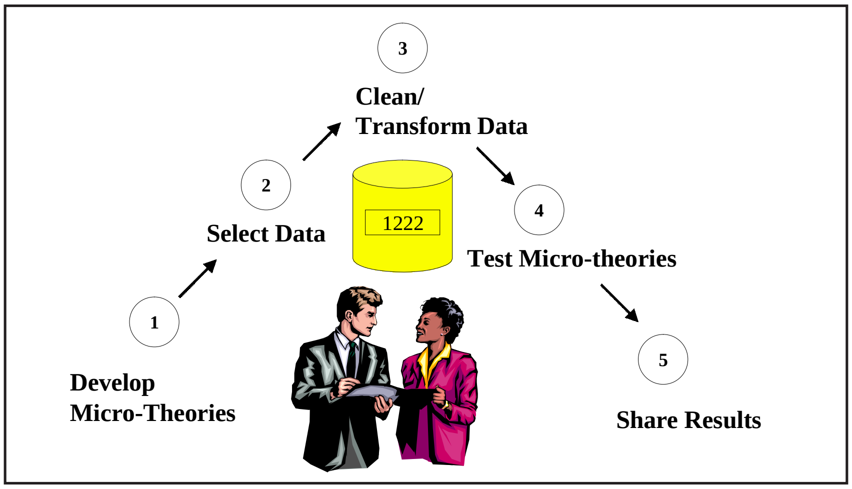
MAIN THRUST

What sort of beliefs should an analyst select for testing purposes? Porter's framework is widely used by academics and practitioners to understand organizational strategy. It summarizes key competitive forces acting on an organization as follows: a) bargaining power of customers, b) bargaining power of suppliers, c) firm rivalry, d) threat of substitute products, and e) threat of new entrants. To compete effectively, a firm has to counteract these forces.

The framework is useful in organizing micro-theories as well since it describes the entities pertaining to the organization's *task environment*, which govern its inputs and outputs and therefore affect its performance.

As shown in Figure 2, a firm's beliefs can be organized by each of the entities in the firm's task environment, including suppliers, customers, competitors, and substitute products. For instance, how do customers perceive the products of a company? How does the firm feel about a particular substitute? Ultimately, these perceptions

Figure 1. Knowledge discovery process with micro-theories (Adapted from Mackinnon & Glick, 1999)



influence strategy formulation and therefore need to be verified. The reader should note that perceptions about the firm, its management, and its employees are also included in the framework since a firm's internal resources and capabilities are very pertinent to the strategic decision-making process.

As a first step in the KDD process, the analyst needs to identify these assumptions. Decision mapping is a suitable technique here. A *decision map* is a chart depicting the decision processes in the organization (Ashworth & Goodland, 1990). For each of the task areas, the analyst should identify decisions made with a view to identifying underlying micro-theories. For instance, for the entity suppliers, *decisions faced* are: What type of a relationship should a company have with its suppliers? Should it have a long-term or a short-term relationship? Should it trust a single supplier for a critical component or should it maintain alternative sources? Should it attempt to develop offshore suppliers based on price or are there other considerations? How can it optimize a contract in terms of price/delivery time/lead time?

The beliefs that can underlie these decisions include (see Figure 2):

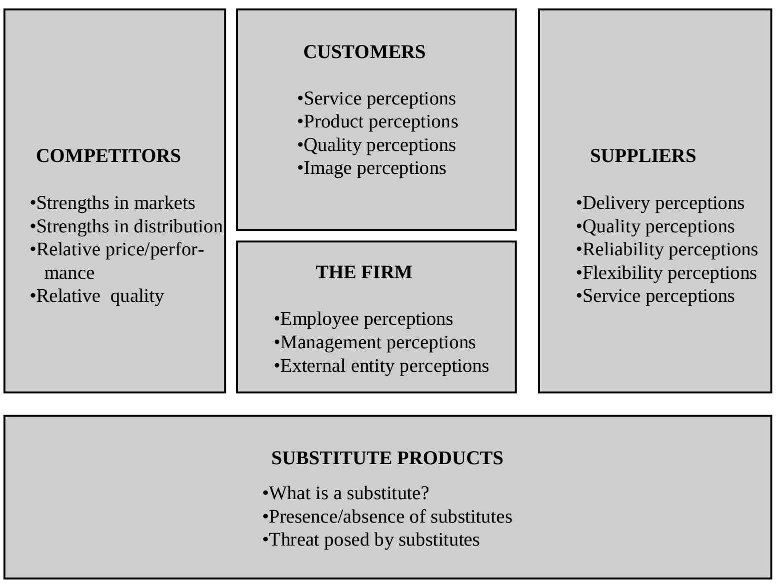
- The supplier is reliable.
- The supplier delivers on time.
- The supplier produces quality products.
- The supplier has historically offered good pricing/ delivery combination.
- The supplier is flexible in producing products to specifications.
- The supplier can operate with a small lead time.
- The supplier is quick in resolving problems.

Similar beliefs underlie other key task entities that have been identified. Typically, organizations will have dozens of such beliefs embedded in their SDM processes. To identify those that are relevant, the analyst can study the decisions, prepare a checklist of all MTs, and have senior management select the most important. This list will then drive the remainder of the KDD process.

The Testing Process

Once micro-theories are identified and data sets are selected/transformed, the next step in the KDD process is testing. Testing proceeds in two stages, first with "test data" which is usually 10-20% of the actual data to develop the model, and then with the remainder of the data to validate the model. As mentioned, the DM techniques include clustering, association, classification, and dependency analysis. The MT test list is used by the analyst as a guide in selecting a suitable technique. For instance, an assumption about the reliability of a supplier could be confirmed by an association analysis between suppliers, delivery times, and the number of times the specifications were met 100%. It should be noted that the raw data may not be available in this form, and therefore may require tabulating and aggregation, especially with respect to the variable, *specifications being met 100%*. If the association analysis confirms some vendors meeting these crite-

Figure 2. Porterian Framework for Characterizing Micro-Theories



ria, this is again tested on the remainder of the data in the second stage. A number of situations may arise with tested hypotheses: a) the hypothesis is supported in its entirety at the 90% confidence level or higher; b) the hypothesis is not supported at the 90% confidence level, but at a lower level of confidence; c) the hypothesis is not supported at any confidence level. Situations "a" and "c" are clear cut, resulting in confirmation or disconfirmation of the MT, but "b" can place the analyst in a quandary. In such cases, an alternative hypothesis may be sought by modifying the MT. For instance, an alternative hypothesis for the case above is that delivery times and specifications may be contingent on the delivery quantities. Thus testing is not always straight-forward and the strategy may need modification.

FUTURE TRENDS

The utilization of data mining in organizations will continue to increase. It is expected that some of the simpler data mining techniques will be incorporated into management support tools (Shim et al., 2002). If the assumption surfacing process could be automated (Conklin & Begeman, 1988), it will streamline the verification of micro-theories. Progress in data visualization could add to the efficacy of the process (Thearling et al., 2001). The integration of data mining with systems managing soft information is another important challenge.

CONCLUSIONS AND IMPLICATIONS

The strategic usage of data mining technology requires a hypothesis-driven approach to DM. The hypotheses to be tested are often embedded in the strategic assumptions of management. Referred to as micro-theories, or beliefs that underlie and influence critical decisions in an organization. A Porterian framework has been provided to serve as a guide to surfacing these MTs. IBIS (Conklin & Begeman, 1988) and SAST (Mason & Mitroff, 1981) are similar frameworks. IBIS was developed in the context of recording planning activities in governmental agencies, while SAST was specifically developed for strategic decision making. IBIS is concerned more with the rationale for decision making, while SAST is concerned with identifying assumptions through dialectic among stakeholders, *during* the decision-making process. Neither approach addresses the content or nature of the assumptions.

Using the framework, along with decision mapping, the analyst should surface strategic assumptions and test them with the usual techniques of mining. Typically the results will confirm the MT, but this may not always be the case. Studies have shown that managers are often too optimistic or too pessimistic, leading to divergence between MTs and conclusions from KDD. Not all MTs will be testable. For instance, the belief that a supplier is potentially valuable cannot be tested except through "soft" methods such as consensual validation. The ultimate result of such efforts is that executives can make strategic decisions with greater confidence.

KEY TERMS

Association: A technique in data mining that attempts to identify similarities across a set of records, such as purchases that occur together across a number of transactions.

Beliefs: Summaries of perceptions that members in an organization typically share, such as “Sales are strong in the Southwest.”

Classification: A technique in data mining that attempts to group data according to pre-specified categories, such as “loyal customers” versus “customers likely to switch.”

Clustering: A technique in data mining that attempts to identify the natural groupings of data, such as income groups that customers belong to.

Data Driven: If the data drive the analysis without any prior expectations, the mining process is referred to as a data-driven approach.

Micro-Theories: Beliefs that need to be tested during the data mining process.

Multi-Dimensional Databases: A virtual database where data is organized according to dimensions or aspects of the data—such as product, location, and time for sales data—to facilitate queries, such as: “How many shoes were sold by Store #4 in January?”

OnLine Analytical Processing (OLAP): Performing high-level queries on multi-dimensional databases.

Question Driven: In question-driven or hypothesis-driven approaches, the analysis is preceded by an identification of questions of interest.

Strategic Vision for Information Technology

Mary Elizabeth Brabston
The University of Manitoba, Canada

INTRODUCTION

Today's dispersal of information technology (IT) decision making across many organizational managers and employees offers the promise of greatly increasing the extent to which IT is applied to the organization's managerial and operational work systems (Boynton & Zmud, 1987; Jarvenpaa & Ives, 1990). Along with the advantages of distributed action, however, come the potential disadvantages of inappropriate allocations of effort and resources and associated outcomes — chiefly poor investment decisions, lost opportunities, duplicated efforts, and incompatible platforms and applications.

One strategy for minimizing these disadvantages lies in the development of a common understanding among an organization's members concerning the primary roles to be served by information and by IT throughout the organization. One tactic for achieving this common understanding is through the development, articulation, and dissemination of a strategic vision for IT (Brabston, Zmud & Carlson, 2000; Collins & Porras, 1991; Nanus, 1992; Parker & Benson, 1991; Robbins & Duncan, 1988).

A 1994 study of banking showed that "while only 9% of CIOs interviewed said their firms have failed to effectively outline an information systems vision to the lines of businesses they support, a full 30% of business leaders reported a void in this area" (Hoffman, 1994). Effective development, implementation, and communication of a strategic vision for IT should significantly reduce this gap.

BACKGROUND

An organizational strategic vision is the shared understanding of what an organization should be and how it must change to get there (Schoemaker, 1997). According to Mintzberg, Ahlstrand, and Lampel (1998), "vision serves as both an inspiration and a sense of what needs to be done – a guiding idea…vision often tends to be a kind of image more than a fully articulated plan…that leaves it flexible, so that the leader can adapt it to his or her experiences" (pp. 124-125). By sharing a common strategic vision, organizational members will better understand how their individual roles contribute to their organization's strategic mission and will be more likely to act in an appropriate and consistent manner when faced with uncertain or ill-defined situations.

"Having a strategic vision redefines the rules for acting opportunistically or incrementally. The strategies, plans, and budgets should be determined by the vision" (Schoemaker, 1997). Similar benefits are believed to arise when a strategic IT vision is shared by an organization's managers and employees (Parker & Benson, 1991). If an organization's managers and employees are aware of the organization's strategic IT vision, they are more likely to make more effective IT decisions.

MAIN THRUST OF THE ARTICLE

The process by which a strategic IT vision is developed is clearly important. If the process produces an appropriate, aligned IT vision, one that its developers believe in, one that they can strongly sell to others in the organization, then the IT vision may become reality.

An organization's overall strategic vision is a shared, realistic, yet idealistic and attractive view of the organization that inspires and motivates others, through their individual and collective efforts, to move toward the vision (Collins & Porras, 1991; Nanus, 1992). Figure 1A graphically represents how an organizational strategic vision can serve as the stimulus for all organizational planning. Figure 1B depicts a similar role for the strategic IT vision. The intent is similar but with a narrower scope involving only the organizational role of information and IT. As shown by the dashed lines, the IT strategic vision must be aligned with the organizational strategic vision (Henderson & Venkatraman, 1993; Parker & Benson, 1991).

Figure 1 models the relationship between an organization's strategic vision and its subsequent planning and goal setting and those of the IT strategic vision. The typical process at the organizational level is that a group of individuals develop the organization's enterprise-wide strategic vision (e.g., Gerber's vision that "Babies are our most important product"). This vision is then communicated to others in the organization, resulting in the setting of strategic goals, from whence tactical goals are set, and finally, operational goals are developed based on the tactical goals. Each of these goal sets should be aligned with the enterprise-wide strategic vision.

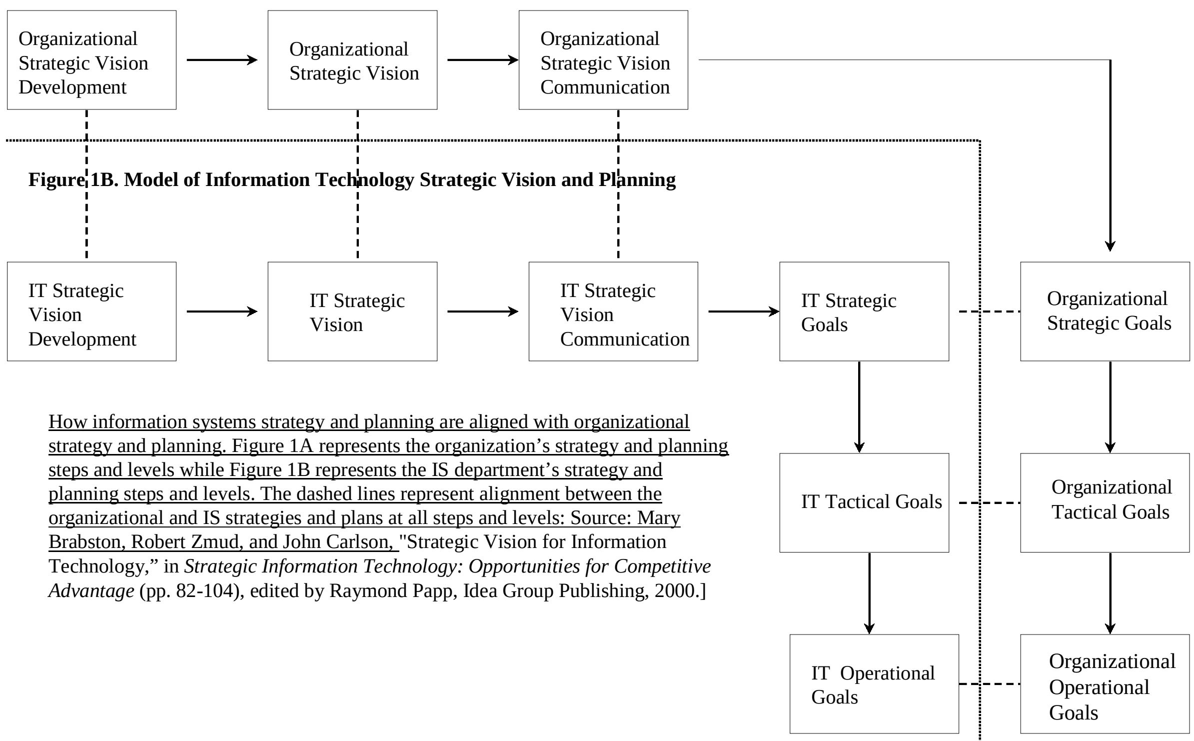
In the same way, a group of individuals would develop the IT vision, communicate it, and set goals at each level. At each stage of the IT strategic vision process, the vision and goals should be aligned with the vision and goals of the enterprise-wide strategic vision, as indicated by the dashed lines.

If appropriately developed, articulated, and disseminated, a strategic IT vision should both formally and informally influence the many IT-related decisions made throughout an organization so that these decisions, taken together, enable progress toward achieving the organization's overall strategic vision. In the absence of an enterprise-wide strategic IT vision, information and IT decision making will most likely be framed, rather than by an overarching organizational purpose, by the numerous (and potentially conflicting) mental models that are maintained in the minds of individuals, as well as those that are collectively developed by formal and informal groups throughout the organization concerning the appropriate roles of information and IT (Boland & Tenkasi, 1995).

Most often, strategic visions are phrased somewhat generically in order to increase the applicability of the vision to each organizational member (Nanus, 1992). This may be particularly important for a strategic IT vision so that this vision is not unintentionally restricted to a particular time frame, IT platform, or set of IT applications. However, although the vision is abstracted to apply across diverse organizational contexts, it should not be worded ambiguously or in such a manner as to create confusion on the part of organizational managers and employees working to apply the vision.

It is important here to distinguish between a strategic IT vision, our focus here, and a strategic vision for an organization's IT (or information services) function. The IT function's strategic vision articulates the organizational role of the IT function as well as the dominating values applied in carrying out these roles (c.f., Nanus, 1992). It may be valuable, but not necessary, that the strategic vision of the IT function be communicated across an organization; it is only necessary that it be communicated to those organizational managers and employees who significantly affect the IT function's efforts in carrying out that area's mission, for example, IT departmental employees, IT vendors, and so forth. Essentially, then, the strategic IT vision paints a picture of the what and why associated with an organization's use of

Figure 1A. Model of organizational strategic vision and planning



information and IT while the strategic vision of the IT function captures one aspect of the how.

A strategic IT vision can be explicitly or implicitly developed. With an explicit vision, a top management group conducts a formal process for developing the vision and, at the conclusion of this process, a formal vision statement is articulated and disseminated throughout the organization. With an implicit vision, the top management group evokes the vision through its ongoing decision-making processes, communication activities, and behaviors.

Ideally, strategic-level IT planning, including the development of a strategic vision for IT, should be integrated with the organizational planning process (Tapscott & Caston, 1993). This integration should ensure alignment of the strategic vision for IT with the organizational strategic vision and alignment of the IT strategic goals with organizational strategic goals (refer back to Figure 1). A number of researchers (Feigen, 1997; Harvey Jones, 1998; Tapscott & Caston, 1993) also promote the inclusion of non-strategic level employees in developing the strategic vision for IT to achieve "buy in" for the vision.

Wilson (1992) seconds the argument for a group as opposed to individual planning process. Reich and Benbasat (2000) found that "only a vague idea exists of how (IT) visions are nurtured and refined over time". This points to problems in both the development and communication of IT visions.

Although we are unaware of any objective supporting data, our experience strongly suggests that, while few organizations have developed explicit strategic IT visions, many organizations have evolved implicit strategic IT visions. Current research (Brabston, Zmud & Carlson, 2000) indicates that most organizations only develop an IT function vision, with little regard for the merits of a strategic IT vision. This is one of the reasons that information technology so frequently does not add its expected value to an organization. The lack of a strategic vision for IT results in various entities within an organization taking a shotgun or unplanned approach to their IT management and investment. Without a vision of what IT should be in the organization, development of a plan to manage IT has no foundation on which to build (c.f., James, 1985; Knorr, 1993; Nanus, 1992; Taylor, 1994; Wilson, 1992).

After a strategic vision for information technology has been developed, it must be effectively communicated to all managers and employees who need to know and understand – and hopefully, agree with – the strategic vision for information technology. Studies show that this is more difficult to accomplish than it would appear (Brabston, 1993; Brabston, Zmud & Carlson, 2000; Coulson-Thomas, 1993). Appropriate use of multiple channels for repeated messages in different media (e.g., printed, online, e-mail, meetings, etc.) can help the message to get through. It appears that those who are higher in the organization's hierarchy receive messages about the strategic vision for IT across more channels and understand the messages more readily than those lower in the hierarchy (Brabston, Zmud & Carlson, 2000). It also appears that many organizations use a "filter-down" approach, using informal communication means rather than a formal plan to communicate their strategic vision for IT (Brabston, Zmud & Carlson, 2000).

Feeny, Edwards, and Simpson (1992) found that the quality of the relationship between the CEO and the CIO is affected by the shared vision held by these two executives of "the role of IT as an agent of transformation" (p. 435). In contrast to the filter-down approach and agreeing in essence with Feeny, Edwards, and Simpson, Reich and Benbasat (2000) found that shared domain knowledge held by both business and IT executives (presumably achieved by communication) had a significant effect on long-term alignment. They proposed that substantial effort should be aimed at building this shared knowledge. In a previous study, Reich and Benbasat (1996, p. 55) had a similar finding, that "understanding of current objectives and shared vision for the utilization of information technology are the most promising potential measures for short-and long-term aspects of the 'social' dimension of linkage," which we call alignment here.

FUTURE TRENDS

There is little ongoing research about strategic vision for IT, its implementation, and its communication. Carr (2003) made a case for an approach to IT as a commodity utility, just like electricity. Carr's view rejects the importance of a strategic vision for IT, defining IT as a support tool rather than a strategic tool. Other authors came forward to offer support for the strategic view of IT, rejecting the strict IT-as-support-only view (Bartholomew, 2003; Delisi, 2003; Keefe, 2003; Schrage, 2003). This debate is ongoing among both scholars and managers.

Another issue is that some feel that IT strategy – whether general or specific – should be kept on a need-to-know basis and not communicated throughout an organization and its strategic partners. Certainly, there is good reason for keeping the competition in the dark but not at the expense of distributed decision-making capability and progress toward strategic goals within the organization. It is the author's view that strategic vision can be communicated, but perhaps, the strategic goals that are derived from that vision should be kept to a need-to-know basis.

Sabherwal and Chan (2001) found that alignment of business and IT strategies does in fact matter, but only for proactive organizations – those they categorized as prospectors and analyzers – but not for defensive organizations. This makes sense since "defender" organizations would primarily focus their IT plans on responding to their external competitive environment and not on longer-range plans of the organization as a whole.

CONCLUSION

There is little wonder, given the communication environment for communicating or implementing the strategic vision for information technology, that this has not become a strategic necessity, particularly for information-intensive organizations. In this enlightened digital age, it is surprising that so few organizations have a strategic vision for IT while so many have a strategic vision for their IT function. Yet the potential of developing and effectively communicating a strategic vision for information technology still remains high.

KEY TERMS

Alignment: In this context, alignment means the alignment of the strategic vision for information technology with the organization's strategic vision, ensuring the strategic vision for information technology supports the organization's strategic vision.

Operational Goals: Very specific targets that represent the desired outcomes the organization expects to achieve over the short term; operational goals are derived from the tactical goals.

Organizational Strategic Vision: A vision statement that determines where the organization will go and how it will get there in general; contrasted to a mission statement, which is more specific and shorter in term.

Strategic Goals: Broad targets that represent the desired outcomes the organization expects to achieve over the long term.

Strategic Vision for Information Technology: A vision statement of how the organization will use information technology to achieve its organizational vision. Like the organization's strategic vision, it is not as specific as is the strategic vision for the information technology function.

Strategic Vision for the IT Function: A vision statement that articulates the organizational role of the IT function as well as the dominating values applied in carrying out these roles; affects the function of the IT department but not necessarily the rest of the organization directly.

Tactical Goals: More specific targets that represent the desired outcomes the organization expects to achieve over the middle term; tactical goals are derived from the strategic goals.

Vision: A statement of values and beliefs that sets forth the organization's overriding beliefs.

Strategically-Focused Enterprise Knowledge Management

Robert J. Mockler

Dorothy G. Dologite
Baruch College, USA

INTRODUCTION

Many of the knowledge management systems, such as the ones described in this entry, were originally computer information systems to which were added knowledge expertise that complemented the information and data communicated. As use of the Internet expanded and intranets within companies were developed, many new knowledge expertise exchange systems were established. As seen in the following discussions, many knowledge systems are therefore mixed, that is, integrated with traditional information and decision support systems, as at the consulting firm, while many, such as Xerox's, focus specifically on expertise knowledge storage and transfer and so can be designated *focused* knowledge management systems. Expert knowledge-based systems generally are *pure* knowledge systems (Mockler, 1992; Mockler & Dologite, 1992).

BACKGROUND

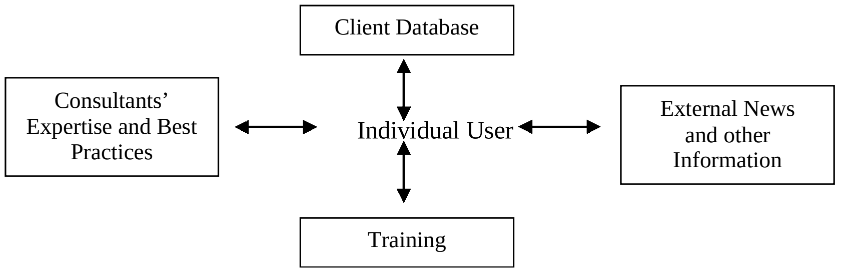
Narrowly defined, knowledge refers to practical skills or expertise gained from actual experience. In practice, however, knowledge management generally refers to the process of identifying and generating, systematically gathering, organizing and providing access to, and putting to use anything and everything that might be useful to know when performing some specified business activity. The knowledge management process is designed to increase profitability and competitive advantage in the marketplace.

As seen in the Key Terms section at the end of this article, since the knowledge management process involves keeping informed about and getting to know anything useful to doing a business task, the process can encompass data, information, and knowledge. Further, the knowledge management process can involve employing any useful and practical means of communication and storage, manual or electronic. Useful manual means might include: service manuals; professional publications; personal correspondence and conversations; special studies and reports; client correspondence and summaries; competitor role-playing; sales force feedback; current news; supplier feedback; and the like. Useful computer-based electronic technologies might include: e-mail; hierarchical, network, and relational databases and data warehouses; group decision support systems; Lotus Notes; intranets and Internet Web sites; browsers and search engines; expert and knowledge-based systems; and the like.

Because of the wide range of concepts and activities involved, the term knowledge management can more easily be understood by examples. Figure 1 outlines the knowledge management system (KMS) at a large consulting firm (Engoron, 1998).

The strategic focus is the individual consultant who needs access to data, information, and knowledge in order to do his/her job. Since consulting is its business, the

Figure 1. Knowledge management system at a major consulting firm



system is strategic. The system provides this access in large part electronically.

At the top of Figure 1 is a large computer database of information about clients, covering past assignments, consultants who worked on the assigned projects, outcomes, organized data on the company involved, and contacts who can provide further information. On the right, there is a system incorporating expert knowledge-based systems that scans news media and library resources daily and daily directs relevant intelligence material to different consultants. On the left is a database of consultants' expertise or knowledge including that acquired from experience during past assignments. This includes written summaries of what was learned from the assignments, videos in which consultants describe the highlights of their experiences or general knowledge, and contingent best practices guidelines in different areas (such as strategic alliances, all marketing and production areas, human resources management, and the like). At the bottom, there is available a bank of online training programs, which a consultant can make use of (privately) to sharpen skills needed to improve job performance.

On any given day that a consultant receives a new assignment, he/she could immediately review current relevant information in the media (intelligence) about the client and project area, gather information quickly about the client and past assignments involving the client, review the related knowledge expertise of other consultants, and brush up on needed skills. At the same time, the consultant would make use of any relevant personal knowledge sources. The system is a good example of using a knowledge system to strategically manage resources; that is, of a strategic management knowledge system.

Not all knowledge management systems are that complex or that multidimensional in scope. Some are narrowly focused on single activities. For example, Xerox in 1996 developed Eureka, an intranet communication system linked with a traditional corporate computer database that helps service representatives share repair tips; that is, knowledge. To date, more than 500 tips have been entered by Xerox technicians, and this practical knowledge is available to all via their laptops. For employees scattered around the world who travel often, the ability to share such know-how means they do not have to miss out on the kind of knowledge typically exchanged at the water cooler (Hickens, 1999).

A number of key characteristics of knowledge management can be identified from company experiences. These can apply to strategic and operational knowledge systems. First, the types of knowledge management systems vary considerably depending on the company situation requirements, a contingency perspective. Second, knowledge generation involves identifying knowledge relevant to strategic business activities, as well as its source and the way it is used or exploited. Third, *structuring* refers to designing knowledge management systems to capture and deliver the knowledge generated; such structures can range from simple ones involving individual business process areas, as at Xerox, to multidimensional complex enterprise-wide ones, as at the consulting firm. Their content can involve any company activity/ business process or combination of them. Fourth, *diffusing* or communicating any type of relevant data, information, or knowledge involves transferring and absorbing knowledge to put it to work. In the company experiences studied, the main means of diffusion was electronic and audio/video tools. Knowledge is also very often continually transferred and absorbed informally through personal interaction.

Due to the complexity of knowledge management systems, they are best defined by a description of their characteristics, as discussed previously.

ENTERPRISE-WIDE KNOWLEDGE MANAGEMENT SYSTEMS

This section begins by describing a range of systems in use by businesses followed by a discussion of the contingent situation requirement factors of knowledge management systems. This section then continues with discussing the impact of these factors and others on KMS developments as well as their implementation and use in such areas as: knowledge generation and selecting or developing strategic structure, content, and design of the system

Company Examples

The Ford Motor Company case provides an example of how at a large firm the company-wide strategic knowledge systems are closely linked to and dependent on computer information systems (Austin, 1997, 1999). As part of an integration program in the early 1990s, computer information systems at Ford were standardized across the company, which enabled installation of an external Internet network – extranet – with appropriate Web sites linking Ford with its suppliers and with its customers. Most of these were used initially for communication of information on available models, prices and availability of supplies, and other information (that is, targeted organized data). It also enabled development of an internal company intranet system, which also focused mainly on information conveyance initially.

The system also, however, served as a basis upon which to develop broader, more strategic knowledge systems. For example, in the design area, as auto design and development facilities were more closely coordinated worldwide, knowledge about solving design problems and inconsistencies could now be resolved using the intranet, a knowledge exchange process based on experiential expertise. Knowledge about lessons learned from experience in other business process areas, such as manufacturing, could also now be exchanged, since a worldwide system with Web sites was in place.

Complex strategic knowledge management systems can also focus on critical business activity areas. For example, strategic alliances are extremely important to multinational companies today (Mockler, 1999; Sparks, 1999). They involve, however, complex human and business processes whose management requires in-depth expertise gained from experience. Capturing this developing knowledge base is a knowledge management activity. As a company undertakes alliances and begins learning from successes and failures, leaders in alliance management within a company emerge. These leaders, who are essentially gurus with experience and knowledge gained from experience, are the firm's initial imbedded alliance expertise capability. This initial experiential expert knowledge base in successful firms is extended in several ways. First, formal processes and procedures and a staff capable of managing alliance processes are developed. This is the initial knowledge depository for future use. The steps taken to collect, store, and disseminate this knowledge and to train people in order to further institutionalize alliance capabilities vary at different firms (Harbison & Pekar, 1997a, b, c).

Hewlett-Packard (H-P), for example, found that general seminars for managers on alliances were not enough. Managers needed H-P specific information on the best practices guidelines developed from H-P alliance experiences. A database of case histories, tools kits, checklists, and best practices was, therefore, developed and incorporated into training seminars. This database material was supplemented with studies of the best practices of other companies (Harbison & Pekar, 1997a, b, c).

In general, such a knowledge database would include a specific company's experiences with each of its alliance partners in each of the applicable best practices guidelines areas, areas that are outlined in alliance guidebooks (Mockler, 1999). These areas include strategic planning, negotiation, alliance structures and contracts, operational planning and management, and control. Companies such as Ford, IBM, and Dun & Bradstreet, are in various stages of creating such company-specific database repositories; most often these are mixed systems – using computers and other approaches, as for example at H-P. The alliance knowledge bases are Web sites that are accessible from laptop computers by consultants or service personnel at clients' offices (Harbison & Pekar, 1997a, b, c).

As part of their strategic knowledge management systems, dissemination of this knowledge is usually supplemented through seminars and workshops. BellSouth, for example, has offered a two-day alliance workshop for 150 senior managers, a major means of developing personal information networks to encourage ongoing knowledge dissemination. H-P has conducted 50 two-day seminars on alliances for its top 1000 executives prior to 1999 (Harbison & Pekar, 1997a, b, c).

Contingent Solution

As seen from the company experiences described, KM is a contingent process. While it is stimulating and useful to study the different approaches of other so-called models, the final solution will be the one that meets specific situation requirements factors, such as:

- The company's size and nature of its business.
- The company's competitive position.
- The type of business activity(ies) supported.
- The knowledge used for strategic aspects of the business activities targeted.
- The type of knowledge.
- The people involved.
- The state of the organization's culture.
- Available company resources.
- The technologies available and needed.

Knowledge Generation

Knowledge comes from inside and outside the organization. The main criteria are whether and how it is useful in making business activities and processes more effective and efficient (Moore, 1999). Its source – whether created from scratch or borrowed – is a secondary consideration. For example, some companies have an award for the best stolen idea! Five methods of generating knowledge can be identified: acquisition; dedicated resources; fusion; adaptation; and knowledge networking.

Knowledge can be acquired in many ways – for example, through strategic alliances, acquisitions of patents or other companies, engaging consultants, outsourcing research and development, and hiring experts. While each of these sources is useful, additional steps are needed to assimilate acquired knowledge into existing organizations.

Dedicated resources were established at H-P to preserve and transmit company knowledge about strategic alliances. H-P also set up a permanent knowledge system designed to preserve and transmit knowledge to targeted users in a systematic continuing way. This is referred to as institutionalizing or imbedding knowledge within a company.

Fusion involves bringing together people of different perspectives to create new synergies. Sometimes referred to as creative chaos, such interactive collaboration is often needed to create new knowledge. There are several guidelines that help make such brainstorming cross-fertilization work: identify key knowledge workers who might be brought together; provide the time and incentives to fuse knowledge; create specific projects and project goals that inculcate attitudes encouraging such working together; reinforce a sharing culture through incentives and leadership.

Adaptation often arises from competitive market pressures, such as when new technologies are invented, competitors introduce new products, and social changes occur. These pressures can drive knowledge generation. Knowledge is also generated by informal self-organizing networks or "webs" within organizations that may over time become more formalized. There exist communities of knowers within organizations, united by common interests or a common professional vocabulary, who talk with each other in person, by phone or through e-mail or groupware – to share knowledge and solve problems, in essence by word-of-mouth. This kind of knowledge is hard to capture systematically, though at times, such as at Xerox, it can be done. Such informal webs can be nurtured through creating common meeting places, allowing time for people to interact, and generally developing a corporate sharing climate.

Developing Strategic Structure, Content, and Design for the System

These initial decisions are dictated by strategic needs. For example, first the needs of strategic operations are identified – as in the consulting operation described earlier or in the strategic alliance area at H-P. Second, the sources of this knowledge – the people and data/information reservoirs – are identified; for example, the consulting firm's partners' experiences in former assignments, the alliance managers' experiences at H-P, and the repair workers' expertise at Xerox. Third, the form it is in and its suitability to available manual and electronic tools. Five different media were used, for example, at the consulting company: video and audio tools, databases, expert systems, e-mail, and personal interviewing. These were supplemented by personal interaction webs. H-P's system included a variety of electronic and manual approaches in their system, which combined training and computer techniques in a much different way. Fourth, not all knowledge is easily systematically stored, transmitted, and absorbed; for example, knowledge involving planning in rapidly changing markets often requires tacit intuitive knowledge that is not readily articulated and codified. For this segment of a KMS, personal networking or expert systems may be more useful. In contrast, repair procedures learned from experience can be codified, as at Xerox.

Davenport (1997) has described the structure of a KMS at Monsanto. Monsanto's knowledge management architecture system aimed to allow the firm's 30,000 employees to share knowledge and information. In making global knowledge locally available, Monsanto was mimicking GE's strategic posture: combining the knowledge benefits of a large firm (quantity and diversity) with the benefits of a small one (accessibility to knowledge).

As for the system's structure, in classifying existing knowledge and information a distinction was made between quantitative structured content and relatively unstructured qualitative content. Different tools were used to store and manipulate each kind: relational databases with desktop access through appropriate query software for structured material; Web pages and Lotus Notes for unstructured material. This avoided distortions arising from forcing unstructured material into an artificially rigid structure.

The system also provided definitions of key terms, such as "customer," "product" and "material," a necessary step in organizing intellectual material into a single system. Such common definitions were also necessary common ground for communicating and sharing knowledge across boundaries, but they had to be limited to only the most necessary terms, since some local truths and nuances can be lost during the standardization process. Gatekeepers were charged with continually refining this aspect of the system, as well as with organizing and identifying the most important aspects. A large body of material randomly assembled could be counterproductive; editing was needed, as were clearly defined paths to needed knowledge. All of the major systems examined have such gatekeepers and facilitators.

FUTURE OUTLOOK AND CONCLUSION

As discussed in this article, the current and future success of KMS is and will be highly dependent on the strategic fit of structure and content with strategic requirements or critical success factors in the situation. The success of knowledge management also depends and will continue to depend on the participation of people sharing their knowledge expertise with others, which in turn can depend on the way the system is designed, implemented, and managed (the operational fit), as well as on the degree to which a firm has a "learning" organization culture (Lucier & Torsilieri, 1997). Nurturing this sharing culture in the future will require very active leadership by a knowledge management champion, since very often people are reluctant to share their expertise (Manchester, 1999b).

KEY TERMS

Data: Something given or admitted as a fact on which an inference may be based. Simple observations of the world, which are often quantified, and easily structured, captured on machines, and transferred. The number of "baby boomers" born in a given year is data.

Expert Systems: A computer system that attempts to replicate what human experts normally do. Human experts make decisions and recommendations, such as what company strategy to follow or who to give a bank loan to, and do tasks, such as adjust temperature controls in a manufacturing plant. They also assist (or help) and train others to do tasks and to make decisions. So do expert systems.

Information: Knowledge derived from reading, observation or instruction, at times consisting of unorganized or unrelated facts or data. Data endowed with relevance and purpose, for example, a firm's balance sheet and income statement.

Intelligence: Information, news, and advice. Brain power or cognitive skills. IBM uses the term "business intelligence systems" to describe their mixed integrated knowledge systems.

Knowledge: Familiarity gained by actual experience, practical skill, or expertise. The act, or state, of understanding. Valuable information arising from reflection, synthesis, and other cognitive activities of the human mind. It is often, but not always, hard to structure, difficult to capture on machines, sometimes tacit, and hard to transfer. *Knowledge* includes data and information (organized data which are relevant and purposeful), and knowing how to apply and use that information and data. The term "ledge" means to put to work or apply. The word knowledge, therefore, means knowing how to put to work what we know, and so in popular usage can in certain situations encompass information and data.

Learning: In this context it means knowledge and skills acquired by instruction or study.

Technology: Applied science, systematically organized knowledge.

S

Strategies of E-Commerce Business Value Optimization

Ada Scupola
Roskilde University, Denmark

INTRODUCTION

The Internet economy is becoming an integral part of many countries' economies, creating new jobs, giving rise to new companies like the dot coms and transforming traditional jobs and traditional companies. The Internet is increasingly becoming a part of the basic business model for many companies as organizations around the world are adopting new e-business models, integrated solutions to explore new ways of dealing with customers and business partners, new organizational structures and adaptable business strategies (Singh & Waddell, 2004). There are many definitions of electronic commerce (e.g., Wigand, 1997). Here, a classic definition by Kalakota and Whinston (1996) is adopted, where e-commerce is "the buying and selling of information, products and services via computer networks today and in the future via any one of the myriad of networks that make up the 'Information Superhighway (I-way)'" (p.1). A distinction between physical and digital products can be made. A digital product is defined as a product whose complete value chain can be implemented with the use of electronic networks; for example, it can be produced and distributed electronically, and be paid for over digital networks. Examples of digital products are software, news, and journal articles. The companies selling these products are usually Internet-based "digital dot coms" such as Yahoo and America Online. On the contrary, a physical product cannot be distributed over electronic networks (e.g., a book, CDs, toys). These products can also be sold on Internet by "physical dot coms", but they are shipped to the consumers. The corporations using electronic commerce are distinguished into "bricks and mortar" companies, hybrid "clicks and mortar" companies (such as Amazon.com) and pure dot coms (Barua & Mukhopadhyay, 2000).

Many studies from the early days of deployment of information technology (IT) in organizations have struggled to measure the business value and profitability of information technology (Barua & Mukhopadhyay, 2000). Many of these studies have showed that productivity gains are small or non existent and that the effects of information technology and electronic commerce have to be often looked upon from a competitive advantage point of view (Barua, Konana, Whinston, & Yin, 2001; Porter & Miller, 1985; Scupola, 2003). Recent research has argued that increasing the business value of electronic commerce to a corporation is important to shift the focus from whether electronic commerce creates value to a company to "how to create value" and "how to optimize such value" (Barua, Konana, Whinston, & Yin, 2001). This can be achieved by exploring complementary relationships between electronic commerce, strategies and complementarity (Scupola, 2002, 2003).

BACKGROUND

Since the early days of IT use in commercial organizations, researchers and professionals have struggled with the problem of measuring the bottom line contribution of IT investments (Scupola, 2003). Six main areas of IT business value research can be distinguished: information economics-based studies; early IT impact studies; production economics studies that did not find positive impacts; microeconomics studies that found positive impacts of IT; business value studies; and studies involving complementarity between IT and non-IT factors. The information economics-based studies date back to the 1960s, and though relevant to the economic contribution of IT investments, they mainly focus on the changes in information due to IT use and their impact on the single decision-maker. Therefore, while the information economics approach is theoretically sound and rigorous, its unit of analysis, which is either the individual or team decision, makes it difficult to obtain meaningful and insightful results in broader organizational contexts (Barua & Mukhopadhyay, 2000).

In the early 1980s, a stream of research emerges focusing on assessing the contribution of IT investments to performance measures such as return on investment and market share (Barua, Konana, Whinston, & Yin, 2001; Barua & Mukhopadhyay, 2000). The majority of these studies did not find much positive correlation between IT investments and firm performance metrics up to the early 1990s. The lack of correlation between IT investments and productivity made Roach (1988, 1989) to coin the term "IT productivity paradox".

In the 1990s, research on measuring the economic and performance contributions can be divided into two main streams: one based on production economics and one based on "process-oriented" models of IT value creation. The IT production studies based on production economics hypothesize that IT investments are inputs to a firm's production function. These studies (e.g., Brynjolfsson & Hitt, 1993, 1996) finally started finding signs of productivity gains from IT. For example, Brynjolfsson and Hitt (1996) identify three sources of IT value to a corporation: productivity, consumer value, and business profitability. The study shows that information technology contributes to increases in the productivity and consumer value, but not business profitability. Simultaneously, process-oriented studies started hypothesizing relationships between IT and other input factors to performance measures at various levels of aggregation. These studies (e.g., Kauffman & Kriebel, 1988) have laid the foundation of the business value approach to the impact of IT on firm performance. This approach on the contrary of the production function-based approach might have the explanatory power to point out where and how IT impacts are created and where management should act to increase the payoff from IT investments. These explanations are more difficult to get with production function-based approaches since they operate at a very high level of aggregation, thus making it difficult to distinguish between different types of IT investments and their impacts on specific areas of business. After having dispelled the productivity paradox, new refinements to existing approaches are emerging to measure the contribution of IT to business performance. An important stream of research is pointing to complementarity theory to investigate the interactions between IT and other organizational factors (e.g., Barua, Konana, Whinston, & Yin, 2000, 2001; Barua, Lee, & Whinston, 1996; Barua & Mukhopadhyay, 2000). In fact, production economics and business value approaches have mostly ignored the synergy between IT and other related factors such as the level of fit with business strategies, employee empowerment, and team orientation of business processes. Barua and Mukhopadhyay (2000) present a generalized business value complementarity model that explores the synergies among such factors. The basic idea of their business value complementarity model (BVC) suggests that investments in IT should be first related to intermediate performance measures such as time to market, customer service, response time and extent of product mass customization to be able to see any positive results from such investments. In a second moment, the intermediate performance measures can be related to high-level performance metrics such as profitability, return on investment (ROI), market share. The focal point of a business value complementarity model is the complementarity that potentially exists at each level of the model (Barua & Mukhopadhyay, 2000; Barua, Konana, Whinston, & Yin, 2001; Scupola, 2003).

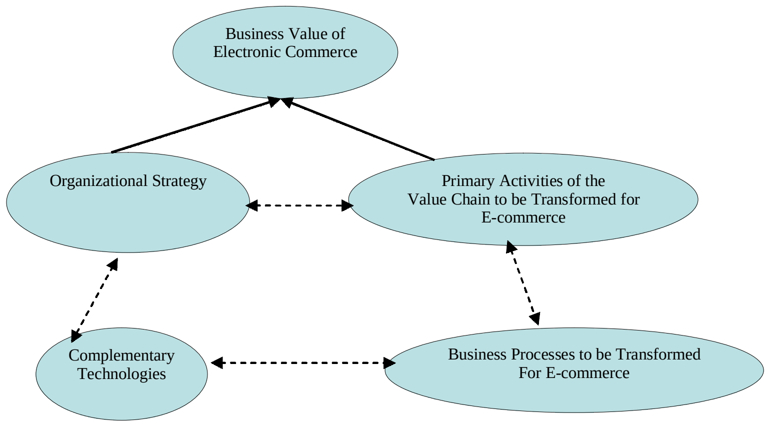
The advent of the Internet, based on open standards and a universal Web browser, raises the question of whether investing more in Internet technology lead to a better financial performance in electronic commerce. This calls for more attention to the specific business processes that have to be reengineered for online commerce and the way they should support the company strategy (Scupola, 1999, 2003).

MAIN THRUST OF THE ARTICLE

A business value complementarity (BVC) model of electronic commerce could be used as a methodology to optimize e-commerce initiatives when entering the e-commerce arena (Scupola, 2003). The BVC model presented here is based on the value chain (Porter, 1980), the theory of BVC (Barua, Lee, & Whinston, 1996; Barua & Mukhopadhyay, 2000; Barua et al., 2002; Milgrom & Roberts, 1990) and the concept of strategy (Porter, 1982). In this model, it is hypothesized that complementarity (represented in Figure 1) exists between the variables of the same level and different levels of the model. It is furthermore hypothesized that the exploration of complementarities and possible synergies between the company strategy, the primary activities of the value chain, corresponding business processes and supporting technologies should: 1) maximize the business value of electronic commerce to a corporation and 2) lead to a better fit between the overall organizational strategy, the business processes that have to be transformed for the online market place, and the information system that should be designed and implemented to support these strategies. The exploration of complementarities, it is hypothesized, can also contribute both to avoid investments into an information system that could not be used at a later point if new e-business processes should be added to the system and avoid the implementation of a business model that does not correspond to the corporation's strategy. It is argued that to succeed in electronic commerce it is important to reengineer the parts of the value chain and the corresponding business processes relevant to the product in question and the company strategy.

The main objective of the model is to make the business value of electronic commerce as close to optimal as possible in terms of one of the performance measures, such as company profitability, competitive advantage, increase in market share, shareholder value or customer satisfaction. This can be done by exploring

Figure 1. Business value complementarity model of electronic commerce



complementarities among the dependent variables of the model: the company strategy, the activities of the value chain, the corresponding business processes, and the technologies available to transform these activities and processes for the marketspace.

Furthermore, to succeed in electronic commerce, it is important to reengineer the parts of the value chain and the corresponding business processes relevant to the product in question and the company strategy. For example, the strategy or combination of strategies a company wants to pursue is relevant for the primary activities of the value chain, and the corresponding business processes that have to be implemented online. The strategy is also relevant to the classes of technologies that have to be chosen to enter the electronic marketplace. For example, a company can use electronic commerce to implement a cost leadership strategy, or to become the low cost producer in the industry. Once decided upon the strategy, it is important to explore complementarities between the strategy and the value chain activities in order to implement online all those activities that would support an optimal implementation of the strategy chosen.

The number of primary activities and corresponding business processes that should be transformed for the marketspace depends also on the company's type of product and strategy. It is important to take into consideration complementarities among the different activities of the value chain when reengineering for electronic commerce. The more activities of the value chain are simultaneously conducted online, the more likely it is that the business value of electronic commerce will be optimized. The adoption of a holistic approach in redesigning the primary activities for electronic commerce would, thus, be a more successful strategy than reengineering only one or some at a time. This is due to potential complementarities between the different activities, which lead to a better performance in one if the others are also reengineered for online commerce.

Furthermore, each business process of each activity of the value chain could be reengineered for e-commerce. This model argues that the exploration of complementarities among the different business processes and the simultaneous transformation of all the complementary processes of a particular activity for online commerce would lead to a higher business value than if only one or a casual numbers of processes were reorganized online (Scupola, 1999).

In the design phase, it is important to consider potential complementarities between the business processes that have to be redesigned for online commerce and the supporting technologies. The exploration of this complementarity should lead to an optimal system design that also offers possibilities for further expansion if other online business processes should be added in the future. For example, electronic search of the company's information will give more accurate and quicker results, the faster and more advanced the search engine is and the better built are the user interface and the repository systems.

Finally, the exploration of complementarities between the different technologies used to implement the system for electronic commerce could bring to a more robust and flexible computer system than a system built without the exploration of complementary relationships between the different component technologies. For example, end user interfaces and repositories are complementary technologies in the sense that the better designed the repository system, the simpler the user interface can be.

FUTURE TRENDS

The studies on IT productivity and business value conducted over the last decade have showed positive impacts of IT investments on firms' productivity both with respect to labor and other non-IT capital used by organizations (Barua & Mukhopadhyay, 2000). However, Internet-based technologies, with their open standards and wide applicability, raise again the issue of profitability and business value of investing in such technologies. Furthermore, the fact that Internet is giving rise to a "new economy", raises a number of questions among which: How productive are the players in this new economy? Does e-commerce increase the profitability and business value of brick and mortars and hybrid click and mortars companies? For dot coms, do more investments in Internet commerce technologies necessarily lead to a better performance of the company? And especially, if all companies have equal access to Internet-based technologies, what are the factors that differentiate their performance in e-commerce?

Recent literature investigating the business value and profitability of electronic commerce is focusing on the exploration of complementary relationships between electronic commerce technologies and other factors in order to see positive returns from investments in these technologies (Barua, Konana, Whinston, & Yin, 2000, 2001; Barua & Mukhopadhyay, 2000; Scupola, 2003). For example, Barua, Konana, Whinston, and Yin (2001) develop a framework of electronic commerce business value that identifies linkages between performance drivers such as Internet applications, processes and electronic business readiness of customers and suppliers and operational excellence and financial metrics. They argue that "firms engaged in electronic business transformation must make synergistic investments and commit resources not only in information technology, but also must align processes and customer and supplier readiness to maximize the benefits" (p.1).

Similarly, an empirical investigation of the business value of e-commerce in small, medium and large companies across Europe and USA (Barua, Konana, Whinston, & Yin, 2000) identifies a set of key e-drivers such as system integration, customer orientation of IT, supplier's orientation of IT, and internal orientation of IT. The study concludes that high performance companies have invested more effort and resources in these e-business drivers than companies who have not benefited from e-business.

To conclude, these studies show that ignoring complementarities in research on business value measurement might lead to misleading results. On the other hand, from a managerial point of view, the non exploration of complementary relationships between IT and related factors such as strategy, business processes, business models, incentives, and so forth, might lead to failure of investments in sophisticated electronic commerce systems and ventures. These considerations point to the need for more empirical as well as normative, prescriptive research on complementarity and business value of IT in general and electronic commerce technologies in particular.

CONCLUSION

Many companies are very skeptical about investing into electronic commerce technologies due to the lack of profitability, (or at least the difficulties to show positive return on IT investments) that until now has characterized the investments in IT and electronic commerce. Here, a framework that can be used as a methodology to analyze organizational strategies and technology choices in reengineering for electronic commerce has been presented. Companies should explore the potential complementarities existing between strategy, value chain activities, business processes and supporting technologies when entering the field of electronic commerce. This should lead to investments in electronic commerce systems that best support the company strategy, thus minimizing failures. This is a future challenge for corporations, industries and researchers.

KEY TERMS

Business Processes: The specific processes into which each primary activity of the value chain can be decomposed.

Business Value: The overall value that an investment brings to a corporation. Examples of performance measures of the business value of electronic commerce can be: (1) profitability, that is, whether electronic commerce contributes to an increase in the profitability of the corporation; (2) competitive advantage that could be measured as an increase in market share, shareholder value or customer satisfaction.

Complementarity: Several activities are mutually complementary if doing more of any one activity increases (or at least does not decrease) the marginal profitability of each other activity in the group. Complementarities among activities imply mutual relationships and dependence among various activities whose exploration can lead to higher profitability.

E-Commerce: The buying and selling of information, products and services via computer networks and especially the Internet.

Internet Economy: A large collection of global networks, applications, electronic markets, producers, consumers and intermediaries.

Re-Engineering: The redesign of a corporation's business processes (or part of them) to take place over the Internet. The main goal is reduced costs, lower product cycle times, faster customer response, and improved service quality.

Strategy: A planning, rational process through which the company chooses a certain mode of development, among all of the possible ones, and maintains that direction through a well-defined period (design view). In the process view, strategy is a process that might change on the way, giving rise to an emergent strategy. The realized strategy might be different then the original intended strategy.

Value Chain: The activities of a corporation such as procurement, production, marketing and sales, and customer support.

Structural Text Mining

Vladimir A. Kulyukin
Utah State University, USA

John A. Nicholson
Utah State University, USA

INTRODUCTION

The advent of the World Wide Web has resulted in the creation of millions of documents containing unstructured, structured and semi-structured data. Consequently, research on structural text mining has come to the forefront of both information retrieval and natural language processing (Cardie, 1997; Freitag, 1998; Hammer, Garcia-Molina, Cho, Aranha, & Crespo, 1997; Hearst, 1992; Hsu & Chang, 1999; Jacquemin & Bush, 2000; Kushmerick, Weld, & Doorenbos, 1997). Knowledge of how information is organized and structured in texts can be of significant assistance to information systems that use documents as their knowledge bases (Appelt, 1999). In particular, such knowledge is of use to information retrieval systems (Salton & McGill, 1983) that retrieve documents in response to user queries and to systems that use texts to construct domain-specific ontologies or thesauri (Ruge, 1997).

BACKGROUND

Structural mining of texts consists of two related tasks: the task of partitioning text into components, for example, topics, sentences, terms, and so forth; and the task of finding relations among found components, for example, term and topic associations. Texts can be divided into three broad categories: free, structured, and semi-structured.

Free texts do not give the computer many road maps to the information they contain. To discover a road map in a free text requires a certain amount of data mining through parsing, statistical analysis, and/or machine learning. Novels and newspaper and journal articles are examples of free texts. Structured texts organize their content according to well understood road maps. Relational databases are structured texts where all of the relations between textual entities, that is, records, are known and can be readily obtained through well-defined queries. Semi-structured texts offer more structure than free texts but less than structured ones. HTML pages are semi-structured texts. While they offer a standard set of tags that point to the structural organization of information in them, they do not specify the types of information that the tags label or the relations among these types.

ISSUES IN TEXT MINING

The three fundamental problems in structural text mining are:

- Text Segmentation;
- Automatic Ontology (Thesaurus) Construction; and
- Information Extraction.

Text segmentation is a process of partitioning free texts into segments of content. The underlying assumption is that texts are intellectual artifacts that consist of words related to each other semantically in a number of complex ways (Bookstein, Kulyukin, Raita, & Nicholson, 2003). The intellectual process of producing texts incidentally leaves behind simple statistical regularities. Capturing those regularities through statistical analysis allows one to arrive at the structural organization of information in the texts.

The two most prominent approaches to text segmentation are statistical and qualitative. Statistical approaches to text segmentation (Hearst, 1997) first parse texts to identify primitive components, for example, sentences, and then combine those primitive components into larger segments by defining various similarity measures between pairs of components. For example, if components are represented as vectors of terms each of which is assigned a specific weight (1 or 0 in the basic case), the similarity between two components can be computed through a range of vector metrics: dot product, cosine of the angle between the vectors, a hamming distance, and so forth. Powerful as they are, statistical approaches to text segmentation have two drawbacks. First, statistical computations are based on the idea of statistical significance. Achieving statistical significance requires large quantities of data. Since many documents are small in size, the reliable discovery of their structural components using numerical methods alone is not always appropriate.

Second, numerical approaches frequently ignore the fact that text writers leave explicit markers of content structure in document texts. The presence of these markers in texts helps the reader digest the information contained in the texts. If these markers are ignored, the texts become much harder to navigate and understand. These intuitions are at the heart of qualitative approaches to text segmentation (Kulyukin & Burke, 2003). In these approaches, the structural organization of information in texts is discovered through mining free text for content markers left behind by text writers. For example, police crime reports and scientific journal papers have well defined structures that can be fruitfully mined for information. The ultimate objective of qualitative approaches is to find scalable data mining solutions for free text documents in exchange for modest knowledge engineering requirements.

Research in automatic thesaurus construction investigates ways to extract thesaurus relations from texts. A thesaurus is a set of terms plus a set of relations among them. Automatic thesaurus construction complements manual thesaurus construction, which, as the argument goes, is expensive in terms of expert time and effort and cannot respond in a timely manner to rapid changes in scientific fields. Automatic thesaurus construction is usually collection dependent, that is, it is done on a specific text collection at hand. Approaches to automatic thesaurus construction include statistical analyses of term co-occurrence data (Dagan, Lee, & Pereira, 1999), syntactic patterns used to extract semantic relations among terms (Grefenstette, 1994; Hearst, 1992), and ensemble methods that combine different information extraction techniques and rank their outputs by their utility to the task at hand, for example, manual query expansion during retrieval (Curran, 2002). Evaluation of automatic thesauri, that is, evaluation of the authenticity of found relations and their utility, remains a major challenge.

Information extraction goes hand in hand with automatic thesaurus construction. In information extraction, the problem of mining text for structure is cast in terms of extracting sets of facts, for example, a specific statistic in a crime report, and/or rules, for example, how to find a victim's name and age in crime reports, from the texts at hand. In particular, many researchers are concerned with the problem of extracting database-like structures from Web pages, in effect reverse-engineering the process of database-backed Web page generation.

Hammer et al. (1997) present a configurable tool for extracting semi-structured data from a set of HTML pages, given a declarative specification of where the data of interest are located. The machine learning approach to this problem has been labeled "wrapper induction" (Kushmerick et al., 1997). The extraction procedure, or wrapper, for a specific resource is learned from a set of representative pages from that resource.

Hsu and Chang (1999) describe a formalism to represent information extractors as Finite-State Transducers (FST). A finite-state transducer is a variation of a finite-state automaton (Hopcroft & Ullman, 1979). The input document is assumed to be tokenized before it is given to a finite-state transducer. The authors distinguish two types of transducers: single-pass and multi-pass. A single-pass transducer scans the text only once. A multi-pass transducer scans the text multiple times, each time focusing only on a specific type of object to extract. The ultimate goal of this approach is the automated construction of extractors from a set of training examples. However, the reported empirical evaluations assume that the space of possible graph structures, that is, finite-state automata, is restricted or that the structure is given to the learner in advance.

Freitag (1998) casts information extraction as a relational learning problem. Relational learning represents hypotheses as sets of if-then rules. Because sets of if-then statements can be viewed as programs in a logic programming language, such as PROLOG, relational learning is often called Inductive Logic Programming (Mitchell, 1997). Freitag describes a general purpose top-down relational learning algorithm for information extraction called "SRV". SRV takes as input a set of token-oriented features that encode most of the domain-specific information. For example, they may encode a standard set of questions that can be asked of someone's home page, such as the owner's name, affiliation, e-mail, and so forth. An answer to each question is assumed to be a text fragment from that home page. Thus, the algorithm solves the problem of finding the best unbroken fragment of text that answers a question from a given set of questions. The SRV algorithm makes no assumption about document structure. Instead, structural information is supplied as input to the system.

Jacquemin and Bush (2000) present a tool for the acquisition of named entities, for example, names of companies, from textual sources. The authors' approach combines lexical indices with formatting instructions. Lexical indices are discourse markers and formatting instructions are HTML tags. The system includes three shallow parsers for mining HTML texts for specific structures such as lists, enumerations, and anchors. The named entities are extracted from the found structures by analyzing discourse markers and HTML tags.

FUTURE TRENDS

The issues discussed in this article are likely to remain major challenges in structural text mining. The push to automation will bring an ever greater emphasis on the issue of the evaluation of automatically discovered results to achieve greater recall and precision. Human judgment, arguably the most reliable way of evaluating automatically extracted information, is not always available and, when available, is expensive in terms of time and effort. Thus, one is likely to see more research effort on automating the evaluation of obtained results through discourse analysis and machine readable dictionaries and ontologies.

CONCLUSION

The three fundamental problems in the structural mining of text are text segmentation, automatic ontology construction, and information extraction. Text segmentation investigates methods of partitioning texts into segments of content. Automatic ontology construction focuses on the problem of finding relations among concepts in texts. Information extraction studies ways to extract specific types of information from texts to create database-like records. Each of the three research areas has a number of well established approaches briefly surveyed in the article.

KEY TERMS

Automatic Thesaurus Construction: The process of using a computer to automatically extract thesauri from texts.

Information Extraction: The process of using a computer to automatically extract specific facts and rules from texts.

Lexical Indices: Lexical items, for example, proper names and events, used to index texts.

Named Entities: Lexical phrases that fall into one of the three semantic categories: TIMEX, NUMEX, and ENAMEX. TIMEX includes temporal expressions, for example, *March 1st*, *noon EST*. NUMEX consists of numeric expressions, for example, *7.5%*. ENAMEX includes: proper names, for example, *Peter the Great*; locations, for example, *St. Petersburg*; and organizations, e.g., *Russian Orthodox Church*.

Ontology: A set of concepts and a set of relations among those concepts.

Statistical Methods: Methods that rely on collecting numerical data on texts and applying statistical techniques to analyze the data and/or to make statistical inferences about the texts.

Structural Mining of Texts: The process of partitioning texts into components and finding relations among the found components.

Text Segmentation: The process of partitioning a text into segments according to a given criterion.

Structure- and Content-Based Retrieval for XML Documents

Jae-Woo Chang
Chonbuk National University, South Korea

INTRODUCTION

The XML was proposed as a standard markup language to make Web documents in 1996 (Extensible Markup Language, 2000). It has as good an expressive power as SGML and is easy to use like HTML. Recently, it has been common for users to acquire through the Web a variety of multimedia documents written by XML. Meanwhile, because the number of XML documents is dramatically increasing, it is difficult to reach a specific XML document required by users. Moreover, an XML document not only has a logical and hierarchical structure in common, but also contains its multimedia data, such as image and video. Thus, it is necessary to retrieve XML documents based on both document structure and image content. For supporting the structure-based retrieval, it is necessary to design four efficient index structures, that is, keyword, structure, element, and attribute index, by indexing XML documents using a basic element unit. For supporting the content-based retrieval, it is necessary to design a high-dimensional index structure so as to store and retrieve both color and shape feature vectors efficiently.

BACKGROUND

Because an element is a basic unit that constitutes a structured (i.e., SGML or XML) document, it is essential to support not only retrieval based on element units but also retrieval based on logical inclusion relationships among elements. First, RMIT in Australia proposed a *subtree model* that indexes all the elements in a document and stores all the terms that appear in the elements (Lowe, Zobel & Sacks-Davis, 1995) so as to support five query types for structure-based retrieval in SGML documents. Secondly, SERI in South Korea proposed a *K-ary Complete Tree Structure,* which represents a SGML document as a K-ary complete tree (Han, Son, Chang & Zhoo, 1999). In this method, a relationship between two elements can be acquired by calculation because each element corresponds to a node in a K-ary tree. Thirdly, University of Wisconsin in Madison proposed a new technique to use the position and depth of a tree node for indexing each occurrence of XML elements (Zhang, Naughton, DeWitt, Luo & Lohman, 2001). For this, the inverted index was used to enable ancestor queries to be answered in constant time. Fourthly, IBM T.J. Watson research center in Hawthorne proposed ViST, a novel index structure for searching XML documents (Wang, Park, Fan & Yu, 2003). The ViST made use of tree structures as the basic unit of query to avoid expensive join operations and provided a unified index on both text content and structure of XML documents. However, these four indexing techniques were supposed to handle tree data. Finally, University of Singapore proposed D(k)-Index, a structural summary for general graph structured documents (Chen, Lim & Ong, 2003). The D(k) index possesses the adaptive ability to adjust its structure according to the current query load, thus facilitating efficient update algorithms.

There have been a lot of studies on content-based retrieval techniques for multimedia or XML documents. First, the *QBIC (Query By Image Content) project* of IBM Almaden research center studied content-based image retrieval on a large online multimedia database (Flickner et al., 1995). The study supported various query types based on the visual image features such as color, texture, and shape. Secondly, the VisualSEEk project of Colombia University in the USA developed a system for content-based retrieval and browsing (Smith & Chang, 1996). Its purpose was an implementation of CBVQ (Content-Based Visual Query) that combines spatial locations of image objects and their colors. Thirdly, the Pennsylvania State Univesity presented a comprehensive survey on the use of pattern recognition methods for content-based retrieval on image and video information (Antani, Kasturi & Jain, 2002). Fourthly, the Chonbuk National University in South Korea developed an XML document retrieval system that can support a unified retrieval based on both image content and document structure (Chang, 2002). Finally, the Chinese University of Hong Kong presented a multi-lingual digital video content management system, called iVIEW, for intelligent searching and access of English and Chinese video contents (Lyu, Yau & Sze, 2002). The iVIEW system allows full content indexing and retrieval of multi-lingual text, audio and video materials in XML documents.

STRUCTURE- AND CONTENT-BASED RETRIEVAL

A structure- and content-based XML document retrieval system consists of five main parts: a preprocessing part for parsing XML documents and doing image segmentation, an indexing part for generating index keys of XML documents, a storage manager part for storing index information into a specific database, a unified retrieval part for finding results and integrating them into an unified one, and a user interface part for answering user queries by using a Web browser.

When XML documents are given, they are parsed, and image segmentation is done through the preprocessing part. The parsed document information is transported into the structure-based indexer in order to index its document structure consisting of element units. By constructing the index, it is possible to support queries based on a document structure as well as a logical inclusion between elements. In addition, the parsed image information is transported into the content-based indexer in order to get the index information of its color and its shape. To obtain an image feature vector for shape, it is possible to use the image object produced by the preprocessing part and generate a high-dimensional feature vector based on distances between the center point and a set of edge points. To generate a color feature vector, it is necessary to generate a color histogram and normalize the color histogram by dividing it by the number of pixels.

The structure-based and content-based index information is separately stored into their index structures, respectively. The index structures for structure-based retrieval are constructed by indexing XML documents based on an element unit and consist of keyword, structure, element, and attribute index structures. The index structure for content-based retrieval is a high-dimensional index structure, like X-tree (Berchtold, Keim & Kriegel, 1996) or CBF (Han & Chang, 2000), so as to store and retrieve both color and shape feature vectors efficiently.

Using the stored index information extracted from a set of XML documents, some documents are retrieved by the retrieval part in order to obtain a unified result to answer user queries. There is little research on retrieval models for integrating structure- and content-based information retrieval. To answer a document structure query, a similarity between an element q and an element t is computed as the similarity between the term vector of node q and that of node t by using a cosine measure (Salton & McGrill, 1983). Also, a similarity between an element q and a document D is computed as Max{COSINE($NODE_q$, $NODE_{Di}$), $0 <= i < n$}. To answer an image content query, it is possible to compute a similarity between the query feature vector and the image feature vector as 1 – (Euclidean distance / maximum distance) and retrieve relevant documents with high similarity in decreasing order of the similarity. In the case of content-based retrieval based on both color and shape feature vectors, a similarity measure is required. A similarity between a query image q and a target image t in the database is calculated as (1-Distc(q,t)/Nc)*(1-Dists(q,t)/Ns) where Distc (Dists) means a color (shape) vector distance between a query image and a target image, and Nc (Ns) means the maximum color (shape) distances for normalization.

Finally, a final document set that is acquired by integrating preliminary results from both structure- and content-based retrieval is given to users through a convenient user interface, such as a Web browser. To design an efficient structure- and content-based query interface, it is necessary to classify XML queries into two types: simple and composite. The simple query can be divided into keyword, structure, attribute, and image query. The composite query is the composition of simple queries, like structure plus keyword, structure plus attribute, image plus keyword, and image plus structure. It is shown from some experiments that it takes much more time to answer the structure query, compared to the other types of simple queries (Chang, 2002).

FUTURE TRENDS

Directions for future work can be studies on new information retrieval models for integrating preliminary results acquired from both structure- and content-based retrieval, because the two types of retrieval are very different each other, in terms of their nature and property. This can be achieved ultimately by trying to handle MPEG-7 compliant XML documents (Haoran, Rajan & Liang-Tien, 2003; Westermann & Klas, 2003).

CONCLUSION

For effective Web document retrieval, it is very important to retrieve XML documents based on both document structure and image content. To support structure-based retrieval, it is necessary to index XML documents based on the basic element unit, thus generating four index structures: keyword, structure, element, and attribute. To support image content-based retrieval, it is necessary to construct a high-dimensional index structure like CBF (Han & Chang, 2000) for retrieving both color and shape feature vectors efficiently.

KEY TERMS

Content-Based Retrieval: Retrieval based on image content. This includes retrieval based on image color, texture, shape and position of salient objects, dominant edges of image items and regions.

Cosine Measure: The vector angle between two documents that is used as a measure of similarity.

Euclidean Distance: Ordinary straight-line distance.

High-Dimensional Index Structure: The organization of indexes for storing the feature vectors of images where the number of their dimensions is large, at least over 10.

HTML: Hypertext Markup Language. A hypertext document format used on the World Wide Web. HTML is an application of SGML. Tags embedded into the text describe certain properties of the text elements and can include other elements such as links to HTML pages or to other resources such as images. HTML is a recommendation of the W3C.

SGML: Standard Generalized Markup Language. A general language for representing documents. SGML is defined in ISO 8879:1986.

Structure-Based Retrieval: Retrieval based on document structure. This includes retrieval based on element units as well as logical inclusion relationships among elements because an element is a basic unit of XML documents.

XML: Extendible Markup Language. The initial proposal for XML was based on an already existing standard called SGML. The XML recommendation was released in 1998 by the World Wide Web Consortium (W3C).

S

Students' Perceptions of Online Courses

Judith C. Simon
The University of Memphis, USA

Lloyd D. Brooks
The University of Memphis, USA

Ronald B. Wilkes
The University of Memphis, USA

INTRODUCTION

An increasing number of traditional colleges and universities, responding to marketplace pressures, are offering online courses and degree programs. According to Weil (2001), 54% of U.S. higher education institutions offer e-learning courses. Many AACSB-accredited business schools provide courses and complete degree programs online. New schools have been created that exist solely in cyberspace (Peltz, 2000). Students can complete undergraduate online degree programs in fields as diverse as nursing, business, engineering, and technology.

Possible reasons for schools offering online courses and degree programs include: increasing revenues and credit hour production; better utilization of limited resources; serving an expanded geographic area or student population; and serving the existing student population differently. Students may take online courses due to their perceptions of location convenience, time convenience, cost, and quality.

Some online courses have been implemented so quickly that insufficient time has been available to allow in-depth assessment of the desires, interests, and concerns of their potential direct customers, that is, students. The study described here was developed to identify students' expectations and current perceptions of online courses and degree programs. The results are expected to facilitate effective planning and development of these courses and programs in the future. The intent is to study the next generation of online learners. This group's perceptions of online coursework are important for course providers as they consider ways to maintain and enlarge their programs, perhaps expanding to meet the needs of younger, more traditional students.

BACKGROUND

Online courses are a form of distance education. Today's widespread availability of the Internet has made online courses and degree programs available to students around the globe. Many traditional colleges and universities have decided to add online coursework so that they can be competitive with the large number of programs now available from private enterprises set up for this purpose. Several issues have emerged related to this instructional delivery format, and studies are now being reported related to advantages and disadvantages of this type of education.

As with other forms of distance education, convenience has been widely quoted as a primary reason for students taking online courses. Another reason is the self-paced nature of many online courses, which allows for a variety of student schedules and comprehension rates. Availability of coursework regardless of the student's physical location is another reason it is used; it would be possible for students in remote locations to take these courses as long as they had the necessary technology. It is also possible that online courses provide more up-to-date materials than that found in some traditional courses and textbooks, due to the ease of making changes to Web sites rather quickly (Accetta & Wind, 2001). Another factor that may make online courses an appealing option is that a person's age or physical limitations may be less likely to prevent the person from succeeding in this format (Brown, 2000).

Faculty who teach online courses may find it rewarding if they enjoy using new technology and also enjoy the challenge of adapting to a different form of course delivery.

Critics of online courses point out that a Web-based educational program has at least one disadvantage in that it does not provide a forum for physical contact and live debate between students and faculty. Representatives of some elite universities claim that it is impossible to replicate a classroom environment with online courses. Harvard University's Professor W. Earl Sasser indicated that Harvard does not plan to offer an MBA degree online because it would distract from the residential experience (Symonds, 2001). Kumar, Kumar and Basu (2002) cite "strong evidence that students perceive interaction, student-to-student and student-to-instructor, to suffer as a result of virtual education" (p. 140). But some information technology professionals argue that there is little difference between getting a degree on-campus or over the Web. Robert Baker, a systems consultant, observes that students taking online courses are not isolated and can get to know faculty and other students by using online discussion boards (Dash, 2000). Schooley (2001) states that online university courses facilitate communication with the instructor and among classmates.

Another concern is that online coursework may worsen the so-called "digital divide" between students in higher-income versus lower-income families, as those with higher incomes will have more Internet access (Accetta & Wind, 2001). However, libraries and schools have increased Internet access availability to people at all income levels and at locations worldwide.

Some questions also exist about the cost of taking online courses. Some students believe that an online course is a less expensive method, and some course providers believe it to be a cost-effective method of course delivery. As a point of comparison, Duke University's Fuqua School of Business offers MBA degrees that provide about 65% of the work online and about 35% of the work in residency. Duke charges up to $90,000 for the program versus $60,000 for its traditional on-campus MBA degree program (Symonds, 2001).

One critical indicator of program success or failure is the extent to which graduates are accepted in the job market. Quigley (2001) cites a *BusinessWeek* magazine survey reporting that most recruiters are skeptical of skills of graduates of online business schools. Many executives do not feel that online degree programs have been offered long enough to prove themselves with on-the-job performance of MBA degree graduates.

Some educators are concerned about the rapid growth of online degree programs. Others have questioned the superiority of online courses when compared with classroom-based courses. Online courses may be developed by curriculum specialists with little or no participation from the faculty member who will conduct the class. Much e-learning is self-directed and not led directly by faculty members. A fear is that faculty members will no longer be curriculum developers and participants in intellectual debates within their disciplines. Accetta and Wind (2001) suggest that "faculty will become mere shepherds herding their passive sheep through pre-prepared fields of outdated and insubstantial information."

Faculty members are also concerned that students will not get the same campus experience that is provided to students who are enrolled in traditional on-campus degree programs. Some schools require that students check in online for a specified number of times each week. Many programs also require some amount of on-campus time, as well as meetings via conference calls. Some programs incorporate team projects that require students being together during specified points during the course. Some programs require one or more retreats in a traditional lecture/seminar format.

Many faculty members are skeptical about the quality when the time period required to obtain a degree is very short. For example, the American InterContinental University-On-line (2002) advertises that a Master's degree can be earned in as little as 10 months.

There are also concerns about technical, administrative, and pedagogical issues that arise as faculty consider moving from a traditional classroom environment into a Web-based environment. Logistical concerns relate to providing students with the same level of support (e.g., library, bookstore, advising) in both environments. Pedagogical considerations involve issues relating to management of course quality and control over the learning environment.

Wonacott (2000) states that instructional design should be the primary factor in implementing online coursework rather than the appeal of technology. He also mentions that students and instructors need appropriate training and guidance if this type of instruction is to be effective.

STUDIES OF EXISTING ONLINE COURSES AND PROGRAMS

Many reports have indicated typical students are "adult learners". Typical participants are between 25 and 50 years of age and are taking online courses either to learn something new or to update their skills (Grill, 1999).

Studies have also indicated that students were more satisfied with online courses when there was more interaction with the course instructor. Interaction with other students was also a factor leading to more student satisfaction (Fredericksen, Pickett, Shea, Pelz & Swan , 2000).

Several comparison studies have been conducted between online and traditional on-campus courses, and most have found no statistically significant difference in test performance and grades. A greater degree of active learning in both settings increases performance and student attitude (Hall, 1999).

Studies of online coursework are being conducted in several countries. For example, one study compared "Anglo-Saxon" students in five countries to "Asian" students in nine countries to see if cultural differences existed related to the use of the Web as a learning environment. Some differences existed in the comfort level of various instructional formats. More Asian students liked the Web environment because of the innovative learning possibilities, while Anglo-Saxon students were more comfortable with the use of discussion groups (Chin, Chang & Bauer, 2000).

POTENTIAL FOR ONLINE COURSEWORK FOR FUTURE STUDENTS

Schools providing online courses and programs will eventually need to expand the attractiveness of their programs to additional markets in order for their programs to remain viable. Since the current programs are predominantly used by students who are older than the traditional full-time college student, an initial step would be to determine the perceptions of the next group of college students regarding these programs. To obtain data related to perceptions of online courses by upcoming college students, a survey instrument was distributed to almost 400 students enrolled in high school business courses. Although participants in existing online courses and programs are older, educational institutions should understand the needs and perceptions of other constituencies if they want to expand their enrollments. These current high school students could represent a large potential target market in the future that will be increasingly computer literate, which would enable more students to take advantage of online coursework.

Demographics

A total of 381 high school students participated in this study. Slightly more than 71% of these students were juniors and seniors. A majority of the participants (58.78%) were female.

A high percentage of students (88.97%) indicated that they have access to a computer at home, which could have a direct effect on ability to participate in online courses. Lack of access to a computer could affect perceptions. A comparison of accessibility by gender showed that the difference between genders was slight (Table 1).

Current Status Regarding Taking Online Courses

Students were asked to describe their current status regarding taking a course online and were allowed to select more than one response. As shown in Table 2, about one-fourth of the respondents indicated that they would not take an online course. There was little difference between males and females on this issue. Not surprisingly, very few had already taken or were currently taking a course online.

Ratings of Issues' Importance

The remainder of the survey had two parts, each with a listing of issues for students to consider. Thirty-eight students failed to respond to a majority of the questions in this part of the survey and were eliminated from further calculations.

In the first section, students were asked to indicate how important each identified issue was to them in deciding whether to take a course online or on-campus. A Likert-type scale was used, with 1 representing "not at all important" and 5 representing "extremely important". A mean was calculated as a basis for determining which issues were considered rather important (defined as a mean of at least 4.0)

Ratings That a Characteristic is More Likely True for Online versus On-Campus

For the second section, students were asked to consider the same issues as in the previous section but to indicate the likelihood that each issue was a characteristic of an online versus on-campus course, with 1 representing "much more likely in an online course" and 5 representing "much more likely in an on-campus course". A mean was calculated to identify which issues were considered much more likely in an online course (defined as a mean of no greater than 2.0) and which were considered much more likely in an on-campus course (defined as a mean of at least 4.0). As shown in Table 4, three issues had a mean greater than 4. Only one issue, "Submitting assignments electronically," had a mean below 3.0.

A cluster plot or "scatter diagram" was developed to illustrate the relationship between the two parallel sets of variables used in the study. As shown in Figure 1, all but one of the items were clustered in the upper right corner, which represents the section for higher importance and higher likelihood that the characteristic would be in an on-

Table 1. Access to a computer at home by gender

Gender	Percentage with Access
Male	89.03
Female	88.50

Table 2. Current status regarding online courses

Status Regarding Online Courses	Percentage of All Respondents	Percentage of Male Respondents	Percentage of Female Respondents
I would not take a course online.	24.87	24.52	24.78
I would consider taking a course online.	58.20	56.77	58.41
I would like to take a course online.	28.04	26.45	28.76
I plan to take a course online.	6.35	6.45	6.19
I am currently taking a course online.	0.26	0.65	0.00
I have completed a course online.	0.49	1.94	0.00

campus course. As discussed earlier, the only item in the left side of the diagram was "submitting assignments electronically."

The issues identified as most important were given further review, since those issues were not given particularly strong ratings as either online or on-campus options. Issues identified as most important in Table 3 are shown again in Table 5, along with an identification of their means for the comparison of "much more likely in an online course" versus on-campus. Table 5 indicates a tendency toward likelihood in an on-campus course for all of the issues identified as most important. All had means greater than 3.0, which is the midpoint of the scale where 1 represented much greater likelihood in an online course and 5 represented much greater likelihood in an on-campus course.

FUTURE TRENDS

Large increases are occurring in the availability of online courses and college degree programs, both at the undergraduate and graduate levels. Many traditional universities are adding online coursework to their offerings in an effort to maintain student enrollments. Consequently, these institutions are concerned about the best methods for providing equivalent course content online.

Significant growth in online programs could lead to an eventual reduction in on-campus course offerings at universities.

Students are becoming increasingly competent in the use of computer technology. Future students, therefore, can be expected to be better prepared and possibly better candidates for online programs.

CONCLUSION

Students who participated in this study indicated that all the specified issues were perceived to be important (a mean greater than 3.0 using a 1 to 5 scale). All but one of the issues were perceived to be more likely to be characteristic of an on-campus course. Educational institutions need to begin considering the needs of this next generation of potential students in order to expand or maintain online course offerings in the future.

The fact that students in this study rated "knowledge gained" as their most important issue in a course or degree and also rated it more likely to be characteristic of an on-campus than an online course indicates that institutions wanting to increase the number of online students might need to look for documentation of high levels of knowledge gained through online course delivery. In addition,

Table 3. Issues considered important in making course environment decisions

Issue	Mean
Knowledge gained	4.35
Skills acquired	4.29
Access to information (resource materials)	4.20
Time required to complete coursework	4.16
Costs of tuition and fees	4.13
Schedule flexibility to accommodate work responsibilities	4.13

S

Table 4. Issues that are much more characteristic of an on-campus course

Issue	Mean
Opportunity for live interaction/discussion among students	4.07
On-campus exams	4.05
Opportunity for live interaction/discussion between faculty and students	4.04

Figure 1. Comparison of importance with likelihood of being on-campus versus online

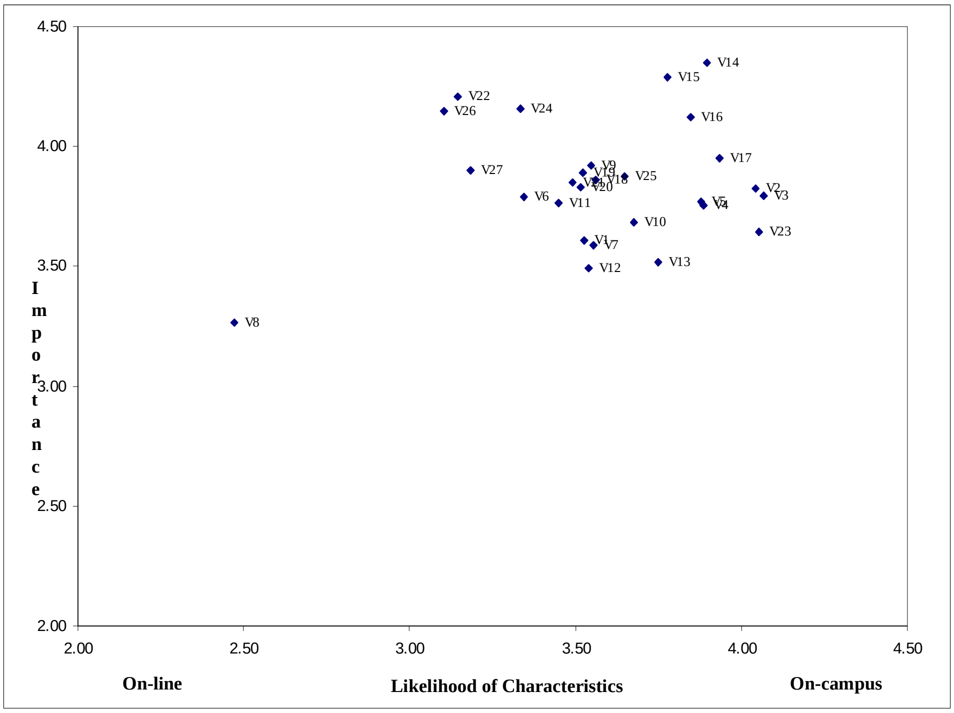

Table 5. Important issues related to online versus on-campus instruction

Issue	Mean
Knowledge gained	3.90
Skills acquired	3.78
Access to information (resource materials)	3.15
Time required to complete coursework	3.33
Costs of tuition and fees	3.85
Schedule flexibility to accommodate work responsibilities	3.10

(Much more likely in an online course = 1; much more likely in an on-campus course = 5)

studies should be done to determine the specific features and programs that would be the best fit for these students in an online learning environment.

Students' perceptions of online programs should continue to be monitored by institutions wanting to increase their participation in these programs.

KEY TERMS

Distance Education: A form of instruction in which a geographical separation exists between instructor and students; it may be same time/different place or different time/different place. Various types of technology may be used as part of this form of education, with more technology required for the same-time format.

Distance Learning: The intended outcome of distance education, characterized by learning through audio-visual delivery of instruction that is transmitted to one or more other locations that may be live or recorded instruction but does not require physical presence of an instructor and students in the same location. Current technology used for distance learning includes text, images, and audio and/or video signals.

E-Learning (Electronic Learning): A form of learning that involves "electronic" or technology-based delivery of learning; examples of forms of delivery include individual computer-based delivery, Internet/Web delivery, and virtual classroom delivery. Media can be in many forms, including videotape and DVD, CD-ROM, satellite transmissions, interactive television, and various Web-based media (Internet, intranet, extranet).

Off-Campus Course: A course offered at a business location, satellite center, or other site other than the main campus of an educational institution.

On-Campus Course: A course offered wholly or in part on the main campus of an educational institution. An on-campus course is typically offered in a traditional lecture/discussion environment, but may include procedures and methodology associated with a hybrid online course.

On-Campus Degree Program: A prescribed program of studies leading to a degree conferred by an educational institution wherein the majority of courses are on-campus courses. (See definition of *on-campus course*.)

Online Course (Fully and Hybrid): An online course may be either a fully online course or a hybrid online course. A fully online course is offered in a format where its content, orientation, and assessments are delivered via the Internet and students interact with faculty and possibly with one another while using the Web, e-mail, discussion boards, and other similar aids. A hybrid online course meets one or more of the following requirements for students: (a) access to the Web to interact with the course content, (b) access to the Web to communicate with faculty and/or other students in the course, (c) on campus for orientation and exams, with other aspects of the course meeting the requirements for a fully online course.

Online Degree Program: A prescribed program of studies leading to a degree conferred by an educational institution wherein the majority of courses are online courses. (See definition for *online course*.)

Success Surrogates in Representational Decision Support Systems

Roger McHaney
Kansas State University, USA

INTRODUCTION

Rapid and frequent organizational change has been a hallmark of business environments in the past two decades. Frequently, technology and new software development are embraced as aspects of complex strategies and tactical plans. Without sufficient analysis, the unforeseen consequences of change can result in unexpected disruptions and the loss of productivity. In order to better control these contingencies, modern managers often employ a variety of decision support aids. One such aid, classified as a representational decision support system, is discrete event simulation (DES).

BACKGROUND

In its purest form, DES is considered to be a branch of applied mathematics. Its considerable popularity is due in part to the availability of computers and improvements in simulation languages and simulator software packages. DES is often the technique of choice when standard analytical or mathematical methodologies become too difficult to develop. Using a computer to imitate the operations of a real-world process requires a set of assumptions taking the form of logical relationships that are shaped into a model. These models assess the impact of randomly occurring events. Experimental designs are developed and the model manipulated to enable the analyst to understand the dynamics of the system. The model is evaluated numerically over a period of time and output data is gathered to estimate the true characteristics of the actual system. The collected data is interpreted with statistics allowing formulation of inferences as to the true characteristics of the system. Table 1 lists primary features of a DES application.

While the value of DES in organizational settings has been accepted and is evidenced by the varied and growing market of related products, not every DES application is suited for every problem domain. For this reason, information systems researchers have worked to identify salient characteristics of DES and its usage and then measure the relationship between its application and successful organizational outcomes. These studies have been conducted in different ways with focuses on independent and dependent variables.

INDEPENDENT VARIABLE RESEARCH

Much DES research has focused on identifying and evaluating software and project characteristics (independent variables) and then producing recommendations that

Table 1. DES features

Feature	Description
Statistics Collection	Tools which gather data for purposes of inferential statistics about the model
Resource Modeling	A means for the representation of a constrained resource in the model
Transaction	A means for representation of the participants in the simulatior model
Simulation Clock	Tools for analysis and step processing of the coded model
Random Number Generators	A means for producing random number streams for randomization of events within the simulation model
Model Frameworks	Generalized frameworks for the rapid development of a model

S

Table 2. List of DES success factors

Factor 1: Software Characteristics
Factor 2: Operational Cost Characteristics
Factor 3: Software Environment Characteristics
Factor 4: Simulation Software Output Characteristics
Factor 5: Organizational Support Characteristics
Factor 6: Initial Investment Cost Characteristics
Factor 7: Task Characteristics

either suggest how a project can be successfully implemented or how failure can be avoided. A variety of useful practitioner-focused articles have been published in this area (Banks, 1991; Law & Haider, 1989; Swain, 2003). These studies provide recommendations, based in part on first-hand experience, of consultants and simulation analysts. In many cases, these recommendations list the packages currently available and focus on the pros and cons of each.

Academic studies of independent variables have also been conducted. In one of the first studies using information systems as basis for DES, McHaney and Cronan (2000) extended a framework of general decision support system (DSS) success factors identified by Guimaraes, Igbaria, and Lu (1992). The developed contingency model was theoretically derived from the simulation literature and empirically tested. The results indicated a seven-factor model that was structured as shown in Table 2.

Academic research by Robinson (1999) approached the problem from the opposite perspective and identified sources of simulation inaccuracy which may result in project failure. Other studies, such as one by McHaney and White (1998), developed a DES software selection framework which matched salient DES characteristics with software package features. The importance of evaluation and selection of appropriate DES packages was determined in relation to the success of simulation implementation. As might be expected, the choice of the wrong simulation package often correlated with simulation system failure. This study provided a set of criteria to be systematically considered when evaluating DES software. The taxonomy for simulation evaluation, together with importance ratings provided by the collective expertise of a large number of DES users, was used as a guideline in deciding the relative weighting to give various software package capabilities.

Other research (McHaney, White, & Heilman, 2002) attempted to develop an understanding of DES project success by determining which characteristics of a simulation project were more likely to be present in a successful simulation effort. Potential success factors were derived from the simulation literature and used to develop a questionnaire. Based on the findings, projects perceived as failing were often characterized by high costs, model size constraints, and slow software. Successful projects were characterized by teamwork, cooperation, mentoring, effective communication of outputs, high quality vendor documentation, easily understood software syntax, higher levels of analyst experience, and structured approaches to model development. By understanding the simulation process and characteristics of successful simulations, practitioners will find it easier to avoid common mistakes that can ruin a modeling effort.

DEPENDENT VARIABLE RESEARCH

The studies mentioned in the previous section focused on understanding independent variables defining successful representational decision support system applications. A problem with research that considers only the independent side of the equation is the lack of objective measures of whether suggested recommendations correlate with desired outcomes. This dilemma has been problematic throughout information systems research in general and has been the subject of academic debate (Delone & McLean, 1992). DES researchers recognize that the identification of a meaningful, reliable, and robust dependent variable is central to being able to conduct accurate comparisons between competing tools, techniques, software implementations, project approaches, and modeling perspectives.

A wide variety of dependent variables have been investigated in the broader fields of information systems (Delone & McLean, 1992) and decision support systems. Among these, DSS researchers have focused on success surrogates and investigated the possibility of assessing DSS success or failure. Representational DSS researchers have extended the use of these surrogates.

The first information system success surrogate validated in the context of DES was the end-user computing satisfaction instrument (Doll & Torkzadeh, 1988). The EUCS instrument, shown in Figure 1, is of particular interest because most applications of discrete event computer simulation can be categorized as end-user computing. McHaney and Cronan (1998) collected data from 411 participants using a variety of discrete event computer simulation software packages. The analysis indicated the instrument retained its psychometric properties and provided a valid success surrogate for end users beyond the introductory stages of using representational DSSs. The study established the use of information systems surrogate success measures for applied instruments. The results suggest EUCS can reliably and confidently be used in the investigation of competing tools, features, and technologies in the area of DES. Later, EUCS was the subject of a test-retest reliability study that was distributed to users of DES through a mail survey. One month later, follow-up surveys were administered. The original respondents were asked to again evaluate the same system. The two data sets were compared and the results supported the instrument's internally consistency and stability (McHaney, Hightower, & White, 1999).

Another success surrogate, the technology acceptance model (TAM), was also investigated within the context of representational decision support systems. TAM was developed by Davis (1989) to provide a theoretical explanation of factors influencing technology usage. Davis' theory is derived from the theory of reasoned action (TRA) model (Fishbein & Ajzen, 1975). The TRA model explains actions by identifying connections between various psychological constructs such as attitudes, beliefs, intentions, and behaviors. TRA posits that an individual's attitude toward a given behavior is determined by the belief that this behavior will result in a particular outcome. TAM expands upon this framework to provide a theoretical explanation of factors influencing technology usage. However, instead of relying on purely attitudinal determinants, TAM hypothesizes that perceived ease of use and perceived usefulness influence a person's intention, which in turn determines actual technology usage. In essence, Davis' research identifies the external variables which influence attitude towards voluntary use of technology. TAM has been validated and tested in a variety of technology-related studies (Adams, Nelson, & Todd, 1992; Davis, Bagozzi, & Warshaw, 1989; Mathieson, 1991). Figure 2 illustrates the Davis instru-

E1: Is the simulation system user-friendly?
E2: Is the simulation system easy to use?

T1: Do you get the output information you need in time?
T2: Does the simulation system provide up-to-date information?

ment and TAM. McHaney and Cronan (2001) focused on external validity aspects of TAM when applied to users of DES. The findings suggested that TAM provided a reasonable surrogate measure for success within this domain. An updated version of this study was developed into a book chapter (McHaney & Cronan, 2002).

FUTURE TRENDS

Representational decision support systems will continue to become more important to managers, particularly as computing power continues to increase and costs decrease. Web-enabled DES, applications embedded in enterprise computing systems, visualization, and use of DES to fine-tune manufacturing operations and supply chain operations on-the-fly will become more commonplace. Representational decision support system research will continue to seek dependent variables and related surrogates that enable competing tools and techniques to be evaluated and compared. Mainstream DSS and information system research will continue to contribute methodologies and techniques that can be adopted for use in this field.

CONCLUSION

Representational decision support systems, particularly as manifested in DES, have become an important tool in a modern manager's decision-making arsenal. In order to determine the effectiveness of these applications, researchers have investigated characteristics of the technology and determined the suitability of various success surrogates to enable comparisons between competing packages, approaches, and methodologies. Future research in this field may determine whether other surrogates are suitable for use with DES and will provide managers with quantitative comparisons to aid in their software selection processes.

Figure 2: Davis instrument

KEY TERMS

Dependent Variable: A value representing the presumed effect or consequence of various states of related independent variables. In other words, a dependent variable is the condition for which an explanation is sought.

Discrete Event Simulation (DES): Use of a computer to mimic the behavior of a complicated system and thereby gain insight into the performance of that system under a variety of circumstances. Generally the system under investigation is viewed in terms of instantaneous changes due to certain sudden events or occurrences.

End-User Computing Satisfaction: A widely accepted information systems success surrogate that measures the degree to which a technology provides the user with a sense of satisfaction that meaningful usage has been affected.

Independent Variable: A value representing a presumed cause of a particular outcome.

Representational Decision Support System: Computer-based information system that combines models with data in a fashion that closely resembles the system that is being studied. Computer simulation is a form of representational decision support system.

Success Surrogate: A proxy for information systems success that takes the form of measurable values. A success surrogate is a dependent variable.

Technology Acceptance Model: A theoretical explanation of factors influencing technology usage that hypothesizes perceived ease of use and perceived usefulness influence a person's intention, which in turn determines actual technology usage.

Theory of Reasoned Action (TRA): This theoretical model explains actions by identifying connections between various psychological constructs such as attitudes, beliefs, intentions, and behaviors; then posits that an individual's attitude toward a given behavior is determined by the belief that this behavior will result in a particular outcome.

Successful Health Information System Implementation

Kristiina Häyrinen
University of Kuopio, Finland

Kaija Saranto
University of Kuopio, Finland

INTRODUCTION

A Standish Group (1994) study showed that only 16% of all information technology projects come in on time and within budget. The situation is not better concerning health information systems. Many health information system implementations are less than completely successful (Berg, 2001; Giuse & Kuhn, 2003; Lorenzi & Riley, 2003). In this article, the health information system means "a system, whether automated or manual, that comprises people, machines and /or methods organized to collect, process, transmit, and disseminate" data that represent user information in healthcare (Kuhn & Giuse, 2001, pp. 275). What is successful implementation and whose success is measured? Successes can be measured in many ways. Delone and McLean have been finding out the success factors of management information system which are also applicable to health information system. The success factors are: system qualities, *e.g.*, the ease of use or time savings, information quality, *e.g.*, completeness or data accuracy, usage, *e.g.*, the frequency of use or the number of entries, user satisfaction, *e.g.*, user-friendliness or overall satisfaction, individual impact, *e.g.*, changed work practices or direct benefits and organizational impact, *e.g.*, communication and collaboration or impact on patient care. Furthermore, user involvement during system development, implementation and organizational culture have been identified as possible factors measuring the success. However, the need for further research to determine which attributes are the most useful ones in measuring success has also been revealed. (van der Meijden, Tange, Troost & Hashman, 2003).

The different phases in implementation process are, in general, user needs and requirements analysis (specification), system design, initial system implementation and testing (Ahmad, Teater, Bentley, Kuehn, Kumar, Thomas & Mekhjian, 2002; Schuster, Hall, Couse, Swayngim & Kohatsu, 2003; Souther, 2001). The system requirements analysis includes workflow analysis, and the initial system implementation includes the technical installation of the information system, integration of the information system to other information systems and users' training. Project management is an important factor in every phase of the implementation project.

The purpose of this article is to highlight the health information system implementation process from end-user perspective. Which factors are crucial in the implementation process from the point of view of the end-users? How does project management contribute to the implementation process, what is the role of the end-user in system designing and how does training effect the information system implementation?

BACKGROUND

The lack of financial support was the most significant barrier to successfully implementing information technology in healthcare from both clients' and vendors' perspective. The vendors' inability to deliver products, and difficulties in achieving end-user acceptance or use were the other barriers from the point of view of the clients. (HIMSS, 2002.) Costs are often underestimated because the cost of the software is only the beginning of other expenditures, *e.g.*, person-hours for training and support have been forgotten (Ash, Stavri & Kuperman, 2003).

The social and organizational issues, not only the technical ones, are the critical issues in the implementation of information systems. The health information systems do not effectively support the health processes, and terminology for the healthcare environment is needed. (Ahmad et al., 2002; Berg & Toussaint, 2003; Berg, 2001; Giuse & Kuhn, 2003; Kuhn & Giuse, 2001; Littlejohns, Wyatt & Garvican, 2003).

Human-computer interaction is also perceived as unsatisfactory. The human-computer interaction indicates the means by which humans interact with computers, *e.g.*, users enter and retrieve data. To optimize the design of the human-computer interaction, concepts are needed (Berg, 2001; Kuhn & Giuse, 2001). Technical issues, *e.g.*, integration with other information systems and the need for open systems are also issues which must be solved (Giuse & Kuhn, 2003; Kuhn & Giuse, 2001).

The reasons for failures were that the complexity of healthcare tasks and social and professional cultures of healthcare organizations was not taken into account and, furthermore, the education of the users was insufficient and the timing of the education was wrong (Littlejohns, Wyatt & Garvican, 2003). Lorenzi and Riley (2003) report that the failures of the implementation of the health information system can be classified into four categories: technical shortcomings, project management shortcomings, organizational issues and information explosion. The technical failures contain, *e.g.*, the old system maintenance and staff training. Project management issues are, *e.g.*, project management skills. Organizational issues are concerned with constant changes. Information explosion means that knowledge has increased exponentially and new technical tools have been developed to cope with the information. Berg (2001) notes that it is important to notice that the implementation is not only a technical installation, and also that the project is not only a technical project but also an organizational development project.

The three major reasons that a project will succeed are user involvement, executive management support and the clear statement of requirements (Standish Group, 1994). Doolan, Bates and James (2003) reported that the factors associated with successful implementation are unusually strong leadership, a clearly defined long-term commitment, clear focus on improving clinical processes and gaining clinical involvement and support improving productivity. Lorenzi and Riley (2003) included technical skills, project management skills and people and organizational skills to the success factors. The skills mean knowledge, experience and abilities in each area. Ahmad et al. (2002) stated that success factors are a continuous executive support, engagement of physicians, an effective implementation team, a consistent user-friendly interface and on-going user support.

User involvement during system development, implementation process and organizational culture may explain the failure of the information system. The attributes assigned to system development were the extent of user involvement, redesigning work practices and the reconstruction of content and technical limitations. Communication, training and technical support were attributes addresses to implementation process. Organizational aspects attributes were organizational culture, *e.g.*, control and decision-making, management support, professional values as well as support and maintenance. (van der Meijden, Tange, Troost & Hashman, 2003.)

THE ROLE OF THE PROJECT MANAGEMENT

A project approach is the most common way to implement health information systems. Project management is the process of planning for organizing and controlling projects. From the end-users' point of view, the objectives of health information system projects must make explicit, *i.e.*, improve patient care or efficiency. It is recommendable to set a stage for improvements, *e.g.*, reduce the number of phone calls or move manual files to on-line files. The objectives of the project must also improve workflows and work practice, in other words the hospital managements and also clinicians involved in the project must also upgrade their work performance. The implementation of information system must add value for the end-user. Clear objectives motivate the end-users for implementation. (Ash, Stavri & Kuperman, 2003; Berg, 2001; Berg & Toussaint, 2003; Doolan, Bates & James, 2003, FitzHenry & Snyder, 1996; Giuse & Kuhn, 2003; Littlejohns, Wyatt & Garvican, 2003; Lorenzi, Riley, Blyth, Southon & Dixon, 1997; Nikula, Elberg & Svedberg, 2000; Lechleitner, Pfeiffer, Wilhelmy & Ball, 2003)

The information system implementation process must be seen as an organizational change process (Anderson & Stafford, 2002; Berg, 2001; Lorenzi, Riley, Blyth, Southon & Dixon, 1997). Change management, which means "the process of assisting individuals and organizations in passing from an old way of doing things to a new way of doing things" (Lorenzi & Riley, 2003 pp.200), should be taken into account from the start of the implementation process. Organizational resistance always occurs during the implementation of new information systems. The change management is one reason why the leader has an important role in projects. (Lorenzi & Riley, 2003; Lorenzi, Riley, Blyth, Southon & Dixon, 1997; FitzHenry & Snyder, 1996) Furthermore, the implementation process itself requires effective leadership (Ash, Stavri & Kuperman, 2003;Lorenzi & Riley, 2003; Souther, 2001). Leadership is needed at multiple levels in organizations; high-level leadership was considered the single most important factor. It was demonstrated by the long-term commitment of resources. (Ahmad et al. 2002; Doolan, Bates & James, 2003; Littlejohns, Wyatt & Garvican, 2003). At the executive level, leadership is needed to promote a shared vision the purpose of health information system, which is e.g. to improve patient care. At the project management level, the leadership is needed to make practical, effective and useful decisions (Ash, Stavri & Kuperman, 2003). The need for bottom-up participative and top-down authoritarian approaches are also useful when changing organizational behavior. (FitzHenry & Snyder, 1996; Souther, 2001). External consults can also be used as change agents. (FitzHenry & Snyder, 1996; Lechleitner, Pfeiffer, Wilhelmy & Ball, 2003; Souther, 2001)

There is a need for different people, and many types of skills, both technical and medical, in implementation process. The persons who are assigned to the projects must be influential and knowledgeable and they must represent significant organizational groups and professionals. The challenge is to find the right persons. The multidisciplinary team approach has proven advantageous in health information system implementation.(FitzHenry & Snyder, 1996; Lechleitner, Pfeiffer, Wilhelmy & Ball, 2003; Littlejohns, Wyatt & Garvican, 2003; Souther, 2001) There must be different levels of teams: an executive steering team, a project steering team and a project work team. The end-users are representatives in different levels of teams. It is important that physicians and nurses belong to the project steering team, which makes major policy decisions based on user needs and requirements, organization infrastructure and general implementation strategies. The end-users also belong to the project work team, whose focus is training, user-interface, testing, security policy and pilot implementation. (FitzHenry & Snyder, 1996; Souther, 2001) The end-users' participation to the project enhanced their involvement.

The organizational readiness for information system innovation could also be assessed in advance. The information about the organizational readiness could be used in planning implementation strategy (Nikula, 1999; Snyder-Halpern, 2001; Yetton, Sharma & Southon, 1999), *e.g.*, in what order to engage different parts of the organization or in which phase of implementation process managerial influence must be at its highest. The healthcare organizational readiness for information system innovation could be assessed by the validated eight sub-dimensions of knowledge, end-users, technology, administrative support, management structures, processes, resources, values and goals. The end-user readiness themes include, *e.g.*, skills to use computers or involvement in the change process. The information about the end-user readiness could be used in planning their training. (Snyder-Halpern, 2001)

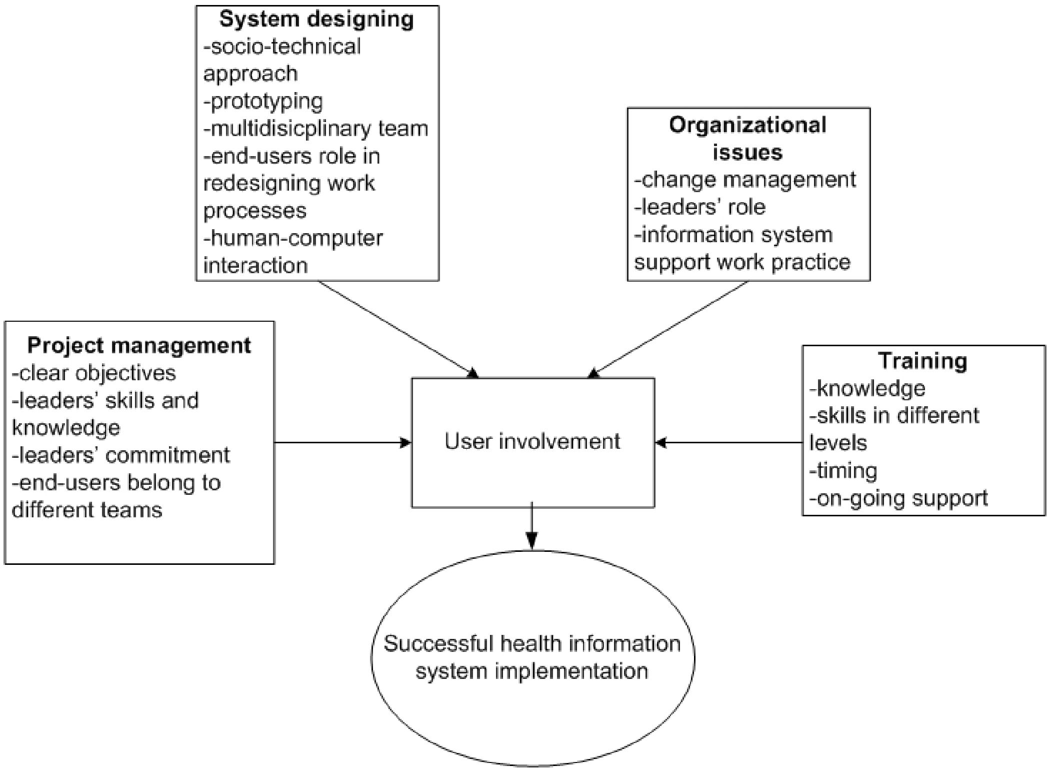
THE END-USERS' ROLE IN DESIGNING INFORMATION SYSTEM

For the design of information systems, the conventional approach has been to model a system completely before implementing it (Berg, 2001; Kuhn & Giuse, 2001; Lorenzi, Riley, Blyth, Southon & Dixon, 1997). Prototyping has proven a successful project (Ahmad et al., 2002; Doolan, Bates & James, 2003; Lechleitner, Pfeiffer, Wilhelmy & Ball, 2003; Lorenzi, Riley, Blyth, Southon & Dixon, 1997; Schuster, Hall, Couse, Swayngim & Kohatsu, 2003). Prototyping requires an iterative approach, in which information system analysis, design, implementation and evaluation merge. It is evident that the information system changes work practices and vice versa. Therefore, the first step is to model the environment of the system. A socio-technical approach is suitable for system design. It means that the work practices in which information systems will be used are the starting points for design and implementation of the information systems. This means defining the core actors, their core tasks, the flow of work and the flow of data. The present workflows are analyzed, the future workflows described and documented. (Berg & Toussaint, 2003; Berg, 1999; FitzHenry & Snyder, 1996; Schuster, Hall, Couse, Swayngim & Kohatsu, 2003; Souther, 2001) The interactive model increases end-user involvement. The need for optimally adapting information systems to the work practice in the healthcare organizations and the users' terminology are important, as well as reducing workload and simplifying the workflow (Anderson & Stafford, 2002; Berg & Toussaint, 2003; Doolan, Bates & James, 2003; Giuse & Kuhn, 2003, Kuhn & Giuse, 2001; Lechleitner, Pfeiffer, Wilhelmy & Ball, 2003; Lorenzi, Riley, Blyth, Southon & Dixon, 1997). Health professionals must develop the information system together with the vendors. The interaction between the vendor, the teams installing the information system and the users is a crucial point. Representatives must include all different health professionals and administrative personnel (Anderson & Stafford, 2002; Berg & Toussaint, 2003; Doolan, Bates & James, 2003; Kuhn & Giuse, 2001; Lechleitner, Pfeiffer, Wilhelmy & Ball, 2003; Lorenzi, Riley, Blyth, Southon & Dixon, 1997 Nikula, Elberg, Svedberg, 2000; Schuster, Hall, Couse, Swayngim & Kohatsu, 2003; Sleutel & Guinn, 1999)

TRAINING AND SUPPORT

The proper training and support are an essential part of the health information system implementation process (Ahmad et al., 2002; Anderson & Stafford, 2002; Ash, Stavri & Kuperman, 2003; Doolan, Bates & James, 2003; Littlejohns, Wyatt & Garvican, 2003; Lorenzi, Riley, Blyth, Southon & Dixon, 1997; Schuster, Hall, Couse, Swayngim & Kohatsu, 2003; Souther, 2001). An implementation of the health information system requires extensive support and training in order to achieve user acceptance. The training plan must be completed before the initial

Figure 1. The factors of successful implementation process- end-users perspective



implementation and it should also include intensive support at the time of the implementation. In the most successful implementation the end-users have more support after initial implementation than before it (Ash, Stavri & Kuperman, 2003).

There are also differences between computer literacy within healthcare professionals. (Saranto & Hovenga, 2004; Souther, 2001). Computer literacy means basic skills in computers use, *e.g.*, read and write. Information literacy consists of computer literacy, information retrieval abilities and communication skills. (Saranto & Hovenga, 2004) Therefore, the skills of the users, as well as their needs, must be taken into account when planning the training of a new information system. The quality of user training has a key role for a good user acceptance of information system (Anderson & Stafford, 2002; Quinzio, Junger, Gottwald, Benson, Hartmann, Jost, Banzhaf & Hempelmann, 2003). Disagreement on the efficiency of the system training has occurred (Lechleitner, Pfeiffer, Wilhelmy & Ball, 2003; Quinzio et al., 2003). The well-trained users were significantly more satisfied with the information system in routine use. A three-step training strategy has been recommended. First, the employees should be informed of the planned information system. The second phase includes general on-job training, and the third phase includes the opportunity to work on the individual problems of each user. (Quinzio et al., 2003) Whitman, Hamann & Vossler (1997) have also introduced a training plan. The strengths of the training plan are the contract that identified the roles and responsibilities of staff, management, and information services and staff development. Peer trainers have proven useful. Everyone must also have their own computer during training sessions. A competency test has been suggested as improvement to training plan. Ahmad et al. (2002) report a formalized training program for all users which precedes the implementation by two or four weeks. In addition, extensive on-site training occurred during the implementation period. The traditional help-desk phone has been found inadequate for user support.

FUTURE TRENDS

From the end-user perspective, the critical issues concerning the health information system implementation are project management, system designing, organizational issues and training and support. First of all, the project must have clear objectives. The teams must consist of different types of healthcare professionals, vendors, management and so on. It is important to find the right people to engage in the project. Project management task and responsibilities must be clear for each level of the teams and the interaction between the teams will also be efficient. The teams must work actively with the vendors. The management must also commit to the implementation process so the end-users notice that the project is important. The project management aids the change management, which is one of the critical issues of information system implementation process. The leaders can use the information about the organizational readiness in planning the implementation strategy.

It is crucial that both representatives from the future users and leaders are involved in the design process. They are the experts of their work. The iterative development process will be used and the information systems adapting to workflows is important. When the information systems' requirements and future workflows are modeled properly it becomes evident that the work processes change, because the healthcare professionals must consider what they do and why they do it.

The training plan must be designed carefully. The information literacy of the end-users will be taken into account. A multilevel approach is good. First, the vendor can present the main functions of the information system. After that the tutors teach the users to use the information system and the users can train the system themselves. The users are also supported, they can ask questions. After that the users themselves can practice and also contact the tutors if they have any problems using the information system.

CONCLUSION

In the first stages the point of view in health information system implementation was only technical. The implementation process paid no attention to workflow patterns prior to the implementation, or to the computer experience among personnel or aspects of the organizational culture. Strategies for the successful management of health information system implementation must be planned carefully. The personnel of an organization must learn to use the information system and also change their working processes. Education is the critical point of the implementation process. Knowledge about end-user attitudes and skills prior to computerization is useful. The training will be tailored to meet the varying needs of user groups. There is a need for research in the area of evaluating health information system implementation.

KEY TERMS

Change Management: Change management is the process of assisting individuals and organizations in passing from an old way of doing things to a new way doing things.

Health Information System: Health Information System is the system, whether automated or manual, that comprises people, machines and /or methods organized to collect, process, transmit and disseminate data that represent user information in health care.

Implementation: The implementation of information system includes different phases: user needs and requirements analysis (specification), system design and initial system implementation and testing. The system requirements analysis includes workflow analysis; the initial system implementation includes technical installation of information system, integration the information system to other information systems and users' training.

Information Literacy: Information literacy consists of computer literacy and information retrieval abilities and communication skills. Computer literacy means basic skills in computers use, *e.g.*, being able to read and write with computers.

Project Management: Project management is the process of planning for organizing and controlling projects. The multidisciplinary team approach in project management means that there are different levels of teams: the executive steering team, the project steering team and the project work team. Different teams have their own tasks.

Prototyping: Prototyping is the development approach in which prototypes are produced. It is an iterative approach to the developing of the information system. The distinctions of the different phases of development of the information system, *e.g.*, analysis, design, implementation and evaluation are not clear.

Socio-Technical Approach: Socio-technical approach means that the work practices in which information systems will be used are the starting points for design and implementation of the information systems.

Supporting Assurance and Compliance Monitoring

Peter Goldschmidt
The University of Western Australia, Australia

INTRODUCTION

Governments and commercial organizations typically use monitoring facilities that depend on data that identify source agents and their relationships, to detect and draw attention to possible anomalies and potential non-compliance.

The assurance of compliance monitoring requires decision support and appropriate domain knowledge, relevant to the level of user, to manage the results of the surveillance. This is required in order to fulfill the necessary and sufficient evidence verifying or refuting this output.

BACKGROUND

This article discusses methods to support assurance of surveillance monitoring and output verification knowledge management (CV-KM), including a brief discussion on primary monitoring systems; the different environments in which they operate; the verification problem solving and decision making tasks; the problem structure and the coordination of the review process to facilitate truth maintenance. The surveillance operation is considered a primary monitoring function, with the analysis of the resulting output the secondary monitoring function - the assurance component.

Examples of monitoring systems range from standard data processing routines that ensure internal control, such as data input, processing and output compliance. Weber (1999) provides a comprehensive discussion on these processes, to the monitoring of events transacted in more complex environments, such as fraud detection, intrusion detection, data mining systems and the like, via sophisticated statistical, artificial intelligence and neural computing techniques, or hybrid combinations. These devices are termed primary monitoring systems (PSS).

Assuring, verifying and managing PSS information quality and integrity is fundamental to the success of modern information-dependent organizations. Concurrent with the need for surveillance is a need to maintain personal privacy, due diligence, and accountability (Cillufo, 2000).

Clarke (1988) highlights the inherent dangers of drawing conclusions resulting from the electronic monitoring of data related to individuals and groups of individuals, and points out that a major problem in "dataveillance" is the high noise to signal ratio, which may be misleading. Davis and Ord (1990) acknowledge the problem of setting threshold levels in an ever-changing environment. With any set of tolerance levels, deviant (even fraudulently motivated) behaviour may escape detection. Tightening tolerance levels limits increases the likelihood that exception conditions will trigger an alert but also increases false positive alerts since the number of instances that fall outside the tolerance increases. The cost for the analyst (the decision-maker) to review the additional non-exception condition alerts must be assessed in relation to the imputed value of identifying the additional true exceptions detected by more stringent limits (Davis & Ord, 1990).

Advances have, in general, reduced the problem of misleading results produced from "noisy data," including improvements in data processing and the increased use of sophisticated computational techniques such as statistical, knowledge-based and artificial neural computational methods. These systems are centered on the events being monitored and the events' source agents. Their results, however, may still require human judgment to determine their validity (Goldschmidt, 2001). CV-KM systems act as a secondary monitoring facility supporting, verifying and assuring data and information compliance by assisting in analyzing and categorizing exceptions, or results, generated by PSS. CV-KMs assist in assuring the fulfillment of the necessary and sufficient evidence supporting (true positive/negative) or refuting (false positive) hypotheses of non-compliance. The input to CV-KMs requires the output resulting from the organization's domain-specific PSS plus related information. Operationally, the CV-KMs are a bolt-on addition to the PSS.

WHAT ARE PRIMARY SYSTEMS?

Typically, these systems examine the integrity of transaction data as well as the entire transaction, or event, to ensure compliance with predetermined conditions. An exception report identifies any variances. This identification either fulfills the conditions of necessary and sufficient evidence and determines an instance of non-compliance, or indicates possible non-compliance. In the latter case further evidence may be sought to substantiate the hypothesis of non-compliance.

The function of PSS is twofold: identifying a variance, and producing and accumulating supporting evidence. When both these conditions are met, the evidence points to the detective, corrective or preventative actions required.

The detective function is fulfilled by recognition of the variance; correction can then be made to the data or the event, which is then reprocessed. The preventative function is fulfilled by the recognition of the variance resulting in the rejection of the event. Decision-makers must interpret ambiguous evidence to determine what action is required, or if the non-compliant indicator is a true or a false positive directive.

Examples of PSS range from standard data processing routines that ensure internal control, such as data input, processing and output compliance, to the use of sophisticated statistical (procedural) techniques, artificial intelligent (declarative) techniques and neural (associative) techniques, or hybrid combinations. In general, computational techniques are either demons or objects (O'Leary, 1991; Vasarhelyi & Halper, 1991). Demons are computerized routines that are instantiated by data or events received, as opposed to being requested by some program. "Demons add knowledge to a system without specification of where they will be used ... like competent assistants they do not need to be told when to act" (Winston, 1977, p. 380). They are data or event dependent, rather than program dependent, and provide intelligent self-activation for monitoring data triggered by compliance threshold levels. O'Leary points out that demons have been developed to monitor patterns for the purpose of auditing activities conducted on computer-based systems. Vasarhelyi and Halper describe an alternate: CPAS, Continuous Process Audit System. CPAS allows for the continuous audit of on-line systems by monitoring transactions to determine variance between monitored information and expected information.

THE PSS AND CV-KM ENVIRONMENT

PSS and CV-KM can be classified by levels of complexity, characterized by their place on the simple or complex environmental continuum in which they operate and the decisions required to determine instances of non-compliance. Constraints may take the form of an organization's predetermined policies and procedures, needed to ensure data and event integrity, contractual agreements, and statutory requirements. These constraints are not mutually exclusive and can be seen as bounds or threshold levels. The parameters used to construct these levels may change with modifications to threshold requirements such as evolutionary changes in constraints and changes in data and event requirements. A simple environment is so-called because: 1) the threshold levels either seldom change or only change over the longer term; 2) the identification of the variance fulfils the conditions of necessary and sufficient evidence to determine an instance of non-compliance; and 3) the decisions, needed to determine if events comply, lie on the structured to highly structured portion of the decision-making continuum. The degree to which the bounds of the threshold levels are set, very narrow to very broad, determines the type of decision required. Under a simple environment the bounds or threshold limits are narrow, characteristic of structured decisions such as data input integrity and customer credit checks. Decision-making in this environment is ex-ante, made of a single step, and the constraints are all predetermined.

In a complex environment, decision-making is ex-post, complex and may require multiple steps. Initial monitoring uses a priori thresholds broader than in a simple environment, that is, more granular and produces exceptions that identify suspected non-compliant events (SNCEs). Once these exceptions have been produced, the decision-maker must substantiate true positive exceptions. This task must be broken down into smaller components and subgoals must be developed (Simon, 1973) to identify, categorise and discard any false positive exceptions. False negatives do not generate an exception, and allow possible suspect events to slip through the surveillance sieve. If the threshold limits are stringent enough, marginal false negatives could be subsumed and later considered. Nevertheless, this would not necessarily reduce the occurrences of *true* false negatives, as their characteristics may not be known. True positives are those exceptions that the decision-maker has determined are indeed anomalous. Evidence for this decision uses the results of the initial monitoring as well as important information related to the event, characterized by a need for judgmental expertise. Examples of these approaches to complex environments include: Byrnes et al. (1990), Major and Riedinger (1992), Senator et al. (1995), and Kirkland et al. (1999).

CV PROBLEM SOLVING AND DECISION-MAKING TASKS

Secondary monitoring problem solving, human evaluation of the exceptions produced by the primary monitoring system, determines if a generated exception is feasible. This is similar to an analytical review (AR) conducted by auditors, characterised by Libby (1985) as a diagnostic-inference process. Koonce (1993) defines AR as the diagnostic process of identifying and determining the cause of unexpected fluctuations in account balances and other financial relationships. Similarly, secondary monitoring problem solving identifies and determines the causes of unexpected variances resulting from the primary monitoring facility. Blocher and Cooper (1988) found that analytical review (AR) typically follows four distinct diagnostic inference components: accumulation and evaluation of relevant information; initial recognition of unusual fluctuations; subsequent hypothesis generation; and information search and hypothesis evaluation.

With CV-KM, accumulation and evaluation is guided by the results of the PSS. Subsequently, a hypothesis of the potential causes of the observed variance is generated. The diagnostic approach takes the form of defeasible logic, which means that any inference made may be only tentative, as the inference may require revision if new information is presented. The decision-maker must evaluate all possible legitimate reasons for the occurrence of the variant. If none is found, the hypothesis of non-compliance is strengthened.

CV PROBLEM STRUCTURE

Following Sol (1982), structuredness of the complex problem is twofold: the variance identification is the structured component, and the accumulation of evidence supporting or refuting the non-compliant event (NCE) hypothesis is the ill-structured component. The variance is typically the product of some algorithm indicating a possible occurrence of NCEs, but in order to substantiate a true NCE the required accumulation of evidence requires judgment of agent behaviour. The agents include the source of the event, the identification of the source agents' possible motivations, the environment in which the source agent is operating and the impact this event may have on the environment.

COORDINATION: THE REVIEW PROCESS TO FACILITATE TRUTH MAINTENANCE

Coordination refers to the managing of interactions between multiple agents cooperating in some collective task. Pete et al. (1993) show that optimal organizational design depends on the task environment and, as with an audit team or group, is hierarchical. The objective is to reduce the problems discussed by Freedman (1991), to reduce any potentially redundant activities conducted by the evaluating agents, and to increase efficiency and effectiveness. The agent or agents may be human or machine based. Machine based or independent software agents function as repositories of human opinions related to the event under scrutiny.

The process of review when evaluating judgments made on accounting data and information is well established in the auditing literature (Libby & Trotman, 1993). To facilitate coordination, evaluating agents should communicate their findings via a communication protocol. Communication protocol establishes the means and modes of communication between agents. Information exchange can be either via an implicit communication mechanism such as a common memory or blackboard (Hayes-Roth et al., 1983), or via explicit communication mechanisms, such as message sending. Using the blackboard approach, the SNCE's details plus the evaluating agents' assumptions and results are posted. This facilitates the more senior agents imposing their criteria on lesser agents' results, as well as using their task-specific criteria to further refine the classifications.

Computerised decision support systems have been proposed and built to address some of the previously mentioned problems. A limited framework for a CV-KM intelligent decision support system using multi-agent technology is presented in Chang et al. (1993) and Goldschmidt (1996, 2001).

FUTURE TRENDS

With the increase in the reliance of electronic communications for business, industry, medicine, defense and government, assuring, verifying and managing the integrity of transactions and managing the results of these monitoring systems for information quality and integrity

S

Advantages of CV-KM

The company ALERT-KM Pty Ltd holds the CV-KM IP in 24 countries and is currently commercializing this technology.

Adds functionality to primary monitoring infrastructure, without modifying primary system.
Proposes a framework for compliance verification knowledge management.
Provides for the decomposition of surveillance tasks.
Provides a consistent evidence evaluation and combination structure.
Provides records of evidence from each stage.
Adds value to surveillance operations by reducing the cost of surveillance monitoring, assisting in surveillance accountability and providing transparency, when required, thereby contributing to surveillance governance and due diligence.
Employs a method that adds value to a generated exception by encapsulating and associating the event's attributes, its source agent's characteristics, the evaluating agent's analysis and the recommended remedial action plus the substantiating evidence.
Exploits an infrastructure support construct and secondary filter, allowing for collaboration, truth maintenance, audit trails and decision support, thereby facilitating decision consistency and greater processing volume.
Using the approach as a decision aid and secondary filter, analysis of results can then be used to review the analyst's decision-making processes and to refine the primary filter tolerance levels.
Supports a structured, flexible and inclusive approach to surveillance analysis.
By adding a cost function to the surveillance-monitoring infrastructure can capture cost-benefit trade-off.
Insight is gained from the knowledge acquisition component when setting up parameters and heuristics.
Assists in the development of an effective accountability structure.
Reduces distrust of surveillance monitoring systems, by reinforcing accountability and transparency.

is fundamental to the success of modern information-dependent organizations. Concurrent with the need for surveillance is a need to maintain personal privacy, due diligence, and accountability (Cillufo, 2000).

Data mining technology, distributed heterogeneous database access and information distribution has moved from a silo approach to a more pooled approach within organizations. This has led to further need for information assurance that is reliant on data monitoring. Therefore the management of the accuracy and validity of the monitoring output necessitates the assurance of decisions made based on this information.

CONCLUSION

CV-KM operates in highly complex environments, domains where the threshold granularity is high and the decision-making time factor is short may benefit from the decision support discussed. It is essential for accountability that organizations in these domains ensure transactions identified as suspected NCE are scrutinized and substantiated. This assists in minimizing false positive conclusions that may result from the speed, volume and increased complexity of transactions, and the information used to analyze them. CV-KM also addresses some of the problems highlighted by Clarke (1988), that electronic monitoring of data related to individuals and groups of individuals is subject to inherent dangers of drawing misleading conclusions from these data. Assurance and compliance monitoring team infrastructure support includes aspects of information systems, cognitive sciences, decision support and auditing judgment. Fuzzy set theory is advocated in decision environments where there may be a high degree of uncertainty and ambiguity, catering for qualitative and quantitative evidence validating and assuring the assertion of noncompliance.

Current research efforts in monitoring and assurance systems (Roohani, 2003; Schneier, 2001; SRI, 1999; UCD, 1996)still concentrate on improving the efficiency and accuracy of primary monitoring systems. Whilst this is necessary, further research opportunities exist in addressing and improving the utility and effectiveness of supporting the analysts responsible for evaluating the results of these primary systems and ensuring their accountability.

KEY TERMS

Complex Environments: Complexity increases as: the granularity increase, the frequency of changes increases, the time availability decreases, and the degree of judgment required increases. Decision-making is ex-post, complex and may require multiple steps. Initial monitoring uses a priori thresholds broader than in a simple environment, that is, more granular and produces exceptions that identify suspected non-compliant events (SNCEs). Evidence for decision-making uses the results of the initial monitoring as well as important information related to the event, characterized by a need for judgmental expertise. Examples of these approaches to complex environments include: Byrnes et al. (1990), Major and Riedinger (1992), Senator et al. (1995), and Kirkland et al. (1999).

Compliance Verification: Ensuring the necessary and sufficient evidence supports the assertion of non-compliance.

Dataveillance: Surveillance of data using automated data analysis to identify variances. These typically depend on data that identify source agents and their relationships and is used to draw a compliance analyst's attention to a particular event or group of events that indicate possible anomalies.

Primary Surveillance Systems (PSS): Processes, methods or devices that monitor data identifying events, their source agents and their relationships, to draw attention to possible anomalies and potential non-compliance.

Secondary Monitoring: Secondary monitoring supports agents with verifying and assuring data and information compliance by assisting in analyzing and categorizing exceptions, or results, generated by PSS. This assists in assuring the fulfillment of the necessary and sufficient evidence supporting (true positive/negative) or refuting (false positive) hypotheses of non-compliance. The input is the results of the organization's domain-specific PSS plus related information and human judgment from either human agents or machine agents encoded with heuristics.

Simple Environments: Monitoring environments in which the threshold levels either seldom change or only change over the longer term; the identification of the variance fulfils the conditions of necessary and sufficient evidence to determine an instance of non-compliance; and the decisions, needed to determine if events comply, lie on the structured to highly structured portion of the decision-making continuum. Decision- making in this environment is ex-ante, made of a single step, and the constraints are all predetermined.

Supporting Compliance Monitoring Assurance: A process or method supporting human or machine agents in verifying and assuring the validity of generated suspected non-compliant event by assuring the necessary and sufficient evidence supporting the hypothesis of non-compliance.

Suspected Non-Compliance Event (SNCE): An event triggering an exception by the primary monitoring facility that indicates instances of possible non-compliance. The exception still requires verification.

Supporting the Evaluation of Intelligent Sources

Dirk Vriens
Radboud University of Nijmegen, The Netherlands

INTRODUCTION

To survive, organizations need to produce and process information about their environment, for instance, about customers, competitors, suppliers, governments, or all kinds of socioeconomic and technological trends. The process of obtaining this information is often called competitive intelligence (cf Fleisher & Blenkhorn, 2001; Kahaner, 1997; Vriens, 2004). An important stage in the competitive intelligence process is the collection stage. In this stage, one has to determine relevant sources, access them, and retrieve data from them (cf Bernhardt, 1994; Kahaner). For each data class, many possible sources are available, and determining the right ones is often difficult. Moreover, accessing sources and retrieving data may require a lot of effort and may be problematic (cf Cook & Cook, 2000; Fuld, 1995; Kahaner, 1997). In this chapter, we present a tool for supporting the effective and efficient use of sources: the source map. In essence, a source map links data classes to sources and contains information about these links. This information indicates the adequacy of sources in terms of ease of access, ease of retrieval, and usefulness of the retrieved data. A source map can support the selection of appropriate sources and it can support the assessment of the overall adequacy of available sources.

BACKGROUND

The process of competitive intelligence is often described as a cycle of four stages (the intelligence cycle; see Kahaner, 1997; Vriens, 2004). This cycle comprises (a) the direction stage (in which the organization determines about what aspects in the environment data should be collected), (b) the collection stage (where sources are determined and data are collected), (c) the analysis stage (in which the data are analyzed to assess whether they are useful for strategic purposes), and (d) the dissemination stage (where the data are forwarded to decision makers; Bernhardt, 1994; Gilad & Gilad, 1988; Herring, 1999; Kahaner, 1997; Sammon, 1986). The collection stage is considered to be the most time-consuming stage (e.g., Chen, Chau, & Zeng, 2002) and if it is not performed carefully, many difficulties arise (e.g., too much time spent on search, collection stage leads to irrelevant data, information overload; see, for example, Cook & Cook, 2000; Chen et al.; Teo & Choo, 2001; Vriens & Philips, 1999). For successfully carrying out collection activities, knowledge about what sources contain what kind of data and knowledge about how to approach these sources (metaknowledge regarding the collection of data) would be very helpful. This chapter presents a tool to structure and deal with this metadata: the source map.

To collect data about the environment one has to

1. identify possible sources,
2. judge the value of the source (in terms of different criteria; e.g., does it contain relevant data? What are the costs of employing this source? Is it reliable?), and
3. use value judgments to select the appropriate sources.

Many authors discuss Step 1 by pointing to a variety of available sources (cf Fuld, 1995; Kahaner, 1997; Sammon, 1986). Typical sources include the Internet, online databases, sales representatives, internal or external experts, CEOs, journals, tradeshows, conferences, embassies, and so forth.

The literature treats the valuation step more implicitly. It discusses distinctions regarding sources, such as open versus closed sources, internal versus external sources, or primary versus secondary sources (Fleisher & Blenkhorn, 2001; Kahaner, 1997). These distinctions implicitly refer to criteria used in the valuation of sources. The distinction of open versus closed sources implicitly refers to, for instance, criteria such as ease in collection or relevance. The distinction of primary versus secondary sources implicitly refers to the criterion of the reliability of the data. In our view, it is possible to value sources more precisely when the valuation criteria are stated explicitly and not implicitly in the form of these distinctions.

The selection step is even more elusive in literature (and practice). This step integrates value judgments to select appropriate sources for collecting the required data. Few methods seem to be designed for source selection.

In this article, we propose a tool to structure and support the valuation and selection of sources: the source map. This tool builds on Fuld's (1995) intelligence maps and knowledge maps (e.g., Davenport & Prusak, 1998).

The purpose of the source map is to help pin down the appropriate sources quickly and detect weaknesses in the available sources.

THE SOURCE MAP AS A TOOL FOR ASSESSING SOURCES

What is a Source Map?

A source map links data (or classes of data) to sources in such a way that the (most) appropriate sources can be selected for the collection of the requested data. If viewed as a matrix, the column entries may refer to data classes (e.g., products under development by competitor X) and the row entries to possible sources. Each column then indicates what sources may be used to gather the requested data (e.g., a patent database, economic journals, or the Internet site of competitor X). To determine what sources are (most) appropriate, the source map needs to contain information about criteria for appropriateness and their valuation. The cells in the source map (connecting the data classes to sources) should contain this information. To get this information, it should be clear (a) what the relevant criteria are, (b) how they can be given a value, and (c) how to integrate them into an overall judgment of the appropriateness of the sources. The next two sections deal with these issues.

Note that we treat the source map as a tool for supporting and structuring collection activities *given* the data classes. We assume that the data (classes) are already defined in the direction phase (the first phase of the intelligence cycle).

Criteria and Scores for Judging Sources

The criteria for assessing the appropriateness of sources link up with the three activities required to deal with sources. These activities are the following.

1. Accessing the source. Accessing means determining the exact location and approaching the source to prepare retrieval.
2. Retrieving (in interaction with the source) the data from the source.
3. Using the retrieved data in further processing (i.e., for the production of intelligence).

Referring to these activities, the appropriateness of sources depends on four dimensions: (a) ease of access, (b) ease of retrieval, (c) usefulness of the content of the retrieved data and processing ease, and (d) cost effectiveness. Below, we discuss criteria in these dimensions.

Criteria for Access and Retrieval

To assess the appropriateness of sources regarding access and retrieval, barriers in employing a source can function as criteria (cf Fuld, 1995; Davenport & Prusak, 1998). Examples of these barriers are as follows.

- A language barrier.
- A cultural barrier (i.e., a difference in culture between collector and source).
- An institutional barrier. In some (bureaucratic) organizations, it may be very hard to locate and approach certain people and documents.
- A personal barrier. Personal characteristics can make it difficult to approach and interact with someone.
- A geographical barrier. Some sources need to be dealt with on location.
- A technological barrier. Accessing some sources and retrieving data from them may sometimes be possible only by means of specific information and communications technology, requiring specific knowledge or skills.
- A fee barrier. For accessing some sources and/or retrieving data, a fee may be charged.
- A time barrier. For some sources, the response time may be very slow.
- A clarity barrier. This barrier refers to the effort one has to give to make sense of the data from the source. Factors that increase this barrier are the use of specific jargon and the lack of (requested) structure in the data.
- A stability barrier. This barrier refers to the stability of access to the source (some sources may cease to exist, some are not available at the expected moment, others may decide to stop providing their services, etc.).

In our view, these criteria can also be used to express the costs associated with using a particular source. We therefore prefer to deal with the above criteria, instead of using cost estimates that may be derived from them, because (a) it is difficult to translate the criteria into costs and (b) if only cost estimates are used, one loses information about the appropriateness of sources.

Using a barrier as a criterion to assess appropriateness, it can be scored on a five-point Likert scale where 1 means *very problematic* and 5 means *nonexistent*.

Criteria for the Use of Data

There are four criteria for assessing the appropriateness of sources regarding the use of the data for the production of intelligence. One of them is a processing criterion and three of them are content criteria.

The processing criterion refers to the ease of processing. This can be determined by the format in which the data are delivered; that is, does the source deliver the data in a format that can be used directly for the purposes of the collector or does it need reformatting? One may score this criterion on a five-point scale ranging from 1, *much reformatting needed*, to 5, *right format*.

The content criteria are completeness, reliability, and timeliness (cf O'Brien, 1998, for a summary of these criteria). When applied to the value of sources, these criteria mean the following.

- Completeness: The source can deliver all the data required to gain insight into the data class for which the source is used. This can, for instance, be measured in terms of the number of times the source was unable to deliver the requested data and/or the number of aspects of a data class for which the source could not provide data.
- Reliability: This refers to the reliability of the data from the source. It can be measured, for instance, in terms of the number of times the data from the source proved to be incorrect.
- Timeliness: The data from the source is up to date. It can be measured in terms of the number of times that the source delivered obsolete data.

In literature, one often finds relevance as an additional criterion to assess the content of data. Relevance then refers to the suitability of the data in gaining insight into the data class for which the source was used. However, relevance can be adequately expressed in terms of completeness, reliability, and timeliness. Completeness links the data provided by a source to the required data defined by the data class. Given the completeness, the data should further be correct and up to date to be relevant. Relevance, therefore, can be treated as an overarching concept, referring to the other three content criteria.

The content criteria can, again, be scored on a five-point scale, where 1 means *very incomplete*, *very unreliable*, and *very obsolete*, respectively, and 5 means *very reliable*, *very complete*, and *very timely*.

Content of Source Map Cells

The criteria for the appropriateness of sources and their scores should be put in the source map. To this end, each cell in a source map contains the following information (see also Figure 1).

1. General information about the source, consisting of the name of the source, the data-carrier (human, data or electronic) and (if known) the exact or default location.
2. Scores on the criteria for access, retrieval, content and processing of the (data from the) source.
3. Information about what data could not be delivered if the source was incomplete. This is useful for analyzing the appropriateness of the sources (see next section).
4. Remarks concerning one of the above aspects.

Using the Source Map

A source map allows for two different uses. First, it is used to find appropriate sources for a particular data class. Second, it is used to assess the overall adequacy of the sources. For both types of use, it is necessary to compare the sources. In this section, we discuss how to compare sources and how to use this method for comparison for the two different uses.

Comparing Sources

Sources can be compared using a single criterion (e.g., which source scores highest on completeness?). It is also possible to integrate the values of (several) individual criteria and compare these integrated scores. To integrate these values into an overall score, we propose the following procedure.

1. Define two classes of criteria: efficiency criteria and effectiveness criteria. The class of efficiency criteria consists of the access criteria, the retrieval criteria, and the ease-of-processing criterion. The class of effectiveness criteria consists of the criteria completeness, reliability, and timeliness.
2. Estimate weights for the criteria in the two classes. A possible way of determining the weights of the individual criteria is to have CI professionals produce a rank order of the criteria (in each of the two classes) expressing their ideas about the relative relevance of the criteria. Next, one could discuss the results and produce one rank order for each class. (This procedure could be supported by groupware, such as Group Systems; cf Nunamaker, Dennis, Valacich, Vogel, & George, 1991).
3. Compute, for each source, the overall scores for the two classes. For both classes, we suggest taking the weighted average score for the given criteria. To compute these scores, the scores on the individual criteria should be available. These scores might be obtained initially by asking CI professionals. From that moment on, they should be evaluated every time a source is used and updated when necessary.

Finding Appropriate Sources

The most straightforward use of the map is to find out what sources are available for a particular data class. A step beyond merely enumerating available sources is to give a judgment about the appropriateness of these sources in terms of the criteria presented in the previous section. To this end, we use the efficiency and effectiveness scores of the sources. For a particular data class, all the available sources can be plotted regarding these two scores (see Figure 2).

The figure states that Source 5 scores best on effectiveness, Source 4 best on efficiency, and Source 1 scores lowest on both classes of criteria.

Figures like the above can help in analyzing the appropriateness of a source for a particular data class. As a general heuristic for ranking the sources, we suggest that sources in the upper right quadrant should be preferred to those in the lower right quadrant, and these should be preferred to the ones in the upper left quadrant. Sources in the lower left quadrant should probably be discarded.

Sources that come up as appropriate should be checked for completeness. If they are complete, they can be added to the list with preferred sources. If they are incomplete, it is necessary to find out if there are sources that can compensate for this lack. To this end, information about what data the source is unable to deliver can be used. This information directs the search for an appropriate compensating source.

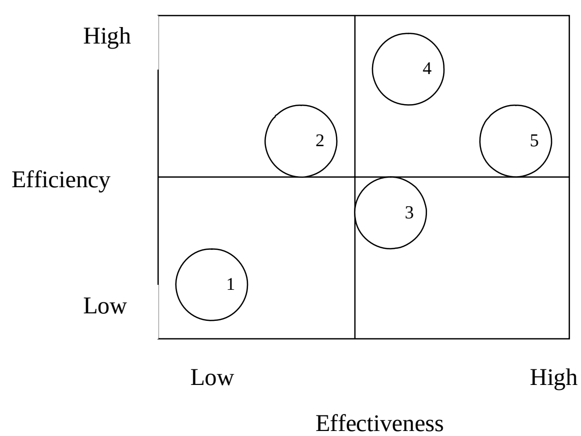
For sources that score high on effectiveness but low on efficiency (lower right quadrant), it should be examined (a) whether the relevance of the data class makes the effort (and costs) worthwhile and/or (b) whether measures can be taken to make the use of the source more efficient, for example, the efficiency of scale in gathering data (a subscription to an often-used online database).

For sources that score in the two left quadrants, it can be established what exactly causes the score. Dependent on the outcome of this investigation, it may be decided to stop using the source.

Assessing the Adequacy of Sources

To judge the overall adequacy of the sources, the map may help in answering the following questions.

Figure 2. Scores of five sources regarding their appropriateness for a particular data class (see text)



1. Do the sources cover all data classes?
2. Do we have adequate sources for the required data classes? If some data classes only have sources that have scores in the lower left quadrant of Figure 2, problems may arise. If a rank order of the data classes regarding their relevance exists, one can also establish whether the most relevant data classes are covered by appropriate sources.
3. Do we have enough different sources for the (most important) data classes? This question refers to the flexibility in collecting data. If a source is suddenly unavailable, one needs to have adequate alternatives. It is also useful to have different sources for the purpose of validating the data.

Answers to these questions help intelligence officers to identify weaknesses in the available sources and direct their efforts to repair them.

Implementing a Source Map

To build, maintain, and use a source map does not require exceptional resources. IT applications for implementing the map range from sophisticated applications to simple solutions. An example of a simple solution is an implementation of the map by means of Microsoft Excel sheets. However, it is also possible to use more sophisticated application, for instance, Web-based applications of the map. Making the map available via an intranet, for instance, can enhance its use and maintenance. In addition to these technological issues, it is important to define and allocate tasks and responsibilities regarding maintenance and use of the map. Finally, data collectors should be motivated to use the map to define their search strategies. In our experience, data collectors see the benefits of a good map and will be inclined to use and maintain it.

FUTURE TRENDS

To aid intelligence officers in their task to evaluate sources, the source map was introduced. Given the increasing need for organizations to collect data about their environment, it can be expected that the need for tools to evaluate sources (like the source map) will also increase. In order to deal with this, information technology tools may be tailored to support the implementation of source maps and the process of keeping them up to date (see, for instance, Philips, 2004).

CONCLUSION

To produce actionable intelligence, the efficient and effective use of sources is imperative. However, up until now, little attention has been paid to supporting the selection of sources. In this paper, we deal with this omission by presenting the source map as a support tool. Properly implemented source maps can be valuable instruments in the support of collection activities. In our view, they can aid in both the everyday use of sources and in the assessment of the overall adequacy of available sources.

KEY TERMS

Collection Stage: Stage of the intelligence cycle. In this stage, sources regarding the required environmental data are located and accessed, and the data are retrieved from them.

Competitive Intelligence: In the literature, two definitions are used: a product definition and a process definition. In the product definition, competitive intelligence is defined as information about the environment, relevant for strategic purposes. The process definition highlights producing and processing this environmental information. Process definitions often refer to the intelligence cycle.

Intelligence Cycle: Cycle of four stages (collections of intelligence activities). The stages are direction (also referred to as planning, in which the strategic information requirements are determined), collection (determining sources and retrieving data), analysis (assessing the strategic relevance of data), and dissemination (of the intelligence to strategic decision makers).

Source: Something or someone containing data and from which the data can be retrieved. Many distinctions regarding sources are given in the competitive intelligence literature, for instance, open versus closed sources, primary versus secondary sources, internal versus external sources, and a distinction referring to the carrier of the data (human, electronic, or paper).

Source Evaluation: The process of assessing the efficiency and effectiveness of a source or several sources, given certain criteria. The result of this process can be (a) a judgment about the usefulness of a particular source for collecting data and/or (b) an insight into the relative usefulness of all available sources. See also "Source map."

Source Identification: Identifying suitable sources (i.e., efficient and containing the relevant data) given a certain data need. See also "Source map."

Source Map: A source map is a matrix linking data classes to sources. In the cells of the matrix, the sources are valued according to different criteria (e.g., accessibility, costs, timeliness of the data, etc.).

Survey of 3D Human Body Representations

INTRODUCTION

The problem of human body modeling was initially tackled to solve applications related to the film industry or computer games within the computer graphics (CG) community. Since then, several different tools were developed for editing and animating 3D digital body models. Although at the beginning most of those tools were devised within the computer graphics community, nowadays a lot of work proceeds from the computer vision (CV) community. In spite of this overlapped interest, there is a considerable difference between CG and CV human body model (HBM) applications. The first one pursues realistic models of both human body geometry and its associated motion. On the contrary, CV seeks more of an efficient than an accurate model for applications such as intelligent video surveillance, motion analysis, telepresence, 3D video sequence processing, and coding.

Current work is focused on vision-based human body modeling systems. This overview will present some of the techniques proposed in the bibliography, together with their advantages or disadvantages. The outline of this work is as follows. First, geometrical primitives and mathematical formalism, used for 3D model representation, are addressed. Next, a brief description of standards used for coding HBMs is given. Finally, a section with future trends and conclusion is introduced.

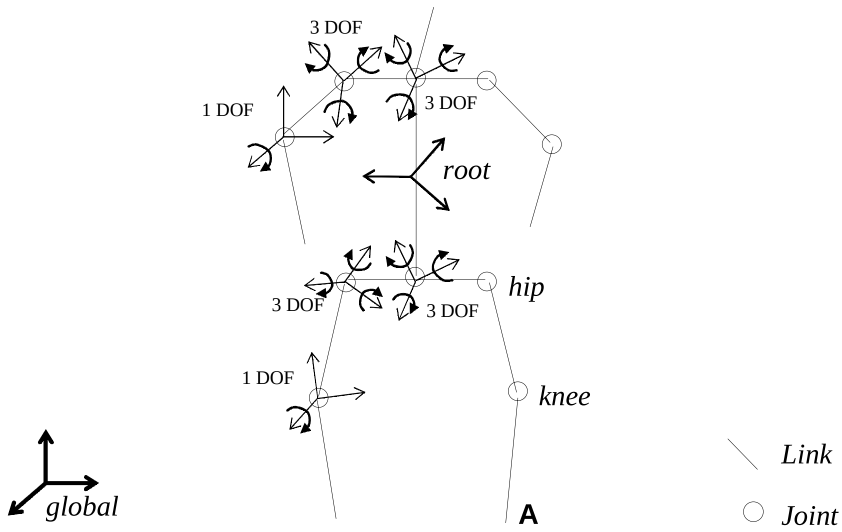
3D HUMAN BODY REPRESENTATIONS

Modeling a human body implies firstly the definition of an articulated 3D structure, in order to represent the human body biomechanical features. Secondly, it involves the choice of an appropriate mathematical model to govern the movements of that articulated structure.

Several 3D articulated representations and mathematical formalisms have been proposed in the literature to model both the structure and movements of a human body (Green & Guan, 2004). Generally, a HBM is represented as a chain of rigid bodies, called *links*, interconnected to one another by *joints*. Links can be represented by means of sticks (Yoo, Nixon & Harris, 2002; Taylor, 2000), polyhedron (Saito & Hoshino, 2001), generalized cylinders (Sidenbladh, Black & Sigal, 2002), or superquadrics (Marzani, Calais & Legrand, 2001). A joint interconnects two links by means of rotational motions about the axes. The number of independent rotation parameters will define the *degrees of freedom* (DOF) associated with a given joint. Figure 1 presents an illustration of an articulated model defined by 12 links (sticks) and 10 joints. Other HBM representations, which do not follow the aforementioned links-and-joints philosophy, have been also proposed in the literature to tackle specific applications. For example, Douros, Dekker and Buxton (1999) present a technique to represent HBMs as single entities by means of smooth surfaces or polygonal meshes. This kind of representation is only useful as a rigid description of the human body. On the contrary, Plänkers and Fua (2003) and Aubel, Boulic, and Thalmann (2000) present a framework that retains an articulated structure represented by sticks, but replaces the simple geometric primitives by soft objects. The result of this soft surface representation is a realistic model where body parts such as chest, abdomen, or biceps muscles are well modeled.

The simplest 3D articulated structure is a stick representation with no associated volume or surface (Liebowitz & Carlsson, 2001). Planar 2D representations, such as cardboard models, have also been widely used (Huang & Huang, 2002). However volumetric representations are

Figure 1. Stick representation of an articulated model defined by 22 DOF



preferred when more realistic models need to be generated. In other words, there is a trade-off between accuracy of representation and complexity. The utilized models should be quite realistic, but they should have a low number of parameters in order to be processed in real-time. Table 1 presents a summary of some of the approaches followed in the literature.

Each of the aforementioned geometrical structures is complemented by means of a motion model that governs its movements (Rohr, 1997); the objective is that the full body performs realistic movements. There is a wide variety of ways to mathematically model articulated systems from a kinematics and dynamics point of view. A mathematical model will include the parameters that describe the links as well as information about the constraints associated with each joint. A model that only includes this information is called a *kinematics model* and describes the possible static states of a system. The state vector of a kinematics model consists of the model state and the model parameters. A system in motion is modeled when the dynamics of the system are modeled as well. A *dynamics model* describes the state evolution of the system over time. In a dynamics model the state vector includes linear and angular velocities as well as position.

After selecting an appropriate model for a particular application, it is necessary to develop a concise mathematical formulation for a general solution to the kinematics and dynamics problems, which are non-linear problems. Different formalisms have been proposed in order to assign local reference frames to the links. The simplest approach is to introduce joint hierarchies formed by independent articulation of one DOF, described in terms of Euler angles. Hence, the body posture is synthesized by concatenating the transformation matrices associated with the joints, starting from the root. In order to illustrate this notation, let us express the coordinates of point **A** in the global reference frame associated with the root of the model (see Figure 1):

$$\mathbf{A}_{global} = Trans_{root\text{-}global} \ x \ Trans_{hip\text{-}root} \ x \ Trans_{knee\text{-}hip} \ x \ \mathbf{A}_{knee}$$

where $\mathbf{A}_{knee}$ represents the coordinates of points **A** relative to the local reference frame placed in the *knee-joint*; $Trans_{i\text{-}j}$ is the corresponding transformation matrix to express reference frame *i* in reference frame *j;* this matrix is defined as:

$$Trans_{i-j} = \left[\begin{array}{c|c} R & T \\ \hline 0 & 1 \end{array}\right] = \begin{bmatrix} C\phi C\theta C\psi - S\phi S\psi & -C\phi C\theta S\psi - S\phi C\psi & C\phi S\theta & t_x \\ S\phi C\theta C\psi + C\phi S\psi & -S\phi C\theta S\psi + C\phi C\psi & S\phi S\theta & t_y \\ -S\theta C\psi & S\theta S\psi & C\theta & t_z \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

C and *S* represent the cosine and sine respectively, and (ϕ, θ, ω) are the Euler angles. This kind of matrix concatenation can be used to express every body part in the body global reference frame.

3D HUMAN BODY CODING STANDARDS

In order to animate or interchange HBMs, a standard representation is required. Related standards, such as

Web3D H-anim standards, the MPEG-4 face and body animation, as well as MPEG-4 AFX extensions for humanoid animation, allow compatibility between different HBM processing tools (e.g., HBMs created using an editing tool could be animated using another completely different tool).

The Web3D H-anim working group was formed so that developers could agree on a standard naming convention for human body parts and joints. This group has produced the Humanoid Animation Specification standards, describing a standard way of representing humanoids in VRML. These standards allow humanoids created using authoring tools from one vendor to be animated using tools from another. H-anim humanoids can be animated using keyframing, inverse kinematics, performance animation systems, and other techniques. The three main design goals of H-anim standards are:

- *Compatibility:* Humanoids should be able to display/animate in any VRML compliant browser.
- *Flexibility:* No assumptions are made about the types of applications that will use humanoids.
- *Simplicity:* The specification should contain only what is absolutely necessary.

For this reason, a H-anim file defines a hierarchy of *Joint* nodes, each defining the rotation center of a Joint, which are arranged to form a hierarchy. The most common implementation for a Joint is a VRML Transform node, which is used to define the relationship of each body segment to its immediate parent. Each Joint node can contain other Joint nodes, and may also contain a *Segment* node, which contains information about the 3D geometry, color, and texture of the body part associated with that joint. Each Segment can also have a number of *Site* nodes, which define specific locations relative to the segment. Joint nodes may also contain additional hints for inverse-kinematics systems that wish to control the H-Anim figure.

The hierarchy of H-anim Joint and Segment hierarchy is shown in Figure 2.

Furthermore, the MPEG-4 SNHC (Synthetic and Natural Hybrid Coding) group has standardized two types of streams in order to animate avatars:

- The Face/Body Definition Parameters (FDP/BDP) are avatar specific and based on the H-anim specifications.
- The Face/Body Animation Parameters (FAP/BAP) are used to animate face/body models. More specifically, 168 Body Animation Parameters (BAPs) are defined by MPEG-4 SNHC to describe almost any possible body posture. Thus, a single set of FAPs/BAPs can be used to describe the face/body posture of different avatars. MPEG-4 has also standardized the compressed form of the resulting animation stream using two techniques: DCT based or prediction based. Typical bitrates for these compressed bitstreams are 2 kbps for the case of facial animation or 10 to 30 kbps for the case of body animation.

In addition complex 3D deformations that can result from the movement of specific body parts (e.g., muscle contraction, clothing folds, etc.) can be modeled by using Face/Body Animation Tables (FAT/BATs), which specify sets of vertices that undergo non-rigid motion and a function to describe this motion with respect to the values of specific BAPs/FAPs. However, a significant problem with using such tables is that they are body model-dependent and require a complex modeling stage. In order to solve such problems, MPEG-4 addresses new animation functionalities in the framework of AFX group by including also a generic seamless virtual model definition and bone-based animation. Particularly, the AFX specification describes state-of-the-art components for rendering geometry, textures, volumes and animation. A hierarchy of geometry, modeling, physics and biomechanical

Table 1. Human body structure representations

Authors	***DOF***	***Geometrical Model Representation***
Delamarre and Faugeras (2001)	22	Truncated cones (arms and legs), spheres (neck, joints, and head), and right parallelepipeds (hands, feet, and torso)
Gavrila (1999)	22	Superquadrics
Barron and Kakadiaris (2000)	60	Sticks
Cohen, Medioni and Gu (2001)	32	Generalized cylinders
Ning, Tan, Wang and Hu (2004)	12	Truncated cones (torso, arms, and legs) and a sphere (head)

models are described, along with advanced tools for animating these models (Figure 3).

Specifically, the new Humanoid Animation Framework, defined by MPEG-4 SNHC (Preda, 2002; Preda & Prêteux, 2001) is defined as a biomechanical model in AFX and is based on a rigid skeleton made of bones. The skeleton consists of bones, which are rigid objects that can be transformed (rotated around specific joints), but not deformed. Attached to the skeleton, a skin model is defined, which smoothly follows any skeleton movement.

FUTURE TRENDS AND CONCLUSIONS

Vision-based applications have been growing considerably fast during the last two decades. As a result of that growing, the current technology can tackle—at the moment only under well-defined constraints—complex tasks such as human body modeling. In addition, the knowledge collected during this time from different research areas (e.g., video processing, rigid/articulated object

Figure 2. The H-anim 1.1 Joint and Segment hierarchy (from H-anim Website). Three sets of joints are identified, classified according to their significance, so that H-anim models of different complexity can be produced. Segments are shown with dark grey color and Sites with light grey color. Each object beginning with l_ (left) has a corresponding object beginning with r_ (right). The chart was produced by J. Eric Mason and Veronica Polo, VR Telecom Inc.

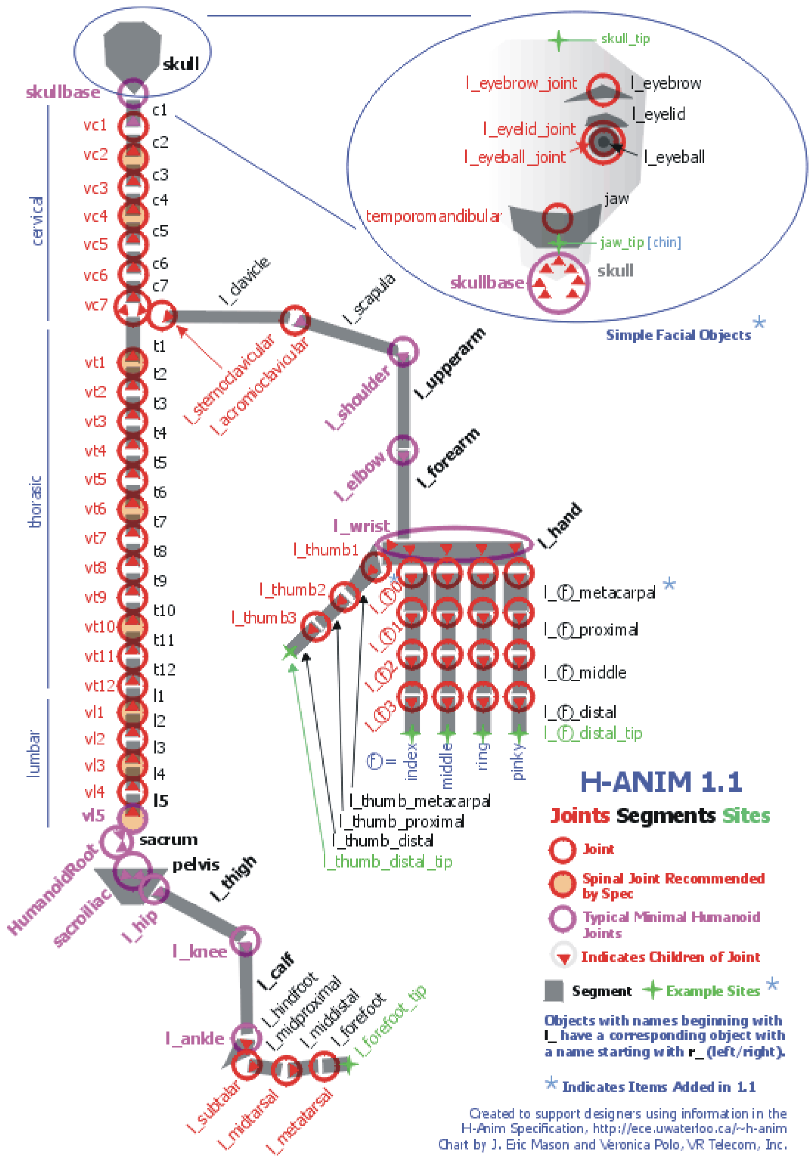


Figure 3. Hierarchy of AFX animation models

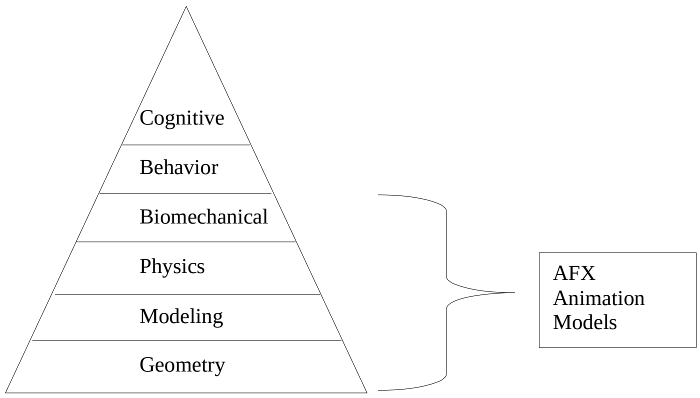

modeling, human body/motion models, etc.) also helps to face up to vision-based human body modeling. However, in spite of all this large amount of work, many issues are still open. Problems such as development of models including prior knowledge, modeling of multiple person environments, and real-time performance still need to be efficiently solved.

In addition to the aforementioned issues, the reduction of the processing time is one of the milestones in the non-rigid object modeling field. It is highly dependent on two factors: on one hand the computational complexity, and on the other hand the current technology. Taking into account the past few years' evolution, we can say that computational complexity will not be significantly reduced during the next few years. On the contrary, improvements in the current technology have become commonplace (e.g., reduction in acquisition and processing times, increase in the memory size). Therefore, algorithms that nowadays are computationally prohibitive are expected to have good performance with next technologies. The latter gives rise to a promising future for HBM applications and, as an extension, to non-rigid object modeling in general.

KEY TERMS

Articulated Object: Structure composed of two or more rigid bodies interconnected by means of joints. The degrees of freedom associated with each joint define the different structure configurations.

H-Anim: VRML Consortium Charter for Humanoid Animation Working Group. This group has recently produced the International Standard, "Information technology—computer graphics and image processing—humanoid animation (H-anim)," an abstract representation for modeling three-dimensional human figures.

Human Body Modeling: Digital model generally describing the shape and motion of a human body.

MPEG: Moving Picture Experts Group; a group developing standards for coding digital audio and video, as used for example in video CD, DVD, and digital television. This term is often used to refer to media that is stored in the MPEG-1 format.

MPEG-2: A standard formulated by the ISO Motion Pictures Expert Group (MPEG), a subset of ISO Recommendation 13818, meant for transmission of studio-quality audio and video. It covers four levels of video resolution.

MPEG-4: A standard formulated by the ISO Motion Pictures Expert Group (MPEG), originally concerned with similar applications as H.263 (very low bit rate channels, up to 64kbps). Subsequently extended to encompass a large set of multimedia applications, including over the Internet.

MPEG-4 AFX: MPEG-4 extension with the aim to define high-level components and a framework to describe realistic animations and 2D/3D objects.

MPEG-7: A standard formulated by the ISO Motion Pictures Expert Group (MPEG). Unlike MPEG-2 and MPEG-4, which deal with compressing multimedia contents within specific applications, it specifies the structure and features of the compressed multimedia content produced by the different standards, for instance to be used in search engines.

Rotation Matrix: A linear operator rotating a vector in a given space. A rotation matrix has only three degrees of freedom in 3D and one in 2D. It can be parameterized in various ways, usually through Euler angles, yaw-pitch-roll angles, rotation angles around the coordinate axes, and so forth.

Virtual Reality: 3D digital world, simulating the real one, allowing a user to interact with objects as if inside it.

VRML: Virtual Reality Modeling Language, a platform-independent language for virtual reality scene description.

Surveying Mobile Commerce Environments

Mathias Weske
University of Potsdam, Germany

THE EMERGENCE OF MOBILE COMMERCE

During the last five years, the term mobile commerce (m-commerce) has appeared in the vocabulary of business people and researchers. Historically and conceptually, m-commerce can be regarded a new phase in electronic commerce (e-commerce). Although the term was introduced without a clear meaning and it is still lacking a single widely accepted definition, most people would say that the term m-commerce refers to e-commerce activities performed by people while on the move. Thus, m-commerce involves e-commerce transactions where a mobile terminal and a wireless network are used to conduct them. Therefore, m-commerce takes advantage of the e-commerce infrastructure developed for Internet e-commerce. Although in some cases an m-commerce transaction might be an alternative to a regular e-commerce transaction (such as buying a book) performed using a workstation and wired network, in many cases this is not the situation. The limitations of the mobile device - for instance, user interface limitations - are such that it is not attractive to perform typical Internet e-commerce transactions on them. Wireless technologies, combined with so-called 'Internet-enabled' terminals, constitute an ideal platform to realize new types of e-commerce transactions that are not possible or reasonable for wired terminals. The small and light, yet powerful, mobile terminals are almost always carried by their owners, just like wallets or watches. They can indeed also store electronic cash, credit card information, tickets, certificates of the Public Key Infrastructure (PKI), and so forth. Thus, they can assume the role of an e-wallet, as well as function as authentication and authorization devices in various contexts.

The wireless mobile terminals can be *positioned* either by using satellite technologies, terrestrial network facilities, or indoor mechanisms. Recent developments in these technology areas seamlessly extend the positioning of wireless devices into several environments. Thus, services based on the current position of the terminals, and their past or future movement patterns on earth, have become widely possible. These so-called location-based services (LBSs) are a new service class for mobile networks and make new kinds of location-related transactions viable. Thus, LBSs represent a new business area in e-commerce that is typical of m-commerce. For the above reasons, the telecom industry has begun to call portable wireless terminals with the above functionalities Personal Trusted Devices (PTDs).

It is worth noticing that a user can do many things with a PTD that are not m-commerce in the above, rather restricted, sense. Some of these activities can still be closely related with business, such as browsing catalogs, or receiving offers and discount coupons (see Funk, 2004). Those activities that precede or follow the actual m-commerce transactions belong rather to m-business activities (Kalakota & Robinson, 2002). We confine ourselves in the sequel mostly on the m-commerce aspects, although the network infrastructure and many other aspects we are modeling below support m-business and activities that fall outside of both. This is natural, because the wireless infrastructure is indeed common to m-commerce and many other activities.

All in all, there are hundreds of papers written on various aspects of m-commerce so far, and published in journals and conference proceedings. Regarding other approaches to model the entire m-commerce environment, it seems that there are only a few so far. One was presented in Varshney and Vetter (2001) and refined in Varshney and Vetter (2002), but the emphasis was on technical aspects. Another characterization is presented in the preface of Mennecke and Strader (2003) in order to differentiate between general e-commerce and m-commerce. The book (Sadeh, 2002) contains a balanced snapshot of m-commerce applications and business models, but does not present a clear overall model of the m-commerce environment. The E-Factors network in Europe (E-Factors, 2003) has addressed a wide variety of issues in e-commerce and m-commerce, but has not presented a succinct model for the environment. Mobile Internet Technical Architecture (Nokia, 2002) models the entire wireless Internet environment primarily from the network architecture perspective, and m-commerce is an activity supported by certain applications. An application-centric view is also adopted in Varshney (2003). Camponovo and Pigneur (2003) present a rather good overview of the pertinent issues, published literature, and also a description of their view of the m-business environment.

MODELING GLOBAL MOBILE COMMERCE ENVIRONMENT

A model in general is an artificially produced object that reflects the structure and other properties of an object of interest (e.g., a part of reality) in a simplified manner and thus makes it easier to gain knowledge of it or produce the actual object of interest. Creating a model (i.e., *modeling*) is always performed from a certain perspective and with certain goals in mind. These determine what kind of a model is created (physical, conceptual, computer simulation, etc.) and what kind of questions it is expected to answer. The original questions in our modeling attempt were: Are there any entities, structures, or phenomena that are *persistent* in the m-commerce environment? If there are, what could they be and what are the persistent *relationships* between those entities and phenomena? What we have in mind are concepts and relationships with a lifetime of, say, tens of years, instead of a couple of years. Should we be able to identify those, we could write down a framework that could be used in further research and practice for several years to come. This framework should make it possible to distinguish between entities, structures, and phenomena that are persistent and at the same time also inherent in m-commerce, and those that are not. We show below that there are persistent and inherent properties in the environment that are desirable, but others that are not desirable.

Wireless Terminals: Personal Trusted Devices

The first evident thing that is rather persistent and is embedded into the very definition of m-commerce is the terminal. It is indeed immediately clear and trivial as such that m-commerce cannot be performed without a terminal, where terminal is meant in an abstract sense. What forms the concrete terminals adopt in their development over time have of course much influence on the concrete m-commerce transactions that can be performed. But always a terminal is needed in m-commerce, be it a powerful one mounted into a car, be it a personal area network with many wirelessly connected nodes, or a telecom terminal or a PDA as we know them now. As indicated above, the current top-end terminals are called Personal Trusted Devices or PTDs.

Wireless Access Networks, Core Networks, and the Internet

A wireless access network and a larger e-commerce infrastructure including m-commerce servers and authentication servers is needed. Again, the concrete forms these take vary over time, but they are needed in some form.

The main components of the infrastructure are mobile telecom networks - access networks and core networks (Kaaranen et al., 2001) - Internet, and various servers providing the contents and services for e-commerce. The important additional persistent property of the infrastructure is that it consists of pieces that are controlled by different autonomous organizations. There are hundreds of separately controlled 2G telecom networks in the world and roughly the same number of mobile telecom operators that control the networks. Further, there are millions of servers providing for e-commerce services.

Persistent Organizational Structures

Autonomous organizations make autonomous decisions. This leads to heterogeneity of the infrastructure, as concerns the services, protocols, and so forth. A further consequence is that the development speed and stage of the network infrastructure in different parts of the world vary considerably. This situation will prevail because there is no one external force in the world that could stop this development. Only if the organizations themselves decide on a voluntary basis to provide interoperability of their systems can the problems arising from the different stages and development speeds be solved or at least mitigated.

Concerning the regional development, there are currently three large regions in the world, namely the EU, Japan, and the USA, that have reached the m-commerce phase. The rules are more or less homogeneous inside a region, but not necessarily between the regions. Other large regions, like China, might develop their own rules, or they might adopt those of the leading regions. We expect the three most advanced regions to be the dominant ones also in the foreseeable future, although new regions with new rules might emerge. We call such a region *regulatory area*.

Japan and the USA (as well as China, Korea, and Australia) are homogeneous in natural language, whereas Europe is divided into tens of smaller and larger language areas. Thus, although the rules applied would be the same, as is roughly the case in the European Union, the concrete m-commerce services could still be obtainable in different language. Thus there is no guarantee of m-commerce in Europe in a strong sense.

So far in Japan, the mobile telecom operators have taken the initiative in the mobile arena, and government has observed the development. The Japanese approach has been most successful in m-commerce, whereas in the EU, the Commission has established rules for e-commerce including m-commerce, but the development of the latter lags behind the Japanese market. Operators in the U.S. have relied mostly on market actors; the situation is somewhat similar to Europe. The other side of the coin is, however, that the Japanese market is fragmented, because the operators have created "walled gardens," and the competition happens between these. To come to a different market structure, that is, relationships between m-commerce companies and customers, requires different actions from the players than what were taken in Japan. The newest development in the Japanese market can be found in Funk (2004).

Mobility as a Persistent Property

Mobility is inherent in the definition of m-commerce, and it is one of the persistent properties of m-commerce. As is understood now, different mobility patterns have different consequences for the service provisioning. The 2G and 3G access networks support continuous service provisioning for moving customers through handovers within a network controlled by one operator. *Roaming* is also supported, that is, services are offered for customers of other network operators. From an m-commerce point of view, the above regulatory areas and the homogeneous language areas are important while roaming. Thus, if a person travels within a language area, he or she would not encounter language problems while using the m-commerce services. In theory, roaming within a regulatory area should be possible without service access problems, but in practice the geographic areas where certain m-commerce services are currently offered are within individual countries and even in a certain mobile telecom network as indicated above. Roaming from one regulatory area to another means that currently m-commerce services are not at all available, or if they are, they are designed in a local language and thus difficult to use for foreigners. This and problems with lower level protocols in the protocol stack needed in m-commerce can be perceived as an interoperability problem that is unfortunately rather persistent. This is one of the few persistent properties that should be made non-persistent in m-commerce environments, should the market become truly global and accessible for large numbers of roaming customers. Whether this happens depends largely on the economic feasibility of providing services for "overseas" roaming customers, because it is unlikely that authorities would enforce interoperability by rules.

Business Model as a Persistent Entity

M-commerce is a form of business, and is also a persistent and inherent property. In our modeling we go a step further and say that what is persistent, but at the same time varying, is a *business model* (Timmers, 1998). Our idea is that in a concrete m-commerce environment, there is always a business model, but depending on the regulatory area, technology in use, culture, and other factors, it can and will be different. Business models are designed by business actors. We perceive them to be primarily companies.

Continuous Change as a Persistent Phenomenon

Just like in other areas of modern information technology, in m-commerce the only stable property is change. The concrete elements change over time, including base technology, business models, and rules and regulations. New technology that has been deployed, especially in the mobile telecom networks, has made m-commerce possible, and we envision it to be the main driver, at least in the first phase, although business models and emerging needs have quickly begun to form the technology to fulfill needs (e.g., camera and video phones). We tackle this movement from a new technology to an established and deployed one by introducing the concept of *enabling technology*. It is technology that is being developed in laboratories and will perhaps be deployed in the future. Partially it is technology that is necessary in the current situation (e.g., security and privacy protection), partially explorative (wireless transmission technology with very high transmission capacity, measured in Gigabits-per-second, Gbps). It is worth noticing that a concrete enabling technology can exist long before it is actually used in m-commerce (for instance, message encryption), or it can be developed in a short time as a response to the emerging needs of m-commerce, for instance mobile digital rights management.

THE FRAMEWORK IN MORE DETAIL

The basic structure of the m-commerce framework is presented in Figure 1; components of this framework are explained in more detail below. A more elaborate treatment is provided in Veijalainen and Weske (2003).

- Regulatory Frameworks*:* The organizational and technical aspects of laws, standards, and recommendations, as well as the bodies involved in their definition. The main actors here are international

Figure 1. Spheres of concern

<table>
<tr><td rowspan="3">Regulatory Frameworks</td><td>Business Models</td></tr>
<tr><td>Global Infrastructure</td></tr>
<tr><td>Enabling Technologies</td></tr>
</table>

organizations, such as OECD and EU, governments, standardization bodies (ISO, ANSI, ETSI), and interest groups formed by diverse industry sectors to develop standards, such as 3GPP (2003) and Open Mobile Alliance (2003). The persistent entities and their relationships are presented in a more detailed way in Figure 2.

- Business Models*:* Business aspects, including business players, provided services, business protocols, revenue sharing, and code of conduct are important artifacts in this sphere (Timmers, 1998). This sphere captures the pertinent business aspects, persistent concepts and structures. At any moment and in different parts of the world, the business models have a different shape, due to differences in regulatory environment, local (business) culture, economic strength of the individuals, and companies in a particular region. Concrete business models change over time, once new technologies and new business opportunities can be concretely deployed. The persistent entities and their relationships are presented in detail in Figure 3.
- Global Infrastructure: The global infrastructure sphere deals with the global network and the concrete terminals that facilitate m-commerce, as well as the real services. The real global infrastructure is a patchwork of many wireless access networks and backbones, including the Internet. It is and will be heterogeneous at different architectural levels at any point of time. This is because in different parts of the world the development will progress with different pace. The sphere is represented in more detail in Figure 4.
- Enabling Technologies: This sphere includes emerging technologies for user terminals and network technologies, such as new cryptography, privacy-protecting technologies, positioning with high accuracy, and new batteries and other energy sources for the terminals. It also includes standardization and business interest groups and other organizations developing these emerging technologies. Typical examples are 4G (and beyond) technologies, which are currently being researched and which will move later into standardization. The sphere is represented in more detail in Figure 5.

The division of the m-commerce environment into four spheres of concerns, as we call them, is motivated by the observation that these spheres seem to be very persistent and their life span is much longer than that of any of the concrete ingredients. The reasons are basically simple. Regulatory frameworks address in our model the organizational aspects that are necessary to regulate the business environment, the deployed networks, and the development of new technologies. Enabling technologies are in a way a basis for everything, because their change is a necessary condition for the deployment of new technologies in the global infrastructure and business models. Should the development of new technologies stop, this would mean stagnation in the upper spheres in Figure 1.

Global infrastructure is the totality of the terminals, access networks, backbones, servers, and other components that are deployed at a certain moment. It also contains the technical support for concrete m-commerce transactions, that is, implementation support for business models in place. Business models also address many and mainly other aspects than the technical level, including the business partners, money and contents flow, and so forth. They live their own life within organizations and as interaction patterns between organizations.

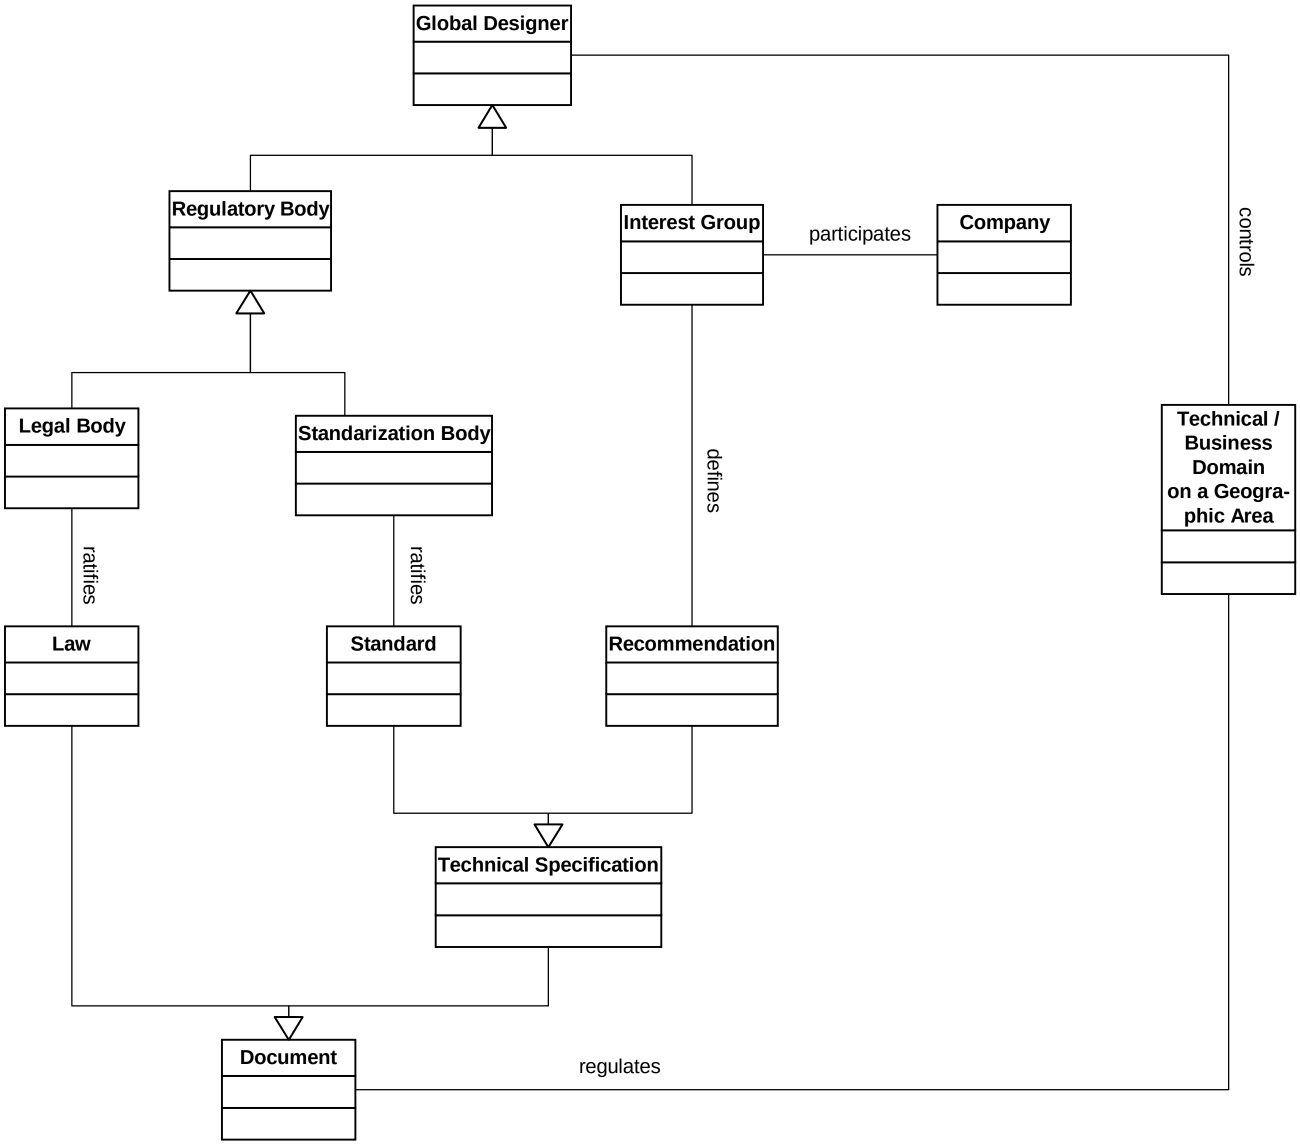
The identified entities and the persistent relationships between these are presented in the diagrams below. They were obtained from Veijalainen and Weske (2003) and explained more thoroughly there.

CONCLUSION

We have attempted to describe the most common persistent properties of the m-commerce environment. Some of them are non-desirable and require concerted action if one wants to avoid them. Others are inherent properties of the very concept of m-commerce, as we have defined it in this context. The main contribution of the framework is perhaps the separation of the four rather persistent spheres of concern that have their own, relatively independent rules of development, but which are still tightly coupled with the other spheres. We also identify some entities within the spheres that are more persistent than the others. This does not mean, however, that these would be the only important entities for understanding current m-commerce.

The interesting questions are related to the relationships between the spheres and their development. For instance, which regulations inhibit the business model, infrastructure, and enabling technology development?

Figure 2. Regulatory frameworks (Figure 3 from Veijalainen & Weske, 2003)



S

Figure 3. Enabling technologies (Figure 4 in Veijalainen & Weske, 2003)

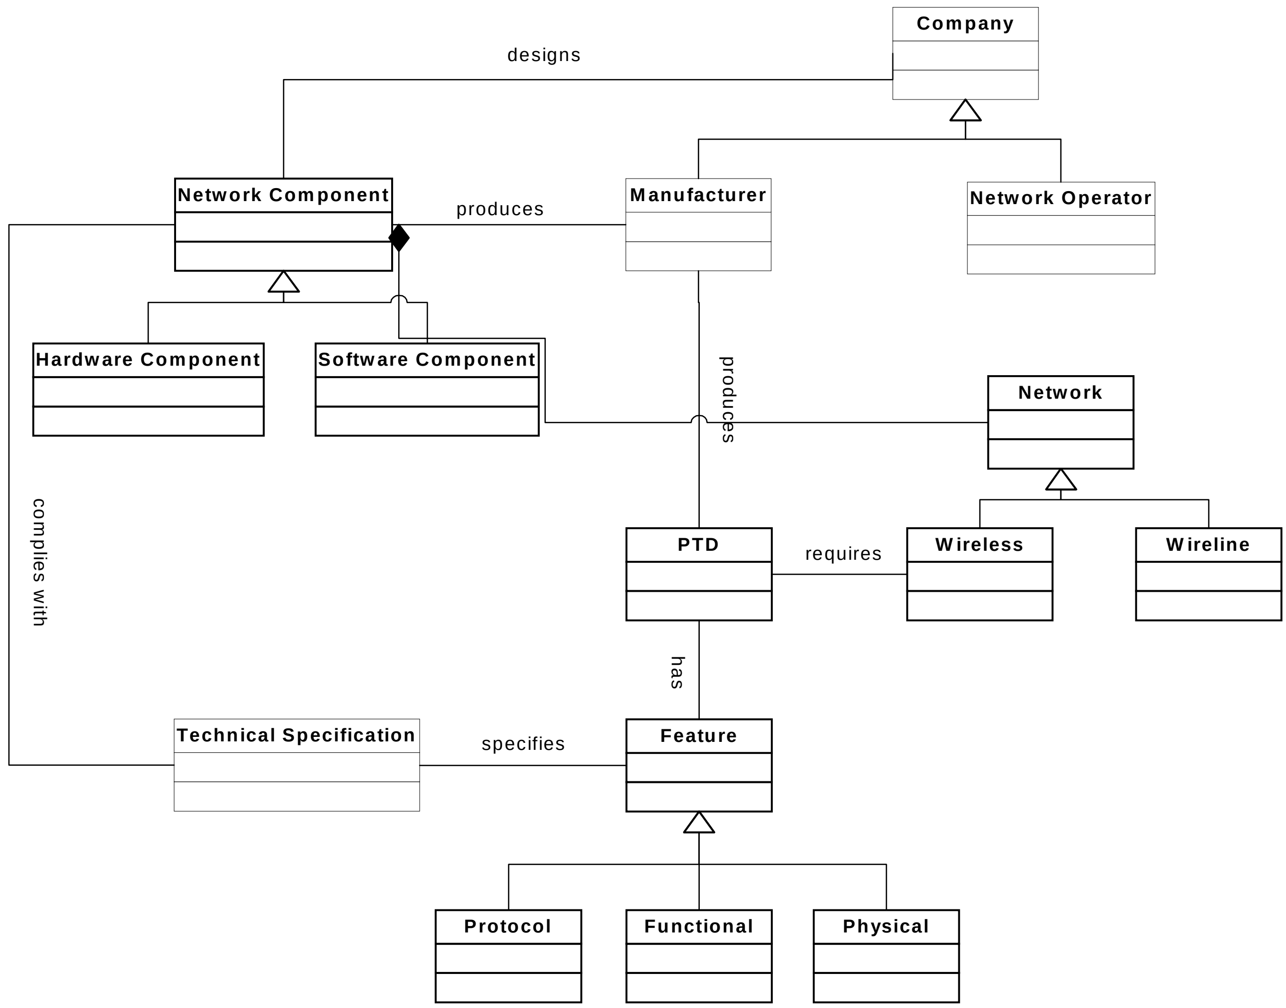


Figure 4. Global infrastructure (Figure 5 in Veijalainen & Weske, 2003)

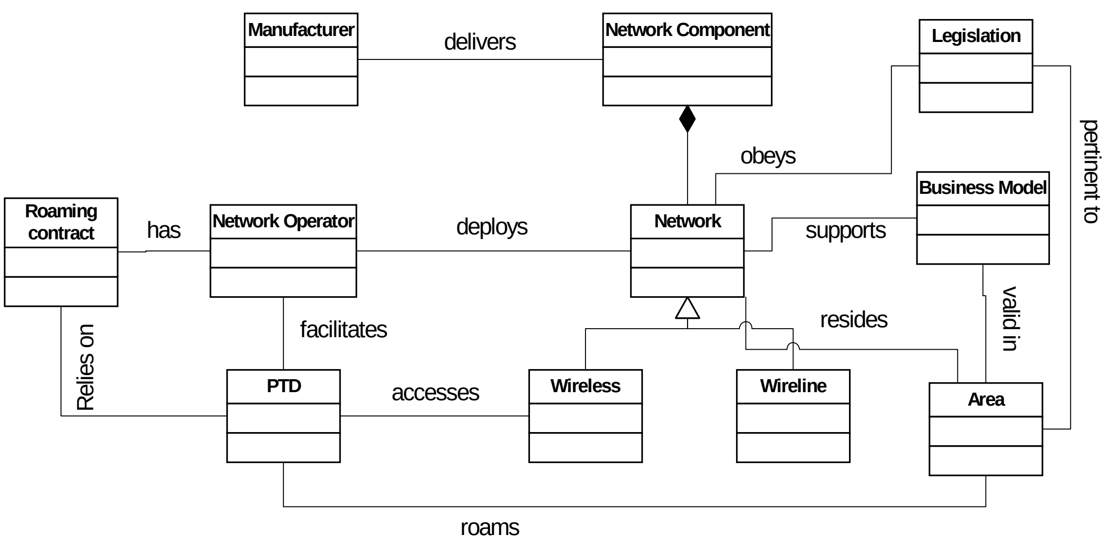

Figure 5. Business models (Figure 6 in Veijalainen & Weske, 2003)

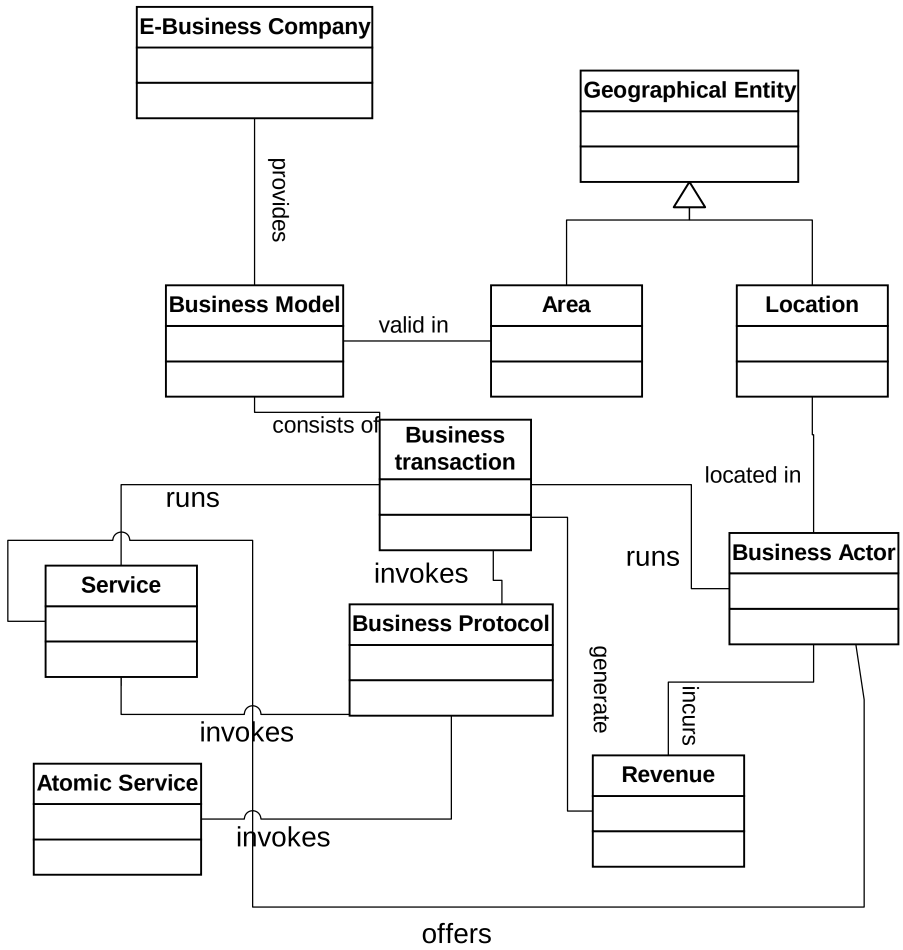

Figure 6. Overall framework of m-commerce environment

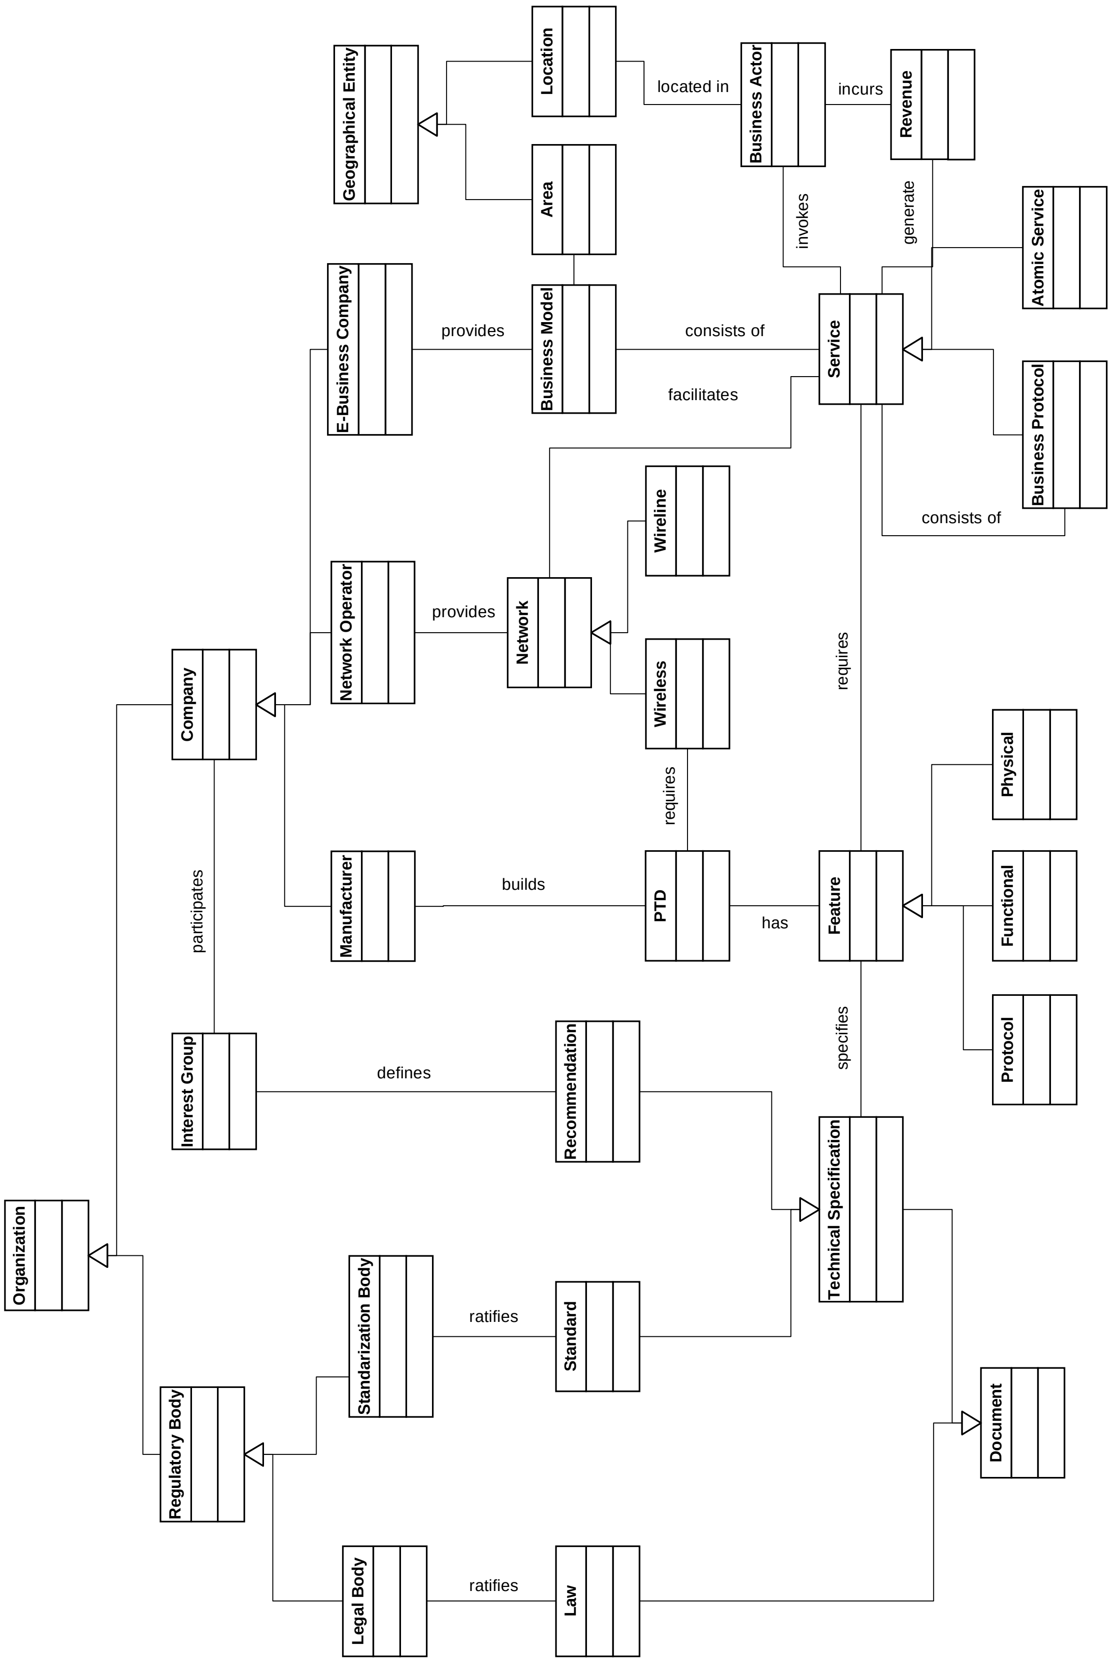

Which would foster it? We have discussed privacy in Veijalainen and Weske (2003) as a concept that penetrates the spheres, and treated privacy protection in Veijalainen et al. (2003) as a requirement that addresses different issues in different spheres. Further, what are the concrete interdependencies between the companies and other actors within the regulatory frameworks sphere? What are such concrete business models that foster or inhibit the development of new enabling technologies? What are the economic parameters of the different spheres: how much does the infrastructure cost, how much the development of the new enabling technologies, and how much should the m-commerce yield in economic terms? An important question is: which are such entities and issues within various spheres that are shaped under competition? Which issues should be agreed upon globally or regionally among business actors and regulators?

KEY TERMS

Business Model: A sphere of concern; addresses business aspects, as perceived by companies, including business players, provided services, business protocols, revenue sharing, and code of conduct are important artifacts in this sphere of concern (Timmers, 1998). A concrete business model is facilitated by (a part of) the global infrastructure (that is, the concretely deployed technology), and simultaneously restricted and enabled by the legislation in force.

Electronic Commerce Transaction (broad definition): An (e-commerce) electronic transaction is the sale or purchase of goods or services, whether between businesses, households, individuals, governments, and other public or private organizations, conducted over computer-mediated networks. The goods and services are ordered over those networks, but the payment and the ultimate delivery of the good or service may be conducted online or off. Includes orders received or placed on any online application used in automated transactions such as Internet applications, EDI, Minitel, or interactive telephone systems (OECD, 2002).

Enabling Technologies: A sphere of concern; consists of those technologies that are under development at a certain moment and that have potential to become part of the global infrastructure in the future. Currently, new 3G terminals and 4G network technologies are typical examples.

Global Infrastructure: A sphere of concern; consists of the wireless access and backbone networks, as well as servers and terminals that are necessary for e-commerce in general and m-commerce in particular at a certain moment. Global infrastructure is shaped by the organizational entities within the regulatory framework sphere, and controlled and operated by companies and governments. Global infrastructure consists of heterogeneous components (WLANs, 2G and 3G telecom network, wireline telecom networks, Internet, proprietary IP networks, and a great variety of wireless terminals) and evolves over time as new technologies are adopted from the enabling technologies sphere, where they are developed.

Mobile Electronic Commerce (M-Commerce): Activity that consists of launching and controlling mobile electronic commerce transactions. Note: m-commerce also includes pure machine-to-machine e-commerce transactions, although human involvement is assumed in most cases at the mobile terminal.

Mobile Electronic Commerce Transaction: An e-commerce transaction that is conducted using a mobile terminal (e.g., a PTD) and a wireless network or link.

Personal Trusted Device (PTD): A mobile communications device that can be personalized (through the registration of service certificates), and trusted by the user and service providers requiring application-level public key security (MeT, 2002).

Regulatory Frameworks: A sphere of concern; organizational level that is required to control the interoperable technical domain or legislation pertinent in m-commerce. Most important current concrete entities within this sphere of concern are governments and intergovernmental organizations (EU, OECD, UN, etc.), industry associations (OMA, W3C, etc.), and proper standardization bodies (ISO, ETSI, ANSI, etc.).

Sphere of Concern: A set of issues and entities relevant for a particular modeling process, in this case modeling of m-commerce (c.f., Universe of Discourse (UoD) in conceptual modeling).

System Development for E-Business

Theresa A. Steinbach
DePaul University, USA

Linda V. Knight
DePaul University, USA

INTRODUCTION

This article first introduces both the technical and business environments in which Web information systems are developed and the unique project variables of these systems. Characteristics are identified where e-business projects differ from traditional information systems projects. The next section presents various system development methodologies, provides a categorization framework and analyzes these categories for situations where each is best utilized. The synthesis of applying the environmental and project variables to the system development methodology categories provides the main contribution of the article. Conclusions are drawn that a project is unlikely to align perfectly with any one methodology. The project manager should select the methodology that is the "best fit" from the model presented here. Finally, the project manager should customize the process based on the unique characteristics of the organization, project, and team.

BACKGROUND

The speed demanded of e-business developers and the ever-fluctuating nature of the technical and business environments in which they must function combine to demand new approaches to the system development process. Traditional methodologies were designed for vastly different environments and cannot be easily transplanted into this new Web setting. In the practitioner press, Yourdon has called for a new "light" version of traditional methodologies (2000) for use in e-business development. Avison and Fitzgerald (2003) have found many Web-based applications being developed in an ad-hoc, trial-and-error manner.

The E-Business Environment

E-business projects are developed in a unique environment that is characterized by "perpetual ambiguity and rapid change" (Nadherny and Stuart, 2000). A Web Information System (WIS) is usually tightly integrated with other non-WISs, such as databases and transaction processing systems (Isakowitz and Bieber, 1998) to support the work of the organization. "Internet time," the perception that product development and consumer acceptance now occur in a fraction of the time that they traditionally took (Odlyzko, 2001), has increased time-to-market pressure in WIS projects. These distinctive characteristics set e-business projects apart from other types of information systems (IS) projects.

(1) Web Technical Environment

The technical environment for a Web Information System is vastly expanded compared to traditional IS projects. In most traditional projects, an organization builds their information systems in a closed setting, limiting external organizations' access based upon the controlling organization's technology choices. Web Information Systems are different in that both external and internal users often access WISs using a variety of different hardware, software, and networking technologies. To further complicate matters, compatibility issues arise when new WISs must interface with existing legacy systems.

(2) Competitive Marketplace

The competitive marketplace plays a far greater role in Web Information Systems than it does in most traditional projects. WIS marketplace impact can be direct and immediate. This situation offers the promise that an organization could quickly gain competitive advantage through its Web Information Systems. However, according to Porter (2001), the five underlying forces of competition: the intensity of rivalry among existing competitors, the threat of substitute products or services, the barriers to entry for new competitors, the bargaining power of suppliers, and the bargaining power of buyers, have been negatively affected by the shift away from quality, features, and service toward price. This has resulted in a dampening of overall profitability, and has reduced the ability of any company to establish an operational advantage that can be sustained. Thus the e-business competitive environment is characterized by the ability of any competitor to rapidly change marketplace dynamics, coupled with the likelihood that any such change will be quickly be supplanted by another competitor's actions.

(3) Organization's Culture

Each organization brings to every project its own culture. An organization's culture is comprised of values, behaviors, and attitudes (Hatch and Schulz, 2001). It provides continuity, structure, common meaning, and order, giving rise to stable patterns of interaction within the organization. However, that stability can be upset by the creative, more liberal culture characteristics of many Web development efforts. Developers who challenge the advisability of traditional project phases and approvals also challenge the established culture and order.

(4) Organizational Strategy

An organization's Web strategy should be viewed as a continuous cycle that builds on the current strategy of the organization while creating new business models (Venkatraman, 2000). Yet, for some organizations, e-business brings with it a change in strategic emphasis from internal operations to customers. In the world of Web Information Systems, branding has become increasingly important. A brand is the relationship between a company and its customers that is based on vision, culture, and image (Hatch and Schultz, 2001). Personalization of the Web interface and creation of online communities can extend the traditional brand relationship and increase customer loyalty and profitability. The customer, viewing their experience with the organization, should see only a seamless integration of the organization's overall strategy and their Web initiatives.

(5) Organization's Technical Environment

Web Information Systems complicate the organization's technical environment. In the 1970s mainframe era, most organizations had single-site implementations, where all hardware and software came from one manufacturer, and there were designed to work together. The introduction of client/server technologies in the early 1990s replaced this single source with the challenge of integrating hardware and software from multiple vendors. Web Information Systems operate in a distributed world with a multitude of different manufacturers' components, many of which were not engineered to work together. Organizations have the option of retaining this technology in-house or outsourcing, or a combination of both.

(6) Project Characteristics

Web Information Systems concentrate more heavily on Information Architecture than the average traditional IS

Table 1. E-business development methodology variables (Knight et al., 2003)

Organization			
Culture:	Conservative	→	Innovative
Strategy:	Committed	→	Evolving
Technology:	Stable	→	Experimental
	Non-integrated	→	Integrated
Project			
Objectives:	Clear	→	Unclear
Requirements:	Stable	→	Changing
Users:	Known	→	Unknown
Implementation:	Long	→	Rapid
Team			
Skills:	Technical	→	Creative
Composition:	Stable	→	Changing
Member Experience:	Less Experience	→	Highly Experienced
Leadership:	Less Experience	→	Highly Experienced

project. In a Web Information System context, Information Architecture refers to the design of organization, labeling, navigation, and searching systems to help people find and manage information more successfully (Rosenfeld, 2000). WIS Information Architecture concentrates heavily on the human-computer interface.

A project budget for traditional information systems is often based upon data gathered through historical experience. Web Information Systems generally do not have this kind of past experience to draw upon for estimating. Further, the question of which department should sustain the cost of a project becomes more complex for many WISs, where project ownership issues are often less clear.

Whereas traditional IS projects are largely limited to the IT department, with some involvement of primary users, the development of Web Information Systems requires teams that include a broad range of technical, user, and creative talent. Many WIS teams include marketing staff, business analysts, graphical artists, human-computer interaction specialists, and branding specialists.

System Development Methodology

System development methodology refers here to the framework that is used to structure, plan, and control the process of developing an information system. Most models can be placed into one of four major categories: linear, iterative, parallel, or agile.

(1) Linear Models

While Boehm (1986) tracks system development methodology to Bennington's 1956 Stagewise model and Royce's 1970 Waterfall model, other authors suggest that the System Development Life Cycle (SDLC) evolved primarily during the 1970s (Harrison, 1985), in response to organizations' needs to better organize, plan, schedule, and control projects (Hall, 1980). The SDLC is based upon two principles: dividing projects into phases, and using written documentation and approvals to maintain control. While the exact phases in the cycle vary from one author or organization to the next, they generally follow along these lines: initial investigation, conception or feasibility study; requirements definition; system design; coding, unit testing, integration and system testing; implementation; and ongoing system maintenance. The Waterfall model, which allows some overlap and splashback between the phases, is a variation of the SDLC that loosens this type of control slightly. Another variation on the SDLC is the V Model (Plogert, 1996), which emphasizes system quality assurance. In this model, the stages are partnered in a sort of V shape, with, for example, system design on the left leg of the V paired with system testing on the right leg, and requirements definition on the left leg paired with acceptance testing on the right leg.

Table 2. Situations where linear development models are most beneficial

- Clear project objectives
- Stable project requirements
- Knowledgeable user
- No immediate need to install
- Inexperienced team members
- Fluctuating team composition
- Less experienced project leader
- Need to conserve resources
- Strict requirement for approvals

(2) Iterative Models

Prototyping is an iterative process that lets users work with a small-scale mock-up of their system, experience how it might function in production, and request changes until it meets their requirements. As Janson and Smith (1985) noted, "Prototyping addresses the inability of many users to specify their information needs, and the difficulty of systems analysts to understand the user's environment, by providing the user with a tentative system for experimental purposes at the earliest possible time." Maturity of the prototype methodology led to a further type of iterative development model, Rapid Application Development (RAD). RAD methodologies aim at producing high quality systems quickly, primarily through the use of iterative prototyping, active user involvement, and computerized development tools.

The Spiral model developed originally by Boehm (1986) is an iterative approach that is focused on minimizing project risk. Each trip around the Spiral traverses four basic quadrants: (1) determine objectives, alternatives, and constraints of this iteration; (2) evaluate alternatives; identify and resolve risks; (3) develop and verify deliverables from this iteration; and (4) plan the next iteration (Boehm, 1986; 1988). Boehm's more recent work reflects an expanded view of the Spiral, requiring identification of stakeholders and their win conditions at the very start of each cycle, and ending the cycle with review and commitment. This broader view of the Spiral merges elements of Boehm and Ross's Theory W into the Spiral Model (Boehm, 2000). Under Theory W, the primary job of the software project manager is to insure that all of the project's stakeholders become winners (Boehm and Ross, 1989).

Table 3. Situations where prototyping/RAD is most beneficial

- Project objectives are unclear
- Functional requirements are changing
- User is not fully knowledgeable
- Immediate need to install something
- Experienced team members (particularly if the prototype is not throw-away)
- Stable team composition
- Experienced project leader
- No need to absolutely minimize resource consumption
- No strict policy or cultural bias favoring approvals
- Analysts/users appreciate business problems involved, before they begin project
- Innovative, flexible designs that will accommodate future changes are not critical

(3) Parallel Models

Parallel models resemble those used by some advertising agencies when they are under competitive pressure to produce the best possible presentation for their client in the least possible time. The advertising agency's "three creative comps" becomes three creative treatments of a Web site. With parallel models, different approaches are tried at the same time by different individuals or teams, and then as the project progresses, less productive paths are pruned. Alternative paths may be followed simultaneously just at the project start, or new alternative paths may be introduced when the project reaches critical points. An alternative path model creates multiple paths and prunes as the project progresses.

(4) Agile Development Models

During the late 1990s and early 2000s, a variety of new methodologies were put forth, most aimed at creating a lighter, faster, more flexible and responsive approach to development. Beck's Extreme Programming (1999) user requirements are noted on index cards and programmers work in pairs, with two developers sharing one computer workstation. Bad code is weeded out regularly through a process called refractoring. Initial studies have indicated that pair coding results in less initial productivity, but that pairs do write code with fewer defects (Radding, 2001; Williams et al., 2000). Highsmith's Adaptive Software Development (1999) emphasizes developing a flexible team that can function in a complex, rapidly changing environment. Adaptive development grew out of Highsmith's attempt to apply Rapid Application Development techniques to larger, more complex projects. His adaptive development cycle consists of three major phases or stages: (1) speculate (project mission statement, initial requirements and cycle plan); (2) collaborate (short cycles where system components are developed concurrently and delivered); and (3) learn (review work and team's performance.)

APPLYING THE MODEL TO SPECIFIC PROJECTS

Table 7 is an enhancement of *Table 1*, showing the relationships between various development methodologies and organizational, project, and team variables. These were culled from the background section.

When an organization applies the model in *Table 7* to a particular project, considering all their organization, project, and team variables, the model is unlikely to align

Table 4. Situations where the spiral model is most beneficial

- Risk avoidance is a high priority
- No need to absolutely minimize resource consumption
- Project manager is highly skilled and experienced
- Policies or cultural bias favor approvals
- Project might benefit from a mix of other development methodologies
- Organization and team culture appreciate precision and controls
- Delivery date takes precedence over functionality, which can be added in later versions

Table 5. Situations where parallel models are most beneficial

- Rapid installation is a primary goal
- Solid, experienced team
- Strong project management
- Excellent project-related communications
- Stable team composition
- Experienced project leader
- Little pressure to conserve resources
- Uniquely flexible development team

perfectly with any one methodology. At this point, the project leader may select a methodology model that is a close fit, cognizant of that model's limitations when applied to his or her project. For example, an innovative Web Information System might line up well with a agile method except for the lack of experience of the project team. By using the model, the project leader is able to identify this discrepancy and make plans in advance to compensate. Such plans may include team-building exercises, mentoring, weekly status meetings, and skill-building training, for example. Alternatively, when there is not a single methodology that is clearly the best fit, the project leader may elect to create his or her own "best practice" by combining various aspects of those models that most effectively address the organization, project, and team variables.

FUTURE TRENDS

Various development methodologies have risen to the forefront at different times in history. Royce proposed his linear model in the 1970s. Iterative development was widely discussed in the 1980s. Parallel models were popular in the early 1990s. Agile development emerged in the late 1990s. Currently, various agile methods are in vogue. As each new methodology has emerged, its proponents have espoused its virtues. Over time, each methodolody's limitations have become known as well. The model presented here recognizes both the advantages and the limitations of each methodology. As new methodologies continue to emerge, the model provides a way for project managers to incorporate these emerging methodologies in a way that is appropriate for their organization, team, and project.

CONCLUSION

The rapidly changing business and technical environment that characterizes Web-enabled e-business, coupled with the unique nature of Web development teams themselves, combine to demand a new approach to system development methodology. No existing methodology is ideally suited for all e-business development endeavors. However, existing methodologies do provide a storehouse of options from which project managers can and should select and customize methodologies best suited to their organizations, their projects, their teams, and the unique nature of Web-enabled e-business. When a project most closely aligns with a single methodology, the project leader can compensate in the management of those few variables for which the chosen methodology is not a good fit. If project variables do not clearly indicate a preferred methodology, the project leader must employ those tools and techniques from each methodology that address the "best practice" of each variable. The model proposed here for Web-based systems could be applied to all types of information systems.

Table 6. Situations where agile development models are most beneficial

- Rapid installation of the bulk of the system is not a critical goal
- Users have ability to make rapid, binding decisions
- Users are flexible and willing to work through many small implementations
- Collaborative team atmosphere
- Team with substantial system design experience
- Experienced project leader
- Minimal pressure to conserve resources with some models

Table 7. Model for evaluating e-business development methodology (Knight et al., 2003)

<u>*Organization*</u>			
Culture:	Conservative (Linear, Spiral)	→	Innovative (Parallel, Agile)
Strategy:	Committed (Linear)	→	Evolving (Prototyping, RAD, Agile)
Technology:	Stable (Linear, Spiral)	→	Experimental (Parallel, Agile)
	Non-integrated (Linear, Spiral)	→	Integrated (Parallel, Agile)
<u>*Project*</u>			
Objectives:	Clear (Linear, Spiral)	→	Unclear (Prototyping)
Requirements:	Stable (Linear, Spiral)	→	Changing system fundamentals (Parallel, Agile)
Users:	Known (Linear)	→	Unknown (Spiral, Prototyping, RAD)
Implementation:	Long (Linear, Spiral)	→	Rapid (Prototyping, RAD, Parallel, Agile)
Budget/schedule risk: *(risk of not meeting)*	Low (Disruptive)	→	High (Linear, Spiral)
Requirements risk: *(risk of not identifying)*	Low (Linear, Spiral)	→	High (Prototyping, RAD, Parallel, Agile)

KEY TERMS

E-Business Environment: The business environment that is characterized by rapid time-to-market pressures, heterogeneous technical access, and quick IT strategic response requirements.

Extreme Programming: An agile system development methodology that decomposes very large projects into many small projects with minimal requirements and taking just a few weeks to complete, characterized by pair programming and refractoring.

Internet Time: The perception that product development and consumer acceptance now occur in a fraction of the time that they traditionally took (Odlyzko, 2001).

Prototyping: A tool used in system development methodology that lets users iteratively work with a small-scale mock-up of an information system, experience how it might function in production, and request changes until it meets their requirements.

Rapid Application Development: A system development methodology that aims to produce high quality systems quickly, primarily by using iterative prototyping, active user involvement, and computerized development tools.

Spiral Model: A system development methodology that utilizes an iterative process that is focused on minimizing project risk.

System Development Life Cycle: A system development methodology that divides projects into phases and uses written documentation to maintain control.

System Development Methodology: A model that is used to structure, plan, and control the process of developing an information system.

V Model: A modified system development life cycle which emphasizes quality assurance.

Waterfall Model: A modified system development life cycle which allows some overlap and splashback between phases.

Web Information System: An information system that is accessed through the Internet and usually tightly integrated with databases and transaction-processing systems.

Systems Thinking and the Internet

Kambiz E. Maani
University of Auckland, New Zealand

INTRODUCTION: EVOLUTION OF MODERN THINKING

Despite our most impressive advances in science and technology, our prevailing worldview and the way we work and relate are deeply rooted in the thinking that emerged during the Renaissance of the 17th century. This thinking was influenced by the sciences of that era and, in particular, by Newtonian physics. Newton viewed the world as a machine that was created to serve its master—God (Ackoff, 1993). The machine metaphor and the associated mechanistic (positivist) worldview, which was later extended to the economy, the society, and the organization, has persisted until today and is evident in our thinking and vocabulary. The mechanistic view of the enterprise became less tenable in the 20th century, partly due to the emergence of the corporation and the increasing prominence of human relation issues in the workplace. As the futurist Alvin Toffler (1991) declared, "the Age of the Machine is screeching to a halt" (Toffler, 1991).

In the early part of the 20th century, a new breed of scientists, in particular, quantum physicists such as Werner Heisenberg (Uncertainty Principle) and Norbert Weiner (Cybernetics), began to challenge the Newtonian precepts (Zohar & Marshal, 1994). The 1960s saw the publication of Austrian biologist Von Bertalanffy's seminal text, *General Systems Theory* (1968), a major milestone in this field. Later, Jay Forrester of MIT introduced and demonstrated the applications of feedback control theory in simulation models of organizations (Forrester, 1958). Forrester's seminal work marks the birth of the professional field known as System Dynamics. System Dynamics is concerned with applications of systems theory and computer modeling in business, economics, and environment. System Dynamics is the forerunner and the scientific foundation of Systems Thinking.

BACKGROUND: CRITICAL ISSUES

Machine-age thinking, still prevailing today, is based on the following assumptions.

- Complete understanding of the universe is possible.
- All relationships can be described through simple cause-and-effect relationships.
- The world could be understood through analysis (breaking the wholes into pieces).

For well over a century, the western world has subscribed to a way of thinking known as analysis (Ackoff, 1995). In analysis, in order to understand something—a concept, a product, a law, an organization, the human body—we break it into pieces and study the pieces separately. This approach tends to overlook the interdependencies and connections among the constituent parts that are responsible for change and dynamics in systems.

On the one hand, this divide-and-conquer approach has served us well. It has enabled efficient mass production of goods and services, which has brought a new social and economic order and has produced unprecedented wealth and standards of living in the industrialized world. On the other hand, this thinking has resulted in the fragmentation of functions and has created complexity and cross-purposes within organizations.

The major intellectual and philosophical precepts that form the bedrock of our modern society, such as division of labour, free-market economics, mass production, and scientific management, are characterised by the following (Zohar & Marshal, 1994).

- The hierarchy
- Need for certainty, stability, and the absolute
- Treating organizations and the society as consisting of isolated, separate, and interchangeable parts
- Relationships based on conflict and confrontation
- Desire for control and bureaucratic methods
- Persistence of single points of view leading to friction and polarisation
- Overemphasis on specialist expertise, leading to fragmentation and loss of relevance

SYSTEMS THINKING

Systems Thinking (ST) is a discipline for understanding the dynamics of change and complexity underlying business, economic, scientific, and social systems. Systems Thinking has three distinct but related dimensions: para-

Table 1. Why we need Systems Thinking (Maani & Cavana, 2000)

• Increasing complexity in our lives
• Growing interdependence of the world
• Revolutions in management theories and practice
• Increasing global consciousness and yet local decision-making
• Increasing recognition of learning as a key organizational capability

digm, language, and methodology. These dimensions are outlined below (Maani & Cavana, 2000),

- Paradigm: Systems Thinking is a way of thinking about the world and relationships. This paradigm relates to the dynamic relationships that influence the behaviour of complex systems. A number of expressions that we use in daily language reflect the Systems Thinking paradigm—vicious/virtuous cycle, ripple effect, snowballing, spiral effect, domino effect, and chronic behaviour.
- Language: As a language, Systems Thinking provides a tool for understanding complexity and dynamic decision-making. The Systems Thinking language is known as Causal Loop (or Influence) Diagrams.
- Methodology: Systems Thinking provides a sophisticated computer modeling technology and associated learning environments for group interactions and learning.

FUTURE TRENDS: SYSTEMS THINKING AND THE INTERNET

In the past few decades, two movements have had a profound influence on the way we think and communicate—the Internet and Systems Thinking. Both are grounded in science and technology and complement each other in principle and practice. While one has become a household name, the other still remains relatively obscure. The Internet was born in military and academic quarters in the late 1960s. In the 1990s, the Internet moved into the public domain and rapidly became a mass movement. Today, the Internet and its associated e-commerce is the engine driving the globalization and convergence of various markets, services, and industries (Query et al, 2003).

Systems Thinking likewise originated in scientific circles and is slowly growing in appeal and applications. It offers a way of thinking based on the primacy of the whole and relationships. Systems Thinking deals with hidden complexity, ambiguity, and mental models. It provides tools and techniques to leverage change and to create lasting interventions (Maani, 2001).

For centuries, information and knowledge were the preserve of the clergy and the aristocrats who used them to dominate and manipulate the masses. In the past century, knowledge privilege extended to the boss, the manager, and the teacher who assumed this as part of their role and superiority. This knowledge divide, for its part, has strengthened the hierarchy and widened the gap between the haves and have-nots.

Although they may be regarded as purely technical advances, both Systems Thinking and the Internet challenge the age-old paradigms and the ways information and knowledge are disseminated. At a more fundamental level, they challenge the hierarchy and authority, power, and leadership. In essence, the Information Age has ushered in a new culture, new social movements, and new politics around the globe (Webster, 2001).

The Internet, through its unimpeded access and speed, has brought down in effect the boundaries that define business, trade, and even nationhood. Likewise, through compelling and coherent scientific principles, Systems Thinking breaks down the superficial dichotomies of the whole vs. the part; the individual vs. the community; integration and autonomy; and business, nature, and society. Together, the Internet and Systems Thinking can provide powerful synergies blending new concepts, tools, and technologies.

Over the past 20 years, new concepts and models have emerged that have dramatically challenged the prevailing assumptions and practices in business and management. Among these are the just-in-time philosophy and techniques, total quality management, and, more recently, supply chain management and enterprise systems. These paradigms have progressively removed the conventional boundaries between the organization, the customer, the supplier, and, to some extent, the competition.

An example of the Internet-Systems Thinking synergy is the supply chain management (SCM) practiced in businesses worldwide. The conceptual underpinning of SCM is systemic in nature in that the business or organizational boundaries span to cover the entire chain of supply. In this model, the stakeholders regard themselves as partners and collaborators in an enterprise system who seek the good of the whole. This notion stands in sharp contrast to the business models preceding it, which were characterized by control, competition, and the optimization of the parts in isolation.

In turn, the reach and speed of the Internet have enabled such cross-boundary and integrative business models as supply chain management and e-business/e-commerce, such as business-to–customer (B2C) and business-to–business (B2B), to rapidly grow and multiply. With the daily spread of globalization and e-commence, there is a dire need for reliable and efficient ways to manage, monitor, and control global large-scale projects that contain thousands of workflows and hundreds of organizations located at different sites. "Companies are faced with an increasingly competitive and hostile environment. The terms 'information exchange,' 'compatibility,' and 'interoperability' have become ubiquitous in this environment" (Badir et al, 2003). To survive, companies will have to constantly develop innovative ways for managing and controlling information and for doing business. These can be accomplished efficiently and effectively with Web-based models that automate the business processes and extend them beyond the organization.

The astronomical growth of the Internet is epitomized in China where, between July 2000 and January 2002, the number of Internet users doubled to 34 million. This, for example, has enabled over 50% of domestic Chinese insurance companies to offer policies online (Query et al, 2003).

In summary, the Internet has steadily pushed our thinking and our practices closer to a systemic model of the enterprise within the organizations and industries. At a higher level, the accelerated interdependence and interconnectedness of the global economy, trade, and governance calls for a systemic (holistic) view of the global community, the environment, and nationhood. To this end, the Internet has substantially shifted the distribution of economic activity around the world through its impact on transportation, uniform pricing, and marketing strategies that target individuals rather than regions, creating in essence a new economic geography (Anderson et al, 2003) and a single invisible continent (Ohmae, 2004). Thus, Systems Thinking and the Internet can play a synergistic role in the transformation of social, cultural, and political paradigms toward a global socioeconomic order. Given the evident trends, this appears not only plausible, but also inevitable.

CONCLUSION

Contemporary society is characterised by constant change, increasing complexity and speed, greater interdependence, and a rapid breakdown of social and political norms. In order to succeed (or even to survive) collectively, we need new paradigms and tools. According to Ackoff (1995), there is a progression from information to knowledge, to understanding, and to wisdom. So far, the Internet has provided for part of this progression—information abundantly and freely available to all, as well as a mechanism of instant and global communication transcending the conventional barriers of the past.

Systems Thinking, on the other hand, addresses a compelling need to gain a deeper understanding of the ever increasing complexity and interdependence of the world and the underlying forces shaping this interdependence. In this regard, Systems Thinking makes it possible to do the following.

- Examine and foresee the consequences of policy and strategic decisions
- Implement fundamental solutions to chronic problems
- Avoid mistakenly interpreting symptoms as causes
- Test assumptions, hypotheses, and scenarios
- Find long-term solutions and avoid "fire-fighting" behaviour
- Boost employee morale and improve productivity
- Implement change management without adverse side effects

The most urgent and fundamental dilemmas that we face today in the organization and in society require a collective will that comes from a deeper understanding of our place in history and our collective destiny towards an organic unity. Systems theory provides a scientific way of thinking about the world and relationships. It offers the art and the science of seeing the tree *and* the forest; it reconciles the superficial dichotomy between the individual and the collective, and focuses attention on the common good. The principles of systems theory collectively provide a paradigm and a language for deeper understanding of the chronic issues besetting our times. Used appropriately and with care, these principles can transform our age-old views and assumptions and move us towards a shared understanding. In this respect, the challenge for the Internet is to transcend its status as an information repository and a business tool, and become a channel to enhance understanding and goodwill. The evidence to date is promising inasmuch as the Internet continues to break down national, political, and social boundaries, thus bringing us closer to a holistic and systemic understanding of our global society.

KEY TERMS

Balancing (Counteracting) Feedback: A systemic pattern that is responsible for stability, balance, and control. It represents adjusting, correcting, and counteracting processes that resist, slow down, or impede change and growth.

Causal Loop Diagram (CLD): A tool that captures the causal interrelationships among a set of variables. CLDs reveal systemic patterns underlying complex relationships and highlight hidden causes and unintended consequences.

Flow or Rate: The amount of change in a variable over time. Flow represents the change in the status or the quantity of a variable over a specified time unit.

Leverage: Knowing which actions may yield long lasting outcomes. Knowing where and when to intervene or influence a system to gain long lasting desired change using minimal effort and energy.

Reinforcing (Positive) Feedback: A systemic pattern that represents growth and self-feeding processes. It explains the dynamics underlying vicious and virtuous cycles with downward and upward spiral effects.

Stock: The accumulation of a variable such as asset, debt, energy, morale, and reputation. Stock represents the status or the quantity of a variable at a given point in time (i.e., a snapshot of reality).

System: A purposeful entity whose parts interact with each other to function as a whole. Thus, a system is not the sum of its parts; it is the product of their interactions (Ackoff, 1993). A system can be part of a larger system.

System Dynamics: A scientific tool that embodies principles from biology, ecology, psychology, mathematics, and computer science to model complex and dynamic systems.

Systems Archetype: A generic pattern of relationships that occurs in a wide range of systems and circumstances—natural, biological, political, social, and economic. A powerful tool for seeing high-level dynamics.

Systems Delay: The time lapse between action and response. Delays often destabilise the system and slow down a system's progress towards reaching its goal. Systems delays often mask anticipated outcomes as well as unintended consequences of actions since the intervening time lapse is often longer than expected.

Systems Thinking: Thinking holistically and conscientiously about the world by focusing on the interaction of the parts and their influence within and over the system.

Tacit Knowledge and Discourse Analysis

Michele Zappavigna-Lee
University of Sydney, Australia

Jon Patrick
University of Sydney, Australia

INTRODUCTION

Much of human experience is *below-view*, unattended to as we operate in the world, but integral to our performance as social creatures. The tacit knowledge involved in our practice allows us the experiential agility to be at once efficient and creative, to assimilate the novel and the familiar: in essence, to develop expertise. The possessors of skilful practice, the artisan, the witchdoctor or the physician, have occupied a position of both importance and mystery in most cultures since ancient times. Our interest over the ages in such hidden knowledge has caused us to mythologise expertise, placing it beyond the common by constructing it as unspeakable. Thus, in contemporary times it is not surprising that the dominant research perspective on tacit knowledge maintains that it is ineffable, that is, tacit knowledge cannot be understood by looking at what and how people communicate verbally. Indeed the word tacit has its origins in the Latin, *tacitus*, meaning silent.

As information technologies have begun to alter the way in which we think about our own processes while looking for ways to automate and retain our practices, we have been compelled to consider how the experience of the artisan mentioned above can engage with the constraints of the computational world. Capturing and sharing tacit knowledge has thus been a consistent problem in information systems and knowledge management research (Boisot, 1995; Nonaka & Takeuchi, 1995; Tsoukas, 2002; Wenger, 1998). Polanyi's Theory of Tacit Knowing (TTK) is the dominant theoretical perspective in this research. In this theory, Polanyi (1958) suggests that tacit knowledge is inherently personal, underlying our ability to perform tasks we find difficult to explain, such as facial recognition. Concepts in TTK have been made available to the information systems (IS) community largely through the work of Nonaka & Takeuchi (1995) who reinterpreted the theory, precipitating research directions in information systems that are misaligned with Polanyi's theses. A notable example is the movement in IS research to differentiate tacit and explicit knowledge (Johnson & Lundvall, 2001). In contradistinction, Polanyi asserts that explicit knowledge cannot be adequately separated from its tacit coefficient:

Now we see tacit knowledge opposed to explicit knowledge; but these two are not sharply divided. While tacit knowledge can be possessed by itself, explicit knowledge must rely on being tacitly understood and applied. Hence all knowledge is either tacit or rooted in tacit knowledge. A wholly explicit knowledge is unthinkable. (Polanyi, 1969, p. 144)

The emphasis in information systems research is typically on converting tacit knowledge into explicit knowledge (Hershel, Nemati, & Steiger, 2001). Attention is also given to setting up a dichotomy of tacit and explicit knowledge in terms of articulation (can it be carried in language?), codification (can it be turned into an artifact?) or judgment (is it objective or subjective?).

This article is structured to critique the dominant position in information systems research that tacit knowledge is ineffable. The background section provides an introduction to the extensive interdisciplinary literature on tacit knowledge, providing context for the subsequent section that deconstructs the assumptions that this literature makes about what it means to, in Polanyi's (1966, p. 4) terms, "know more than we can tell." To conclude, the role of linguistic and semiotic analysis in realising the growing trend toward theorising "community knowing," rather than knowledge as an artifact, is suggested in the final sections.

BACKGROUND: UNDERSTANDING TACIT KNOWLEDGE, AN INTERDISCIPLINARY PURSUIT

Both prior and adjacent to the popularisation of Polanyi's TTK, there has been extensive interdisciplinary research in tacit knowledge and a very large body of research looking at the implicit, situated nature of practice. These disciplines include philosophy, psychology, linguistics, semiotics, sociology, history, philosophy of science, and, most recently, knowledge management. A theme running through all these domains is uncovering the below-view. For example, Freud's (1970) theory of psychoanalysis and his corresponding concept of the unconscious locates a significant aspect of human experience below the view of awareness. Similarly, a movement in psychology investigates implicit learning (Reber, 1993), that is, learning that is below-view in the sense that it occurs without the attention of the subject on the process of learning. Recently, there have been attempts by psychologists to create psychological metrics for tacit knowledge. Wagner & Sternberg (2000) develop a method for measuring tacit knowledge in psychology and business management. Their "Tacit Knowledge in Management" (TKIM) inventory seeks to "identify individuals whose 'street smarts' indicate the potential for excellent performance in managerial and executive careers" (Wagner & Sternberg, 1991, p. 1). Conceiving of tacit knowledge as a facet of *practical intelligence*, they construct a triadic view of tacit knowledge as "managing self," "managing tasks" and "managing others," and test subjects in each area through multiple-choice responses to scenarios.

In the social sciences, the focus has been on identifying the implicit subject positions which have been naturalised by culture (Bernstein, 1971; Bourdieu, 1990). This naturalisation means that these positions remain below scrutiny. This is part of a research program that suggests that our experience is constructed through implicit social processes and parallels a body of research in psychology that claims that social behaviours are encoded automatically and without intention (Bargh, 1999). Bourdieu (1990) suggests that the individual internalises the cultural habitat in which they reside, their *habitus*. This means that they form dispositions to behave and construe their experience in certain ways. The acquisition of these structural constraints is a process of acculturation into specific socially-established groups or classes (Bourdieu, 1990, p. 130) and is akin to Bernstein's (1971) notion of *code orientation*. This is a different conceptualisation to the structuralist position, which argues that we follow unconscious rules in enacting our practice. Instead, it is a view of socially constructed dispositions that are inscribed in the habitus but which may shift with changes in context: "Agents to some extent fall into the practice that is theirs rather than freely choosing it or being impelled into it by mechanical constraints" (Bourdieu, 1990, p. 90).

Research in the history and philosophy of science examines science as a discipline that operates to efface the tacit component of its practice in order to maintain an ideology of objectivity (Collins, 1974, 2001a; Kuhn, 1962; Ravetz, 1971; Turner, 2001). In their investigation of science as a social practice, theorists in this domain have sought to reveal the tacit nature of the methods scientists employ. In fact, Polanyi's model of tacit knowledge itself was directed at critiquing the scientific method and to providing "a stable alternative to…[science's] ideal of objectivity" (Polanyi, 1966, p. 25). It provided a conceptual basis for understanding scientific activity as the practice of a craft (Ravetz, 1971). This is part of a program which deconstructs what Schuster (1984) refers to as the mythic construction of method. Method discourses in science typically try to generate the idea that they are systematic, explicit and objective (Collins, 2001a, 2001b; Ravetz, 1971). As such, they present themselves as incommensurable with other practices such as astrology, which they claim to be pseudoscience. Here we have an example of an institutional discourse, science, operating to efface the role of tacit knowing in the production of knowledge.

IS TACIT KNOWLEDGE INEFFABLE?

The attribute most consistently ascribed to tacit knowledge across the disciplines is ineffability (Baumard, 1999; Collins, 2001a; Nonaka & Takeuchi, 1995; Reber, 1993). The strong position is that tacit knowledge cannot be articulated in any linguistic form, while the weak position holds that it is difficult to articulate. Polanyi's (1966:4) widely cited suggestion that "we know more than we can tell" asserts the epistemological significance of tacit knowing in terms of its ineffability. In assessing this proposal, it is important to consider what it means "to tell." If telling means making explicit, codified artifacts that are directly transferred to the mind of the listener, then this kind of telling is not a possible means of exposing tacit knowledge. However, if we allow that telling involves processes of which the speaker is not necessarily aware and which are, in turn, subject to both unconscious and conscious interpretation by the listener, linguistic structure is reinstated as relevant to understanding tacit knowledge. These below-view processes are akin to Peirce's notion of the interpretant in semiosis, introduced in the previous section.

Thus, it appears that Polanyi's statement needs to be refined. We know more than we can tell only if we think about telling as making explicit knowledge. Such an assumption utilises an impoverished model of communication. This model, referred to as the mathematical model of communication (Shannon & Weaver, 1949), presupposes that meaning in communication is absolute and, as such, may be seamlessly transferred from the mind of the speaker to that of the listener. It applies what Reddy (1979) terms the *conduit metaphor*, that is, the notion that words are boxes with meanings inside that are unpacked by the person to which they are directed. Reddy (1979:287) argues that the metalingual resources of English privilege this kind of view, as the following examples suggest:

Whenever you have a good idea, practice capturing it in words
You have to put each concept into words very carefully

Just as in uttering the sentences above we are unlikely to focus on the presuppositions about communication that they presume, when we speak, that which we utter cannot be viewed as an overt object. We may well articulate what we know implicitly through patterns and features of language to which we do not directly attend. This is an argument that articulation does not produce a form that by definition is explicit, or in alternative terms, that articulation is not the equivalent of codification. However, many studies in information systems research equate these two modes of meaning-making.

There is a substantial tradition within psychotherapy that has approached language as a way of understanding a person's unconscious experience (Ferrara, 1988, 1994; Freud, 1960; Labov & Fanshel, 1977; Lentine, 1988; Parker, 1995; Pittenger, Hockett, & Danehy, 1960). This notion is further specified in linguistics by Halliday & Webster (2002, p. 303) who assert the significance of the relationship between grammar and the unconscious. Meaning-making with grammar is, according to this view, implicit meaning-making:

Conscious language achieves its creative force mainly by lexical means; and lexical items are semantically close to experience. Unconscious language depends much more for its creative force on grammar – and grammatical categories are far removed from experience. (Halliday & Webster, 2002, p. 303)

This appears in accord with the argument that description of the grammatical features in a subject's discourse will give us insight into the nature of their unconscious experience. It follows from this, that if the features of a subject's grammar involving meanings that are effaced are explicated, then the knowledge to which they point may be elicited. In looking at implicit meaning, Hasan et al. (1996) introduce the notion of implicit style in discourse. They give the example of the clause, "they will," which they argue is an example of maximal implicitness as it does not contain a string that is not implicit. The clause raises the questions: whom "will" and what "will" they? Hasan et al. (1996, p. 194) argue that we may distinguish between implicit and explicit ways of saying and that, when an implicit style is adopted by a speaker, "precise meanings become available only if certain additional conditions are met; the average working knowledge of the language is necessary but not sufficient." It is at this point that we require the services of a linguist.

Zappavigna-Lee & Patrick (2004) present a method for eliciting tacit knowledge from the language of interviewees through a process of directed interviews based on a linguistic model of tacit knowledge. This process centers upon the interviewer identifying semantic and grammatical features in the interviewee's language that suggest knowledge that the participant possesses, which remains "below-view." The knowledge is below-view in the sense that the linguistic-choice that the interviewee has made indicates *under-representation*. Under-representation occurs when components of knowledge are effaced in discourse, as they have been automatised by the individual. For example, the agent in a clause may be omitted. In addition to simply being left out of discourse, the knowledge may be effaced through generalisation that construes it as unavailable for deconstruction. For example, a verb may be nominalised meaning that something that was a process with component steps is rendered as a static object This means that there is less potential for these steps to be analysed. Tacit knowledge is subsidiary in the sense that we do not attend to such obfuscation. The directed interview method entails:

1. Identifying the semantic feature that suggests knowledge that is under-represented in the interviewee's discourse and important for their current knowledge management task.
2. Asking a question that elicits a more delicate response from the interviewee and which prompts them to elaborate on this feature.

In applying this interview method in an on-going case study in an Australian broadcasting organisation, Zappavigna-Lee & Patrick (2004) demonstrate that identifying such features will contribute in eliciting a more delicate description of the interviewees' meaning than a strategy based solely on eliciting content. The description is more delicate not only in the sense of being more specific lexically, but also in the sense of being increasingly precise lexicogrammatically.

In a directed interview with a senior manager in the digital media division of the organisation the interviewer noted that the manager possessed tacit knowledge that was embedded in nominalizations. For example, the manager described his division as a "service area" that "provide[s] services including IT services." "Service" is the nominalisation of a range of processes involving understanding, communicating and delivering feedback to clients. An underlying component of these processes is negotiating shared cultural experience. Through elaborating this nominalisation in the directed phase of the interview the interviewer uncovered that the manager believed that the greater the shared cultural experience and active cultural processes that he was able to foster, the greater the shared knowledge and cohesion of his employees. This information was not elicited merely by asking the manager to be more specific, as this would simply have elicited a more detailed rendering of his explicit style. This may have merely produced a taxonomy of the IT services in the organisation. Instead, embedded phenomena about the manager's beliefs and practices were uncovered by analysing his implicit style. This phenomenon is more "specific" in a particular way: it is the elaboration of parts of the interviewee's language of which they were not aware. This is an exercise below the surface of the text, and below the content plane on which most interviews are conducted. As such it involves a richer elicitation of the interviewee's experience.

FUTURE TRENDS: TACIT KNOWING OR TACIT KNOWLEDGE?

There is a growing movement in the IS literature that argues that it is not possible to capture tacit knowledge but that we should instead manage processes which facilitate its social transfer (Boland & Tenkasi, 1995; Stenmark, 2001; Wenger, 1998). This is part of a movement which acknowledges that that knowledge is human and social rather than an artefact that can be abstracted in a database (Weick, 1995; Wenger, 1998). It suggests that tacit knowledge is dynamic and carried in communities of practice (Huysman, 2004; Wenger, 1998). Rather than taxonomising tacit knowledge as if it were an object, this movement adopts a community-oriented model of knowledge management in which IT services are aimed at connecting people with relevant experts rather than attempting to externalize and codify this expertise (Swan, Newell, Scarborough, & Hislop, 1999).

The community-oriented model is aligned with the post-critical epistemological orientation of Polanyi's thesis, which deals with "knowing" rather than "knowledge;" with a process rather than an object. This conceptual position is in accord with the movement in semiotics and other disciplines concerned with theorising knowledge, such as philosophy and linguistics, away from reification: that is, away from a constituency-based view of knowledge as an object, toward a view of knowledge as dynamically produced by human subjects. Future research adopting this kind of framework should seek to employ existing tools such as linguistic analysis to understand how humans "do knowing" as opposed to "construct knowledge."

CONCLUSION

Polanyi's maxim that "we know more than we can tell" remains the dominant perspective on tacit knowledge in information systems research. However, few studies consider what it means to "tell" and the implications this has on asserting the ineffability of tacit knowledge. As this research begins to shift to considering tacit knowledge a process rather than an object and draws upon the large body of existing scholarship in other disciplines, attention should be given to what kind of meaning-making tacit knowledge involves. Tacit knowledge is potentially not as taciturn as we have assumed.

KEY TERMS

Below-View: Elements of experience which are not available to direct inspection without applying some semiotic tool such as linguistic analysis.

Conduit Metaphor: A metaphor about communication, which suggests that an addresser's ideas are objects contained in packages, known as words, that are directly sent to the addressee.

Focal Awareness: Polanyi's term for conscious perception that the individual can directly access. Contrast with *subsidiary awareness*.

Habitus: Bourdieu's term for the cultural context in which an individual resides and which influences their practice.

Subsidiary Awareness: Polanyi's term for perception to which an individual does not have direct access, as it is not part of their focal awareness. Contrast with *focal awareness*.

Tacit: From the Latin *tacitus*, meaning silent.

Tacit Knowing, Tacit Integration: Polanyi's concept of the process of implicit integration of subsidiary and focal elements by an individual. The individual attends "from" the element in their subsidiary awareness "to" the element in their focal awareness.

Tacit Knowledge: Implicit understanding of which the individual is not directly aware and which is involved in their skilful practice.

Under-Representation: Zappavigna-Lee & Patrick's term for a set of specific linguistic features that indicates the presence of tacit knowledge in an individual's talk.

Tailorable Information Systems

INTRODUCTION

The quest for the business fit of information systems is as old as the history of computers. In the past, computers used to lag behind the daily needs of the users because they lacked the capabilities of tackling the issues raised by the users. In the late 80's, the fourth generation of computers was a decisive step toward the acquisition of such system capabilities that allowed powerful software to be developed (O'Brien, 2002), rendering them able to tackle almost any business problem.

However, the previous decade has been marked by failures of big information systems (IS) projects, despite the sound accumulated knowledge on various information systems development methodologies and the advent of software engineering tools. The examples of IS that failed to deliver their premise are abundant, to name but a few: the U.S. IRS tax system modernization (Hughes & Cotterell, 2002); the London Ambulance Service's information system and the UK automated stock brokerage system TAURUS (Beynon-Davis, 1995); the automated train seats' reservation system SOCRATE in France (Eglizeau, Frey, & Newman, 1996). Of course, a variety of reasons could lead an IS project to a disaster, and the sources of the failure could stem from project management malpractice to poor software engineering techniques, to wrong leadership choices, and so forth. Apart from them, research has shown (e.g., Fitzgerald, 1990; Oei, Proper, & Falkenberg, 1994; Robertson, 1997) that any IS, no matter how "perfect" it can be built, is immediately being undermined for the forces of change. These forces of change inherently exist in any organization and have to do not only with the constant expansion or modification of the user requirements day-to-day, but also with the user's computer and information literacy. The latter means that the familiarization of the user with an IS creates new needs that IS maintenance comes to respond to. Maintenance is a corrective action, aiming at endowing the IS with improved functionality, in contrary to the irrational inference that a "finished" IS product is supposed to operate in the same business/organizational context meeting always to the same set of initial requirements (Bjerknes, Bratteteig, & Espeseth, 1991). No matter how precise and complete the elicitation of user requirements may be, the behaviour of an IS is constantly diverging from the evolving needs of the business/operational context (Stamoulis, Martakos, & Introna, 1998).

BACKGROUND

All methods and techniques used so far to produce flexible enough IS which can achieve business fit have all fallen victims of the fixed-point pseudo-theorem (Paul, 1993): "There exists some point in time when everyone involved in the system knows what they want and agrees with everyone else." This statement can never be verified in practice, and subsequently, describes a dead-end situation. User requirements are the result of the evolving business/organizational context of the IS, whereas the IS itself has been built to an exact specification which had been based on a snapshot of its business context's operation. Ideally, IS should behave like living organisms (Paul, 1993) that have the ability to adapt to changes of their operating environment. But, the software engineering technologies along with the way of thinking of the IS development discipline cannot escape the destiny of their determinism. This is where ateleology and tailorable IS (TIS) come into play. The former negates the mentality of constructing an IS as a product developed to meet a specific telos (purpose, definition) and the latter provides the theoretical framework for a new breed of truly flexible IS to appear. The questions of whether TIS are feasible and if software can even be tailorable are answered by means of the Atoma architecture, which has already been implemented.

MAIN THRUST OF THE ARTICLE

Tailorability is not another word for customization. IS flexibility has been based for years on how many parameters of the IS functionality can be configured by the end-user without taking any maintenance action. The tailorable IS thinking immediately focused on adaptivity. A program is adaptive when it changes its behaviour depending on its current contextual situation (Gouda & Herman, 1989). If everything in an IS may change, then tailorability affects the user interface in terms of the user dialogue, the screen layout, the help function, the icons and the functions themselves, as well as the functionality in terms of input, processing and output (Patel, Gardner, & Paul, 1995). Of course, this flexibility should be realized in real-time, without disrupting the IS operation, upon user's demand. If all of these features of an IS could change, then IS would really behave like a living system, and then it could be named as a tailorable IS (Patel et al., 1995) whose purpose is to "provide control over systems to a user". Looking at the problem at the macro level, an abstract systems architecture model has been proposed (Stamoulis, Patel, & Martakos, 1996), which describes the need for tailorability at three software layers: IT infrastructure (hardware, operating system, data sources); application logic (workflow, process logic, and facilities layers); and presentation logic layer. For each one of these layers, emerging software technologies that demonstrate tailorability traits or characteristics have been identified (Stamoulis, Kanellis, & Martakos, 2000).

In the old vein of thought, an observer was looking at an IS as an autonomous organ within a living organism's context, that is, its business environment, expecting from the IS to follow the needs and the commands of its context. From a different perspective, the user-IS system co-evolutes as a closed system (Stamoulis et al., 1998) towards a destination, a purpose, a telos that cannot be known in advance. Having used the self-organizing theory coming from the physical sciences to explain the theoretical foundations of TIS (ibid), the embracement of the ateleology ideas comes as a natural subsequence. At about the same time, research work (Baskerville, Travis, & Truex, 1992, 1996; Truex, Baskerville, & Klein, 1999) in the same area – but not starting from the need for true flexibility – started converging to the need for ateleological IS development, by means of a methodical systems development, where a methodical means is not obeying to well-structured techniques through which compliance with a specific goal can be achieved. In theory, the problem was well-defined. In practice, there was a missing link that would connect the tailorability concept with possible implementation routes. The definitive characteristic of a TIS – the key to achieve tailorability – is the deferred design decisions (Patel, 1999, 2003) mechanism.

Design decisions translate the user requirements into rigid specifications, which render an IS short-living by definition. Since an IS must constantly adapt to changing user requirements, design decisions must be deferred until run-time, when the ultimate judge, the user, determines the preferable IS behaviour and, consequently, fixes the appropriate design decisions for the IS to run. If ever these need to be changed, this IS behaviour change must occur at the user's control, at run-time, while the IS remains operating. To prove realistic, this new way of thinking had also to define other issues such a method of work for implementing TIS, a security and stability framework for TIS that constantly changes and so forth. As far as the former is concerned, the concept of an IS blueprint has been devised (Stamoulis, Theotokis, Martakos, & Gyftodimos, 2003). In line with the ateleology and a methodical IS development, TIS are initially constructed as blueprints with minimal features that correspond to a vague problem definition within a problem domain, as the user starts using the TIS, co-evolutes towards an end, a goal, a telos, and takes design decisions that implement a specific, well-defined IS behaviour, pertinent to each and every problem situation. To arrive at an IS blueprint, the Soft Systems Methodology (Checkland & Scholes, 1990) can be perfectly used, as explained in Theotokis (2003). As far as the latter is concerned, a model with separations of concerns in terms of security and change authorization domains has been proposed to guarantee for the stability of TIS (Farmakis, Kanellis, Martakos, & Stamoulis, 2000).

In the following, an innovative implementation of the deferred design decisions mechanism is been presented called the Atoma architecture and new developments towards tailorability are being discussed. This approach is based on the concept of separation of concerns as proposed by Morch (2003) and Randall and Lycett (2003). Concern separation is key in realising deferred design decisions as it facilitates the notion of "injectable" behavioural adjustments in existing operational IS. As such, Atoma was selected as representative of systems supporting concern separation and consequently behavioural variations.

The Atoma model was developed in order to better model cross-cutting behavioural changes related to the evolution of the behavioural landscape of an information system, by alleviating the problem associated with traceability and monitoring, scattering and tangling and, at the same time, enable the incorporation of modelled behavioural changes into an existing system without affecting in any form the system's stability. An implementation of the model exists and is based on the Java programming language. The key idea behind Atoma is to improve the effectiveness in realizing modifications, of the behavioural landscape of object, in a dynamic, transparent and natural way, so that systems are considered as "living", evolving and tailorable entities, both from a conceptual viewpoint, as well as that of implementation.

The Atoma model allows object-oriented design and code to be decomposed into units, describing basic behaviour, as this is captured during the initial design phase from the contractual requirements, and units that specify either variations or changes to these requirements, or in fact new requirements, as these emerge in time. Both at design and implementation level, the former are represented as standard object-oriented classes, while the latter are roles that, when composed with classes, realize the ever-emerging requirements. Each role can, therefore, be refined separately to a code artefact, and the details of the code composition can be derived from those of the design composition. There is excellent traceability and monitoring at this level, because code and design units correspond directly, and so do requirements and design. Furthermore, within a single composition, standard object-oriented design or code is used. This traceability and monitoring facilitates both evolution and "round-tripping": Projecting design changes into the code and requirements or, for that matter, reflecting the changes made in the code back into the design and requirements.

When a new requirement is added or an existing one is changed, a new design aspect, a role, is created to address it. The new design aspect can then be composed with the existing design. Then, the design aspect can be refined to a code aspect (role implementation), which is similarly composed with the existing code. The changes are localized without risking the rest of the system's stability, so there is no tangling, and both traceability and monitoring are preserved. In addition to this, dealing with the alignment problem, the decomposition into roles alleviates the monolithic nature of the design, and allows for concurrent development, while the composition underlying the Atoma model provides a powerful mechanism for integration, evolution, customization, adaptation, tailorability and improved reuse.

It is, in fact, this composition mechanism that provides a remedy to the problem of constructing rigid systems. The necessary, inflexible mapping of requirements to design units is no longer required, and design decisions, which fix requirements into design, and subsequently code, are no longer necessary. By separating the various cross-cutting aspects of a system, modelling them independently and composing them back to deliver the required function of the information system, we advocate that deferred design decisions can be realized, and thus enable the construction of truly tailorable information systems.

FUTURE TRENDS

Although a number of approaches towards behavioural tailorability have and are being proposed including, but not limited to role modelling, aspect-oriented programming, multidimensional separation of concerns, not much work has been done addressing the issue of data tailorability The area of tailorability plays a key role in achieving a fully tailorable system. Currently, techniques such as data migration are being employed for tailoring data according to new requirements. However, thorough consideration must be given to techniques and approaches that will allow data modelling to take into account the need for change, whether such change is anticipated or not. Modelling techniques need to be limited to data, but they should address roadmaps and methodological procedures that will enable analysts, designers, and developers to design tailorable systems. Another important issue that must be considered in great depth concerns the degree to which platform (software and hardware) architectures are tailorable or support tailorability. Model driven architectures take into account the need for change, but not as their first priority. However, if tailorable systems are to be successful, all aspects of software construction, operation and maintenance should focus on the issues governing and characterizing tailorable information system.

CONCLUSION

Tailorable information systems are becoming a necessity as they support the evolving nature and world an IS models. Based on the concept of deferred design decisions, they provide the means to accommodate change as it occurs, when it occurs. In as such, they differ from traditional IS in that they do not embed any rigid design decisions. Instead they support the notion of behavioural evolution in terms of "injectable" behavioural modifications. Role-based models and role-based programming are seen as the vehicle for this purpose, since they are underpinned by the concept of separation of concerns, a concept that supports deferred design decisions.

KEY TERMS

Ateleology: In the context of IS development, refers to the development of an IS which does not aim at the attainment of a specific set of goals only, expressed in the form of user requirements as they have been articulated at a specific point of time, but rather refers to the developing an IS that addresses a range of issues within a specific problem domain and, at the same time, is flexible enough to accommodate changes and extensions of the IS behaviour while it is being operated.

Behavioural Landscape: The set of behavioural characteristics an object possesses at a given time during its lifetime.

Behavioural Variations: Modifications on the functionality exposed by an object. Behavioural variations occur as a result of changes in the state, context, perspective and use of an object, and as such, they can be categorized as internal or external ones.

Deferred Design Decisions: The cornerstone of implementing tailorable information systems, the DDD mechanism through which decisions traditionally are taken during the design phase of an information system development project, as a result of a set of user requirements elicited during analysis, are now being deferred at run-time, until after the user decides about the required information system behaviour. The information system can then follow the new design specifications without any maintenance or redevelopment action, and execute them to provide the user-defined behaviour.

Information System Blueprint: An initial, functioning skeleton of a tailorable information system, built to reflect a problem solving framework within a specific problem domain which, by means of an inherent deferred design decision mechanism, can be tailored by the end-user to acquire or amend its existing behaviour, in order to meet the specific needs of a particular business/organizational context. A blueprint of a tailorable information system can truly achieve flexibility.

Role: A concept that its individuals stand in relation to other individuals, and that they can enter and leave the extent of the concept without losing their identity.

Tailorable Information System: An information system whose behaviour is dynamically user-controlled at run-time, without causing instability and disruption to the rest of the information system, not affected by the change(s) initiated by the user, aiming at endowing the information system with the capability to meet new or altered user requirements, and, thus, rendering it adaptable to any contextual change within a problem domain.

Teams and Electronic Technologies

INTRODUCTION AND BACKGROUND

Teams[1] are integral elements in today's corporate and industrial worlds, considered by some to be the fundamental units of organizations, and technology has become essential to teamwork. Just as it is nearly impossible to engage in any type of organizational task without team support today, it is equally impossible to engage in effective teamwork without technological support. Technology, particularly computer and digital technology, has become essential to the functioning of both traditional teams (face-to-face) and virtual (distributed or geographically separated) teams. Technology and virtuality arguably change work groups in three important ways: they introduce new dimensions of communication among members by breaking down traditional barriers of space and time; they modify traditional group processes; and they enormously enhance the group's capacity to access, share, manipulate, retrieve, and store information.

There are inherent advantages of technology for teams. For example, technology frees team members from geographical constraints. People no longer must work in the same physical location to work together; participants can contribute from any part of the world, at any time of the day or night. By breaking down the barriers of space and time, technology enables teams to fully utilize the expertise of the members of an organization (or of several organizations) without pulling them from other projects or incurring relocation expenses. Hence, at least notionally, such teams have immense potential for improving organizational effectiveness.

Although there is a substantial amount of research on teams and technology, the focus on the technologies available to team members has hitherto remained the domain of Information Technology. This article takes an interpersonal focus to consider the software and communication technologies that allow individuals and teams to communicate, exchange information, interact collaboratively, and manage data within and outside of a group, synchronously and asynchronously. The technological support systems discussed here cover a wide range of technological applications, primarily, but not limited to, computer, audio-visual, and phone applications. To organize our discussion, we will use the classification scheme of messaging and conferencing systems (e.g., e-mail, discussion lists, electronic bulletin boards, Web logs and short message services), information-exchange and data-management systems (e.g., Internet, File Transfer Protocol, Gopher, Telnet, the World Wide Web, and Internet alternatives), and commercial groupware packages. Note that as our focus is on the team member as end-user rather than on the hardware, installation, programming, and setup as considerations of hardware and programming will not be discussed[2].

MESSAGING SYSTEMS

Messaging systems enable and facilitate communication among team members, which an be one-to-one, one-to-many, and synchronous or asynchronous. The earliest methods using computers and the Internet were largely asynchronous, with limited synchronous communication. The advent of the World Wide Web and wireless technology have increasingly allowed people to use messaging systems to communicate in real time. In this section, we will consider asynchronous messaging (e.g., e-mail, discussion lists, bulletin and message boards, Web logs, and short message service [SMS]), synchronous messaging (e.g., chat and instantaneous interactive messaging), and conferencing.

ASYNCHRONOUS COMPUTER MESSAGING SYSTEMS: FROM E-MAIL TO SMS

E-mail is the simplest form of messaging, with information-management features that allow for easy storage and retrieval, as well as easy editing, replying, and attaching. Perhaps because e-mail is transparent, it is the primary means of communication in organizations today (Barnes, 2003). Wireless access to the Internet, through personal digital assistants and cell phones, frees users from the constraints of a networked computer.

Evolutions in technology increasingly facilitate vocal and visual features for e-mail. Verbal elements require software and a microphone, and visual add-ons utilize Web cameras. The advent of cheaper technology and freeware may see catalyzed change in traditional text-based e-mail. For example, video software like CyberLink's VideoLive Mail (www.cyberlink-usa.com/), Cornell University's CU-See Me (www.cuworld.com/) is inexpensive, and Talk99 from MediaRing.com (http://www.mediaring.com) is a freeware telephony program melding voicemail and e-mail.

Electronic bulletin boards or BBSs are "worldwide, posted public messages on a wide variety of subjects" (Lamb, 1999, p.23), posted by individuals and read by groups. BBSs provide connected or disconnected individuals with a means of sharing knowledge and information, and help close the distance and isolation gap between individuals. Team members can utilize BBSs through links to their personal Web pages or through free task-focused BBSs like InsidetheWeb (http://www.insidetheweb.com) or NgBook (www.bigfoot.com/~huangng).

Discussion Lists provide an asynchronous communication medium with some similarities to BBS and e-mail. While listservs and newsgroups are rarely a primary means of communication for teams, moderated listservs can be useful for threaded discussion. Discussion lists can be set up through any networked computer system.

A final asynchronous messaging system is Web logs or blogs, Web-based individually maintained journaling sites. Like other technological innovations, Web logs have integrated themselves into the corporate world. Business software like Manilla (http://manila.userland.com) and Traction (http://www.tractionsoftware.com) allows corporate intranet teams to converse with each other and serves as a "community-building and coordinating tool" (Herman, 2003). Business blogs also allow for instantaneous communication between team members, tracking of team communication and decision-making, and communication with clients and other business partners; they serve as informational references for team members and clients to consult (Herman, 2003).

SMS is a growing phenomenon in the United States and Canada. SMS allows individuals to exchange short (less than 160 characters) wireless text messages with one to several recipients (Devi, 2003). At five to 20 cents per message, SMS messages are typically cheaper than voicemail messages (*Computer Weekly*, 2003), with limited character length allowing for straight-to-the-point messages and discouraging superfluous text (Yap, 2003). SMS is growing in popularity in the business sector for its many benefits to teams, such as global applications like general staff and other internal communication, specific applications like reminders of, or changes, in meeting times, or quick answers to questions (Mills, 2003).

SYNCHRONOUS MESSAGING SYSTEMS: FROM IM TO CHAT

Synchronous interactive communication programs (SCs) are available in many different computer platforms—UNIX platforms "Talk" and "nTalk," BM VM/CMS systems "Tell," VAX systems "Send," and the popular America Online software "Instant Messenger" or "IM." All these systems allow for real-time communication among communicators, and, to facilitate use, most systems allow participants to check whether others are logged on at the same time, employing user IDs or preestablished lists. Since its adoption by such subscription services as America Online, Yahoo, and MSN, synchronous communication using freeware has achieved great popularity and expanded into use in business and industry. In fact, 42% of business Internet users report use of IM in the workplace, even though 70% of IT departments don't support it (Schwartz, 2002); it is predicted to rise from 5.5 million users in 2000 to 180 million in 2004 (Schwartz. 2002). A number of SC software programs exist for business use: Lotus' Sametime (used by the U.S. Navy), QuickConference (http://www.quickconference.com), and Ikimbo's Omniprise (http://www.ikimbo.com).

A sophisticated software protocol that enables participants to interact virtually is Chat. Internet Relay Chat (IRC) is Internet-based network that enables multiple communicators to synchronously interact in an online environment. IRC is easily undertaken by connecting to a server on the IRC network. While IRC can be a convenient and powerful virtual meeting tool, it is a public forum and can lead to lack of privacy. This issue can be circumvented by using cyber-meeting places on commercial networks, proprietary groupware and course management software, or by using chat rooms designed specifically for business and industry such as Webtrain (http://www.webtrain.com), Magma Communication's Chat Server (http://www1.magma.ca), ParaChat (http://www.parachat.com), Volano Chat (http://www.volano.com), and Divine's eShare Expressions (http://www.divine.com).

SYNCHRONOUS CONFERENCING SYSTEMS

Conferencing systems are more specifically designed to facilitate synchronous virtual meetings than Chat or IM. While many corporate and higher education facilities maintain on-site teleconference rooms with computer controlled audiovisual transmission between locations, teams lacking this equipment can use computer-enabled conferencing to work together in real time using free proprietary software. For example, Microsoft Corporation's Netmeeting[3] (http://www.microsoft.com/windows/netmeeting) allows users to engage in audio and video conferencing, as well as white boards, online chats, file transfer, and program sharing. Another example is Sun Microsystems (freeware.thesphere.com) Java-oriented (mostly educational) software programs and iVisit (http://www.ivisit.org), as well as the Java Shared Data Toolkit, Java Web Server, and Java WorkShop.

Videoconferencing adds a visual dimension to computer conferencing, making it "richer" as it "returns" some of the dimensions of traditional F2F communication lost in computer conferencing. High-end business videoconferencing vendors include First Virtual Communications (http://www.fvc.com) and Polycom iPower (formerly PictureTel) (http://www.polycom.com), which operate over private ISDN lines or private IP networks; lower-end vendors include GrassRoots Communications' Grass Roots Live (http://www.grassrootscommunication.com) and SeeSaw.com (http://www.realityfusion.com) (Metz, 2001).

Videoconferencing systems can also be built around Chat systems, incorporating audio and visual elements. WebCast ProServer (http://bant.ms.ornl.gov) is an example of a computer program that allows users to broadcast live audio and video and participate interactively. A related service is WebCast Personal ICQ (http://www.icq.com), an Internet telephony software package that weds message boards, chat rooms, data conferencing, and file transfer. Other software programs that allow for real-time business collaboration include Netopia's Timbuktu Pro (http://www.netopia.com), Genesys' Meeting Center (http://www.genesys.com), Altiris' Carbon Copy (http://www.altiris.com), and Tandberg's Management Suite (http://www.tandberg.net).

INFORMATION-EXCHANGE/ DATA-MANAGEMENT SYSTEMS

Finding, exchanging, and managing information, as well as sharing data and information resources are essential to the functioning of teams. Team functioning has been revolutionized by computer technology.

THE INTERNET

The Internet as it exists today is a vast system of networked computers, reaching across the globe. The Internet originated in the 1970s with the first wide-area computer network, the Advanced Research Projects Agency Network (ARPANET), a government sponsored experiment that linked research universities and the military. ARPANET grew to encompass other networks, including the National Science Foundation Network (NSFNET) and tens of thousand of local, regional, national, and international networks (Barnes, 2003; Sudweeks et al., 1995). The Internet utilized packet switching and communication protocols to enable the transmission and sharing of information across the Internet (Barnes, 2003). Today, the global network that is the Internet houses and accesses enormous amounts of information and is the single largest information resource in existence.

The immense amount of information on the Internet requires shared communication protocols and necessitates software programs to search, retrieve, and manage information. Before the World Wide Web, such programs as File Transfer Protocol (FTP) and Gophers were used.

FTPs are programs for transferring information and public domain software from one computer to another. The host computer stores (archives) and maintains information, which can be obtained by any user using anonymous FTP. The program ARCHIE is a useful related service that can be used to search the contents of most FTP archive sites. Post-Web iterations of FTP include Netmanage (www.ftp.com). Gopher was developed by the University of Minnesota to find information on many different computers on the Internet, including public access databases, online books, news, and phone directories. The program VERONICA works with Gopher, providing the ability to do keyword searches (Sudweeks et al., 1995). Telnet is a software application that can be used with FTP and Gopher. It connects remote computers, generally through a telnet port. Users "telnet in" and execute commands remotely through a telnet interface (Telnet, 2003). Telnet's usefulness as an information management tool comes from its ability to obtain information from public access databases.

INTERNET ALTERNATIVES

To bypass the delays, slowdowns, and interruptions that plague the Internet, a number of alternative networks are in development. Access to these alternatives can expedite the working of virtual teams. Some of these alternatives are Internet II, National Science Foundation's very high performance Barebone Network Service (vBNS), the Department of Energy's Energy Sciences network (Esnet), and NASA's Research and Education Network (NREN). The alternative network that has received the most publicity is Internet II. This faster, more powerful network was set into motion in 1997 by 34 universities. Internet II was projected to run up to 1,000 times faster than the existing Internet, with correspondingly increased capacity and potentials for communication, information management, and audio and video capabilities.

WORLD WIDE WEB

One aspect of the Internet demands special consideration. The World Wide Web is the largest part of the Internet and globe-spanning (still growing), and the single largest source of information in existence. The Web is an Internet medium that uses hypertextual links, an "interconnected assortment of Internet computer servers that conform to the same network interface protocols" (Barnes, 2003, p. 11). Put more simply, it is "a collection of commercial, educational, and personal 'Web sites' that contain electronic pages of text and graphics"(Cozic, 1997, p. 6). The Web brings together to a hitherto unprecedented extent research, history, literature, art, science, news, and entertainment, as well as commercial information and personal Web pages, all in text and multimedia form. Through the use of search engines, virtual teams can access data, information, and records on almost any issue of interest. As of 2001, there were over 26,000,000 host sites on the Web (Barnes, 2003).

The Internet and the Web enable access to thousands of online databases, which have made collections of information available online. Library catalog systems (OPACs), specialized information (scientific, legal, medical, etc.), news services, business and academic databases, to name but a few, are all online. Library systems like the New York Public Library (http://www.nypl.org), newspapers (e.g., the *New York Times* at www.nytimes.com), and television news sources (e.g., CNN at www.cnn.com) all provide access to archived information online. Similarly, many universities make academic databases available to both account holders and nonaccount holders. The sheer number of databases available today makes a detailed consideration impossible here. One suggested resource for learning more about online databases is Radford, Barnes, and Barr's (2002) *Web Research: Selecting, Evaluating and Citing*.

The remarkable amount of information on the Web necessitates specialized software tools for information locating and retrieval. Browsers enable the finding, interpretation, and display of documents in hyptertext markup language (HTML) through a point-and-click function. The first text-based browser evolved into today's popular Netscape Navigator, with rival browsers such as Internet Explorer (Barnes, 2003). Miniature browsers in PDAs and cell phones make possible wireless access to the Web. Search engines are related software tools that help users locate and retrieve information on the Web. Search engines (i.e., Yahoo! and Alta Vista) and meta-search engines (i.e., Google, Dogpile, Profusion, Webcrawler, Metacrawler, and Ask Jeeves) are free to all users, with some competition among providers.

COMMERCIAL/PROPRIETARY GROUPWARE

The pivotal role commercial groupware plays in teams calls for a discussion, but so abundant are the proprietary groupware systems now available that a detailed consideration is beyond the scope of this article. Therefore, this section will provide a discussion somewhat limited in scope by considering representative commercial groupware from three perspectives: comprehensive groupware packages as provided by commercial giants; specialized and smaller providers; and course management software. Additional information on the host of other commercial software systems can be found on the Groupware yellow pages (http://www.csua.berkeley.edu/~mogul/groupware/) that provides links to academic and business resources, or through discussion on the Group Support Systems List.

COMPREHENSIVE PROPRIETARY GROUPWARE PACKAGES

Several software companies, both large and small, have groupware packages, some reaching back across three decades. In the category of software packages developed specifically as groupware are Lotus Notes and Domino (http://www.lotus.com), Novell Groupwise (http://www.novell.com/products/groupwise), Netscape Collabra (http://wp.netscape.com/collabra/v3.5/index.html), Fujitsu Teamware (http://www.teamware.com), and NCSA Habanero (http://www.isrl.uiuc.edu/isaac/Habanero/). Other software systems (i.e., Microsoft Exchange (http://www.microsoft.com/exchange/), Oracle Collaboration Suite (http://www.oracle.com/ip/deploy/cs/, and various Course Management Software) have larger functions, but can also be applied as collaborative tools.

Two representative software giants are Lotus and Microsoft. Lotus Notes and Domino are the most widely used groupware systems in terms of market penetration (Lotus, 2003). Microsoft Exchange is the major competitor. Both systems conveniently provide synchronous and asynchronous messaging, collaborative application development, information management through shared databases, data exchange, Web functions, and other tools essential to team functioning.

Specialized conferencing tools are a rapidly growing sector. For instance, one growing trend is the use of Web services or application service providers (ASPs) instead of comprehensive proprietary groupware packages. Web services and ASPs use the World Wide Web to allow for project collaboration among multiple partners and organizations (New Straits Times-Management Times, 2002). Alwang (2001) points out that "web-based collaboration provides a cost-effective solution without the headaches inherent with supporting complex in-house systems." Services like Thurport's HotOffice (http://www.hotoffice.com), OnProject's OnProject (http://www.onproject.com), NetDocuments Enterprise (http://www.netdocuments.com), Punch Web-Groups (http://www.punchnetworks.com), and TeamDrive (http://www.teamstream.com) all narrowly focus on document management, as do numerous other specialized services; whereas services like Entellium (http://www.entellium.com), eRoom (http://www.documentum.com), and BlueStep (http://www.bluestep.net) are broader in nature and offer several services and subservices, including communication services.

Other specialized conferencing tools include "a new generation of universally accessible collaborative environments built by developing and extending existing robust frameworks" (Narayan, 1997, p. 3.), such as the National Center of Supercomputing Applications' Habanero, or Vermics, which bridges course management software and commercial Groupware. A different example is eStudioLive, which specializes in a desktop Webcasting system and multimedia online presentations with interactive features.

COURSE MANAGEMENT SOFTWARE

In higher education, most of the commonly used instructional technology software packages contains features that are useful to teams. Although such software was created for educational use, primarily as course support, or as a vehicle for online courses, its uses go beyond the classroom. Team members with access to the software can find useful tools, both for groupware and other features.

The three most widely used course management systems are WebCT, Blackboard, and eCollege. All three packages offer team options comparable to comprehensive proprietary groupware, including messaging tools, conferencing tools, information management, and data resources. Messaging tools include e-mail to individuals and groups, with file attachment options, and some searchability. Discussion lists options are numerous, with posts possible in plain text, formatted text, or html, with attachments and URLs. Threaded discussions can be viewed by date, thread, and topic. Conferencing tools are provided with Chat and internal groups. Private chat rooms can be created, and all chats are archived. Internal small groups can be created with their own whiteboards, discussion forum, and synchronous tools. Information management and data resource options include file exchange, with options to upload files to a private or shared group folder. Whiteboards also exist, with image and PowerPoint uploading and group Web browsing. Most information, including whiteboard sessions, is archivable (Edutools, 2003).

Although lacking in some of the features of the three packages considered above, free instructional technology software programs are available (e.g., ThinkWave Educator, ClassBuilder, NgBook, and Class Information Manager).

CONCLUSION

"As businesses become more interconnected and more global, they must learn to make faster and smarter strategic decisions, and to take advantage of technological advancements" (Solomon, 2001). Teams today need to take advantage of all available technological resources. We hope that this survey of the existing support systems and technologies will assist teams, both traditional and virtual, to maximize their effectiveness, development, and growth, and to minimize problems and errors that can arise when working with technology.

KEY TERMS

Commercial Groupware Packages: Proprietary software that provides bundled software, including synchronous and asynchronous messaging, collaborative application development, information management through shared databases, data exchange, Web functions, and other tools.

Conferencing Systems: Conferencing systems are specifically designed to facilitate synchronous virtual meetings by phone or computer. Teleconferencing utilizes computer-controlled audiovisual transmission. Computer conferencing uses computer-enabled conferencing to work together in real-time using free proprietary software.

Course Management Software: Instructional technology software packages created for educational use, primarily as course support or as a vehicle for online courses. Groupware features include messaging tools, conferencing tools, and information management and data resources.

Group Support Systems (GSS): Computer software and hardware used specifically to support group functions and processes. GSS can be defined as tools for group communication, process, and task achievement. It should be noted that GSS often comprise technologies that are not necessarily limited to computers and are often used in everyday life, such as telephones and videoconferencing. Non-computer and computer technologies may be determined to be GSS if they possess one of the following characteristics: it fosters collaboration between people; it fosters the sharing of information; or it enables the communication between groups of people (Burns, 1995, in Brusic, 2003, p .13).

Information-Exchange/Data-Management Systems: Systems designed for finding, exchanging, and managing information, and sharing data and information resources. They include the Internet (a globe-spanning system of networked computers, utilized packet switching and communication protocols), and the World Wide Web, an Internet medium that uses hypertextual links (Barnes, 2003).

Messaging Systems: Messaging systems enable and facilitate communication among team members. Communication among team members can be one-to-one, one-to-many, and synchronous (IM and Chat) or asynchronous (e-mail, bulletin boards, discussion lists).

Team: A collection of four to 12 individuals collaboratively working on a common and interdependent task or goal. The goal is often one requiring a decision or a solution to some problem. The elements of common tasks, goals, and interdependence are integral to our definition of a team, at least with respect to an imposed need to arrive at a collective position on a matter under consideration.

ENDNOTES

1 We use the term *team* in this book in the commonly accepted sense; that is, a team refers to a collection of four to twelve individuals collaboratively working on a common and interdependent task or goal. The goal is often one requiring a decision or a solution to some problem. The elements of common tasks/goals and interdependence are integral to our definition of a team, at least in respect to an imposed need to arrive at a collective position on a matter under consideration.

2 Note also that the technologies discussed here are current as of spring 2004. Technology rapidly changes and grows, and we have no doubt that within the next year new developments will emerge.

INTRODUCTION

A hypercompetitive environment of global competition, reduced product cycle times, and rapid change has forced organizations to seek new structures and practices that allow them to react with speed and agility. One structure that has gained increasing support among organizations seeking to improve organizational agility has been the virtual team (Mowshowitz, 1997). Virtual teams are the application of virtual organization concepts to team environments. Virtual teams use information technology (IT) to remove barriers of time, location, and organizational boundaries to allow the integration of skills through collaborative relationships based on trust and professionalism to meet specific objectives. Despite the growing popularity of virtual teams among businesses, more needs to be known about the nature of these teams (Bell & Kozlowski, 2002). For example, some research has found virtual teams to outperform traditional face-to-face teams (e.g., Majchrzak, Malhotra, Stamps & Lipnack, 2004; Schmidt, Montoya-Weiss & Massey, 2001), while other research indicates otherwise (Cramton, 2002). It is important that organizations understand the implications of these virtual teams so that they may be used in the most effective manner, and under the most appropriate circumstances.

BACKGROUND

Virtual teams appear to exhibit many of the same characteristics of virtual organizations. These common characteristics include opportunism, excellence in technology, excellence in skills, borderlessness, and reliance on trust (Goldman, Nagel & Preiss, 1995). Opportunism indicates that the virtual team is created to meet a specific need or leverage a specific opportunity. Once the objective has been met, the virtual team is typically disbanded (Jarvenpaa, Knoll & Leidner, 1998). While it is the nature of virtual teams to be temporary, they can exist as long as the opportunity that they were created to exploit exists, which can result in practical applications of virtual teams that last for decades. Excellence in technology is achieved by the contribution of the best technologies ("best" in this case meaning the most appropriate for the needs of the team) from each of the virtual team members. This contribution of technologies is not only critical to the functioning of the virtual team, but is also of interest to business researchers as virtual teams place a greater reliance on technology for the completion of team tasks and activities than previously experienced. Excellence in skills refers to the manner in which participants in the virtual team are selected. Typically, each virtual team member is selected to participate on the team because that member has, in a high degree, a skill that will be needed by the team. Borderlessness refers to the manner in which virtual teams tend to cross traditional, functional, and even organizational boundaries. Often, individuals performing in these teams may be internationally dispersed and include constituents from other firms. These geographically and organizationally dispersed teams are made viable through the use of information technology (Dube & Pare, 2001; Townsend, DeMarie & Hendrickson, 1998). The interorganizational and international aspects of the virtual team interfere with, and often invalidate, traditional mechanisms for control of team members. Dube and Pare (2001) report that global virtual teams rarely, if ever, meet in a face-to-face environment. As a result, trust is believed to become a critical component in effective virtual team operation (Larsen & McInerney, 2002; Jarvenpaa & Leidner, 1998).

The reliance on trust is dictated due to the lack of authoritative controls found in virtual structures. In place of traditional command-and-control authority structures, virtual teams rely on trust and professionalism to create interdependent, collaborative relationships. Given the importance of establishing and maintaining control with the organization, it is understandable that the departure from traditional control structures to a trust-based environment has generated interest among researchers and practitioners alike. Unlike the other characteristics of virtual structures, such as duration, and geographical and organizational dispersion that can be directly observed and controlled, the reliance on trust as a characteristic of virtual teams is a logical conclusion that is being explored in the research literature (Majchrzak, Rice, Malhotra, King & Ba, 2000). Researchers have already recognized that the unique characteristics of virtual teams will require the re-examination of existing theories and have called for additional research into areas such as trust, organizational context, and team norms (Bell & Kozlowski, 2002; Majchrzak et al., 2000; Townsend, DeMarie & Hendrickson, 1998; Warkentin, Sayeed & Hightower, 1997).

TRUST IN VIRTUAL TEAMS

Trust has frequently been assumed to be one of the key ingredients necessary for a virtual organization or team to be successful (Suomi, 1988; Konsynski, 1993; Duffy, 1994; Handy, 1995; Cohen, 1997). Currall and Judge (1995) defined trust as "an individual's behavioral reliance on another person under a condition of risk" (p. 153). Empirical research into the role of trust in the virtual team setting, however, is just emerging.

The role of trust, or the lack of trust, in human behavior as it pertains to the development of organizations and teams can be clarified using transaction cost economics (TCE) (Williamson, 1975). TCE explains the development and growth of organizations and teams as a solution to the costs of conducting transactions in a market. The principle components of TCE are opportunism, bounded rationality, small-numbers bargaining, and uncertainty. Opportunism is the behavioral tendency of an entity, either an individual, a team, or an organization, to act in its own self-interest, even at the expense of another entity. Bounded rationality describes the limitations placed on an entity in determining behaviors that are in its self-interest due to limited or imperfect knowledge. Small-numbers bargaining refers to a shift in negotiating power that occurs when only a small number of entities in a market can meet the needs of another entity. Uncertainty is defined as the inability to predict relevant future events (Williamson, 1975).

Transaction cost economics posits that there are costs associated with conducting transactions in a market, such as searching costs, transportation costs, and communication costs (Gurbaxani & Whang, 1991). These costs are complicated by the presence of uncertainty so that entities have difficulty in predicting future demand and supply. To reduce transaction costs, entities may create standing relationships with each other in the form of contracts. Even though transaction costs are associated with the creation and enforcement of the contract, use of the contract may still be more economical than transactions in a market. Because each entity in the relationship has limited knowledge of the activities of the other entity, the potential for opportunistic behavior still exists. That is, the entity is restricted by its bounded rationality, so its transaction costs increase while the other entity enjoys greater profit. To prevent this opportunistic behavior, the contract must account for contingencies, causing an increase in the costs of writing and enforcing the contract (Perrow, 1986; Gurbaxani & Whang, 1991). Opportunistic behavior may also occur if either entity in the relationship must deal with uncertainty in a fluctuating industry. To prevent opportunistic behavior, contractual costs are increased as contingencies are taken into account.

During the course of the relationship, entities make investments in the relationship, such as time spent learning procedures and the development of communication channels. If these investments are significant, they can be a catalyst for small-numbers bargaining at the time of renegotiations. Small-numbers bargaining allows one entity to act opportunistically against the other to achieve greater profit, while still engaging in a relationship that is more economical to both entities than leaving the relationship.

In order to reduce the costs of opportunistic behavior, and the costs of protecting against opportunistic behavior, one party of the relationship may assume authoritative control over the other through acquisition. While opportunism, bounded rationality, uncertainty, and small-numbers bargaining still exist as influences within the organization created by that acquisition, they can be curbed through the exercise of authority.

In terms of transaction cost economics, virtual organizations and teams represent the transition from large hierarchical structures to flatter, collaborative structures (Drucker, 1988). By losing the authoritative control of the hierarchical structure, the members of the virtual organization and team must deal with greater risks of opportunism from the individuals that they must collaborate with and rely upon. Researchers have proposed that the environment created by a virtual structure will force its members to rely more heavily on trust instead of relying on control structures to ensure the performance of others (Clemons & Row, 1992; Konsynski, 1993; Bleecker, 1994; Handy, 1995; Barner, 1996; Cohen, 1997).

In addition to the application of TCE to the issue of trust, research efforts have begun investigating trust in virtual teams. Larsen and McInerney (2002) looked at inter-university virtual teams developing information products and found that team performance was closely related to issues of trust. Lurey and Raisinghani (2001) found that relations among virtual team members had a very strong relationship to virtual team performance and virtual team member satisfaction. Interestingly, Lurey and Raisinghani (2001) found little relationship between internal group dynamics, and team performance and team member satisfaction. This is in direct contrast to Montoya-Weiss, Massey, and Song (2001), who found that management of internal conflict was critical to virtual team performance. Jarvenpaa, Knoll, and Leidner (1998) found that the development of trust is different from the development of trust in traditional face-to-face teams. They suggested a model for the development of "swift" trust, whereby the virtual team members assume an attitude of trust instead of engaging in traditional trust-building. Markus (2004) found interpersonal issues such as trust to be the greatest challenge facing virtual teams.

TECHNOLOGY IN VIRTUAL TEAMS

Researchers have long theorized about potential impacts, such as the elimination of middle management levels, that information technology could have on organization structures (Leavitt & Whisler, 1958). Advances in IT have supported the development of IT-enabled organization design variables that were not previously available. Table 1 summarizes findings from an exploration of IT-enabled design variables that organizations can use to supplant traditional design variables in the design of new organization forms, such as virtual organizations and virtual teams (Lucas & Baroudi, 1994).

The IT-enabled nature of virtual teams causes employees to rely heavily on IT to complete and coordinate tasks (see e.g., Legare, 2001; Barnatt, 1997). Therefore, the degree to which the system meets the employee's information needs is of critical importance. Markus (2004) investigated the IT tools used by virtual team members. She reported virtual team members had to employ a number of unintegrated tools since there was no single IT that met all of the team members' needs. However, the virtual team members overwhelmingly indicated the vital nature of IT for virtual team performance. Suchan and Hayzak (2001) reported in their case study of the use of virtual teams in a Fortune 500 organization that team members' attitude toward the technology was vital to the success of the virtual team structure. Larsen and McInerney (2002) found that virtual team members' perceptions of the virtual team experience were influenced by their perceptions of the technology used to implement the virtual structure. Malhotra, Majchrzak, Carman, and Lott (2001) conducted a case study of virtual teams at Boeing-Rocketdyne. They reported that the technology used by the virtual team was so critical to the virtual team members that 23 versions of the technology, based on recommendations of the team members, were developed throughout the life of the virtual team, and a dedicated technology facilitator was deployed to each teleconferencing session.

FUTURE TRENDS

Despite the many unanswered questions about virtual structures, it is clear that market demands for agile competition will continue to push organizations to seek out and exploit these types of structures. Initial research has

Table 1. Conventional and IT-enabled design variables (Adapted from Lucas & Baroudi, 1994)

Class of Variable	*Conventional Design Variable*	*IT-Enabled Design Variable*
Structural	Definition of organizational subunits	Virtual components
	Linking mechanisms	Electronic linking
	Staffing	Technological leveling
Work Process	Tasks	Production automation
	Workflows	Electronic workflows
	Buffers	Virtual components
Communications	Formal channels	Electronic communications
	Informal channels/collaboration	Technological matrixing
Interorganizational Relations	Make versus buy decision	Electronic customer/ supplier relationships
	Exchange of materials	Electronic customer/ supplier relationships
	Communications mechanisms	Electronic linking

Table 2. Trust and technology issues in virtual teams

- What factors influence the development of trust among virtual team members?
- How can trust be strengthened among virtual team members?
- Are there any viable substitutes for trust?
- What roles do cultural, national, and organizational diversity play in establishing and maintaining trust?
- What types of authoritative control structures are still viable and appropriate in a virtual team setting?
- What technologies best support virtual teams?
- What is the impact of the intensified reliance on technology within a virtual team setting?
- Can information technology be used to create systems to provide a substitute for trust?
- What impact does the mandatory use of IT in a virtual team have on team member motivation and job satisfaction?
- How does one assess the success of an information system used to support a virtual team?

shed some light on the complex nature of virtual teams. However, a great deal of future research will be necessary before the full impacts of these structures on the organization, and on the individuals involved, will be understood. Empirical research has supported some of the previously untested theories about virtual teams, and the roles that information technology and trust play within them. Other theories have not been supported, and these findings continue to give birth to additional theories and hypotheses. Future research in this area will have to find the missing pieces of the puzzle that explain the equivocal results of existing research on the performance expectations for virtual teams (Cramton, 2002; Majchrzak et al., 2004). The nature of trust in virtual teams has been shown to differ from traditional teams both in its formation and its role in shaping virtual team member expectations; however, the exact nature of the differences and why the differences exist is still under investigation. While the impact of reliance on information technology is not a new subject in the research literature (e.g., Lucas & Baroudi, 1994), the increased dependency on information technology in a virtual team setting raises several issues regarding the impact of IT on individuals, best practices for IT usage in a virtual team setting, and task interdependency. Future research will have to address these issues and many more. Table 2 lists a small sample of the questions that organizations need answered that researchers are investigating.

CONCLUSION

Virtual teams promise to help organizations improve their agility in responding to an ever-changing marketplace that demands rapid response. This agility, however, comes with a price: organizations are committing themselves to a structure whose dynamic is still largely unknown. Two areas of interest in the efforts to understand virtual teams are the issues of reliance on trust and reliance on information technology. Research and practical experience have both shown that the nature of trust is different in virtual teams, and that virtual team structures require a new level of intensity of reliance on IT. The consequences of these changes are not yet understood. Jarvenpaa et al. (1998) noted a difference in trust development that researchers are exploring. Current research is concerned with better understanding these differences in trust development, and the consequences that it may have for the maintenance of trust. This research makes it important to reexamine many of the more established trust-related concepts, such as cultural differences in trust. Other researchers are investigating the role that IT currently plays in virtual teams, as well as exploring new roles that IT could play to improve virtual team performance.

KEY TERMS

Design Variables: Characteristics of an organization, its processes, control, and coordination structures that can be varied to produce a specific organization design.

IT-Enabled: Indicating that a design variable or team can only function through the use of information technologies.

Opportunism: In terms of virtual teams, the characteristic of existing to capitalize on a specific opportunity or meet a specific, temporary need. In terms of TCE, the characteristic of an entity that indicates the entity will act in its own best interest even at the expense of other entities in the market.

Organizational Agility: An organization's ability to respond quickly and appropriately to changes in the organization's environment to solve problems and capitalize on opportunities.

Transaction Cost Economics (TCE): An economic paradigm of organization analysis that explains the development of organizations and organizational hierarchies as a function of the costs of conducting transactions in a market.

Trust: An entity's willingness to rely on another entity under a condition of risk.

Virtual Team: A team constructed of collaborative relationships supported by information technology to overcome boundaries of time, location, and organizational boundaries.

Technology and Knowledge Management

Helen Mitchell
Unitec, Auckland, New Zealand

INTRODUCTION

Rapid and extensive advances in technology, particularly in the area of communications, have had a considerable impact on the way organizations operate and opened pathways to access vast amounts of information. Information, however, is static unless knowledge is applied to translate it into something meaningful and with the potential to be actionable. From the time organizations commence business, they accumulate information about the markets in which they operate, yet often, knowledge is not applied in a way that it can be exploited to bring benefit. The ability to share knowledge, to develop ideas, and to become more innovative is increasingly important for businesses, and the range of technologies now available provides a conduit for knowledge to flow through the organization to enable sharing to occur. Technology is frequently referred to as "just an enabler," but it can also be identified as a value-adder.

INFORMATION AND KNOWLEDGE

In their paper, Evans and Wurster (1997, p. 71) referred to changes that had taken place over the previous 10 years as organizations adapted their "operating processes" to "information technologies," recognizing that accessing information was going to have an important bearing on where industries would be going in the future. During this period, technology was moving forward at a rapid rate, and organizations were investing huge sums of money in information technology.

Information is defined as facts and data organized to describe a particular situation or problem. The definition used for knowledge is that by Davenport and Prusak (1998):

Knowledge is a fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers. In organizations, it often becomes embedded not only in documents or repositories but also in organizational routines, processes, practices, and norms. (p. 5)

Connectivity, it is suggested by Evans and Wurster (1997), provided the most important change in the information revolution: "What is truly revolutionary about the explosion in connectivity is the possibility it offers to unbundle information from its physical carrier" (p. 73). Amidon (1997) referred to the major change from information processing to knowledge processing that has taken place, "which includes the concepts of learning tools, intelligent electronic coaching, decision-making systems, and more" (p. 87). The availability of such tools, and their ongoing development, add considerable value to an organization by providing a means through which more efficient and effective management techniques can be introduced. This evolving of expectations indicates that organizations are not only anticipating more from technology but are also becoming more reliant upon it.

As interest grows beyond information per se, organizations are looking to technology to progress toward the development of knowledge management systems. Bhatt (2001) referred to business managers who believe computers and communication technologies provide an avenue for the harvesting of knowledge from data repositories of organizations, while other managers say knowledge "resides in human minds, and therefore, employee training and motivation are the key factors to knowledge management" (p. 68). The development of technology has taken the drudgery out of searching, analyzing, and converting data into information to which knowledge can be applied.

Technology and knowledge, however, do not stand in isolation. There are many interacting factors, not least of which is the environment in which the organisation operates. According to Bhatt (2001), the "…pattern of interaction between technologies, techniques and people is unique to an organization" (p. 69). Such uniqueness is important, because it is not easy to replicate. The organisation that promotes the value of the knowledge, skills, and competencies of its people, and recognizes the importance of technology, is providing well for its future (Carneiro, 2000; Bhatt, 2001).

From a productivity perspective, Grant (2000) indicated the value of digital technology. He referred to knowledge no longer being held exclusively by people. Codification and use of technology provides the opportunity for knowledge replication. While costly to create, replication and distribution can be reduced to almost "zero marginal cost" (Grant, 2000, p. 32). In the long term, and with the arrival of new technologies, the rate of productivity growth is likely to accelerate (Grant, 2000). People have skills and knowledge, but it is technology that enables them to access in a timely manner huge amounts of data available both internally and externally to the organization. While technology enables people to access data, the added value comes in its ability to allow the data to be assembled in a meaningful way for the purpose of decision making.

SHARING KNOWLEDGE

An environment in which knowledge sharing is encouraged leads to the creation of new knowledge, but as Marshall, Prusak, and Shpilberg (1996) indicated, it is not easy to encourage voluntary sharing of knowledge by employees. An organisation that develops a knowledge-sharing environment increases opportunities for the creation of new ideas that have the potential to add value to it.

Barriers to sharing knowledge exist, and for managers advocating knowledge sharing, they should examine the existing practices within the organization. It is possible that somewhere in the organization, the "knowledge is power" syndrome exists, and if so, it does not auger well for knowledge sharing. There may also be concern over job security, "if I share my knowledge, I am no longer of value to the organization, and therefore, my job will be in jeopardy." A barrier to knowledge sharing may simply rest on the premise that a person may not realize that knowledge acquired in another situation could be of value to the organization. Managers may need to look to changing the organizational culture to one that recognizes, and acknowledges, the value of shared knowledge.

Bhatt (2001), referring to the need for the distribution and sharing of knowledge throughout the organisation, suggested that interactions among technologies, techniques, and people have a direct bearing on the effectiveness of the distribution of knowledge.

RANGE OF TECHNOLOGIES

According to Frappaola and Capshaw (1999): "Knowledge management refers to the practices and technologies that facilitate the efficient creation and exchange of knowledge on an organizational level" (p. 44).

From the literature, it appears that there are a number of applications specifically designed for sharing knowledge (Davenport, 1997; LaPlante, 1997; Fahey & Prusak, 1998). The benefits of applications, such as groupware, data warehousing, knowledge maps, client server systems, and chat rooms, are recognized as providing the means through which knowledge can be shared. A useful aspect of such applications is that they allow for interaction and sharing of information that is highly unstructured in nature (Shani, Sena, & Stebbins, 2000). Research carried out by Mitchell in 1999 indicated that people are finding groupware applications useful mechanisms for sharing knowledge.

A number of writers, Allee (1997), Amidon (1997), Marshall (1997), Watt (1997), and Davenport and Prusak (1998), refer to the intranet as providing channels through which organizational knowledge can flow. E-mail is now well accepted as a useful and valuable medium of communication, and for knowledge to flow through an organization (Bontis, Fearon, & Hishon, 2003). The advent of electronic conferencing provides an avenue through which people geographically dispersed can interact without the time and cost involved in traveling. Networking, bulletin boards, and the establishment of virtual teams also provide opportunities for people to interact over distances and to share knowledge.

Reference is made by Beckett (2000) to the "Data warehousing knowledge set" containing reference data, defined as market trends, operational data, and customer performance needs. From this knowledge set, actions can be taken that ultimately benefit stakeholders and customers. While the knowledge set may be considerable, ideally, its value only becomes realistic when there is in place the means to allow for the "free" flow of knowledge throughout the organisation and when there are people who can recognize that value can be gained from it. It is most unlikely that organizations allow for a free flow of knowledge, because issues such as privacy and confidentiality, "need to know," and other constraints restrict access to knowledge. However, providing access to knowledge that can be made available should be the aim of organizations wanting to encourage a knowledge-sharing environment.

Technology has opened avenues to the customer to search for opportunities and products that may better serve their needs. The opportunity, however, is also open to the organization to exploit the potential of technology to create greater value for its customers.

KNOWLEDGE MANAGEMENT STRATEGY

Hansen, Nohria, and Tierney (1999) identified management consultants as being among the first to recognize the potential of information technology for the capture and dissemination of knowledge. It was found that organizations tend to employ two very different strategies for the management of knowledge. One is the "codification strategy," where maximizing the use of technology shows a strong focus on codifying knowledge and storing it in databases for access by anyone in the company. The second approach viewing knowledge being shared through person-to-person contacts is identified as the "personalization strategy" (Hansen, Nohria, & Tierney, 1999, p. 107).

From their research, Hansen et al. (1999) found that organizations pursuing "an assemble-to-order product or service strategy emphasized the codification and reuse of knowledge. Those that pursued highly customized service offerings, or a product innovation strategy, invested mainly in person-to person knowledge sharing" (p.112). Whichever strategy is used, there is inevitably the inclusion, as a support mechanism, of an element of the other strategy. Hansen et al. suggest an 80:20 split, that is, "80% of their knowledge sharing following one strategy, 20% the other." They go on to say that "Executives who try to excel at both strategies risk failing at both" (p. 112).

In his article, Beckett (2000) referred to the fastest knowledge-transfer vehicles, relating them to the work of Nonaka and Takeuchi (1995). The tacit/tacit transfer is fast, "because people use multiple sensors in working together in teams" (p. 317). Using electronic media for the transfer of explicit/explicit transfer can also be fast. However, there is evidence that "tacit/explicit transfers are slow, as specialist skills are needed to draw out and carefully enunciate tacit knowledge" (p. 317). Becket indicated that explicit/tacit transfers are similarly positioned, and provides the example of formal education.

Giving consideration to the perspectives of Hansen et al. (1999) and Beckett (2000), and others, such as Ericsson and Avdic (2003), Mockler and Dologite (2002), Jentzsch and Prekop (2002), and Frappaolo and Capshaw (1999), determining a knowledge management strategy needs careful thought if it is to meet the requirements of the organization.

TECHNOLOGY: ENABLER OR VALUE-ADDER?

Lloyd (1996) referred to the use by organizations of worldwide networks and said that new technology is "the catalyst which is forcing all organizations to re-evaluate what they know, what they do with that knowledge, and how they continually add value (or not) to that knowledge in meeting changing customer needs" (p. 576). Technology has advanced considerably since Lloyd made this comment, and it will continue to evolve in the years ahead, providing for greater enrichment of organizational operations. While the cost of "keeping up" with technological developments has always been a problem for organizations that have made a strong commitment to technology, others recognize that they need to work smarter with what they have.

If technology is just an enabler, what is it that adds value to the organisation? Binney (2001, p. 33) addressed the question of knowledge-management (KM) investments. What has emerged is the KM spectrum, in which he identifies KM applications and places them into "six common categories to establish the elements of the KM spectrum" (p. 34). Binney identified from the literature six categories to provide the elements of the KM spectrum: transactional, analytical, asset management, process, developmental, and innovation and creation. He then mapped KM applications to the elements:

1. Transactional—Order entry applications; help desk applications
2. Analytical—Data warehousing, customer relationship management, DSS, MIS
3. Asset management—Document management, intellectual property
4. Process—TQM, process automation, benchmarking
5. Developmental—Skills development, training
6. Innovation and creation—Communities, virtual teams, networking

The next stage of the process added to the various elements, enabling technologies:

1. Transactional—Expert systems, probability networks
2. Analytical—Intelligent agents, data analysis and reporting tools
3. Asset management—Document management tools, knowledge maps
4. Process—Workflow management, process-modeling tools
5. Developmental—Computer-based training, online training
6. Innovation and creation—Search engines, voice mail, groupware

The KM spectrum provides organizations with the means to identify their present positions and to make use of the framework to map their future investments in knowledge management. The examples given above illustrate the wide range of applications available to organizations, and their potential and value emerges through maximizing their use for the purpose of effective decision-making in an increasingly competitive environment.

Technology has provided the impetus for the growth of the information age, but it should not be regarded as a dominant partner. As Pemberton (1998) commented, "The IT exponents of KM tend to downplay the central role of human factors in KM…IT doesn't itself create knowledge any more than does a library, an office, or a classroom" (p.60). But, as Carneiro (2000) indicated, the combining of knowledge and information technology is a major success factor in strategic planning formulation. The future will bring ever more sophisticated advancements in technology providing new avenues of exploration for seeking, creating, and sharing knowledge.

CONCLUSION

Is technology just an enabler, or is it also a value-adder? From the literature, technology, while recognized as being important, tends to be regarded as an enabler rather than a value-adder. Yet the continual movement in technological progress, as shown in Binney's KM spectrum, clearly identifies the developments that have taken place in technology to enhance the operation of business. People provide value through the application of their knowledge, but their ability to do so is considerably enhanced by the availability of technology. Technology enriches opportunities for disseminating and sharing knowledge, and through providing the means to access information for decision making. While the role of technology may be seen as that of enabler to access information, value is added through the ability to assemble data, put it into meaningful information, and manipulate it into various scenarios before determining the best decision. Technology is adding value by allowing organizations to do this. Without the range of technology available to organizations, they would be considerably restricted in their ability to effectively manage their business. Therefore, technology should be identified as an adder of value.

KEY TERMS

Adding Value: This is giving something that was not anticipated, e.g., selling a customer a product, and then giving additional information about gaining maximum benefit from it, or giving advice about safety issues relating to the product.

Codification: Putting knowledge into a form that makes it accessible to others, e.g., writing down a formula.

Groupware: Computer software allowing groups, teams, and people in different locations to work together and share information.

Knowledge Management (management perspective): This is the process whereby knowledge is managed to provide a competitive advantage for the organization.

Knowledge Management (technology perspective): Practices and technologies that facilitate the efficient creation and exchange of knowledge on an organizational level.

Knowledge Management (KM) Spectrum: This is a management tool for organizations that provides insight into knowledge management options and assists with the assessment of the many applications and technologies that are available.

Knowledge Management System: Using technology to manage knowledge systematically to enable it to be gathered, organised, and shared for the benefit of the organisation.

Productivity: A measure of the performance of the production process in transformation of the input of resources to the output of goods and services.

T

Technology and Work in the Virtual Organization

Paul M. Leonardi
Stanford University, USA

INTRODUCTION

With the proliferation of industrial manufacturing plants in the United States during the first half of the 20th century, work was traditionally understood not only as something you did to earn a living, but someplace you went. The industrial revolution fundamentally changed the nature of work as it tied the practices of manual laborers to specific technologies such as the assembly line and the printing press, which were located in specific factories, plants, and offices. Today when we talk about work as a place we go rather than a thing we do, our rhetoric is a remnant of an image of manual work that dominated the 20th century.

BACKGROUND

Coinciding with the influx of post-war university enrollments in the '40s and '50s, in the latter half of the 20th century there was an explosion of jobs requiring "knowledge work." This work included computational and analytical functions not tied to a specific workplace technology and that could be performed from anywhere. By the 1970s the combination of widespread knowledge work, high gasoline prices, and new capabilities for data communication spurred a wave of telecommuting. Working from a remote location as one would do in the office allowed people to work at home while still maintaining contact with colleagues and clients (Nilles, 1975). Today, numerous terms are used to describe such work arrangements: "Telework," "distance work," "mobile work," and "virtual work" are among the most common.

The word "virtual" has gained increasing currency as a way of talking about organizational interactions that occur outside traditional barriers of time and space. In fact, today many organizations describe themselves as virtual organizations. As Dutton (1999) describes, a virtual organization is "composed of private firms or public agencies that have employed information and communication technologies (ICTs) to transform business processes within the organization or among themselves and other organizations" (p. 474). Many organizations that have decided to enable virtual work have been enthusiastic about the possibilities of virtual meetings, work teams, offices, factories, firms, and alliances (Burn & Barnett, 1999; DeSanctis & Monge, 1999). Table 1 summarizes some of the reasons organizations have made it possible for employees to work virtually.

ROLE OF TECHNOLOGY

Digital telecommunications technologies have been the primary enablers of virtual work.

While there is growing evidence that technology does not *drive* virtual work—that is to say, influence people to work virtually (Jackson, Leonardi, & Marsh, 2004; Scott & Timmerman, 1999)—technological infrastructures and applications do make virtual work possible. The earliest modern infrastructural technology was the telephone. Through the use of the telephone, workers could conduct their work individually from remote locations and report back to the office when necessary. Soon, dial-up modems became an efficient way for a virtual worker to log in to the organization's server and access information. Today, residential broadband services provide "always on" connections that enable online access with similar speeds and bandwidth to what workers are used to in traditional workplace offices. Certain applications have also been

Table 1: Some reasons organizations enable virtual work

Employee-Driven	Organizationally Driven
• Increased control of schedule	• Decreased maintenance/facility costs
• Eliminate/reduce commute	• Leverage diverse expertise
• Freedom from interruptions	• Decentralization
• Less formal work environment	• Employee health/welfare

key enablers of virtual work. Early database technologies allowed workers who worked remotely to access information collected and stored in computers at the organization. Aside from word processing applications, e-mail is perhaps the most important tool most used by modern virtual workers (Scott & Timmerman, 1999). E-mail allows the virtual worker to send and receive important documents and messages to colleagues and clients. Today we are beginning to see the use of instant messaging (IM) and teleconferencing technologies, with which virtual workers can communicate more efficiently with one another.

Digital telecommunications technologies must perform two important tasks if they are to enable successful virtual work. First, they must allow the worker to establish a telepresence. Steuer describes telepresence as "the experience of presence in an environment by means of a communication medium" (Steuer, 1992, p. 76). Although virtual workers are not physically copresent with their colleagues and clients, they must be able to work with them as if they were. For this reason, when communicating important information those who work with others at a distance often chose to communicate through the electronic medium that most mimics a face-to-face context (Trevino, Daft, & Lengel, 1990). Second, for technologies to effectively enable virtual work they must be transparent to the user. Virtual workers are typically not technological innovators and thus prefer to use technologies that do not interfere with the ways in which they would normally work at the office (Jackson et al., 2004). To the extent that the virtual worker has to think about when and how to use a technology to complete a work task, he or she will prove to be more ineffective. The most valuable technologies are those that the virtual worker does not have to think about when using and that do not interfere with normal work practices.

FUTURE TRENDS: PRACTICE OF VIRTUAL WORK

Work is the fundamental constitutive feature of the organizing process. To organize virtually, organizational members work in similar ways as they would in the office, but also in ways specific to their virtual arrangement. Specifically, virtual work makes explicit the task-based and relational aspects of ordinary office work and adds the dimension of presence practices. Table 2 summarizes these virtual work practices.

- **Task-Based Practices:** Work practices related to a specific job description that must be carried out to produce a deliverable product, process, or idea.
- **Relational Practices:** Work practices related to communication with others, including formal and informal interaction.
- **Presence Practices:** Work practices that establish the presence of a worker in the organization as experienced by coworkers and managers.

Task-Based Practices

Although stories persist in the popular and trade presses that the invention of new telecommunications technologies will fundamentally change the way individuals work, research on work in virtual organizations has shown that the task-based work practices of those who work virtually differs little from practices conducted in the office. In fact, knowledge workers who adopt virtual work arrangements must often convince their managers that they will be able to conduct the same work, of the same quality, and at the same speed from a virtual location as they would if they remained working at their workplace office (Leonardi, Jackson, & Marsh, 2004). As a result, virtual workers rarely talk about the practices of their task-based work when discussing their work arrangements, and when they do, they discuss how little has changed from the way they worked in the office. Instead, when reflecting upon their virtual work practices, most virtual workers cite the schedule flexibility, freedom from interruptions, and time saved in commuting as major changes wrought by their virtual work arrangements (Bailey & Kurland, 2002). Task-based work practices change little as a result of a move toward virtual work, but the nature of the task itself does affect the type of technology used to conduct those work practices (Haythornthwaite & Wellman, 1998).

Table 2: Types of virtual work practices

Task-Based Practices:	Work practices related to a specific job description that must be carried out to produce a deliverable product, process, or idea.
Relational Practices:	Work practices related to communication with others, including formal and informal interaction.
Presence Practices:	Work practices that establish the presence of a worker in the organization as experienced by coworkers and managers.

Relational Practices

All work involves the maintenance of relationships. In the virtual organization relational work practices are made explicit. Because there is no "water cooler" around which members can gather, virtual workers must strategically plan to communicate with coworkers. Typically, virtual workers communicate with other virtual workers more often than they communicate with office employees (Belanger, 1999). To maintain these relationships many virtual workers plan communication time into their interactions with others. For example, virtual workers often create special occasions for coworkers to come together for conversation and interaction in a face-to-face context. Inviting colleagues to social gatherings and holding annual meetings are ways that relationships are maintained. Also, virtual workers will exchange digital images and call a colleague before a conference call or meeting in order to "chat" before beginning to work (Leonardi et al., 2004). The distance inherent in virtual work requires that virtual workers pay specific attention to the relational elements of their work. Instead of taking social interaction for granted, virtual workers must communicate strategically with others in order to maintain healthy and productive interpersonal relationships. Organizational structures and practices that encourage and facilitate such relational work improve the effectiveness of the virtual worker.

Presence Practices

Perhaps the most salient fear for virtual workers is that not being physically copresent with colleagues and managers will prohibit them from "getting ahead" in the office (Leonardi et al., 2004; O'Mahony & Barley, 1999; Orlikowski & Barley, 2001). The major driver of this fear is the distance inherent in virtual work arrangements. To combat this problem, virtual workers conduct a variety of practices that help them to establish a virtual presence. For example, virtual workers communicate via e-mail much more frequently than do traditional office employees, and their e-mails are typically shorter and more informal (Jarvenpaa & Leidner, 1999; Scott & Timmerman, 1999). Communicating often via e-mail allows the virtual worker to establish his or her presence with coworkers by letting them "see," figuratively, the virtual worker hard at work and letting them "see," physically, his or her name in their e-mail in box. In this way the virtual worker is present in the work of others. Additionally, many virtual workers establish their presence in the organization by recreating the sense of an office virtually through the use of electronic lists and online newsletters (Leonardi et al., 2004). Moreover, using technologies traditionally deemed as informal and used out of the workplace, such as IM and chat groups, in order to communicate with colleagues allows the virtual worker to be present with others while enjoying the advantages of solitary work.

CONCLUSION

With the proliferation of virtual organizations, traditional images of work are shifting. "Work" in a virtual setting is enabled by digital telecommunications technologies, but not driven by them. As a consequence, virtual work makes explicit the task and relational elements of work practices. Virtual workers must proactively manage these two as distinct from one another. Additionally, virtual work must include practices that serve to establish the worker's presence in the organization. The enactment of these work practices creates and recreates virtual organizations through the content and structure of virtual work.

KEY TERMS

Knowledge Work: Conceptual and analytical practices that require domain-specific knowledge and can be conducted from a variety of locations and, thus, are not tied to processes or technologies of specific workplace locations.

Presence Practices: Work practices that establish the presence of a worker in the organization as seen by coworkers and managers.

Relational Practices: Work practices related to communication with others, including formal and informal interaction.

Task-Based Practices: Work practices related to a specific job description that must be carried out to produce a deliverable product, process, or idea.

Telepresence: The experience of presence in an environment by means of a communication medium.

Transparent Technology: Technology that workers use on a daily basis without thinking about it. Most often a technology is considered transparent when a worker forgets that he or she uses it. When a worker must think about how and when to use a specific technology it is no longer transparent.

Virtual Work: The combination of task-based, relational, and presence practices conducted by workers who work from a remote location.

Technology in the Foreign Language Classroom

William J. Switala
Duquesne University, USA

INTRODUCTION

America is a country made up of people from all corners of the globe. Although this is the case, few Americans can communicate in a language other than English. The major reason for this is that Americans do not study foreign languages to any great extent in school, and those who do, have not developed a facility to speak the language they have studied. The American Council on the Teaching of Foreign Languages found, in its survey entitled "Foreign Language Enrollments in U.S. Public High Schools, 1890-2000," that there was a steady decline in the numbers of students studying foreign languages from 1976 to 1994. From 1995 to 2000 this trend was reversed and the number of students learning new languages in the year 2000 almost matched that of the enrollment for 1974. However, this still only accounted for 42.5% of the total number of students attending American high schools (ACTFL, 2004). A possible explanation for this low number may rest in the methodology used to teach foreign languages in our schools. (Brecht, 2002).

BACKGROUND

The Evolution of Technology in Foreign Language Teaching

The approach used for teaching foreign languages in the past was to provide the student with enough vocabulary and grammar so that they could read a language. Speaking the language was not as important as reading it. The current philosophy in language instruction emphasizes speaking over reading. Today to meet this end every effort is made to engage the students in more productive activities, resulting in greater use of communication skills. A way to do this is to incorporate more technology in the foreign language classroom. Technology, for the purposes of this discussion, will consist of software programs, the Internet and distance learning satellite transmissions.

The use of technology in foreign language teaching began over 60 years ago. Starting with the use of language labs by the military in World War II, the utilization of technology has gotten much greater since then. From 1950 to 1980 the teaching of foreign languages entered what has been called the "Age of Methods". Language labs with their interconnected tape recorders moved from the military setting to high schools and colleges. During the 1960s and 1970s, the audio-lingual method, in which the student imitated correct pronunciation by listening to native speakers on tape recordings, became the rage in foreign language instruction (Rodgers, 2001). The use of videotape based language programs became popular in the 1980s. The most famous of these was the Capritz series for learning the French language entitled "French in Action". It was also during the 1980s that the computer as a device for enhancing language study appeared. Initially, consisting of simple vocabulary development programs, this technology expanded to include complete language learning programs, authoring programs for teachers, and computerized language lab systems (Earp, 2001). In the 1990s the advent of distance learning opportunities through language programs broadcast and received over satellite transmissions added to the technological possibilities in foreign language instruction.

The applications of technology in the teaching of foreign languages today fall into three major categories: basic language instruction; reinforcement of language skills; and enhancement of the target language. Each of these categories is open to multiple applications of technology. Each of them have available support from computer programs, Web sites and satellite transmissions. What follows is a discussion of each of these aspects of teaching a foreign language and how technology can augment that teaching.

BASIC LANGUAGE INSTRUCTION

Basic language instruction deals with the acquisition of a new language. Three fundamental modes of delivery exist in using technology to accomplish this. They are: software programs; the Internet; and distance learning, using a program of instruction transmitted via satellite. Each of these has special requirements, advantages, disadvantages and potentials. There are numerous software applications on the market today that aid the individual student in learning a new language. There are two ways to use them. First, the teacher can place students in a computer lab setting and share the instructional disk through a file-server. All of the students may then receive the basic instruction at the same time. In this approach the teacher will need to receive special training in the operation of the program. It is also advisable to have a trained computer aid on hand to help with the operation of the program. A second possibility is to have students work individually in an independent setting to learn the language. In this situation the teacher acts more as a mentor than as a primary instructor. The advantage to the CD-ROM program approach is that the student can proceed at his/her own pace and not be restricted by the progress of other students. A major disadvantage to this technique is that if the students are studying the language as individuals, there is no one with whom they can interact, especially in practicing the oral skills of the language. Two excellent sources for information on software applications of this nature are Applause Learning Resources (Web site: *applauselearning.com*) and Teacher Discovery Company (Web site: *teacherdiscovery.com*).

The Internet is also a source of opportunities for learning a foreign language. The same practical considerations listed for using software programs also apply to the use of the World Wide Web. Having computers available that can access the Internet is a must if one is to use this resource. The configuration of these computers is the same as for the software packages: they may be used in a lab setting for group instruction of the language, or as individual stations for one-on-one learning. In either case the need for a teacher or a mentor is also the same. There are two major Web sites that offer foreign language course instruction. The first of these, about.com, is the most comprehensive one, offering the greatest number of languages. The full address for the site is *http:// (the language you want).about.com/homework/(the language you want)*. For example, if you were looking for the program that teaches French, you would enter: *http:// french.about.com/homework/french*. The languages offered on this Web site include: Chinese, French, German, Italian, Japanese, Latin, Russian and Spanish. Parlo.com is another site that offers instruction in French, Italian and Spanish. The address for this site is *www.parlo.com*. As with the software applications, a teacher should be present to monitor the students.

The final possibility for teaching a foreign language is to use one of the distance learning offerings sent by satellite transmission. The major provider of this service is the Satellite Educational Resources Consortium (SERC). SERC was the pioneer in offering foreign languages via satellite transmission. It offers instruction in high school level German, French, Japanese and Latin. It also provides a Spanish program designed for elementary and middle school students.

There are several factors that one must attend to when using this technology. The most important of these is the obtaining of the equipment necessary for the operation of the program. A satellite dish must be purchased, located in an appropriate place at the school, and protected from vandalism. Reception and distribution equipment are needed to acquire the signal from the satellite dish and to channel the program to a specific classroom. A television monitor, speakerphone and a dedicated phone line are also needed in order to operate the program successfully. The dedicated phone line and speakerphone facilitate the two-way communication between the students and the teacher presenting the course. Finally, it is essential that someone be trained in the proper operation of the entire system.

REINFORCEMENT

Reinforcement is the process by which learned material is ingrained to a greater depth. It increases retention of the subject matter. This is especially important in the study of foreign languages, where learning is cumulative. Technology can achieve this goal and focus student attention to a degree often superior to regular classroom instructional techniques. Once again, there are three major formats through which this can occur: software programs, the Internet and satellite transmissions.

Most foreign language textbook series come with computer disks containing exercises that are drill and practice in nature. These are specially designed to reinforce concepts, usually grammatical and vocabulary, covered in the chapters and units of the textbook. Basically they consist of students manipulating objects or statements presented with well-developed graphics, usually with sound accompaniment, to complete the exercises. Self-tests are typically part of the program and students can obtain instant feedback on their performance. The teacher can use these programs, either as a general reinforcement for the entire class, or as a tutorial for individual students. In addition to programs that come with the textbook, other sources are also available. Offerings appear in several formats: drill and practice for grammar, vocabulary builders, reading comprehension programs, dialogues, puzzles and games. A wide variety of packages of this nature for classes in German, French, Latin and Spanish are available in the catalogues of the Discovery and Applause Companies.

Another option for reinforcement is to access programs on the Internet. Many textbook companies have a Web site related to their foreign language series. These sites typically offer self-progress assessments, remedial activities and review exercises. Glenco (*www.foreign language.glenco.com*), Holt Rinehart Winston (*www.hrw.com*), and Prentice Hall (*www.phschool.com/foreign_languages/index.html*) have especially effective sites.

The third option for providing reinforcement is to make use of selected satellite transmissions. These are not found on the satellite venues used for basic instruction. Instead, they involve commercial television programs. Offerings such as documentaries, soap operas, travelogues and commercials are broadcast over satellites in native languages, especially Spanish and French. Native speakers provide the dialogue and students can hear the correct pronunciation, idiomatic expressions and proper grammar of their target languages. Teachers can have students watch these transmissions in real time, or the teacher can videotape them and show them at a more convenient or effective time.

ENHANCEMENT

Enhancement is whatever the teacher does to make the learning more vivid and interesting. It enriches the students' understanding of the culture they are studying. Opportunities for enhancement are exceptionally varied today. They include offerings in art, music, customs, foods, dress styles, geography, history and the political structure of the native lands related to the languages students are studying. They are also available in a software format, through Web sites, and via satellite transmissions.

The most readily available source of enhancement programs is the software package. They accompany many textbook series on the market today and they are also obtainable from independent sources such as Applause Learning Resources. The Internet contains a number of Web sites that also offer effective and attractive learning opportunities in this area such as interaction with speakers from other countries through discussion groups, chat rooms and e-mail pen pals (Pufahl, 2002). Other excellent sources for enhancement programs are the University of Wisconsin Web site (*http://polyglot.lss.wisc.edu/lss/lang/langlink.htm*), the University of Iowa Web site (*www.uiowa.edu/~flesled/resources/resources.html*) and the site of the American Classical League (*www.aclclassics.org*). Distance learning transmissions also provide a source for enhancement possibilities. Many programs of a cultural nature are broadcast in foreign languages via satellite. These include travel shows, tours of museums and visits to other cultural areas. Students may view these programs in real time, or later, through tapes of the offerings made by the teacher.

CONCLUSION

Whatever option the teacher may choose to use, technology can provide a wide range of opportunities and vistas that make the teaching of foreign languages much more effective in the 21st century than at any other time in history.

KEY TERMS

Audio-Lingual Method: This is the method of studying a foreign language that stresses hearing the language spoken by native speakers and then imitating the patterns of pronunciation and grammar heard in the example.

CD-ROM Programs: These are standard computer disk operated software that run on a stand- alone computer, or on multiple computers through a file server.

Computerized Language Labs: Foreign language instructional programs operated via computer disks and distributed to multiple computers by a file server and accessed by an entire class of students.

Distance Learning Satellite Transmissions: Learning programs transmitted via television signals from remote sources and accessed locally by students through a receiver dish antenna.

File Server: A piece of equipment that allows one to distribute a software program from a single source to a number of computers.

Internet: The electronic system that links various computer networks around the world. It includes educational venues, databases, electronic mail, news agencies and chat rooms.

Stand-Alone Programs: Foreign language instructional programs operated by an individual computer in a classroom.

Technology of Formal Education

Donald A. Hantula

INTRODUCTION

Internet distance education is a natural consequence of *fin de siecle* industrial transformations from a manufacturing economy, in which standard educational practices are based, to an information economy, in which greater autonomy, collaboration, flexibility and a project orientation to work are the norm. The Internet did not cause changes in education, but rather enabled educators to meet new demands for instructional practices and outcomes and adapt to a rapidly changing economic and social environment that was beginning to outpace the academy. Today, just as 100 years ago, educational institutions and practices are modeled on prevailing industrial examples of work and organization. This is especially the case in the United States where an overriding intended effect of formal education is to prepare students to fill roles within the prevailing economic system. Against this backdrop, it is only those components of education that reflect and reinforce the prevailing industrial system that are incorporated into the technology known as formal education. Components of education such as teaching machines and distance learning existed throughout the 20th century but never became standard educational practice until fairly recently because they were not acceptable in terms of preparing students to enter the prevailing industrial system.

BACKGROUND

Educational institutions customize many of their services according to what is dictated by industry, "manufacturing" employees who are suitable for the workplace (Jacques, 1996), thereby, completing a system of supply and demand. The classroom was designed as an industrial entity as it mirrored organizational practices and education emulated the factory. Straight lines of desks (often bolted to the floor), uniform curricula, standardized forms and procedures for evaluating students and faculty, strict scheduling, student achievement indexed according to hours worked and units completed all bear more than an accidental resemblance to the manufacturing process. As formal education grew in the United States in the early 20th century, the scientific management movement informed and inspired educators to view schools in the same terms as manufacturing businesses (Spring, 2001), or as "…essentially time- and labor-saving devices, created by us to serve democracy's needs" (Cubberly, 1919, p. 355). Education satisfied these industrial "needs" with a standard "product"—a graduate who not only was trained in the basics of reading, writing, and arithmetic (skills of practical usefulness), but who was also socialized to industry (Robbins, 1997). Educators were trained to consider themselves as administrators or managers, seeking the most efficient ways to teach attendance, punctuality, attentiveness, conformity, rote learning and an acceptance of standardized work, piece-meal production and adherence to a hierarchical order (Spring, 2001). These were the lessons to be learned so that the "industrial capabilities and character" could be shaped (Cubberly, 1909, p. 41). Principals were akin to factory managers, setting general policies and procedures under which teachers — shop managers of their own classrooms — made the process work. Thus, it is not surprising that the physical design of school buildings and their interiors reflected the design of factories; the practices occurring within them attempted to replicate, as closely as possible, the prevailing industrial order.

With the concurrent rise of both formal education and the factory system, it might be reasonable to assume that various technologies would have been quickly applied to produce more efficient education. However, this was not the case. Despite the prevailing machine age, schools for the most part did not adopt mechanized methods of education such as teaching machines. Instead, a more teacher-driven, craft model of education was the norm. Within the constraints of the classroom, teachers as skilled craftspeople assembled education from centrally approved and provided pieces in a custom shop. The craft of teaching was realized through regulating the flow and progress of students through mass-produced mandated material by explaining, illustrating, and answering questions. Teaching filled in the gaps between a standard curriculum and the individual needs of the students. Technologies such as the overhead projector, which could be easily incorporated into the classroom under the teacher's control, were accepted because they did not threaten the status quo (Kipnis, 1994). Table 1 summarizes some of the major educational technologies that had bright promise but were never widely adopted.

The classroom/factory in which the compliant worker-consumer is the end product is no longer acceptable because factories are no longer the dominant models for most business organizations. The transformation from an industrial economy to an information economy has altered the way that organizations are run and the way education is configured (Sumner, 2000). Flat organizational structures, a project versus job orientation to work, less-centralized control and flexible scheduling are current configurations that enable rapid response, new innovations, and the development of new global alliances (Alavi, Wheeler, & Valacich, 1995). In this new economic model, outcomes depend not on goods but on information, and technology is the normative tool. We have seen a precipitous decline in the importance of spatio-temporal constancy; people commonly are not in the same place at the same time when "work" occurs. Because of globalization and the rapid pace of technological change, there is now an imperative to redraw the physical boundaries of the classroom, allowing learning to be continuous and education to occur in any place or at any time. With the rise of knowledge work and increased autonomy, the work model emerging is one of collaborative, rather than individual effort. Because knowledge work requires more flexibility and adaptability, individual employees have freer reign to determine how tasks will be performed. Part of this self-direction is the ongoing option to seek assistance and to reciprocate when the opportunity arises. Because computer technology is now ubiquitous in industry, computers are no longer the tools of the few. Combining the technological imperative with the nearly appliance-like nature of computers, the social and structural determinants are in place for computer-mediated distance education to become the norm. Educational institutions have changed the way education is accomplished in order to "manufacture" the needed graduates who have the requisite skills that the new workplace demands (Jacques, 1996). Trends such as the greater need for life-long learning, the demand for more part-time educational resources, and demographic changes such as an increase in older workers, techno-literacy, networked and team-based learning will continue to pressure educational institutions to adapt their offerings to fit this new industrial order (Sumner, 2000).

FUTURE TRENDS

Networked and team-based learning will become more important in the future as there has been a proliferation of the use of collaboration and teamwork in most organizations, and organizations rely on numerous types of teams to accomplish various tasks and goals (DeRosa, Hantula, Kock, & D'Arcy, 2004). The rise in virtual teams is the result of the growth of teamwork in organizations and increased geographic dispersion of workers (Lipnack & Stamps, 2000). As a result, an emphasis on teamwork and collaboration in educational settings will better prepare employees for the business world (Zaccaro & Bader, 2003). In addition, organizations are also relying more heavily on self-managed work teams (Yeatts & Hyten, 1998). Due to the increase of these teams in organizational settings, it is plausible that SMWTs will become more prevalent in educational institutions of the future.

CONCLUSION

Previous distance and technologically-based educational innovations have not necessarily failed, but did not match prevailing economic and social conditions. The current rise in Internet and technologically-based education mirrors a much larger change in the industrial order. Privateer (1999) asserts that technology should be viewed as a tool to redesign educational curricula, rather than simply as a replacement for traditional instructional methods, and

Table 1. Some promising educational technologies that were not widely adopted

- 1800s postal mail correspondence courses (described in Nasseh, 2002)
- 1920s Pressey's (1926) teaching machine
- 1930s instructional radio (described in Wright, 1991)
- 1950s Midwest program on Airborne Television Instruction (described in Reiser, 1987)
- 1960s Skinner's (1968) teaching machines and programmed instruction; Keller's (1968) personalized system of instruction
- 1980s computer-based educational applications were introduced (Crowell, Quintanar, & Grant, 1981)

Bereiter (2002) further argues that such a profound shift should usher in an entirely new theory of knowledge and learning. Indeed, if a century of educational research and technological experiments have taught us anything, it is that it is the not the medium, but it is the method that makes a difference (Clark & Zuckerman, 1999). Availability of technological media does not guarantee that these media will be properly integrated into instructional techniques. Instead, the greater challenge appears to be the human component of this process. Humans should endeavor to shape technology to fit both their physical and psychological needs (Kock, 2001) and not simply produce advanced technologies that are not comfortable. Ultimately, technology will continue to dramatically redefine learning and teaching and will have a profound impact on the educational institutions that enable these processes, and future research must begin to move beyond simplified models to more theoretically rich ones in order to appropriately deal with the complex set of variables in computer-supported cooperative work (Coovert & Thompson, 2001). Internet-based education is not necessarily a threat to formal education but instead is another form of the larger technology of formal education, a natural part of the evolving social order.

KEY TERMS

Educational Technology: Applications of one or more electronic or computer-based devices used in delivering education.

Information Economy: An economic system characterized by knowledge based work and processing and exchange of information and data as its primary activities.

Knowledge Work: Work accomplished through the manipulation of data and symbols.

Self-Managed Work Teams (SMWTs): Autonomous teams that are responsible for managing and performing various tasks.

Technoliteracy: The ability to understand, use, critically analyze, and improvise solutions within an information technology infrastructure.

Virtual Teams: Teams of people who work interdependently across space, time, and organizational boundaries through the use of technology to facilitate communication and collaboration.

Technology Planning in Schools

Julie Mackey
Christchurch College of Education, New Zealand

INTRODUCTION

Information and communication technology (ICT) planning as it relates to schools can be defined as the process of identifying the information and communication technologies used to support the educational and administrative goals of schools and of deciding how these technologies will be developed and managed (Lederer & Sethi, 1988; Smits & van der Poel, 1996). This article presents a model reflecting the evolution of ICT planning maturity in schools and identifies the factors that influence and characterize integration between ICT planning and educational strategy. The model suggests a common evolutionary pathway for ICT planning in schools and provides a foundation on which to propose a "stages of growth" model for characterizing and evaluating ICT planning in these settings.

BACKGROUND

Information systems (IS) planning[1] and the degree to which that planning is clearly linked into an organization's strategic goals have been widely recognized as key factors in the successful use of information technology (IT)[2] within the organization (see, for example, Watson, Kelly, Galliers, & Brancheau, 1997; Segars & Grover, 1998). Over a decade ago, Telem (1993) suggested that the use of IT as a management tool in educational contexts was a neglected area of research, particularly in terms of lack of an underlying knowledge base. Although in the ensuing years, an increased research focus on ICT in educational management has been seen, this focus has concentrated more on evaluative analysis of the efficacy of management information systems, computerized school information systems, and specific applications of information technology (see, for example, Barta, Telem, & Gev, 1995; Fung, Visscher, Barta, & Teather, 1997; Visscher, Wild, & Fung, 2001) than on understanding how schools develop their ICT systems and integrate them into their management systems and practices. Passey (2002) noted the continuing lack of research relating to ICT and school management within the school sector.

The notion that organizations evolve is encapsulated in various stages of growth models that are widely used in both organizational and IS research. In IS literature, these models are based on the premise that organizations move through various stages of maturity in their use and management of IS (Nolan, 1973; Huff, Munro, & Martin, 1988; King & Teo, 1997; Teo & King, 1997). For example, King and Teo (1997) proposed a four-stage model conceptualizing the integration of IS planning and business planning over time, to better enable the effective support of business strategies. These four stages are separate planning with administrative integration, one-way linked planning with sequential integration, two-way linked planning with reciprocal integration, and integrated planning with full integration between business planning and IS planning.

Although researchers debate the accuracy and completeness of these various models, the models provide organizations with useful benchmarks to determine their current state of maturity and planning for future growth. More specifically, Robson (1997), for example, suggested that such knowledge provides organizations with a base from which to develop appropriate IS-related strategies, management styles, control approaches, and investment levels. Schools similarly can use such models to determine their ICT planning maturity and to develop appropriate strategies for future growth.

ICT PLANNING IN SCHOOLS

The complexity of the educational environment provides an interesting context in which to consider ICT planning. First, unlike businesses, schools tend to focus on the use of ICT to support learning objectives rather than business objectives, yet, like businesses, they work with limited resources and financing. Second, technology in schools is not always well established (Latham, 1998; Knezek & Christensen, 1999), and an Educational Review Office (ERO) report stated that "the overall implementation of ICT was still in its early stages" (ERO, 2001, p. 2). As such, schools provide a contemporary context in which to demonstrate how ICT usage evolves within an organization. They also provide a venue to examine how this process is affected when many of the people within an organization have only a limited understanding of ICT development and planning, as tends to be the case in schools. Teachers and school administrators often acquire their IT skills "on the job" yet are expected to initiate the planning and implementation of ICT within the school (Ministry of Education, 1999). Third, much of the small amount of research that has been conducted on the integration of ICT plans and educational strategic plans focuses on large tertiary institutions (see, for example, Barta et al., 1995; Fung et al., 1997; Rice & Miller, 2001), which have very different organizational structures, more complex IS needs, and greater numbers of specialist IT staff than do elementary and secondary schools.

Identifying how ICT planning evolves within schools and the characteristics of each stage of that evolution enables school administrators to better understand the factors contributing to ICT educational strategy alignment and successful ICT integration and growth.

STAGE THEORY OF ICT PLANNING

The proposed model is based on an interpretive case study that examined the status of ICT planning and its integration with educational strategic planning in eight New Zealand state elementary schools. The model is based on data gathered from interviews with the principals, and analysis of the schools' strategic and ICT plans. The data identified factors that seemed to influence ICT planning in the eight schools, and highlighted a pattern across the schools in which ICT planning appeared to evolve from an unplanned state through to some form of alignment with educational objectives set in the schools' strategic plans. This pattern provided the basis of the proposed four-stage model of ICT planning maturity. The model, detailed in Figure 1, presents not only the characteristics that appear to define stages of planning maturity within schools, but also the evolutionary progression through these stages over time. In addition to outlining the four stages of the model, Figure 1 provides a set of benchmarks that corresponds to each of the stages. These benchmarks are organized across the four categories of *curriculum*, *professional development*, *infrastructure development*, and *school administration*.

The four stages of the model are not intended to be discrete but are signal points along a continuum of planning maturity. The benchmark characteristics associated with each stage are, therefore, similarly, indicators of progress along an evolutionary pathway rather than examples of discrete categories.

Progress in planning appeared to be influenced by internal, rather than external, factors. Even though all of the schools in the study were state elementary schools operating within similar parameters, they were demonstrably different in terms of their ICT-related competence and commitment. The factors that appeared to influence ICT planning and development were related to school size (which impacted human and physical resources); ICT competence and attitudes of top management; ICT competence and attitudes of teachers; the existing ICT infrastructure (relating to the effectiveness of past planning and legacy systems); and the alignment between the school's ICT-related strategies and educational strategies.

Figure 2 identifies some of the drivers that appear to enable schools to progress in their ability to plan effectively for the alignment of ICT and strategic educational goals.

FUTURE TRENDS

The development of a stage model of ICT planning maturity for schools provides a tool for analyzing current planning processes and assessing maturity vis-à-vis each of the planning categories proposed by the model. In this regard, it also offers further evidence of the usefulness of stage theory in understanding organizational development and IS strategy and business/educational strategy alignment. The model descriptors (Figure 1) provide benchmarks for highlighting areas of deficiency, assessing future directions, and providing assurance to school leaders as they work toward planning maturity. The stage drivers (Figure 2) go beyond the basic stage model to provide direction on aligning ICT planning with school strategic planning.

In similar vein to the study conducted by King and Teo (1997), the model depicts a progression from unformulated ICT plans with piecemeal implementation of hardware and software, through to the development of coherent and focused plans that emphasize the strategic goals of the school in the areas of teaching, learning, and administration. It seems that as schools develop skills in planning for ICT, they tend to identify opportunities to enhance the core business of teaching and learning through the innovative use of ICT in administrative, collaborative, and support roles.

The model provides a basis for investigating and analyzing ICT planning maturity in small organizations and, in particular, education contexts. There are opportunities to refine and enhance the model as schools mature in their planning and integration of ICT to achieve educational goals.

CONCLUSION

ICT planning and strategic planning in schools is not a clearly defined area, and numerous factors, both internal and external, impact the planning process and outcomes.

Figure 1. Four-stage model of ICT planning in schools

	Stage 1: Little or No Planning	**Stage 2: Early Formal Planning**	**Stage 3: Focused Formal Planning**	**Stage 4: Mature Integrated Planning**
Descriptor	*Planning has a technical and operational focus; Plans may be informal and not clearly documented*	*Planning becomes more formal and the focus shifts from technical aspects to the educational value of ICT*	*Planning becomes increasingly focused and linked to strategic objectives and teaching and learning*	*ICT planning is aligned with, and is integral to, the school's strategic planning process*
Categories				
Curriculum	Links between ICT use and curriculum objectives are weak or nonexistent	Some focus on how ICT can support teaching and learning	A maturing understanding of how ICT can support and enhance teaching and learning across curriculum areas is evident	ICT is an integral tool in the teaching and learning process
Professional development (PD)	PD develops basic computing skills and confidence for novice ICT users	PD targeted to varying staff needs and links skill development to possible curriculum applications	PD focuses on contextual skill development and curriculum applications as teacher competency increases	Teachers confidently use a range of technologies, and PD is customized and specific
Infrastructure development	Piecemeal technology acquisition and stand-alone configurations	Structured development with emphasis on compatibility, upgradability, and connectivity	ICT infrastructure planning complements school vision and general planning	Strategic planning explores innovations to enhance capability and infrastructure
Administration	Basic office functions are computerized	Communication and additional administrative functions are computerized	ICT enhances efficiency and effectiveness of administrative systems, teacher planning, and wider school objectives	Innovative solutions enhance communication, resource sharing, and student recording and reporting

Figure 2. Summary of stage drivers

Stage 1: Little or No Planning	Stage 2: Early Formal Planning	Stage 3: Focused Formal Planning	Stage 4: Mature Integrated Planning

- Developing a shared vision for ICT with all staff.
- Formal planning and review.
- Principal and staff willing to learn.
- Appropriate professional development.
- Some commitment to resourcing the ICT infrastructure.

- Increasing acceptance and understanding of the role of ICT to support learning.
- Top management commitment (e.g., from Principal and Board of Trustees).
- Planned and effective professional development for all staff.
- Commitment to ICT resourcing for medium-term development.
- Growing knowledge, experience, and understanding of technical aspects.

- A school culture that believes in the value of ICT to enhance and support both curriculum and administrative areas.
- Strong vision and knowledgeable leadership by the principal.
- Commitment to specific and appropriate professional development.
- Innovative approach to ICT use—willing to be leaders.
- Ability to maximize support from external agencies, e.g., business partnerships, professional development contracts.

In spite of this complexity, it is evident that a school's ICT planning matures as the focus shifts from technology and skills acquisition to the effective use and integration of technologies in line with the school's strategic plans.

KEY TERMS

Computerized School Information Systems: Specific information systems for educational management, for example, enrollment systems and assessment and reporting systems.

ICT Integration: The degree to which ICT is used to achieve organizational goals. In the educational context, integration means that ICT is used transparently to achieve curriculum objectives and is not taught for its own sake.

ICT Planning in Schools: Specific school planning relating to the provision, acquisition, implementation, curriculum integration, maintenance, and replacement of ICT, and the professional development of staff relating to ICT.

Information and Communication Technology (ICT): *Information technology* is the term used to describe the items of equipment (hardware) and computer programs (software) that allow us to access, retrieve, store, organize, manipulate, and present information by electronic means. *Communication technology* is the term used to describe telecommunications equipment through which information can be sought, sent, and accessed, for example, phones, faxes, modems, and computers (Ministry of Education, 2003, p. 7).

Information Systems Planning: The term used to describe the process of determining objectives for organizational computing and identifying potential applications that should be implemented in the organization (Teo & King, 1997).

Integrated ICT Planning: Planning that blends ICT planning or information systems planning with strategic planning.

Legacy Systems: Information systems from an earlier period of technology and development.

Stages of Growth Models: Models that attempt to explain evolutionary stages in the maturity of systems or organizations.

Strategic Goals: Specific goals that provide direction for the organization to meet its mission in the medium term.

ENDNOTES

1 Information systems planning is the term used to describe the process of determining objectives for organizational computing and identifying potential applications that should be implemented in the organization (Teo & King, 1997).

2 Information technology is defined as the hardware and software that allow the access, retrieval, storage, organization, manipulation, and presentation of information by electronic means (Ministry of Education, 1998).

Technology-Mediated Progressive Inquiry in Higher Education

Hanni Muukkonen

Minna Lakkala
University of Helsinki, Finland

Kai Hakkarainen
University of Helsinki, Finland

INTRODUCTION

In higher education, students are often asked to demonstrate critical thinking, academic literacy (Geisler, 1994), expert-like use of knowledge, and creation of knowledge artifacts without ever having been guided or scaffolded in learning the relevant skills. Too frequently, universities teach the content, and it is assumed that the metaskills of taking part in expert-like activities are somehow acquired along the way. Several researchers have proposed that in order to facilitate higher level processes of inquiry in education, cultures of education and schooling should more closely correspond to cultures of scientific inquiry (Carey & Smith, 1995; Perkins, Crismond, Simmons & Under, 1995). Points of correspondence include contributing to collaborative processes of asking questions, producing theories and explanations, and using information sources critically to deepen one's own conceptual understanding. In this way, students can adopt scientific ways of thinking and practices of producing new knowledge, not just exploit and assimilate given knowledge.

BACKGROUND

The best practices in the computer-supported collaborative learning (CSCL) paradigm have several features in common: consideration, in an interrelated manner, of the development of technological applications, use of timely pedagogical models, and attention to the social and cognitive aspects of learning. Emphasis is placed on creating a collaborative community that shares goals, tools, and practices for taking part in an inquiry process.

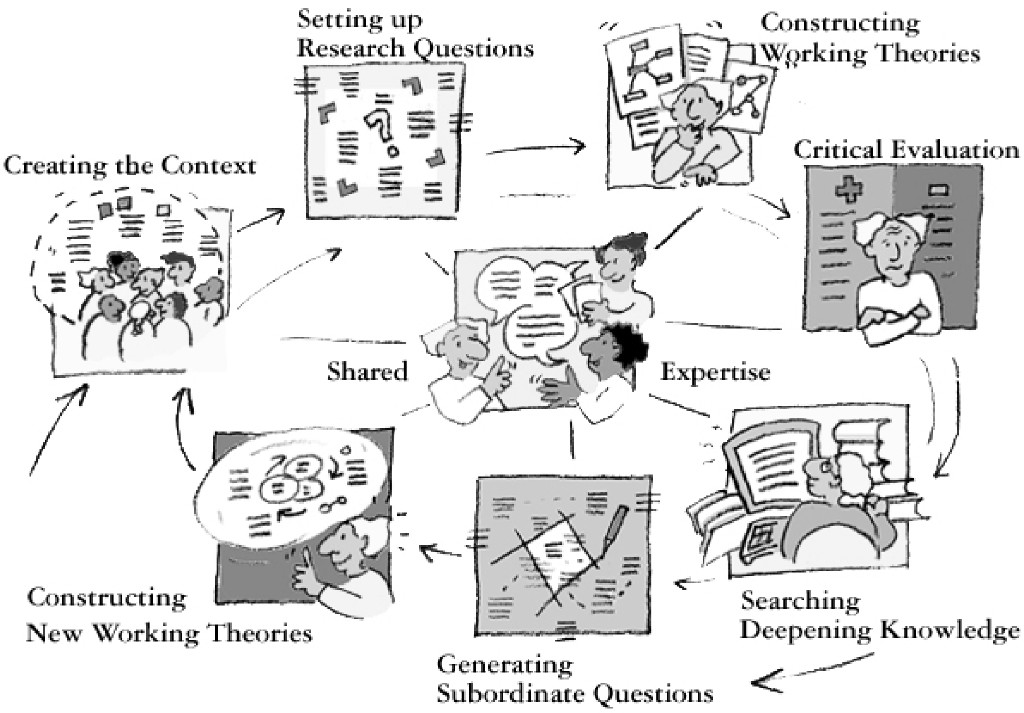
Synthesizing these demands, Kai Hakkarainen and his colleagues at the University of Helsinki have developed a model of *progressive inquiry* as a pedagogical and epistemological framework. It is designed to facilitate expert-like working with knowledge in the context of computer-supported collaborative learning. It is primarily based on Carl Bereiter and Marlene Scardamalia's (Scardamalia & Bereiter, 1994) theory of knowledge building, on the interrogative model of scientific inquiry (Hakkarainen & Sintonen, 2002; Hintikka, 1999), and on the idea of distributed expertise in a community of learners (Brown & Campione, 1994). The model has also been implemented and studied in various educational settings from elementary to higher education (see e.g., Hakkarainen, Järvelä, Lipponen & Lehtinen, 1998; Lakkala, Ilomäki, Lallimo & Hakkarainen, 2002; Lipponen, 2000; Veermans & Järvelä, in press).

THE PROGRESSIVE INQUIRY MODEL

In progressive inquiry, students' own, genuine questions and their previous knowledge of the phenomena in question are a starting point for the process, and attention is drawn to the main concepts and deep principles of the domain. From a cognitive point of view, inquiry can be characterized as a question-driven process of understanding; without research questions, there cannot be a genuine process of inquiry, although in education, information is frequently conveyed or compiled without any guiding questions. The aim is to explain the phenomena in a deepening question-explanation process, in which students and teachers share their expertise and build new knowledge collaboratively with the support of information sources and technology.

The progressive inquiry model specifies certain epistemologically essential processes that a learning community needs to go through, although the relative importance of these elements, their order, and actual contents may involve a great deal of variation from one setting to another. As depicted in Figure 1, the following elements have been placed in a cyclic, but not step-wise succession

Figure 1. Elements of progressive inquiry (Reprinted by permission from Muukkonen et al., 2004)



to describe the progressive inquiry process (Hakkarainen, 2003; Muukkonen, Hakkarainen, & Lakkala, 1999; 2004).

a) *Distributed expertise* is a central concept in the model. Progressive inquiry intends to engage the community in a shared process of knowledge advancement, and to convey, simultaneously, the cognitive goals for collaboration. Diversity in expertise among participants, and interaction with expert cultures, promotes knowledge advancement (Brown et al., 1993; Dunbar, 1995). Acting as a member of the community includes sharing cognitive responsibility for the success of its inquiry. This responsibility essentially involves not only completing tasks or delivering productions on time, but also learners' taking responsibility for discovering what needs to be known, goal-setting, planning, and monitoring the inquiry process (Scardamalia, 2002). There should be development of students' (and experts') social metacognition (Salomon & Perkins, 1998)—students learning to understand the cognitive value of social collaboration and gaining the capacity to utilize socially distributed cognitive resources.

b) The process begins by *creating the context* to anchor the inquiry to central conceptual principles of the domain or complex real-world problems. The learning community is established by joint planning and setting up common goals. It is important to create a social culture that supports collaborative sharing of knowledge and ideas that are in the process of being formulated and improved.

c) An essential element of progressive inquiry is *setting up research questions* generated by students themselves to direct the inquiry. Explanation-seeking questions (Why? How? What?) are especially valuable. The learning community should be encouraged to focus on questions that are knowledge-driven and based on results of students' own cognitive efforts and the need to understand (Bereiter, 2002; Scardamalia & Bereiter, 1994). It is crucial that students come to treat studying as a problem-solving process that includes addressing problems in understanding the theoretical constructs, methods, and practices of scientific culture.

d) It is also important that students explain phenomena under study with their own existing background knowledge by *constructing working theories* before using information sources. This serves a number of goals: first, to make visible the prior (intuitive) conceptions of the issues at hand; second, in trying to explain to others, students effectively test the coherence of their own understanding, and make the gaps and contradictions in their own knowledge more apparent (e.g., Hatano & Inakagi, 1992; Perkins et al., 1995); third, it serves to create a culture in which knowledge is treated as essentially evolving objects and artifacts (Bereiter, 2002). Thoughts and ideas presented are not final and unchangeable, but rather utterances in an ongoing discourse (Wells, 1999).

e) *Critical evaluation* addresses the need to assess strengths and weaknesses of theories and explanations that are produced, in order to direct and regulate the community's joint cognitive efforts. In part, it focuses on the inquiry process itself, placing the process as the center of evaluation, not only the end result. Rather than focusing on individual students' productions, it is more fruitful to evaluate the community's productions and efforts, and give the student participants a main role in this evaluation process. Critical evaluation is a way of helping the community to rise above its earlier achievements, creating a higher level synthesis of the results of inquiry processes.

f) Students are also guided to engage in *searching deepening knowledge* in order to find answers to their questions. Looking for and working with explanatory scientific knowledge is necessary for deepening one's understanding (Chi, Bassok, Lewis, Reiman & Glaser, 1989). A comparison between intuitive working theories produced and well-established scientific theories tends to show up the weaknesses and limitations of the community's conceptions (Scardamalia & Bereiter, 1994). The teacher of a course must decide how much of the materials should be offered to the students and how much they should actually have to search out for themselves. Questions stemming from true wonderment on the part of the students can easily extend the scope of materials beyond what a teacher can foresee or suggest. Furthermore, searching for relevant materials provides an excellent opportunity for self-directed inquiry and hands-on practice in struggling to grasp the differences between various concepts and theories.

g) *Generating subordinate questions* is part of the process of advancing inquiry; learners transform the initial big and unspecified questions into subordinate and more specific questions, based on their evaluation of produced new knowledge. This transformation helps to refocus the inquiry (Hakkarainen & Sintonen, 2002; Hintikka 1999). Directing students to return to previously stated problems, to make more subordinate questions, and answer them are ways to scaffold the inquiry.

h) *Developing new working theories* arises out of the fresh questions and scientific knowledge that the participants attain. The process includes publication of the summaries and conclusions of the community's inquiry. If all productions to the shared database in a collaborative environment have been meaningfully organized, participants should have an easy access to prior productions and theories, making the development of conceptions and artifacts a visible process.

CASES OF PROGRESSIVE INQUIRY IN HIGHER EDUCATION

Progressive Inquiry in a Cognitive Psychology Course

In a study reported by Muukkonen, Lakkala, and Hakkarainen (2001), the progressive inquiry model was implemented in a cognitive psychology course with the use of the Future Learning Environment (FLE). The FLE-environment (http://fle3.uiah.fi) is an open-source collaborative tool that has the progressive inquiry model embedded in its design and functionality (Muukkonen, Hakkarainen, & Lakkala, 1999). All the students in the course were guided, during the first two lectures, to formulate research problems. In the beginning, they individually produced these formulations. They continued by discussing their research problems with a peer and, finally, within a small group, selected the most interesting questions to pursue. These questions were then presented to all the participants in the lecture. After this initial problem setting, the technology-mediated groups (three groups of four to seven volunteers) were instructed to continue their inquiry processes between the weekly lectures in the FLE-environment. The tutor-facilitators took part in the FLE-environment, whereas the teacher conducted the weekly lectures without participating in the database discourse. The rest of the students also formed groups based on their questions, but continued their inquiry process by writing learning logs and commenting on the logs produced by other members of their group without collaborative technology.

A comparative analysis of the knowledge produced by the students in the two conditions provided evidence that the technology-mediated groups were more engaged in problem-setting and redefining practices. Further, they reflected on the process they had undertaken, with respect to the collaboration and their individual efforts. In the productions of the groups who had not used collaboration tools, the social and communal aspects of inquiry and knowledge building were not evident at all in their learning logs, although they were engaged in collaboration during the lectures. The type of the comments they provided to two of the learning logs written by other members of their group were very general, and they concentrated mainly on evaluating the level of writing, not on advancement of ideas. However, many of the learning logs were conceptually well-developed and integrated. Discourse interaction within the FLE environment was different in that the participants sometimes engaged in extensive dialogues about ideas presented by the fellow students.

Progressive Inquiry in a Design Course

Two studies carried out by Seitamaa-Hakkarainen and her colleagues (Seitamaa-Hakkarainen, Lahti, Muukkonen & Hakkarainen, 2000; Seitamaa-Hakkarainen, Raunio, Raami, Muukkonen & Hakkarainen, 2001), analyzed a collaborative design process as it occurred in the complex and authentic design task of designing clothing for premature babies. The framework of the studies was based on evidence from cognitive research on expertise that indicated that novices in design tend to generate problem solutions without engaging in extensive problem structuring; experts, by contrast, focus on structuring and restructuring the problem space before proposing solutions (Glaser & Chi, 1988). The studies described in this case were designed to examine whether an expert-like engagement in design process would be supported in the FLE-environment. Features of the environment were used to encourage the users to engage in expert-like designing and to enable graphic presentation of the knowledge artifacts in the form of importing students' drafts and prototypes into the collaborative environment and developing multiple versions of the designs.

During the collaborative design course, the students were first guided to find out information about the constraints of their design task, such as the size of the babies, special needs for the usability of the clothing, and about the materials. Then they were asked to produce their own sketches and work in small groups to share design ideas and develop their designs. Following this development, each group produced a prototype, which was tested by actual end-users in hospital. Feedback and suggestions were then used to develop advanced design ideas.

In these studies of designing with the support of a networked collaborative environment, Seitamaa-Hakkarainen and her colleagues (2001) found that a key aspect of these environments is its provision of tools for progressive discourse between the designers and users of the future products. Further, the environments offer shared spaces and tools to elaborate conceptual knowledge related to the design problem. The collaborative technology made design thinking more explicit and accessible to the fellow designers and enabled participants to share their ideas and construct a joint understanding of design problems and solutions.

TUTOR'S ROLE AND ACTIVITY

A special question in implementing progressive inquiry and knowledge building practices in higher education is the teacher's or tutor's role in supporting and guiding students' collaborative inquiry. In progressive inquiry, the traditional role of a teacher as an expert who delivers the essential information by lecturing is radically changed. The important roles of the teacher and the facilitators of collaboration are to create the context for collaboration, and provide anchors between the theoretical representations, world knowledge, and the real-life experiences that students report (Muukkonen et al., 2004). It is also necessary for the teacher to structure and scaffold the process, keep it active and in focus during the progression of the course, and to help students to gradually take upon themselves the responsibility for the higher level cognitive processes (Scardamalia, 2002).

FUTURE TRENDS

Productive changes in educational systems towards establishing inquiry-based approaches in studying and teaching call for an alignment of epistemic, pedagogical, and institutional goals and actions (Muukkonen et al., 2004). Learning technologies also need to be critically viewed for their role in fostering expert-like skills in advancing knowledge. For instance, availability of scaffolding, support for multiple forms of collaboration, and shared development of knowledge objects are challenges for designing learning technologies.

CONCLUSION

The progressive inquiry model may be utilized in a variety of educational settings to provide a heuristic framework for the key activities and epistemic goals of a knowledge-building community. The community may provide multiple levels of expertise and, equally important, social support for engaging in a strenuous quest for learning and advancing knowledge. In higher education, a progressive inquiry approach may support the development of academic literacy, scientific thinking, and epistemic agency, particularly when integrated with the use of appropriate collaborative technology and supportive arrangements in curriculum design.

KEY TERMS

Distributed Expertise: Cognition and knowing are distributed over individuals, their tools, environments, and networks.

Epistemic Agency: Taking responsibility for one's own learning efforts and advancement of understanding.

Knowledge Building: A framework for collective knowledge advancement and development of knowledge artifacts.

Learning Community/Community of Learners: All participants in a learning process (students, teachers, tutors, and experts) have valuable expertise and skills, which benefit collective efforts.

Metaskills: Skills involved in academic literacy as well as metacognitive skills related to planning, monitoring, and regulating comprehension-related activities.

Progressive Inquiry: A pedagogical model for structuring and supporting a group of learners in a deepening question-explanation process.

Scaffolding: Providing support that enables a learner to carry out a task that would not be possible without that support, and enabling the learner gradually to master that task without support.

Technology's Role in Distance Education

T

Murray Turoff
New Jersey Institute of Technology, USA

Caroline Howard
Touro University International, USA

Richard Discenza
University of Colorado at Colorado Springs, USA

INTRODUCTION

Learning is enhanced by the physical and social technologies typically used in distance education. Students in distance programs typically have access to tools that allow them to repeat lectures and interact with their fellow students and faculty. Students in all classes, including face-to-face and blended courses, benefit from having similar tools and technologies available. This article will review common tools and technologies used in distance education, and demonstrate why they can facilitate learning and expand the educational opportunities for both distant and traditional students.

BACKGROUND

For many years technologies have been used to facilitate learning. In the early 1980s a group of researchers at the New Jersey Institute of Technology (NJIT) realized the enormous potential of the technology to enhance learning when they used a computer-mediated system to facilitate a regular face-to-face class. The system was introduced to students in a number of Computer Science and Information System courses. Due to the amount of material covered in lectures, there was not much time for dialogue, and only a few students participated when there was a class discussion. The instructors introduced asynchronous group communication technologies to communicate discussion questions and assigned grade point credits for student participation. One hundred percent of the students participated in these discussions outside of regular classroom hours. The extent and depth of the discussions changed the nature of the classes. Most importantly, student contributions were comprehensive, with more well-thought-out comments, because students had the time to reflect on the ongoing discussion before participating. Also very significant was that students, for whom English was a second language, became equal participants. They could reread the online discussion as many times as needed before replying. The computer-based activity monitoring and transcripts, electronic recordings of the discussions, showed that foreign students spent two to three times more time in a reading mode and reread many discussions, far more than the American students.

In addition, professors now have the ability to monitor activities and review the electronic transcripts of student involvement which gives the instructor insights into how students are learning. By reviewing the transcripts of the online discussions, it becomes obvious what and how students are learning. For courses with a high pragmatic content, such as upper-level and graduate courses in topics like the design and management of computer applications, students are required to utilize problem-solving approaches to evaluate the tradeoffs between conflicting objectives. In a traditional classroom environment, especially in large classes, it is very difficult to detect whether students are accurately incorporating the problem-solving mental models that the instructor is attempting to convey. When instructors review the transcripts of class discussions, they give insights into the approaches students are taking to master the material. Unfortunately, in the early 1980s few wanted to hear about a revolution in normal classroom teaching or were willing to expend the effort to dramatically improve classroom education. It was only the rise of distance education that generated interest in learning about the educational potential of the technology.

Hiltz (1994) performed quasi-experimental studies that compared a population of NJIT students (only familiar with face-to-face classroom education) to a population of students taking the same courses in pure face-to-face sections, with pure distance sections using only CMC technology. The students in the matched sections had the same material, the same assignments, the same exams, and the same instructor. They found no significant difference in the amount of learning or the rate of student satisfaction. This finding is much more significant than a determination based on a study that included a population of distance learners already familiar with traditional correspondence classes.

Two critical underlying variables driving the success of this approach were identified by Hiltz (1994). First, the role the instructor needed to take was different from the traditional classroom role. The instructor acted more as an active and dedicated facilitator, as well as a consulting expert on the content of the course, rather than traditional teacher. Second, collaborative learning and student teamwork were the educational methodology (Hiltz, 1994) shown in later studies to be a key factor in making distance courses as good as or better than face-to-face courses (Hiltz & Wellman, 1997). These results show that distance courses can be as effective as face-to-face courses when using any of the traditional measures, such as exams and grades.

Creative, interactive software programs accompanied by background tutoring can effectively teach students to master the skills currently taught in many undergraduate courses. When these courses are automated, the costs incurred are far below typical college tuition. In the future, colleges and universities will not be able to continue to charge current tuition costs for introductory courses that are largely skill oriented. For example, there are many stand-alone and Web-based software programs that offer introductory programming courses, as well as skills in many other areas. These courses are comparable to college courses and some are even based upon a textbook used on some college campuses. They are available for a few hundred dollars. The major difference is that they do not carry college credits.

The technology allows senior professors or department chairs to effectively evaluate and mentor all instructors of particular courses, whether they are teaching traditional classroom courses or distance courses. The ability to review whole class discussions after the class is over gives senior faculty the ability to evaluate distance instructors hired to teach previously developed courses, as well as to review on-site instructors and junior faculty. Thus, they can improve and extend their mentorship and apprenticing relationships.

Today's technology for distance education allows faculty members to live anywhere they want to. Unique benefits will be available to outstanding teaching faculty. For example, one of the best full-time instructors for NJIT, which is located in beautiful downtown Newark, is a mother with two small children who never has to be on campus. She is teaching other instructors how to teach remotely. Similarly, a University of Colorado accounting professor, on sabbatical in Thailand, is able to teach a course in the Distance MBA program. There have been a few master's programs where some or all of the instructors are located anywhere in the world. It is technically feasible for those wanting to escape winter cold to teach in places such as Hawaii that we could only dream about. The technology makes it feasible, but various administrative policies, unions, insurance companies, benefit programs, and so forth have not yet caught up to the technology. There is increasing emphasis by accrediting agencies on treating remote instructors the same as faculty are treated. This is likely to bring about a greater degree of equality between instructors and tenured track faculty. The outcome is uncertain, but it may mean that the costs for remote and traditional classes will equalize so that the profit margin in online classes will not be quite so high.

SPECIFIC FUNCTIONS OF TECHNOLOGY THAT FACILITATE LEARNING

Asynchronous Discussions

In the online environment, students can take as much time as they need to reflect on a discussion and polish their comments. This improves the quality of the discussion, and changes the psychology and the sociology of communications. Students can address topics in the sequence they choose rather than in a predefined order. This leads to the development of different problem-solving strategies among the individual members of the class. Sometimes courses include synchronous conferences, videoconferencing, and/or video presentations to supplement asynchronous discussions.

Instructor Control of Online Conference and Roles

With online course conferences (many per course), instructors control the membership of each, assign roles, and enable other instructors to monitor conferences for joint teaching exercises involving more than one course. Groups within courses are able to set up private online conferences for team and collaborative work group assignments. Joint editing of items facilitates teamwork.

Question-and-Answer Communication Protocol

Instructors are able to ask questions during discussions. They can control who views the answer and prevent other students from seeing the answer of the others or engaging in the resulting discussion until they have entered their answer. In studies of Group Decision Support Systems, it has been shown that asynchronous groups in an online Delphi mode generate many more ideas than unstructured discussions or face-to-face groups of similar size (Cho, Turoff, & Hiltz, 2003). This area has proven to be a valuable tool in forcing equal participation. Use of question-and answer communication protocol can be used to force each student to think independently through their answer without being influenced by the other students.

Anonymity and Pen Name Signatures

When students with work experience are part of a discussion, they can use their real-life experiences to illustrate the concepts the professor is presenting. Such comments from fellow students, rather than the professor, often make the instructor's message more meaningful to the students. A student confirming the theory presented by a faculty member through real-life examples is more effective in making a point than "dry" data from an instructional article. Furthermore, students can talk about disasters in their companies with respect to decisions in any area, and they can provide detail—including costs—when they are not identified and the anonymity of the company they work for is preserved. Also, the use of pen names allows individuals to develop alternative personas without divulging their real identity and is extremely useful in courses that wish to employ role playing as a collaborative learning method.

Membership Status Lists

The monitoring of activities, such as students' reading and responding to communications, allows the professor to know what each individual has read and how up-to-date they are in the discussion. This allows the instructor to detect when a student is falling behind. Student collaborative teams can make sure that everyone in the team is up to date. Furthermore, students can easily compare their frequency of contributions relative to other students in the course.

Voting

Instant access to group and individual opinions on resolutions and issues are enabled by voting capabilities. This is useful for promoting discussion, and the voting process is continuous so that changes of views can be tracked by everyone. Voting is not used to make decisions. Rather, its function is to explore and discover what are the current agreements and disagreements or uncertainties (polarized vs. flat voting distributions) so that the class can focus the continuing discussion on the latter. Students may change their votes at any time during the discussion.

Special Purpose Scaling Methods

These useful methods show true group agreements and minimize ambiguity. Currently we have a system that allows each student at the end of the course to contribute a statement of what they think is the most important thing they have learned in the course; then, everyone votes by rank ordering all the items on the list. The results are reported using Thurstone's scaling, which translates the rank order by all the individuals to a single group interval scale. In this interval scale, if 50% prefer A to B and 50% prefer B to A, the two items will be at the same point on the scale. It has been surprising what some of the results have been in some courses. For example, in a Management of Information Systems course, the concept of "runaway" software projects was felt to be twice as important as any other topic. The professor was quite surprised by this result, until he began to realize that the students were using this concept as a mental model in which to integrate many of the other things they had learned.

Information Overload

This occurs when enthusiastic discussions by students that are meant to augment the quality of the learning process augment only the quantity of the number of comments, instead leading to the problem of "information overload." Currently this phenomenon limits the size of the group in a single CMC class. Online discussions allow individuals to enter comments whenever it is convenient for them, without waiting for someone else to finish the point they were trying to make. This makes it physically possible and also very likely that a great deal more discussion will take place and much more information will be exchanged among the group than if only one person can speak at a time, as in the face-to-face classroom environment. Anything that reduces the temptation of some students to "contribute" comments or messages that have nothing to do with the meaningful discussions underway will increase the productivity of the discussion without information overload setting in. Among such functional tools the computer can provide are:

Class Gradebooks

This eliminates a tremendous amount of electronic mail traffic that would become very difficult for an individual instructor to manage with a large class.

Selection Lists

The instructor can set up lists of unique choices so that each student may choose only one item and others can see who has chosen what. This is very efficient for conveying individualized assignments and reduces a large portion of communications.

Factor Lists

Members of a class or group can add ideas, dimensions, goals, tasks, factors, criteria, and other items to a single, shared list which may then be discussed and modified based upon that discussion and later voted upon.

Notifications

Short alerts notify individuals when things occur that they need to know about. For instance, students can be notified that a new set of grades or vote distribution has been posted, eliminating the need for individuals to check for these postings. People can attach notifications to conference comments from a select list that provides alternatives like: *I agree, I disagree, I applaud, Boo!* Such appendages significantly reduce the need to provide paralinguistic cues of reinforcement as additional separate comments.

Calendars, Agendas, or Schedules

Students have access to a space to track the individual and collaborative assignments and their due dates. These are listed in an organized manner that links detailed explanations for each assignment, as well as questions and answers related to the assignments.

The authors have seen these technologies facilitate learning beyond what can be assessed using traditional measures. Some of the more subtle intangible benefits of technology that we have observed are:

- Due to social pressures, students tend to be more concerned with how other students view their work quality than how the professor views it. They are significantly more motivated to participate in a meaningful way when their fellow students can view their contributions.
- When equality of communications is encouraged, students cannot get away with being passive or lazy. The transcript or electronic recording of the discussions shows who is and is not participating. It is visible to both the instructor and other students that someone is being lazy. (In fact, students seem to be more concerned with what the other students will think of their performance than what the professor will think.)
- The scope of what the outstanding students learn becomes even more noticeable.
- The performance of students at the lower end of the distribution is improved. The communications systems permit them to catch up, because they are able to obtain a better understanding of the material with which they are most uncomfortable or have the least background knowledge.
- The instructor can become more aware of his/her successes or failures with individual students because of the reflective nature of the student contributions to the discussion.

While these dimensions and concepts need confirmation through long-term longitudinal studies of student performances, the marketplace is also providing confirmation of the beliefs held by many experienced in teaching these classes. We are seeing that collaboratively oriented programs offer a solution to the problems, which are inherent in traditional correspondence courses. Students benefit from the ability to electronically store lectures alone or in chunks integrated into other material on the Web. Electronic storage of lectures gives all students the power to choose freely whether they want to attend a face-to-face class or take the same course remotely. Traditional face-to-face students can later hear a lecture missed due to illness or travel. Students with English as a second language can listen to a lecture multiple times. Face-to-face students who have to travel or fall sick can use the same tapes to catch up and/or review material prior to exams.

In our view a student in a face-to-face class that is not augmented by a collaborative learning approach and by asynchronous group communications technology is not getting as good of an education as the distance student who has those benefits. It is the face-to-face student who may be suffering from the segregation of the college system into separate face-to-face and distance courses. These observations about the past and the present lead to some speculations about the future.

THE STATE OF THE TECHNOLOGY

The technology available today includes at least 250 versions of group communication software. However, many of them may not survive the decade. There are a growing number of software packages for course management. The online learning product landscape is changing at a rapid pace as companies are acquiring their competitors to expand functionality. Gray (2002) gives an excellent summary of the popular platforms and the evolving nature of e-learning.

There are only a few of these that have wide usage, and they are beginning to raise their prices to capitalize on their popularity. Most of these packages charge a fee per user, which is not the desirable fee structure for the customer. Many of the older conference systems charge on a per-server basis and it does not matter how many students one has. It is far cheaper to spend more on the hardware and a get a more powerful server. Also, the course management systems do not provide many of the useful software features one would like to have for group communications. Given the way prices are going, it might be better to pay some of the undergraduate students to educate some of the faculty on how to create their own Web sites and have their own pages for their courses that they update and maintain directly. This also has desirable long-term consequences in raising the ability of the faculty in this area. Once you have committed all your content to one vendor's system, you are a captured customer and will have to pay whatever they want to charge. Right now, software development is undergoing rapid evolution, and no customer should put themselves in the box of only being able to use one vendor. If it is clear that you are using a number of vendors, you may even be able to get some breaks on pricing and will certainly get the top level of service when each of them knows there is an alternative service readily available to the customer. In the coming decade, one can expect major upgrades for these software systems every few years, and the best one today may not be the best one tomorrow.

COURSE DEVELOPMENT AND DELIVERY

Unfortunately, many faculty do not know how to use the technology to design a successful distance course. As the historical record shows, it is a mistake when transferring an application to computers to just copy the way it used to be done onto the computer. Utilizing the methodology of collaborative learning is the key to designing courses using group communications technology. Simple systems, which attempt to impose a discussion thread on top of what is electronic mail technology, allow the student or the teacher only to view one comment at a time. This approach does not allow an individual to grasp the totality of any complex discussion. Only by placing the complete discussion thread in a single scrolling page can a person review and understand a long discussion. One can browse the discussion and cognitively comprehend it without having to perform extra operations and lose their cognitive focus. Users of such simple systems cannot generate a large complex discussion and have no way of realizing that complex discussion is even possible. When online discussions are successful, they can easily go from enthusiastic wonderful discussions to information overload. Current technology must evolve to fully support collaborative learning.

FUTURE TRENDS

To facilitate collaborative learning, critical development directions for the future should include:

- Tailorability of communication structures by instructor
- Tailorability of communication protocols by instructor
- Anonymity and pen name provisions
- Delphi method tools and the availability of scaling and social judgment
  (voting methods)
- Tools for collaborative model building
- Powerful information retrieval capabilities
- Tailorability by instructor of application-oriented icons and graphical components
- Tools for the analysis of alternative diagrams

Instructors also need to allow students to extend the discourse structure and to vote on the significance of incidents of relationships among factors in the problem domain by using Group Decision Support processes. These systems should allow students not only to develop their own conceptual maps for understanding a problem, but also to detect disagreements about elements of the conceptual map and the meanings of terms. This is valuable preparation for problem solving in their professional life, a process that requires removing inherent ambiguities and individual meanings in the language used to communicate about a problem with others from diverse backgrounds. Routines should be included that are based upon both scaling and social judgment theories, which improve the ability of larger groups to quickly reach mutual understanding. Currently, few tools exist in current systems that support the use of collaborative model building, gaming, and Delphi exercises. The current generation of software does not often include the functions of anonymity and pen names. Course instructors need to have complete control over course communication structures and processes, and should be able to use their recently acquired knowledge for future offerings of the course. Currently, systems lack the needed integration of functions to easily evolve the changes in both the relationships and the content in a given field. A long-term advantage of teaching in the collaborative electronic environment is that the students create useful material for future offerings and can aid the instructor in monitoring the new professional literature. Future technology will allow faculty to organize their material across a whole set of courses into a collaborative knowledge base available to the faculty teaching those courses. This would allow students and faculty to create trails for different objectives and weave the material in that knowledge base to suit a group of students or a set of learning objectives.

Individual learning teams would be able to progress through a degree program's knowledge base at the rate best for them, rather than setting the same timeframe for all learning teams or faculty teams. Faculty, individuals, or teams would take responsibility for a specific domain within the Web of knowledge representing a degree program.

CONCLUSION

Collaborative technologies are changing the concept of what constitutes a course. Program material could be an integrated knowledge Web, based largely on semantic hypertext structures. Over time, the domain experts—the faculty—would continue to develop and evolve their parts of the Web, and wait for learning groups, composed of any mix of distance and regular students sharing the same learning objectives and needs.

Current vendor systems focus on the mass market and concentrate on tools to standardize and present course content. Group communication tools are usually just disguised message servers that offer only a discussion thread capability and little more, certainly not the complex capabilities discussed above. Vendors have not yet recognized the primary importance of group communications and how faculty members can guide and facilitate the process and be available for consultation as needed. Based upon the conceptual knowledge maps they design, faculty should be encouraged to develop content structures that are characteristic of their subject matter. In the end, faculty should have the ability to insert group communication activities anywhere in their professional knowledge base (e.g., question/answers, discussion threads, lists, voting, etc.).

KEY TERMS

Asynchronous Group Communication Technologies: Allow participants to send and respond to messages without being online simultaneously.

Distance Education: Consists of learning situations in which the students and instructor are located in different localities at least for a portion of the class.

Distributed Learning: Consists of learning situations in which the students and instructor are located in different localities. A bit broader than distance education as it can be used to refer to both education and training.

E-Learning: Using technology to assist in the educational process. It is often used to refer to learning situations (both education and training) in which the students and instructor are located in different localities . However, the instructor and teacher can be in close proximity.

E-Learning Technologies: The technologies used for e-learning.

Pen Name Signatures: Names participants choose for online participation which may or may not allow other participants to identify them.

Synchronous Group Communication Technologies: Allow real-time, interactive communications and require participants to be online simultaneously.

ENDNOTES

1 A great deal of recent evaluation studies are beginning to confirm ourearlier findings based upon extensive and large-scale studies at such placesas SUNY, Drexel, Penn State, and others. Some of these may be found inthe *Journal of ALN (www.aln.org)* and on the ALN EvaluationCommunity Web site *(www.alnresearch.org)*

T

Telemedicine in Healthcare Organisations

Nabeel A.Y. Al-Qirim
United Arab Emirates University, UAE

INTRODUCTION

Diminishing funds from the government and cost control led many health care providers across the globe to search for alternative and more cost-effective means of providing care (*Edelstein, 1999;* Neame, 1995). In many cases, this has become necessary for survival *(Edelstein, 1999) in order to sustain the increased competition as well amongst health care providers*. The business of health care has become so competitive that many small rural hospitals are trying to align themselves with larger tertiary care centres in a community health information network, a telemedicine network, or some other type of partnership in order to survive and to retain their local patients (Huston & Huston, 2000).

Telemedicine means medicine from a distance where distant and dispersed patients are brought closer to their medical providers through the means of telecommunication technologies (Charles, 2000; Noring, 2000; OTA, 1995; Perednia & Allen, 1995; Wayman, 1994). Noring (2000) provided an interesting comparison between the former definition of telemedicine and tele-health, where the term tele-health is defined as expanding the capacity of telemedicine to provide the full continuum of care, from health promotion and disease prevention through curative treatment and terminal care. Tele-health also implies including non-physician based health care providers.

Some researchers even envision telemedicine to be an important building block in the strategic plan of many health care organizations (Charles, 2000). Within these challenges, telemedicine emerges as one possible solution to health providers in reaching out to rural patients (Charles, 2000; Harris, Donaldson & Campbell, 2001), to areas where patient volumes for certain services are limited *(Edelstein, 1999)*, to conduct administrative and clinical meetings, and to conduct different training courses to: patients (smoke treatment centres), doctors, nurses, and other medical staff (Perednia & Allen, 1995; Wayman, 1994).

This research is interested in introducing the concepts underlying the telemedicine technology. The research will highlight the different advantages/disadvantages of this technology, and hence project different motivators and inhibitors to the adoption and use of this innovative technology in health care delivery.

BACKGROUND AND IMPLICATIONS

The first telemedicine initiative emerged in 1959 by employing video conferencing (VC) sessions for medical purposes by using microwave link for telepsychiatry consultations between the Nebraska Psychiatric Institute in Omaha and the State Mental Hospital 112 miles away (Perednia & Allen, 1995). Since then, telemedicine started to grow in different parts in the world. For example, in the late 1980s telemedicine was being used routinely to deliver general health services to remote regions of Norway (Noring, 2000). In the 1990s, telemedicine started to emerge in New Zealand and to be used successfully in Australia. In the United States, interest in telemedicine was initially focused on its use in the military, in space programs, on offshore oilrigs, in prisons, and in rural areas (Noring, 2000).

Telemedicine covers a wide spectrum of benefits through its use in areas such as consultations, diagnostics, therapeutics, transfer of patient related records, case management, training, and meetings. In a rural setting, telemedicine could help health care providers in supplying quality, fast, and economical medical services to rural patients, and hence saves doctors and patients valuable time wasted in commuting large distances. Specialists could utilise this extra time in seeing more patients at the main hospital.

The applications of telemedicine vary from full-motion and interactive video consultations to “store and forward” technologies where static images or audio-video clips are electronically captured, stored, and transmitted to a remote server such as electronic mail (e-mail) using public or private communication channels. The advantage of store-and-forward technology is that it prevents the need for simultaneous availability of the consulting parties. Radiology, dermatology, and pathology are especially suited to a store-and-forward format. Let’s not forget that the earliest form of telemedicine technology was the telephone system, where physicians used to call their patients (e.g., psychiatry) to follow-up a treatment or to check whether they are taking their medicine on time.

However, the telemedicine technology was not successful in its initial stages. Perednia and Allen (1995) reported limited telemedicine growth and pointed to the fact that only few telemedicine projects were instituted in the 1970s and 1980s at several sites in North America and Australia. They confirmed that none of the programs begun before 1986 has survived. Although data are limited, the early reviews and evaluations of those programs suggest that the equipment was reasonably effective at transmitting the information needed for most clinical uses and that users were for the most part satisfied. However, when external sources of funding (donations) were withdrawn, the programs disappeared, indicating that the single most important cause of their failure was the inability to justify these programs on a cost-benefit basis and the failure of these hospitals in addressing the importance of the telemedicine technology as one important tool amongst the other important medical tools in the hospital. Other issues, such as limited physician acceptance, played a less significant role in their downfall (Perednia & Allen, 1995).

However, there are other reasons that affect telemedicine success in health care organisations. Technological limitations were one of the major impediments. For example, until recently, transmission of a high-resolution, real-time video signal was possible only through the use of expensive equipment such as satellite systems and microwave towers. Recent developments in digitisation and data-compression technologies allow transmission of enormous amounts of information needed for video with much less bandwidth at a much lower price. While the equipment cost for video conferencing systems is relatively high, decreasing costs of hardware, software, and transmission suggest that high-resolution, full-motion VC may soon be available to medical clinics and offices at very economical prices. The wide diffusion of wired and wireless telecommunications infrastructure in rural areas has assisted many rural health care centres to interlink with speciality hospitals very easily.

Due to such technological facilitations and enhancements and increased awareness and knowledge about telemedicine technologies and applications, telemedicine witnessed another growth-phase in the 1990s. The innovative return of telemedicine since the early 1990s inspired many innovative ideas. For example, BMI British Midland has become the first airline to install telemedicine technology on planes making long-haul flights to the U.S. Virgin Atlantic has also purchased the system and will start installing it in long-haul aircraft this year. The device monitors blood pressure via a wrist cuff, pulse rate, temperature via an ear probe, electrocardiogram, blood oxygen and carbon dioxide levels. Using a modem, these are sent to physicians who can advise the crew on what action to take (Anonymous, 2002).

However, this growth was not in a straightforward manner and the telemedicine technology started to face different forms of complications. As the technology penetration in health care increases, different organisational, technological, environmental, political, individual and economical factors started to surface and to influence its success. Initially, the views about VC effectiveness in the medical area vary from one adopter to another. Depending on one's viewpoint, VC can be seen as a valuable tool for providing immediate specialty care services to rural areas, a more efficient use of existing medical resources, a way to attract patients living outside a hospital's normal service area, and a way of bringing international health care dollars. On the other hand, others could see it as a serious misallocation of increasingly scarce health care dollars (Perednia & Allen, 1995).

In review of the literature it was observed that despite the rapid growth and high visibility of VC projects in health care (Grigsby & Allen, 1997), few patients are seen through the VC for medical purposes. In almost every VC project, tele-consultation accounts for less than 25% of the use of the system (Perednia & Allen, 1995). The majority of the online time is used for medical education and administration (Hassol, 1996; Perednia & Allen, 1995; Wayman, 1994). Such result eliminates one of the most important functions of the telemedicine technology in health care delivery. The low level of usage can be explained in part by the federal government's position on reimbursement for telemedicine consultations (Hassol, 1996). However, Hassol (1996) pointed to other issues that need to be resolved first before the significance of VC could be realised. The important unresolved issues revolve around how successful VC can be in providing quality health care at an affordable cost and whether it is possible to develop a sustainable business model that would maintain profitability over time. This depends on (Perednia & Allen, 1995):

i. Clinical expectations: health care organisations need to be clear about the intended use of the telemedicine technology in their organisations; for example, will telemedicine be used for medical or administrative purposes; will it be used for general medical purposes or in certain medical specialities.
ii. Matching technology to medical needs: upon satisfying the preceding condition, the telemedicine technology needs to be integrated in the health care area in the sense that telemedicine is being seen as an integral medical tool, not an optional one. A complete protocol needs to be devised that could oversee the effective integration and use of the telemedicine technology in the health care area.
iii. Economic factors like reimbursement are major issues in countries such as the U.S. with vast geographical areas and different interstate laws and regulations. Accepting telemedicine encounters by health insurance companies could assist in increasing telemedicine success and diffusion.

iv. Legal concerns could be one of the largest impediments to the large-scale success of telemedicine in the long term. These concerns range from restrictions of medical practices across state lines (licensure), which are possible to resolve, to issues of liabilities due to malpractice or misdiagnosis. Recent research (Oakley et al., 1997) concluded that VC could be used with a reasonable degree of accuracy, and hence could not be relied on for initial diagnosis or treatment. This finding may cancel the use of telemedicine as a primary medical tool, but that does not cancel its importance as a viable follow-up medical tool and as an effective medical tool in a rural setting.
v. Social implications such as changing physician behaviours and traditional practices and workflow could impede telemedicine adoption (Anderson, 1997).
vi. Organisational factors: as indicated earlier, those are organisational specific, and hence vary from one health care provider to another. Issues such as the decision-making process concerning telemedicine adoption, whether telemedicine is considered part of an organisational strategy or direction, competing departments on resources and adopting/non-adopting telemedicine, motivation and empowerment are some of the factors that could influence telemedicine success in the long term in health care organisations.

CONCLUSION

This research provided different insights pertaining to the different factors that influence telemedicine use and success in health care organisations. Telemedicine offers health care providers many opportunities to provide timely and quality care to rural patients and this process could save them valuable time that could be used to see more patients in the main speciality hospital. There are other clinical and administrative advantages of telemedicine and health care organisations need to identify these opportunities and then devise means by which they could benefit from the different resources offered by telemedicine.

KEY TERMS

Licensure: Legal restrictions of medical practice across state lines and the difficulty of resolving issues of liabilities due to malpractice or misdiagnosis. This is a major issue in countries such as the U.S. with vast geographical areas and different interstate laws and regulations.

Reimbursement: Accepting telemedicine encounters by health insurance companies as one of the different medical outlets and accordingly reimbursing doctors and physicians for their encounters with, for example, rural patients, could assist in increasing telemedicine success and diffusion.

Telecommunication Technologies: All technologies (telephone, telex, fax, video/audio conferencing, e-mail, chat, etc.) and related peripherals (digital camera, scanner, printer, etc.) that communicate with each other via telecommunications channels or networks (e.g., either wired or wireless: local public telephone lines or more sophisticated channels and networks such as ISDN, Frame Relay, DSL, microwave, satellite and LAN & WAN technologies, etc., which could provide up to several gigabits of data transfer per second (Gbps).

Telemedicine: Medicine from a distance where distant and dispersed patients are brought closer to their medical providers through the means of telecommunication technologies.

Tertiary Education and the Internet

Paul Darbyshire
Victoria University, Australia

Stephen Burgess
Victoria University, Australia

INTRODUCTION

For many years, information technology (IT) has been used to find ways to add value for customers to entice them to purchase the products and services of a business. Many educators use the Internet to supplement existing modes of delivery. Importantly, the Internet is providing a number of added value supplemental benefits for subjects and courses delivered using this new, hybrid teaching mode. There are two aspects to subject delivery to where added value benefits may be applied, and that is in the *administrative tasks* associated with a subject and the *educational tasks*. In both instances, IT solutions can be employed to either fully or partially process some of these tasks. Given the complex and often fluid nature of the education process, it is rare that a fully integrated solution can be found to adequately service both aspects of subject delivery. Most solutions are partial in that key components are targeted by IT solutions to assist the subject coordinator in the process. If we examine closely the underlying benefits gained in the application of IT to these tasks, there is a strong parallel to the benefits to be gained by business organizations with similar applications of IT. While the actual benefits actually sought by academics depend on the motivation for the IT solution, the perceived benefits can be classified using standard categories used to gauge similar commercial applications. This article examines the possibility of translating the benefits of added value to the use of the Internet by tertiary educators for subject and course delivery. A brief discussion will occur on aspects of course and subject delivery in tertiary education and the use of information technology for added value. These concepts are drawn together to indicate how the Internet may be used for added value in tertiary education. Finally, these concepts were tested with a survey of members of the IS World list serve.

BACKGROUND

Aspects of Course and Subject Delivery in Tertiary Education

For the purposes of this article, when the authors refer to tertiary education they mean university level education. There are two overall aspects to course and subject delivery, the educational and administrative components (Darbyshire & Wenn, 2000). Delivery of the educational component of a subject to students is the primary responsibility of the subject coordinator, and this task is the most visible from a student's perspective. However, the administration tasks associated with a subject form a major component of subject coordination, but these responsibilities are not immediately obvious or visible to the students.

It is essential that all aspects of subject delivery be carried out as efficiently as possible. To this end, IT, and in particular, Web-based solutions can be applied to both aspects of subject delivery. That Web-based solutions are a suitable vehicle to use has been almost universally accepted by students, teachers and academic administrators (Scott Tillett, 2000). Other advantages are the ease with which information can be disseminated, its interactivity, its use as a real-time communication medium and the ability to use text, graphics, audio and video (Kaynama & Keesling, 2000).

There are a number of administrative tasks associated with subject coordination for which IT solutions can be applied in the application. These include (Byrnes & Lo, 1996; Darbyshire & Wenn, 2000):

- *Student enrollment*. While most universities have a student enrolment system administered at the institute level, there are often local tasks associated with enrolment such as user account creation and compilation of mail lists, and so forth. Some of these tasks can be automated (Darbyshire & Wenn, 2000).

- *Assignment distribution, collection and grading*. The written assignment remains the basic unit of assessment for the vast majority of educators, and there have been many initiatives to computerize aspects of this task. Some of these include *Submit* (Hassan, 1991), *NetFace* (Thompson, 1988), *ClassNet* (Boysen & Van Gorp, 1997) and *TRIX* (Byrnes & Lo, 1996).
- *Grades distribution and reporting*. Techniques for this range from email, to password protected Web-based database lookup.
- *Informing all students of important notices*. Notice boards and sophisticated managed discussion facilities can be found in many systems. Examples include products such as *TopClass*, *Learning Space*, *Virtual-U*, *WebCT*, and *First Class* (Landon, 1998).

Many of the tasks viewed as educational can also employ IT solutions in order to gain perceived benefits. Some of these include: *online class discussions*; *learning*; *course outline distribution*; *seminar notes distribution*; *answering student queries*. Just how many of these are actually implemented will relate to a number of factors, such as the amount of face-to-face contact between lecturers and students. However, using the Internet for many of these can address the traditional problems of students misplacing handouts, and staff running out of available copies.

Discussion management systems are being integrated into many Web-based solutions. These are usually implemented as threaded discussions, which are easily implemented as a series of Web pages. Other tools can include chat rooms or listserv facilities. Answering student queries can take place in two forums, either as part of a class discussion or privately. Private discussions online are usually best handled via an email facility, or in some instances, store and forward messaging systems may replace email.

Implementing IT solutions to aid in the actual learning process is difficult. These can range from intelligent tutoring systems (Cheikes, 1995; Ritter & Koedinger, 1995), to facilitated online learning (Bedore, Bedore, & Bedore, 1998). However the major use of IT solutions in the learning process is usually a simple and straight forward use of the Web to present hypertext-based structured material as a supplement to traditional learning.

Information Technology: Efficiency and Added Value

There are a number of reasons for using IT in organisations today (O'Brien, 1999):

- *For the support of business operations*. This is usually to make the business operation more efficient (by making it faster, cheaper and more accurate).
- *For the support of managerial decision making*, by allowing more sophisticated cost benefit analyses, providing decision support tools and so forth.
- *For the support of strategic advantage*. This refers to the use of Porter and Millar's (1985) three generic strategies as a means of using information technology to improve competitiveness by adding value to products and services.

It has been recognised for a number of decades that the use of computers can provide cost savings and improvements in efficiencies in many organisations. Porter & Millar (1985) have generally been credited with recognising that the capabilities of information technology can extend further to providing organisations with the opportunity to add value to their goods. Value is measured by the amount that buyers are willing to pay for a product or service. Porter & Millar (1985) identify three ways that organisations can add value to their commodities or services (known as *generic strategies for improving competitiveness*):

- Be the lowest cost producer.
- Produce a unique or differentiated good (providing value in a product or service that a competitor cannot provide or match, at least for a period of time). If an organisation is the first to introduce a particular feature, it may gain a competitive advantage over its rivals for a period. Some ways in which information technology can be used to differentiate between products and/or services are (Sandy & Burgess, 1999):
  - Quality
  - Product Support
  - Time
- Provide a good that meets the requirements of a specialised market.

The next sections examine the possibility of translating the benefits of added value to a particular application of IT, the use of the Internet by tertiary educators, to assist with subject and course delivery.

Using Internet Technologies to Improve Efficiency and Add Value

With the recent explosion in Internet usage, educators have been turning to the Internet in attempts to gain benefits by the introduction of IT into the educational process. In this article, subject delivery at the university level is only considered. The benefits sought from such activity depend on the driving motivation of the IT solution being implemented. While many may not perceive a university as a business (and it is not advocated here), it is nonetheless possible to match the current uses of the Internet in tertiary education with traditional theory related to the reasons why firms use IT.

Internet technologies in education, which are used for the learning process itself, target the student as the main stakeholder. While the motivation may be the enhancement of the learning process to achieve a higher quality outcome, we can loosely map this to the "*support of managerial decision making*" concept identified earlier. Such technologies allow educators to obtain a far more sophisticated analysis of individual student's learning progress, and thus provide them with decision support tools on courses of action to take to influence this process.

Technology solutions, which target the academic as the stakeholder (Darbyshire & Wenn, 2000, Central Point), implement improvements or efficiencies that can be mapped to the "*support of the business operation*" previously identified. Improvements or efficiencies gained from such implementations are usually in the form of automated record keeping and faster processing time, ultimately resulting in lower costs in terms of academic time, and added value to the students.

By default, the university also becomes a stakeholder in the implementation of either of the above types of technology enhancements. Benefits gained by students and staff by such uses of technology translates ultimately to lower costs for the institution or the provision of more and/or better quality information. The benefits of such systems can be mapped onto the "*support of strategic advantage*" concept (as Porter's low cost and differentiation strategies), previously identified as a reason for using technology in business. If these institutions are to regard themselves as a business, then the successful use of IT in subject delivery could give the university a strategic advantage over other universities, which it would regard as its business competitors. Most of the reported advantages gained from online supplementation of teaching relate to cost savings in terms of efficiency, flexibility and/or convenience. These represent the traditional added value benefits of lower cost and faster access to goods in the commercial world. Thus, we can use the measures of *money savings*, *time savings*, *improved quality* and better *product information* as categories to measure the benefits gained from the introduction of IT to supplement teaching.

A SURVEY OF IS WORLD MEMBERS

The authors were interested to investigate the extent of appreciation of the added value benefits that the Internet can offer to tertiary educators, institutions and their students. In the first instance, a simple survey was conducted through the IS World discussion list to gain an initial idea of the level of appreciation that existed.

IS World is a Web-based resource which has been set up for the benefit of information systems academics and researchers around the world. A general email was posted to the IS World discussion list on January 29, 2001. A request was made for tertiary educators to respond, outlining their uses of the Internet in tertiary education and how the uses added value for the institution and for students. There were 43 responses to the survey between January 29, and February 4, 2001. Most of these (33) were within one day of the initial email.

All respondents to the survey identified as least one type of Internet usage to assist them. Approximately seven out of 10 adopted administrative uses and roughly the same proportion adopted educational uses. This supports the notion identified in the literature that the technology would be accepted in the tertiary education field. The following findings support the notion that educators identify the added value uses of the Internet in tertiary education.

The most common benefit for administrative uses was to save time for the institution and for students. Most administrative benefits were similar for both groups, except for "save money" (where more than twice the respondents felt that the institution saved money than students). The "information provision" administrative usages were the most commonly used (important notices, schedules/ timetables, assignment and grade distribution). Less common were the more "interactive" options, assignment collection and student enrolment. Educational uses of the Internet were seen as providing slightly more benefits for students than institutions. Their use were seen as providing more information and improving quality more on average than the administrative uses. As with administrative usages, the easiest educational features to set up were the most commonly used (distribute course/ subject notes, provide external links). Less common were the more "interactive" options, discussion lists and online chat groups. About three quarters of respondents used the Internet to answer student queries (probably by email). As with administrative uses, most of the benefits are similar for students and the institution, with (again) some differences for instances where the benefits save money more for the institution than students. More respondents saw the differences in the benefits of educational uses flowing to students than to institutions than with administrative uses. In three of the uses, saving time was not the most common benefit identified. These were the provision of external links to additional resources, discussion lists and online chats, where improved quality of information and more information were more commonly identified.

FUTURE TRENDS

We believe that research into the use of the Internet for educational purposes will continue to expand, as the "added value" opportunities to provide a better service to students begin to mature. At the same time, we believe that the administrative uses will continue to expand, without perhaps the recognition or body of research that is devoted to learning outcomes. Although this is understandable, the administrative improvements that the Internet can provide should not be ignored completely.

CONCLUSION

The majority of tertiary educators use the Internet to supplement existing modes of delivery. Importantly, the Internet is providing a number of added value supplemental benefits for subjects and courses delivered. There are two aspects to subject delivery to where added value benefits may be applied, and that is in the *administrative tasks* associated with a subject and the *educational tasks*. Most of the reported advantages gained from online supplementation of teaching relate to cost savings in terms of efficiency, flexibility and/or convenience. These represent the traditional added value benefits of lower cost and faster access to goods in the commercial world. The measures of *money savings*, *time savings*, *improved quality* and better *product information* can be used as categories to measure the benefits gained from the introduction of IT to supplement teaching.

A survey of 43 tertiary educators, conducted through the IS World discussion list, revealed similar usage levels of administrative and educational features to aid tertiary education on the Internet. The administrative uses showed slightly more benefits for the institution than for students and vice-versa for educational uses. In both types of uses, their adoption seemed to be based upon how difficult the feature was to set up as well as the added value benefits it provided.

KEY TERMS

Administrative Tasks: The tasks that support educational tasks (such as enrolment, recording results, and so forth).

Educational Tasks: Those tasks directly associated with the delivery of the educational component to students (e.g., lecturers, tutorials, assessment, and so forth).

Efficiency: From an IT viewpoint, this usually relates to improvements within the business, so for a business it may mean IT systems that reduce costs or perform tasks more reliably or faster.

Internet Technologies: That group of technologies that allow users to access information and communication over the World Wide Web (Web browsers, ftp, email, associated hardware, internet service providers and so forth).

Value: The amount a "buyer" is willing to "pay" for a product or service. A business can add value by being a low cost providing, providing a unique or differentiated product or service or filling a niche market.

Text Mining in the Context of Business Intelligence

INTRODUCTION

Information about the external environment and organizational processes are among the most worthwhile input for business intelligence (BI). Nowadays, companies have plenty of information in structured or textual forms, either from external monitoring or from the corporative systems. In the last years, the structured part of this information stock has been massively explored by means of data-mining (DM) techniques (Wang, 2003), generating models that enable the analysts to gain insights on the solutions for organizational problems. On the text-mining (TM) side, the rhythm of new applications development did not go so fast. In an informal poll carried out in 2002 (Kdnuggets), just 4% of the knowledge-discovery-from-databases (KDD) practitioners were applying TM techniques. This fact is as intriguing as surprising if one considers that 80% of all information available in an organization comes in textual form (Tan, 1999).

In their popular model to explain the phases of technology adoption (Figure 1), Moore and McKenna (1999) discuss the existence of a chasm between the "early adopters, visionaries," and the "early majority pragmatists" phases that a technology has to cross in order to become extensively adopted. From our point of view, TM is crossing this chasm yet. Although there is the existence of mature tools in the market, and an increasing number of successful case studies have been presented (Ferneda, Prado, & Silva, 2003; Fliedl & Weber, 2002; Dini & Mazzini, 2002; Prado, Oliveira, Ferneda, Wives, Silva, & Loh, 2004), it seems that the community is still leaving the second phase. However, the results presented in the case studies point out that the broad adoption of TM will happen in the near future.

BACKGROUND

When studying the relations between TM and BI, it is necessary to take into account an important intermediate layer between them: the knowledge-management (KM) process. KM refers to the set of activities responsible for carrying the information along the organization and making knowledge available where it is necessary.

To clarify the relations between TM and BI, under the point of view of a KM model, we adopted the generic KM model (Figure 2) proposed by Stollenwerk (2001). The model is made up of seven processes: (a) identification and development of the critical abilities, (b) capture of knowledge, skills, and experiences to create and maintain skills, (c) selection and validation that filter, evaluate, and summarize the acquired knowledge for future use, (d) organization and storage to assure the quick and correct recovery of the stored knowledge, (e) sharing that makes easy the access to information and knowledge, (f) application in which the knowledge is applied in real situations, and (g) creation that comprises the activities of sharing tacit knowledge, creating concepts, building archetypes, and cross-leveling knowledge. Involving the mentioned processes, there exist the aspects of leadership, organiza-

Figure 1. Moore's and McKenna's (1999) life cycle of technology adoption

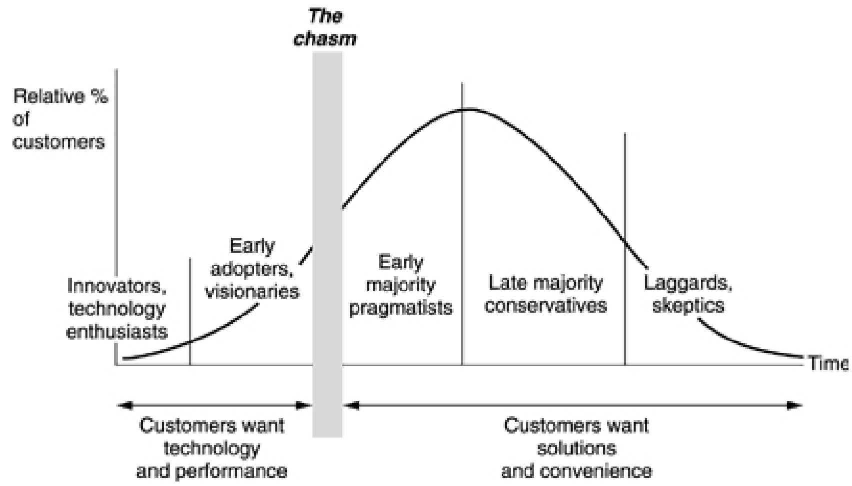

Figure 2. Generic KM model of Stollenwerk (2001)

tional culture, measuring and compensation, and technology. The main relation between TM and KM is located in the creation process. By applying the TM techniques discussed in the next section, it is possible to find patterns that, adequately interpreted, can leverage the concept-creation activity.

METHODS AND TECHNIQUES FOR TEXT MINING

Text mining can be defined as the application of computational methods and techniques over textual data in order to find relevant and intrinsic information and previously unknown knowledge.

Text-mining techniques can be organized into four categories: classification, association analysis, information extraction, and clustering. Classification techniques consist of the allocation of objects into predefined classes or categories. They are used to identify the class or category of texts in tasks such as *topic spotting* (the identification of a known topic or subject in a document) and *document routing* or *filtering* (the selection of relevant documents to a process or to someone).

Association analysis is used to identify correlation or dependencies among elements or attributes (words or concepts present in documents). It helps the identification of words or concepts that co-occur together and, consequently, to understand the contents of a document or set of documents and their relationships.

Information-extraction techniques are able to find relevant data or expressions inside documents. Typical uses of these techniques involve the creation of databases from texts or the identification of specific information (like names, dates, and e-mails) in a large set of documents.

Clustering is the process of finding relationships among texts or words and putting them together in groups of related documents. Clustering techniques are used to understand how the information or knowledge of an entire collection of documents is organized.

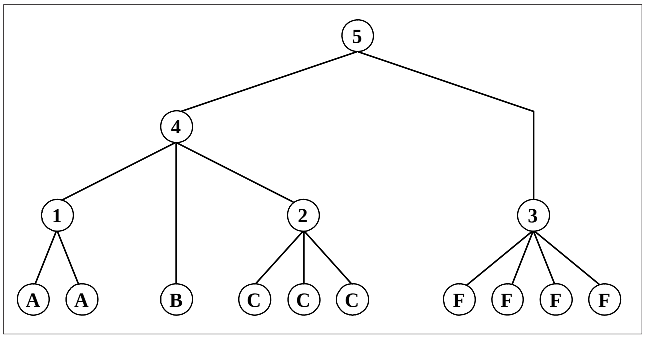
In this chapter we focus on clustering techniques because it is more appropriate to the (concept) creation phase since it helps the user analyze and understand previously unknown data, exploiting the relationship among documents and words present in a large collection of documents. The next section describes the clustering process with more detail.

CLUSTERING

Clustering is a knowledge-discovery process that identifies relationships among objects and builds clusters of objects based on these relationships (Jain, Murty, & Flynn, 1999; Willet, 1988). It is based on the cluster hypothesis (Rijsbergen, 1979), which states that similar objects tend to remain together in the same cluster as a consequence of a specific concept distance metric.

Clustering is a widely employed tool to analyze data in many fields (Everitt, Landau, & Leese, 2001; Jain et al., 1999). The idea behind cluster analysis is to find knowledge about previously unfamiliar data. Clustering methods are able to give suggestions about how specific sets of data are organized or correlated. It is possible to identify the similarity and the dissimilarity among many objects or data patterns and, based on that, construct classes or categories. Categories or classes are very important as they are the basic elements to build new concepts, and concepts are the basis of human knowledge (Aldenderfer & Blashfield, 1984).

Figure 3. Hierarchic scheme of clusters



However, since clustering indicates relationships among objects, it can be used for many other objectives. Aldenderfer and Blashfield (1984), for example, classify the goals of cluster analysis into four categories: (a) to develop a typology or classification, (b) to investigate useful conceptual schemes for grouping entities, (c) to aid in the generation of hypotheses, and (d) to test hypotheses, verifying if types defined through other procedures are really present in the data set.

Clustering Types

There are many clustering methods and this fact generates many types or schemes of clusters. According to Aldenderfer and Blashfield (1984), these methods can be classified into seven families: hierarchical agglomerative, hierarchical divisive, iterative partitioning, density search, factor analytic, clumping, and graph theoretic. Each of them creates a type or scheme of clusters that is very peculiar.

For the sake of generality, we choose to classify and detail the clustering methods according to the categories proposed by Everitt et al. (2001) and Schütze and Silverstein (1997). These categories are (a) *hierarchical* and (b) *nonhierarchical* (or *partitioning* clustering).

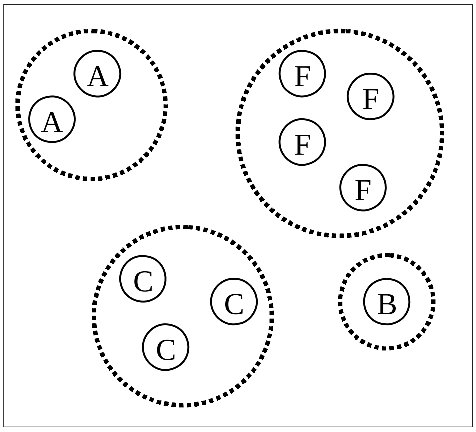
Hierarchical Clustering

In hierarchical clustering, the resulting scheme of clusters is very similar to a tree (see Figure 3). Each node represents a cluster. The intermediate clusters are clusters of clusters and the leaves are objects. The relationship among clusters is of paramount importance as it shows the specificities and abstractions among groups of objects. If the user goes up in the tree of clusters, it is possible to identify more abstract or generic groups. On the other hand, if the user goes down, more specific groups will be identified until the objects themselves are reached.

Nonhierarchical or Partitioning Clustering

When working with nonhierarchical clustering, the objects are allocated in isolated clusters and no relationship among clusters can be found. This type of clustering is also known as partitional clustering, and it is said that it generates flat (without structure) partitions of clusters (see Figure 4).

Figure 4. Flat partition of isolated clusters



Clustering Algorithms

As already stated, there are many clustering methods. More detail on these and other clustering methods can be obtained in Aldenderfer and Blashfield (1984), Jain et al. (1999), Kowalski (1997), and Willet (1988). In this section we will describe only the methods implemented in the tool used in our experiments: the Eurekha tool (Wives, 1999). The algorithms implemented come from the graph theoretic family of algorithms and are described next.

Stars

The stars algorithm analyzes the objects and tries to find groups of similar elements where the resulting aspect or format is like a star of correlated objects. In this case, the center of the star is the element that has a relation with all the other objects in the cluster, linking them together. It means that the other elements should be near or similar to this central element, but not necessarily to the others. To minimize the dissimilarity among an element that is on one side of the star with another element in another side of the star, it is defined a similarity threshold. A larger threshold among all elements in relation to the center makes the group more coherent. The more they are similar to the center (or near to the center), the more they will be similar to each other.

The algorithm starts selecting any element in the set of elements. This selection can be performed randomly or by any other method. However, the selection order influences the resulting clustering scheme.

The selected element is then elected as the center of the star (the center of the cluster). Then, this element is compared to all other elements not yet clustered (i.e., allocated to a cluster). If a relation is found, meaning that it is greater than a previously user-defined similarity threshold, the element being compared to the center is allocated to the cluster. Once all elements are compared to the star center, another unclustered element is selected and the process continues until all elements are analyzed. The elements in which the similarity to another element is not greater than the established threshold are said to be unclustered and are ignored or allocated to an isolated cluster—one to each element.

Best Star

The main problem of the star algorithm is that the order in which the elements are selected as centers influences the clustering result. Another problem is that the user has to select a threshold of minimum similarity between objects and the center, and there is not an optimal threshold to be used as a usual value. Each data set may have a different threshold. These are the greatest problems of cluster analysis that uses this kind (or family) of algorithms[1].

The best-star algorithm intends to solve these problems, allocating an element, even if it is already clustered, to the star where it is more similar (the nearest star). Somehow, a side effect is that the user does not need to establish a threshold. In this case, the elements will be reassigned to the cluster where they are more similar (i.e., nearer to the star's center).

Cliques

This algorithm is similar to the star algorithm. However, the elements are added only if they satisfy the threshold of similarity among all elements already in the cluster and not only with the central element. In this case, the elements are more tightly coupled and the quality of the resulting clusters is better.

Full Stars

Sometimes the user must know all the clusters where an element would be allocated. All the other algorithms discussed in this chapter allocate the element in the best cluster for it, according to its algorithmic restrictions. This algorithm solves this necessity, allocating an element in all clusters it has a relationship with greater than the threshold established by the user.

FUTURE TRENDS

With regard to the trends in the use of TM in BI, we can see the idea of *concept* replacing the usual approach of TM based on the words of a text. Words can lead to semantic mistakes, known as the vocabulary problem, for example, when people use synonyms or word variations.

In the conceptual approach for clustering, concepts represent the content of a textual document in a higher level, minimizing the vocabulary problem. Concepts talk about real-world events and objects, and are used by people to express ideas, ideologies, thoughts, opinions, and intentions through the language (in talks, texts, documents, books, messages, etc.).

In previous works (Loh, Oliveira, & Gastal, 2001; Loh, Wives, & Oliveira, 2000), concepts were used with success in mining processes of textual documents. Thus, using concepts as document attributes in the clustering process contributes to generate better results than using words since the resulting clusters have elements with more cohesion, besides being more understandable.

CONCLUSION

The advent of the knowledge society has imposed an important change in the context of organizations. Business competitiveness is significantly affected by the availability of knowledge about the organizational processes and the external environment. The importance of the information existing in organizations as raw material to create knowledge has been recognized since the late ’80s. As a matter of fact, the use of such knowledge for leveraging the business has led to an increasing number of KDD applications. However, the majority of these applications has been addressed to process structured data rather than the unstructured that is, by far, the biggest part of the organizational information.

The existence of mature tools to develop TM applications and the amount of textual information available in the organizations seem to be a strategic opportunity that cannot be ignored. In this chapter it was discussed the role of TM in BI, clarifying the interface between them.

KEY TERMS

Association Analysis: Use of statistics criteria to measure the proximity of two distinct objects or texts using some of their properties or attributes. A method for identifying corelation or dependencies among elements or attributes, using statistical techniques.

Classification: A systematic arrangement of objects (texts) on groups according to (pre) established criteria, or the process of allocating elements in predefined classes. The classification needs a predefined taxonomy in contrast with the clustering technique that works without previous knowledge. Sometimes it is also associated with the process of identifying classes, that is, discovering attributes that characterize one class and that distinguish this from others.

Cluster analysis: The process that includes the clustering method and the analysis of its results in order to discover and understand the contents of a set of elements, texts, or objects, and the relations among them.

Cluster: A group of elements that have some characteristics or attributes in common

Concept: It is an abstract or generic idea, opinion, or thought generalized from particular instances by the selection of meaningful terms. The concept may be identified by the use of text-mining techniques. They are used to explore and examine the contents of talks, texts, documents, books, messages, and so forth. Concepts belong to the extralinguistic knowledge about the world, representing real things in formal ways.

Knowledge Discovery: A computer-supported process that uses computational algorithms and tools as visualization methods to help a user to discover knowledge from stored data.

Knowledge Discovery from Texts: A computer-supported process that uses computational algorithms and tools as visualization methods to help a user to discover knowledge from stored textual data. It can be understood that this process gives to the user information that would not be recovered by traditional queries since the information is not explicitly stated or declared in the textual data.

Text Mining: A computer-supported process that uses computational algorithms and tools over textual data with the objective of discovering statistical patterns. Most common methods include *clustering*, *classification*, and *association analysis*. Most of the time, the expression is interchangeable with knowledge discovery from texts, however, the last is a larger process where the first one is involved.

Text Mining by Concepts: The application of text-mining methods over textual documents that are represented or modeled by concepts instead of words

ENDNOTE

[1] Another problem, already stated, is related to the algorithms that do not work if the user does not indicate the number of clusters that must be found (*k-means* and *buckshot*). This indication or selection is not necessary in the algorithm described and in all the algorithms of the graph theoretic family.

T

The Changing Library Education Curriculum

Vicki L. Gregory
University of South Florida, USA

INTRODUCTION

Libraries of the 21st century are very different places from those that existed at the beginning of the 20th century, and very different as well from the libraries of only 25 years ago. Library education has striven to keep pace with all the myriads of changes. Within the last 100 years, fortunately and necessarily in order to retain its relevance, professional library education and practice has evolved from the centrality of teaching and writing the "library hand" to providing modern curricula such as services for distance learners and Web-based instruction using course management systems such as Blackboard, WebCT, and so forth. Along the way, the library profession has often been first not only to accept but also to adopt and apply the technological innovations now common to modern civilization. Throughout, library educators have paved the way to the acceptance of innovation in libraries by instructing students to use and apply new technologies.

BACKGROUND

The revolutionary changes over the past 25 years in the educational curriculum for schools of library and information science, which are necessitated by the exponential expansion of computer-based technologies, requires an almost constant and continuous reexamination of the skills and expertise that need to be acquired by the next generation of librarians. Although much has changed in libraries, the core of who we are and what we are truly remains the same. Librarianship is and will continue to be a profession devoted to bringing users and information together as effectively and efficiently as possible. To meet that ideal, librarians have used technology to enhance and create services. In addition, it is important to meet emerging educational needs of our increasingly multicultural and diverse society. Librarians have recognized that changing expectations and lean budgets require organizations to call upon the talents of everyone (Butcher, 1999). And librarians have become more engaged in teaching and research in order to serve the needs of users better (Bahr & Zemon, 2000).

Importance of People and People Skills

Computer technologies and communication systems have had an undeniable impact on society as a whole and on our profession, but it is also critical to remember the importance of the individual and of the need for interpersonal skills in our profession, which at its heart remains basically a "people profession." We harness technology for a reason—to promote learning and the dissemination of information—and we do not simply revere technology for its own sake. With the aid of computer specialists, we could design the best information system imaginable, but unless it operates in a manner that is accessible to people, nobody will use it. The ability of librarians (whether through collecting, organizing, or retrieving information) to act as intermediaries between users and the world's information resources will, in my opinion, never become outdated (Gilbert, 1998). In sum, the rapid changes in all types of libraries and the burgeoning of new technologies for librarians to learn, while increasing the amount of information that students need to have under their "academic belts" if they are to enter successfully into a library career, nevertheless remain rooted in the need to carry out the traditional librarian roles—though hopefully faster, cheaper, smarter, and more effectively.

Preparing Students in Traditional Areas of Library Responsibilities

The traditional heart and sole of a library is and remains, of course, its collections—from the time of the great Alexandrine library of the Classical era, libraries have been, in essence, civilization's repositories of learning, and hence the materials through which learning is transmitted down the generations. Current students preparing for the future (and indeed the present) electronic library cannot be permitted to overlook the continued, lasting importance of print publications in the library's carrying out of its role, but by necessity, they must be equipped to deal with the rapidly expanding world of digital medium. Thus, collection development courses must reflect an appropriately balanced approach, emphasizing the latest technology not as an end in itself, but rather as simply another tool to use in addressing the problems arising in acquiring adequate resources for a library collection in whatever format is most appropriate for the particular library and the "task at hand" (Thornton, 2000).

As librarians and information professionals go about the process of acquiring electronic information resources in carrying out their collection development role, they must also continue to recognize and care about the important questions that have always concerned libraries, in respect to questions of future accessibility and preservation of library resources. Electronic materials—with their typical provision to libraries only through a licensing regime rather than through outright purchase—present altogether different problems for the library than do print materials. Collection development and preservation must remain an important part of the library school curriculum, no matter how dominated the library may become with electronic materials (Kenney, 2002).

In most conceptions of the libraries of the future, reference librarians may expect to continue to play many of the same reference roles that they have traditionally performed in interacting with their libraries' users. Reference librarians will continue to serve in an intermediary role to assist users in finding needed information and providing important "value-added" services through the production of instructional materials and guides to information resources. However, many of these functions, out of necessity, will be performed in media other than those that have been traditionally utilized. Collaboration and instruction may be expected to take place in a Web-based "chat" environment or by e-mail, rather than through a face-to-face meeting over the reference desk (Abels, 1996; Domas, 2001).

Reference librarians of the future must therefore acquire teaching skills as well as informational skills. They will need to be able to teach information literacy skills as students discover that just finding some online information on a topic and pushing the "print" or "download" button is not enough. In the electronic information world, librarians must be prepared to evaluate resources in a somewhat more in-depth way than was necessary when they could often depend upon refereed print journals for the majority of their information (Grassian & Kaplowitz, 2001).

In addition to all the vagaries involved with the classification and cataloging of traditional print materials, technical services librarians today, and doubtless more so in the future, will have to be prepared to cope with all the exponential varieties and forms that electronic resources may take. Technical services professionals are increasingly dealing with so many different formats and kinds of materials that may defy classification and are often not traditionally cataloged; other approaches, such as indexing and abstracting techniques and the development of in-house library-constructed databases, as well as Webliographies, may be undertaken as methods of organizing the access and retrieval process. Future graduates planning a career in the technical services areas should place a much greater focus than is presently typically allowed for in most library school curriculums on the technological aspects of information provision. Concurrently, library and information science schools need to take steps to provide for the programs and/or the courses that will include building student skills in document creation for the digital library environment. Unfortunately, all this cannot be allowed to serve as a replacement for the traditional knowledge and skills involved in cataloging and classification. As a minimum, students will need to gain a hands-on knowledge of the architecture of the infrastructure and databases behind a digital library. This means that LIS schools must develop additional specific courses, rather than trying to make room in the already overstuffed basic "organization of knowledge" classes that most schools currently offer (Vellucci, 1997).

FUTURE TRENDS

In the foreseeable future, it is probable that more and more instruction will be provided in a distance mode utilizing Web delivery, videoconferencing, and other technological means of providing instruction. A burden on many LIS faculty members at present is how to adapt a course, originally designed for a face-to-face classroom encounter to a Web-based encounter. Although the goals, objectives, and major assignments for a class might remain the same, the overall means of delivery puts more pressure on faculty members to devise new ways of delivering material (Gregory, 2003). Both virtual and print reserve materials may become problematic as distance from the home site increases. Compounding the traditional instructional component, there is the additional element of computer support on a 24-hour, 7-days-a-week basis (Young, 2002). Increasingly, when something goes wrong with the computer on a student's end, the faculty member is expected to be able to do computer troubleshooting over the telephone or by e-mail. It is common for programs and universities to provide technical support, but even so the faculty member usually gets caught up in the technical support problems, obviously much more so than when the class is taught in the traditional manner (Carey & Gregory, 2002; Newton, 2003, p. 418). Of course, when the academic computing staff person or the faculty member is unavailable, the next major organization on the campus that fields these questions is—you guessed it—the library. Librarians must be able to deal with technical, computing, or network issues and attempt to aid the beleaguered student (or faculty member). So although these issues primarily affect the teaching of library and information studies classes, they also have a major impact on the services demanded of the library (Barron, 2003).

CONCLUSION

The rapidly changing requirements in the educational curriculum of schools of library and information science resulting from the exponential expansion of computer-based technologies naturally result in a reexamination of the knowledge and skills that need to be acquired by the next wave of library and information professionals. Skills in the use of new technologies are not only important in professional work, but in the education process itself, as more and more LIS courses are being offered via the Web, with faculty and students utilizing course management software.

KEY TERMS

Collection Development: The portion of collection management activities that has primarily to do with selection decisions.

Collection Management: All the activities involved in information gathering, communication, coordination, policy formulation, evaluation, and planning that result in decisions about the acquisition, retention, and provision of access to information sources in support of the needs of a specific library community.

Course Management System (CMS): Computer software system that provides a course shell with a number of integrated tools, which may include chat software, a threaded discussion board, online grade books, online testing, and other classroom functions.

Digital Libraries: Organized collections of digital information.

Distance Education: A planned teaching and learning experience that may use a wide spectrum of technologies to reach learners at a site other than that of the campus or institution delivering the course.

Information Literacy: An integrated set of skills and the knowledge of information tools and resources that allow a person to recognize an information need and locate, evaluate, and use information effectively.

Videoconferencing: Conducting a conference between two or more participants at different geographical sites by using computer networks to transmit audio and video data.

INTRODUCTION OF KNOWLEDGE DISCOVERY IN DATABASES AND CUSTOMER RELATIONSHIPS

Customer relationships are increasingly central to business success (Kotler, 1997; Reichheld & Sasser, 1990). Acquiring new customers is five to seven times costlier than retaining existing customers (Kotler, 1997). Simply by reducing customer defections by 5%, a company can improve profits by 25% to 85% (Reichheld & Sasser, 1990). Relationship marketing—getting to know customers intimately by understanding their preferences—has emerged as a key business strategy for customer retention (Dyche, 2002).

Internet and related technologies offer amazing possibilities for creating and sustaining ideal customer relationships (Goodhue, 2002; Ives, 1990; Moorman, 1992). Internet is not only an important and convenient new channel for promotion, transactions, and business process coordination; it is also a source of customer data (Shaw et al., 2001). Huge customer data warehouses are being created using advanced database technologies (Fayyad et al., 1996).

Customer data warehouses alone offer no competitive advantages; insightful customer knowledge must be extracted from such data (Kim, 2002). Valuable marketing insights about customer characteristics and their purchase patterns, however, are often hidden and untapped (Shaw, 2001). Data mining and knowledge discovery in databases (KDD) facilitate extraction of valuable knowledge from rapidly growing volumes of data (Mackinnon, 1999; Fayyad et al., 1996).

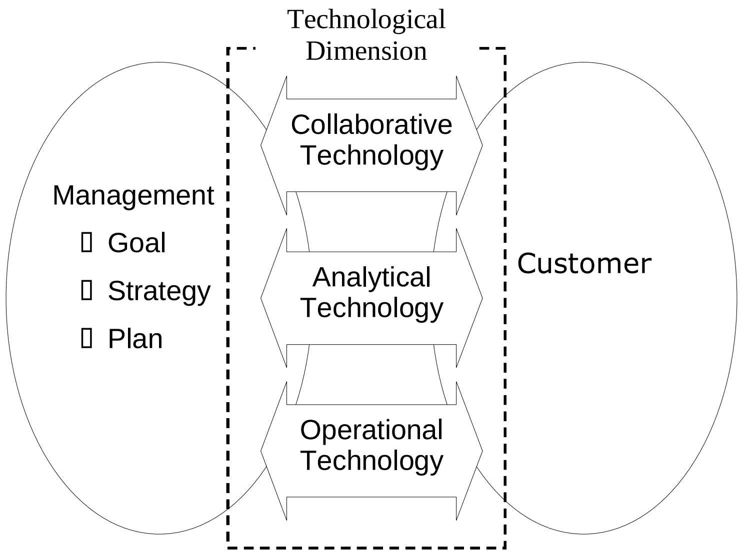
This chapter provides a brief review of customer relationship issues. The chapter focuses on (1) customer relationship management (CRM) technologies, (2) KDD techniques, and (3) key CRM-KDD linkages in terms of relationship marketing. The chapter concludes with the observations about state-of-the-art and future directions.

BACKGROUND: CRM TECHNOLOGIES

CRM is interpreted in a variety of ways (Goodhue et al., 2002; Winer, 2001; Wright, 2002). In some cases, CRM simply entails direct e-mails or database marketing. In other cases, CRM refers to customer interaction centers (CICs) and online analytical processing (OLAP), which are types of online query-driven analyses for examining stored data. Overall, CRM can be seen as a core business strategy to interact with, create, and deliver value to targeted customers to improve customer satisfaction and customer retention at a profit. It is grounded in high quality customer data and enabled by information technology (Ang & Buttle, 2002).

Three core dimensions characterize buyer-focused CRM systems: customers, management, and technologies. *Customer* service and related issues must be included in the design, implementation, and operation of any CRM system. Organizations benefit from CRM particularly when such systems benefit their customers; using CRM merely as a sales or customer service solution is a recipe for failure (Davids, 1999). *Management*'s articulation and tracking of customer relationship goals, plans, and metrics is an essential CRM component (Ang & Buttle, 2002; Greenberg, 2002). Successful CRM implementations rely on management goals, strategies, and plans that reflect customer commitment and promote a customer-responsive corporate culture at all levels of the organization (Ang & Buttle 2002; Smith 2001). *Technologies* for facilitating collaborative, operational, and analytical CRM activities are the manifest aspects of CRM (Goodhue, 2002).

Figure 1. Alignment of three dimensions of CRM



A collaborative CRM system is any CRM function that provides a point of interaction between the customer and the marketing channel (Greenberg, 2002). E-commerce and, in some cases, mobile commerce systems, offer multiple "touch points" for reaching the customers. In employing the Web and mobile technologies, it is important to ensure that such technologies enhance older, preexisting channels (Johnson, 2002). *Operational CRM* systems are technologies that span the ordering-delivery cycle (Goodhue et al., 2002). Operational CRM is concerned with automating the customer-facing parts of the enterprise (Ang & Buttle, 2002). Since the sales process depends on the cooperation of multiple departments performing different functions, integration of all such functions is critical for operational CRM systems (Earl, 2003; Greenberg, 2002). *Analytical CRM* systems analyze customer data warehouses so that the firm can detect valuable patterns of customers' purchasing behaviors. Offline data mining of customer data warehouses as well as online analytical processing (OLAP) can aid in applications such as campaign management, churn analysis, propensity scoring, and customer profitability analysis (Goodhue et al., 2002). It is this component of CRM that has a clear linkage to KDD methods.

BACKGROUND: KDD TECHNIQUES

Since multiple data formats and distributed nature of knowledge on the Web make it a challenge to collect, discover, organize, and manage CRM-related customer data (Shaw et al., 2001), KDD methods are receiving attention in relationship marketing contexts (Fayyad et al., 1996; Mackinnon, 1999). Massive databases are commonplace, and they are ever growing, dynamic, and heterogeneous (Mackinnon & Glick, 1999). Systematic combining of data mining and knowledge management techniques can be the basis for advantageous customer relationships (Shaw et al., 2001).

KDD is defined as the process of data selection, sampling, pre-processing, cleaning, transformation, dimension reduction, analysis, visualization, and evaluation (Mackinnon, 1999). As a component of KDD (Fayyad et al., 1996), data mining is defined as the process of searching and analyzing data in order to find latent but potentially valuable information (Shaw et al., 2001).

KDD constitutes the overall process of extracting useful knowledge from databases. It is a multidisciplinary activity with the following stages (Brachman et al., 1996; Bruha et al., 2000; Fayyad et al., 1996)

- Select the problem area and choose a tool for representing the goal to be achieved
- Collect the data and choose tools for representing objects (observations) of the dataset
- Preprocess the integrating and cleaning data
- Data mine—extract pieces of knowledge
- Postprocess the knowledge derived: test and verify, interpret and apply the knowledge to the problem area at hand

In Web-based relationship marketing, three distinct categories of data mining have emerged: Web content mining, Web structure mining, and Web usage mining (Jackson, 2002). Web usage mining is also referred to as clickstream analysis (Edelstein, 2001). Valuable information hidden in the clickstream data of many e-commerce sites can provide sharp diagnostics and accurate forecasts, allowing e-commerce sites to profitably target and reach key customers (Moe, 2001). Such Web-based CRM systems require large, integrated data repositories and advanced analytical capabilities. Even though there are many success stories, Web-based CRM projects continue to be expensive and risky undertakings. OLAP refers to the various types of query-driven analyses for analyzing stored data (Berry & Linoff, 1997). Data mining and OLAP can be seen as complementary tools (Jackson, 2002). Both Web-based CRM systems and OLAP, in general, involve vast volumes of both structured and unstructured data. One common challenge with managing this data is to incorporate unstructured data into a data warehouse. Traditional database systems are not designed for unstructured data.

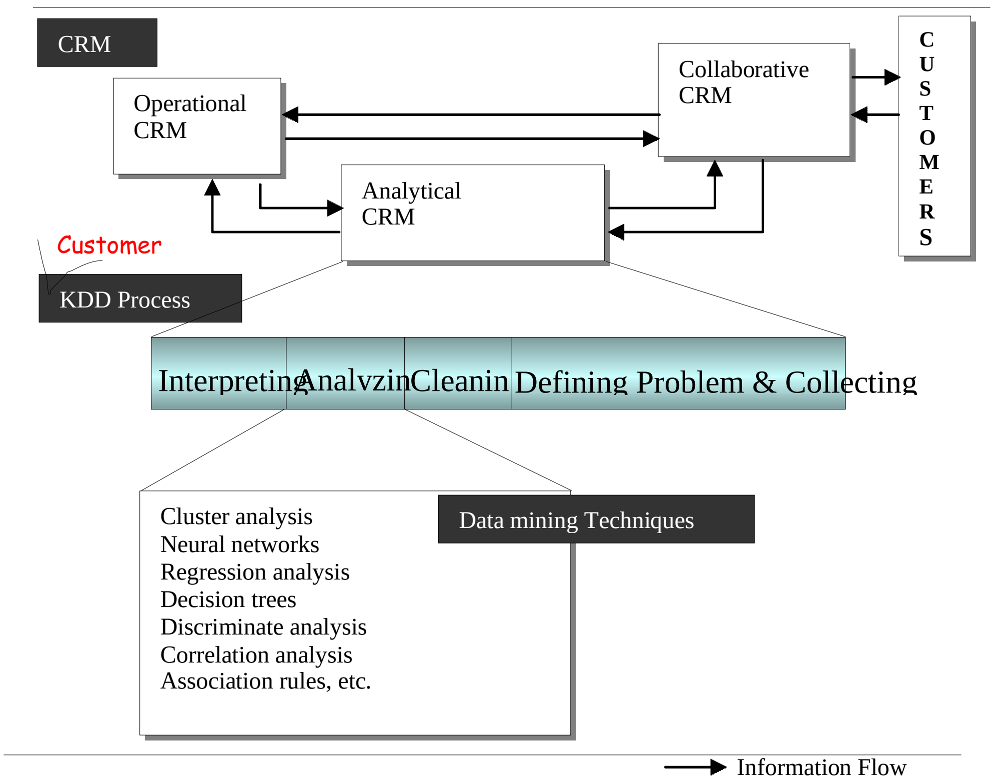
In general, research in KDD is intended to develop methods and techniques to process a large volume of unstructured data in order to retrieve valuable knowledge that is hidden in these databases, and that would be compact and abstract; yet understandable and useful for managerial applications (Bruha et al., 2000).

EXPLORING THE CRM-KDD CONNECTION

Figure 2 explains the CRM-KDD linkage from a process point of view. The importance of gaining knowledge has been well recognized. In line with this notion, CRM starts with understanding customers and gaining in-depth knowledge about customers. Therefore, the intersection between KDD and CRM can be seen as the analytical CRM part of CRM systems and customer knowledge discovery in database processes of overall KDD process as shown in Figure 2. Collaborative CRM systems help collect accurate information from customers, while operational CRM can capitalize on the result of the analyses. The problem definition stage of KDD process can be completed also in the management dimension of CRM. Following the definition of KDD and data mining, techniques for data mining are included under the analysis stage of KDD.

In relation to marketing issues, with help of CRM and KDD technologies, database marketing and one-to-one marketing methods have come to the fore. The strategic goal of database marketing is to use collected information

Figure 2. CRM & KDD process connection



to identify customers and prospects, and to build continuing personalized relationships with them, leading to greater benefits for the individuals and greater profits for the corporation (Kahan, 1998). Database marketing anticipates customer behavior over time and reacts to changes in the customer's behavior. Database marketing identifies unique segments in the database reacting to specific stimuli such as promotions (McKim, 2002).

One-to-one marketing represents the ultimate expression of target marketing—market segments with just one member each—or at least one at a time (Pitta, 1998). It relies on a two-way communication between a company and its customers in order to enhance a true relationship, and it allows customers to truly express the desires that the company can help to fulfill (Dyche, 2002). A promising solution to implementing one-to-one marketing is the application of data mining techniques aided by information technology. Data mining allows organizations to find patterns within their internal customer data. Uncovered patterns can lead to actionable and meaningful target segments.. Armed with such information, organizations can refine their targets and develop their technology to achieve true one-to-one marketing (Pitta, 1998).

As an extension of one-to-one marketing, the concept of permission marketing is focused on seeking customers' consents about desired marketing methods. Customers not only need to communication, they need to be able to stipulate how and when they wish to be approached (Newell, 2003). One-to-one and permission marketing rely heavily on information technology to track individual customers, understand their differences, and acknowledge their interaction preferences (Dyche, 2002).

Data mining methods allow marketers to sift through growing volumes of data and to understand their customers better. Shaw et al. (2001) introduce three major areas of application of data mining for knowledge-based marketing: (1) customer profiling, (2) deviation analysis, and (3) trend analysis. Also, Jackson (2002) notes that data mining may be used as a vehicle to increase profits by reducing costs or raising revenue. Following are some of the common ways to use data mining in customer relationship contexts.

- Eliminate expensive mailings to customers who are unlikely to respond to an offer during a marketing campaign.
- Facilitate one-to-one marketing and mass customization opportunities in customer relationship management.

Many organizations use data mining to help manage all phases of the customer lifecycle, and CRM systems can benefit from well-managed data analyses based on data mining. Table 1 summarizes the relationship marketing issues and includes the possible customer analyses and relevant data mining techniques.

Table 1. Customer relationship related data analysis and data mining tools

	CUSTOMER RELATIONSHIP MARKETING ISSUES		
	Database Marketing	One-to-One Marketing	Permission Marketing
Issue	Understanding customers with the database on customer behavior over time including reactions to changes	Communicating with customers as individuals Developing custom products and tailored messages based on customers' unspoken needs.	Seeking customers' agreement about desired marketing methods.
Challenge	Identifies unique segments in the database	Find patterns within the internal customer data. Track individual customers Understand their differences	Track individual customers Understand their differences Acknowledge their interaction preferences Stimulate the customer's response
Possible analysis	Segmentation	Classification Prediction	Classification Dependency Analysis
Datamining Technique most likely used	Descriptive and visualization Cluster Analysis Neural networks	Regression analysis Neural networks Decision Trees Discriminant Analysis	Descriptive and visualization Neural networks Regression analysis Correlation Analysis Decision Trees Discrimination Analysis Case-Based Reasoning Association Rules

FUTURE TRENDS

Due to the advance of information technology, there are more opportunities to collect data about customers. The Internet provides and promotes interactive communications between a business and its customers and leads to an increasing volume of rich data about customers.

However, in interactive marketing contexts, customers are also able to block out the intrusive marketing actions, and, therefore, appropriate depth and width of permissions should be obtained (Godin, 1999; Krishnamurthy, 2001). Understanding customers will become more critical as new information technology is developed.

Furthermore, companies and customers will have opportunities to co-create products, pricing, and distributions. Information technology provides these opportunities by allowing companies to assess each customer individually, and then to determine whether to serve that customer directly or through a third party and whether to create an offering that customizes the product or standardizes the offering (Sheth et al., 2000). All of the decisions should be based on thorough analyses of customer data and accurate knowledge generation about customers.

In addition to knowledge generation, knowledge sharing and dissemination through the organization should be considered. Shaw et al. (2001) argued that ownership and access to the marketing knowledge, standards of knowledge interchange, and sharing of applications become critical. In various organizational environments, both managing KDD processes to generate customer knowledge and managing customer relationship based on the knowledge generated and shared through organizations are challenges for the future.

CONCLUSION

This chapter offered a brief review of customer relationship issues. CRM systems consist of management, technology, and customer dimensions. CRM technologies are divided into three categories: analytical, operational, and collaborative CRM. As the importance of knowledge increases, KDD techniques are receiving attention as systematic processes to generate knowledge. Although CRM and KDD began separately, the two concepts have points of convergence. This chapter highlighted some of the intersections between the two.

Different relationship marketing issues have emerged; these issues rely increasingly on CRM and KDD technologies, especially for in-depth analysis. Various data mining techniques and KDD processes exist and provide the right tools to solve relationship marketing problems. While companies are eager to learn about their customers by using data mining technologies, it is very difficult to choose the most effective algorithms for the diverse range of problems and issues that marketers face (Kim et al., 2002). Even though Table 1 illustrates the main relationship marketing issues, the challenges, and the potential analytic data mining tools, it is the analyst who decides creatively which tool is appropriate for what situation and how to interpret the results.

From a process point of view, gaining customer knowledge becomes critical for managing customer relationships, and systematic knowledge generating processes are of great benefit. For effective customer-centric marketing strategies, the discovered knowledge has to be managed in a systematic manner.

KEY TERMS

Clickstream Data: Web usage data. A virtual trail that a user leaves behind while surfing the Internet (e.g., every Web site and every page of every Web site that the user visits; how long the user was on a page or a site).

CRM – Customer Relationship Management: A core business strategy that promotes interactions, creates and delivers value to targeted customers to improve customer satisfaction and customer retention at a profit. It is grounded in high quality customer data and enabled by information technology.

DM – Data mining: The process of searching and analyzing data in order to find latent but potentially valuable information and to identify patterns and establish relationships from a huge database.

E-Commerce: Any business done electronically. The electronic business where information technology is applied to all aspects of a company's operations.

KDD – Knowledge Discovery in Databases: The process of data selection, sampling, pre-processing, cleaning, transformation, dimension reduction, analysis, visualization, and evaluation for the purpose of finding hidden knowledge from massive databases.

OLAP – Online Analytical Processing: Various types of online query-driven analyses for examining stored data. OLAP enables a user to easily and selectively extract and view data from different points-of-view.

The Impact of IT on Business Partnerships and Organizational Structures

T

Fang Zhao
RMIT University, Australia

INTRODUCTION

Over the past decade, with the advent of the Internet, organizations have changed the way they communicate internally and externally, the way they are configured, and the way they build partnerships. Today's complex and volatile business world calls for changes and alternatives to the old and conventional paradigm of organizational design and new ways of doing business with others. E-business becomes one of the most important forces shaping today's business. Virtual corporations and e-partnerships become increasingly popular in the perception of managers and in business operations.

This article explores the changing nature, process, and practice of business relationships and network form of organizations in cyberspace. It also identifies and discusses a series of management issues raised in the processes of e-partnerships and virtual organizations.

BACKGROUND

The virtual organization, which is actually a network form of organization, is a revolution in organizational design and has changed the definitions, boundaries, and forms of inter-organizational collaboration and partnerships. The network form of organizations is the defining business transformation of this generation (Malone & Davidow, 1994; Jin, 1999; Hagel & Singer, 2000). Cisco, for example, is a network of suppliers, contract manufacturers, assemblers, and other partners which is connected through an intricate Web of information technology. Seventy percent of Cisco's product is outsourced to its e-partners through Cisco's network (McShane & von Glinow, 2000).

As shown above, virtual organizations rely on IT network and e-partnership. Theoretically, e-partnership refers to a partnership relying on electronic (information) technologies to communicate and interact amongst partners. In practice, the term e-partnership is mostly associated with e-commerce or e-business partnerships. It may take different forms and involve various partners from or between virtual enterprises and brick-and-mortar companies, depending on the nature of e-business activities. It flourishes in particular in supply chains through adding electronic components to the business partnership across firms (O'Toole, 2003). For example, in the manufacturing industry, the e-partners may include raw materials providers, component manufacturers, final assembly manufacturers, wholesalers, distributors, retailers, and customers (Cheng, Li, Love & Irani, 2001). This supply chain may involve a number of—even hundreds or thousands of—suppliers and distributors. The use of the Internet and other electronic media and the introduction of inter-organizational information systems are constitutive to e-partnerships and lead to the growth of virtual organizations.

E-partnerships share some common characteristics with traditional inter-organizational partnerships. But they are different in many ways and thus require different strategies and structures to manage them. Bell (2001) and de Man, Stienstra, and Volberda (2002) studied the differences and found that e-partnerships are generally entrepreneurial and less planned in nature, must move at Web speed, require flexible network structure, and have a short lifespan.

E-partnerships as "a new breed of online alliances, are fast emerging as the result of an incredible amount of Internet business in recent years" (Trask, 2000, p. 46). Entering an e-partnership is no longer a soft option, but a vital need for gaining a competitive advantage and customer satisfaction in the trend of economic globalization (meaning an increasing trend of economic integration worldwide). On the other hand, globalization is pushing companies to build informal network organizations, such as virtual organizations, that are able to work in a faster, cheaper, and more flexible way. E-partnerships and virtual organizations are products of the globalization and IT advancement over the past decade and they have fundamental synergy between them. They interrelate and interact with each other in this digital era.

ADVANTAGES

The greatest advantage of e-partnership and virtual organization lies in the fact that they eliminate the physical boundaries of organizations, and that cross-functional teams and organizations are able to operate and collaborate across space and time by communicating with each other via electronic channels. The Internet becomes the most important interface between participating organizations, teams, and individuals. E-partnerships and virtual organizations enable businesses to sell and deliver products and services across the world in a more efficient way in terms of speed and cost. Amazon.com, Priceline.com, and E*Trade are some of the successful e-businesses that have depended on, and maximized profits from, e-partnerships.

Other perceived benefits of e-partnerships and virtual organizations may include greater business opportunities, better integration of suppliers and vendors, better management information, lower operational costs, better market understanding, and expanded geographical coverage (Damanpour, 2001). E-partnerships and virtual organizations may also offer the opportunity of consolidating resources of all partners and organizational flexibility as other forms of inter-organizational partnerships and alliances do.

In this rapidly changing competitive landscape, few organizations can rely on their internal strengths only to gain a competitive advantage in national and/or international markets. Inter-organizational collaborations, alliances, joint ventures, partnering, and the like are gaining unprecedented momentum, regardless of their organizational and management structures and styles and communication channels. An organization's resources are limited in one way or another. Forming a business e-partnership and taking a network form of organization is increasingly one of the most popular strategies available to an organization to take advantage of an Internet highway on the one hand and share risks, capabilities, and revenue with partners on the other. The driving forces behind building an e-partnership and a virtual organization share a lot in common with those driving any other form of inter-organizational collaboration. They include:

- to gain a competitive advantage or increase market share in national and/or global markets;
- to share revenue and expand sales between merchant and partners;
- to prevent competition loss;
- to meet changing demands of customers and markets; and
- to gain core competencies from competitors (Sierra, 1994; Dussauge & Garrette, 1999; Trask, 2000).

KEY ISSUES

However, like e-business and e-commerce, e-partnership is also facing a range of issues related to the use of the Internet, as well as the reliance on inter-organizational interfaces. The key issues identified are:

- challenges and risks of e-partnerships and virtual organizations;
- productivity and revenue sharing in e-partnerships and virtual organizations;
- transferring and sharing core competencies between participating organizations;
- power disparity; and
- quality and effectiveness of communication.

Addressing each of these issues has posed a formidable task in front of e-managers of various kinds of inter-organizational collaboration through electronic technologies and e-networks. The following discussion explores each of these issues in detail.

Challenges and Risks

On the technological side, companies that are involved in e-partnerships must participate in external business relationships by using computer interactions. This forces e-managers to re-engineer their IT strategies and resources, and re-think their ways of communicating and doing business with e-partners in a virtual environment. Main issues to be considered are IT infrastructure and managers' and operatives' knowledge and skills associated with e-business.

On the human resources' side, e-managers are surely confronting management complexities of making cooperation work. One of the biggest challenges is conflict and differences in organizational and country cultures and systems. Each organization has its own culture developed from its own particular experience, its own role, and the way its owners or managers get things done (Hellard, 1995). In addition to the cultural differences at organizational level, multi-national e-partnerships inevitably encounter barriers caused by cultural differences between nations such as clashes between western and eastern cultures. Differences exist in systems including taxation systems, online intellectual property, and online trade and law. For example, EU member states must enact legislation to ensure that transfers of data outside their boundaries are allowed only to jurisdictions that can offer adequate protection of the data. The U.S. believes that minimal domestic regulation would foster cross-border Internet trade (Damanpour, 2001). Managing the culture and system differences across organizations and across nations is one of the high agendas that challenge managers of e-partnerships and virtual organizations.

While the Internet and network organizations facilitate improved communication of data, information, and knowledge, they give rise to issues and problems of privacy, data security, and intellectual property protection in the Internet. The information database created through Internet transactions may lead to legal disputes among e-partnerships over ownership of the IP and possible loss of the potential profit generated from the IP (Greif, 2000). Moreover, electronic research projects usually involve new technologies and innovative development, which creates a high level of technological, commercial, and legal risks for every organization involved.

Productivity and Revenue Sharing

The primary aim of building e-partnerships and virtual organizations is to generate more profit and achieve the best business results through taking advantage of online resources and extensive e-networks. Trask (2000, p. 46) considered that “a well-designed revenue-sharing program may be the best and fastest way to generate online business.” Revenue sharing becomes the most important issue in e-partnerships and virtual organizations when productivity increases and revenue goes up. The nature, timing, and amount of compensation (in the form of referral fees, royalty, and commission), together with the financial stability and honesty of commission reporting, are core considerations of e-partners and crucial factors of success in sustaining e-partnerships.

Transferring and Sharing Core Competencies

According to Lei, core competencies comprise a company’s specific and special knowledge, skills, and capabilities to stand out amongst competitors. They are intangible and an integrated part of a company’s intellectual capital and un-tradable asset rather than legally protected intellectual property (Lei, 1997, p. 211). Inter-organizational collaboration provides an opportunity for participating organizations to acquire and absorb the core competencies from each other (Couchman & Fulop, 2000). This opportunity is particularly valuable for innovative business such as e-business. However, the greatest barrier is competitive concerns over information leakage. This is an unavoidable dilemma facing e-partnerships, which makes it difficult for e-partners to achieve the potential that IT technology can offer.

Power Disparity

It is normal that a decision-making body of inter-organizational collaboration and partnership is proportionately represented by participating organizations in terms of equity holdings in an online joint venture. It should be noted that due to difference in equity holdings, power disparity occurs and is likely to affect performance of inter-organizational collaboration, although division of power and responsibility has been clearly defined in legally binding agreements between e-partners.

Quality and Effectiveness of Communication

Networking and communication play a key role particularly in coordinating and liaising inter-organizational collaboration. Expanding e-networks and achieving effective communication amongst e-partners are a top priority. Like culture and commitment, communication is a soft outcome of a total quality partnership approach and the foundation for inter-organizational collaboration (Rounthwaite & Shell, 1995; Hellard, 1995; Aggarwal & Zairi, 1998). Effective networking and communication help to eliminate barriers to collaboration. Therefore, continuous improvement of quality and effectiveness of communication amongst partners is another key issue in the agenda of e-partnerships and virtual organizations.

OPTIONS

While sufficient support of IT infrastructure and resources are definitely important to successful e-partnerships and virtual organizations, reducing potential financial, commercial, and legal risks, and effectively dealing with human and cultural factors exceed the complexities of technical setup and support in building e-partnerships and virtual organizations. Organizational culture and human resources are increasingly becoming important sources of competitive advantage, as they are difficult for competitors to imitate. How to foster a robust culture and capitalize on the core competence derived from e-partnerships is a crucial and tough issue for managers. Other critical success factors for e-partnerships and virtual organizations include:

- level of accessibility, security, and compatibility of inter-organizational information systems;
- level of traffic in collaborative e-commerce activities;
- level of customer service and e-partner support service;
- level of transferring and sharing information and knowledge between e-partners;
- building and sustaining an effective virtual network structure amongst e-partners;
- level of individual and organizational commitment to e-partnerships;

- level of mutual trust, understanding, respect, and openness;
- level of corporate and business ethics and integrity;
- level of credibility of e-partners in relation to financial situation and business experience;
- level of mutual benefit through revenue sharing;
- effectiveness and efficiency of a real-time commission reporting system;
- level of performance and productivity of e-partners;
- actively pursuing and sharing core competencies;
- willingness to share power and empower amongst e-partners; and
- quality and effective networking and continuous improvement of communication.

Achieving the best collaboration among e-partners requires more than tangible resources like IT infrastructure and support. Successful e-partnership needs a high level of intangible commitment and efforts to understand the needs and values of e-partners and customers. By resorting to a total quality partnership approach, it means that business ethics, integrity, honesty, trust, and sharing are required of e-managers of inter-organizational entities at the top and of the individuals and teams throughout the entire virtual organization (Rounthwaite & Shell, 1995; Hellard, 1995; Aggarwal & Zairi, 1998). Disputes and conflicts caused by culture and system differences, like those illustrated in this article, could be reduced if e-partners could accept the differences and maintain a flexible and realistic attitude towards the differences.

FUTURE TRENDS

"The world has finally become a Global Village, not just in rhetoric, but in reality" (Hennessey, 2000, p. 34). In today's corporate world, it will be more difficult for businesses to survive without joining an e-partnership and taking advantage of the Internet. The fast expansion of Amazon.com, travel.com, and the like through e-partnerships and e-networks and their business success reinforce the importance of online strategic alliance. Corporate e-partnerships and network-based organizations will be a crucial factor and play a key role in the future development of online business activities. The future trends will be characterized by:

- a more mature (rather than experimental) nature of e-commerce and e-business practices in terms of the scope, quality, and credibility of online customer services and products;
- more needs for devising and popularizing e-supply chains due to the needs for integrating the flow of information with the flow of goods (van Hoek, 2001; Kotzab, Skjoldager & Vinum, 2003);
- greater monopoly of the flow of e-commerce and e-business by bigger online syndicates like Amazon.com through building extensive online alliances with online retailers and suppliers (Werbach, 2000);
- more brick-and-mortar companies moving online to expand their business scope and capitalize on the abundance of the Internet;
- greater reliance on joint efforts across nations in online legislation to protect IP, security, and privacy of e-commerce and e-business; and
- greater challenge for dot.com industries to achieve sustainability, due to a more uncertain economic environment and the increasing complexities of new technologies and the more globalized economy.

CONCLUSION

In today's e-business context, technology, customers, competitors, and partners can change rapidly. Technology can become obsolete in the blink of an eye, and customers can appear and disappear with a keystroke. There are practically no barriers to new entrants (competitors) in an e-business world. E-business partnerships and virtual organizations can become ephemeral and opportunistic in nature, depending on the interdependencies between partners and the extent to which their objectives have been achieved (Robbins, Bergman, Stagg & Coulter, 2003). In such circumstances, it is important that e-business managers have an insightful knowledge and are well prepared to deal with the complexities of e-partnerships and virtual organizations. This article provides a better understanding of the crucial issues in cross-firm business processes and inter-organizational partnerships in cyberspace.

Running inter-organizational partnerships implies multiplication of decision-making bodies from each participating organization, and a potential clash of interest and values amongst participants. As illustrated in this article, total quality partnership embodies the fundamental principles for managing collaborative partnerships including e-partnerships, and can be developed and extended to help inter-organizational collaboration to achieve desired outcomes. However, managing e-partnership and virtual organization is more complex than managing intra-organizational collaboration and collaboration between brick-and-mortar companies due to the IT issues, human and cultural issues, and inter-organizational partnership issues as discussed in the article. Failure to consider the complexities of any of these issues will lead to a divorce of e-partnerships and a collapse of virtual organizations.

KEY TERMS

Brick-and-Mortar Organization: An organization located or serving customers in a physical facility as opposed to a virtual organization.

E-Business (electronic business): A comprehensive term used to describe the way an organization interacts with its key constituencies, including employees, managers, customers, suppliers, and partners through electronic technologies. It has a broader connotation than **e-commerce** because e-commerce is limited to business exchanges or transaction over the Internet only.

E-Partnership: A partnership relying on electronic (information) technologies to communicate and interact amongst partners. It is mostly associated with e-commerce or e-business partnerships.

E-Supply Chain: The physical dimension of e-business with the role of achieving a base level of operational performance in the physical sphere (for more detail see van Hoek, 2001).

Intellectual Property (IP): A product of the intellect (intangible property) that has commercial value such as patents, trademarks, copyrights, and so forth.

Online Syndicate: Association of firms with a common interest formed to engage in e-business. Syndication has become an important e-business strategy of many companies.

Real Time: In the context of e-commerce, a real-time commission reporting system refers to a system in which a commission request is processed within milliseconds so that a commission report is available virtually immediately to an online salesperson.

Virtual Organization: A network form of organization that operates across space, time, and organizational boundaries through an intricate Web of information technology.

T

The Impact of Sound Relationships on Achieving Alignment

Awie Leonard
University of Pretoria, South Africa

INTRODUCTION AND BACKGROUND

International Data Corporation (CIO, 1997) surveyed 283 top executives across three vertical industries: finance, manufacturing, and retail/wholesale. They found "a strong correlation between the effectiveness of the IT department (IS organization) and the relationship between the CIO and the CEO". "We suspect that this relationship, if it is close, permits the CIO to develop the IT department (IS organization) into a service that delivers competitive advantage for the company, thus enhancing the careers of every IT professional in the organization." In other words, "a certain amount of mutual esteem will help IT (IS) function as a business partner".

In terms of alignment, sound relationships between IT and the business become even more important. Boar (1994) states that aligning with anything other than the customer leads to but momentary success. For the IT function to achieve a state of alignment with the business, it must align with the business scope, and through that business scope enable all business functions and processes to serve the customers in a superior manner.

In their research, Reich and Benbasit (1999) point out that there are two dimensions to strategy creation: the intellectual dimension and the social dimension. Research into the intellectual dimension is more likely to concentrate on the contents of plans and on planning methodologies. Research into the social dimension is more likely to focus on the people involved in the creation of alignment. The social dimension of alignment is defined as "the state in which business and IT executives within an organizational unit understand and are committed to the business and IT mission, objectives, and plans".

Another theoretical perspective supporting the concept of the social dimension of alignment is the social construction of reality. This view would suggest that, in addition to studying artifacts (such as plans and structures) to predict the presence or absence of alignment, one should investigate the contents of the players' minds: their beliefs, attitudes and understanding of these artifacts.

This article focuses on the social dimension in terms of the construction and nature of sound IT/end-user relationships and the role such relationships play in aligning IT with the business. Research in this field has shown that relationships between IT professionals and their end users are intriguing and complex, and should be seen and managed as a multidimensional environment.

IT–END-USER RELATIONSHIPS: HISTORICAL FOUNDATIONS

For many years the *culture gap* between IT departments and their end users has been characterized by unfortunate differences like distrust, skepticism and cynicism. This situation impacts negatively on the relationship of IT departments with their end users, and as such on their ability to produce service and support of high quality.

Historically, the gap was caused mainly by the difference in management culture, as well as human behaviour problems on both sides. Umbaugh (1991) states in his argumentation of organizational imbalances that too often IT exists as an adjunct to the organization and not as an integral part of the whole. This situation unfortunately still exists today and contributes to the so-called *culture gap* between IT departments and their end users. Du Plooy (1995) explains this gap as follows:

"...the 'culture gap' should be understood as a gap of misunderstanding in the sense of two different organizational 'cultures' that, according to Grindley, coexist in most organizations. The two cultures under discussion here are the 'culture' of the IT profession and the 'culture' of the rest of the organization."

The culture on both the IT department and the business side is also an important obstacle in building mutual trust, and eventually in building sound relationships between IT and its end-user environment, and as such in creating alignment between IT and the business. According to Moad (1994), the IT professional has been fighting for recognition and relevance at the CEO level for the last 25 years. He gives many examples illustrating the kind of culture that exists, which could be described as the main reason for misunderstandings and misconceptions about IT amongst today's end users.

When a user initially gets involved with the IT department, he/she is introduced to one or more IT professionals who will specifically deal with his/her problem(s). Normally a sense of mutual understanding and trust grows out of this relationship, which will definitely get disturbed the moment elements of such a relationship change without the knowledge or approval of the role players. In practice, end users very seldom get involved in the management of change which will influence a relationship in which they are involved, or even get properly informed of changes that take place on the IT side. Practice has indicated that this is a typical reason for distrust and criticism against IT departments from the end-user environment.

A review of literature on the history of relations between end users and their IT departments in the data processing industry and how they were treated tells a very sad tale. The attitude or behaviour of IT departments or the so-called DP professionals was one of "we know the best," or "we know what the end user needs and therefore we don't need to try and get the end user involved". Furthermore, even today we get end users on the business side of an organization that are illiterate in terms of computer technology. These end users are normally very uncertain when getting involved in systems development projects and in many cases are the "prey" of an IT department. As a result of this attitude, few attempts were made to keep communication with the end user on a sound basis while developing a system.

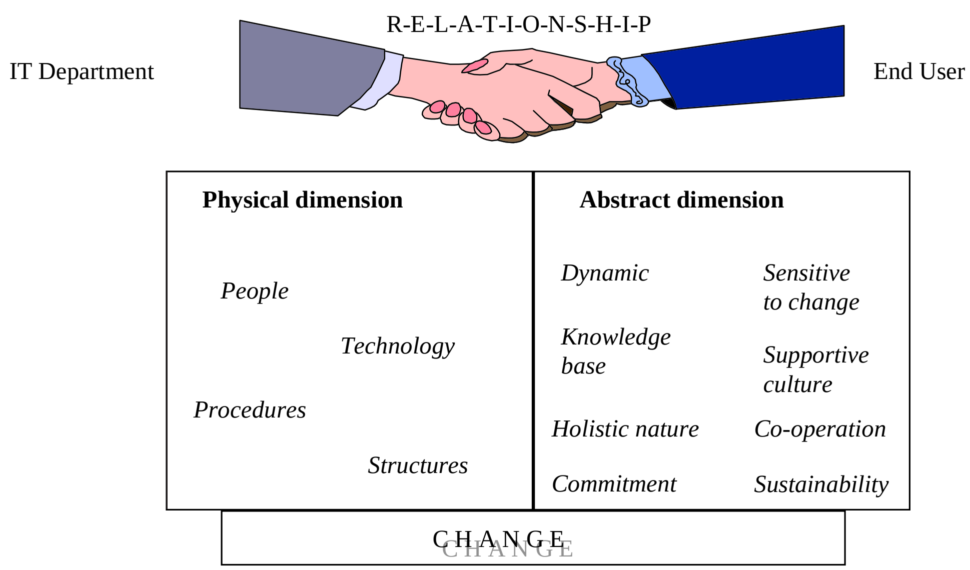
Jackson (1986) describes the traumatic period in systems development in the 1960s and early 1970s. In those days programming was considered an "art," and cost and time overruns were the rule rather than the exception. As systems development methodologies developed, control was tightened and the development process assumed many of the characteristics of an engineering discipline. In order to develop a quality product, especially in a highly complex application system, considerable skill and management expertise were required. One result of the new procedures was, if anything, a lengthening of the time it took to deliver a product. This, coupled with increased user awareness of computer potential, resulted in an increased rather than diminished backlog of applications awaiting development. According to Jackson, a study done by the Sloan School of management found that IT managers considered their application backlog to average 68% of their existing applications software portfolio. However, a survey of users found an additional 112% unbeknown to the IT managers. This illustrates, amongst other things, the typical result of poor relations between IT and its end users.

Although many efforts were made in the past to address these issues, the emphasis mainly fell on putting structures and procedures together in order to get out of the end user what his or her basic needs are. Thereafter, the IT department normally followed a lonely journey through the last phases of the systems development life cycle.

THE NATURE OF IT/END-USER RELATIONSHIPS

The preceeding paragraphs briefly describe the history of how poor relationships emerged over the years between IT departments and their end users, as well as some basic characteristics of such poor relationships. The question one can ask is, what are the characteristics of sound

Figure 1. The basic components of an IT/end-user relationship



relationships between IT departments and their end users, and how are they established? To answer the question, this section gives a definition of IT/end-user relationships and briefly discusses the nature of the different elements.

A relationship between an IT professional and an end user consists of two dimensions, namely a physical dimension and an abstract dimension. The physical dimension describes those elements that are necessary in order to enable contact between IT professional and its end users, whereas the abstract dimension describes the soft issues of such a relationship. These two dimensions enable one to fully describe the holistic nature of such a relationship and encapsulate the important elements of a support-oriented organization, namely mutuality, belonging, and connection, as mentioned by Pheysey (1993) in her book *Organizational Cultures.* The basic components of such a relationship are illustrated in Figure 1.

Without going into all the detail of the different elements of the physical and abstract dimensions as described by Leonard (2002), the article focuses on describing the most important characteristics of these elements. This will give the reader enough understanding of the social nature of IT/end-user relationships.

Physical Elements

As far as the physical dimension is concerned, the following elements could be seen as the most important:

- People: A relationship consists of all the responsible people who are involved in the systems development life cycle at a given time. “Responsibilities are negotiated and shared between systems developers and users” (Dahlbom & Mathiassen, 1993).
- Technology: Technology may be seen as one of the most important elements in such a relationship, enabling the people who participate in the relationship to communicate with one another. The importance of proper communication structures, both vertically and horizontally, are emphasized by Bommer et al. (1991) and could be seen as one of the most important organizational characteristics associated with unethical activity. Apart from the normal communication technology, facilities like help desks and Internet are of the most important factors in this regard.
- Procedures: Two types of procedures are of importance, namely organizational procedures (such as standards and policies) which already exist and which can be seen as a given, and new procedures that are being created by people because of their interaction with the given procedures and technology (DeSanctis & Poole, 1994).
- Structures: Depending upon the “type” of end user, and therefore the service and support that will be offered, relationships will differ in content as far as formal and informal social communication structures are concerned. The most common of these structures are project meetings, JAD sessions and end-user group meetings.

Abstract Elements

As far as the abstract dimension is concerned, the following elements are the most important:

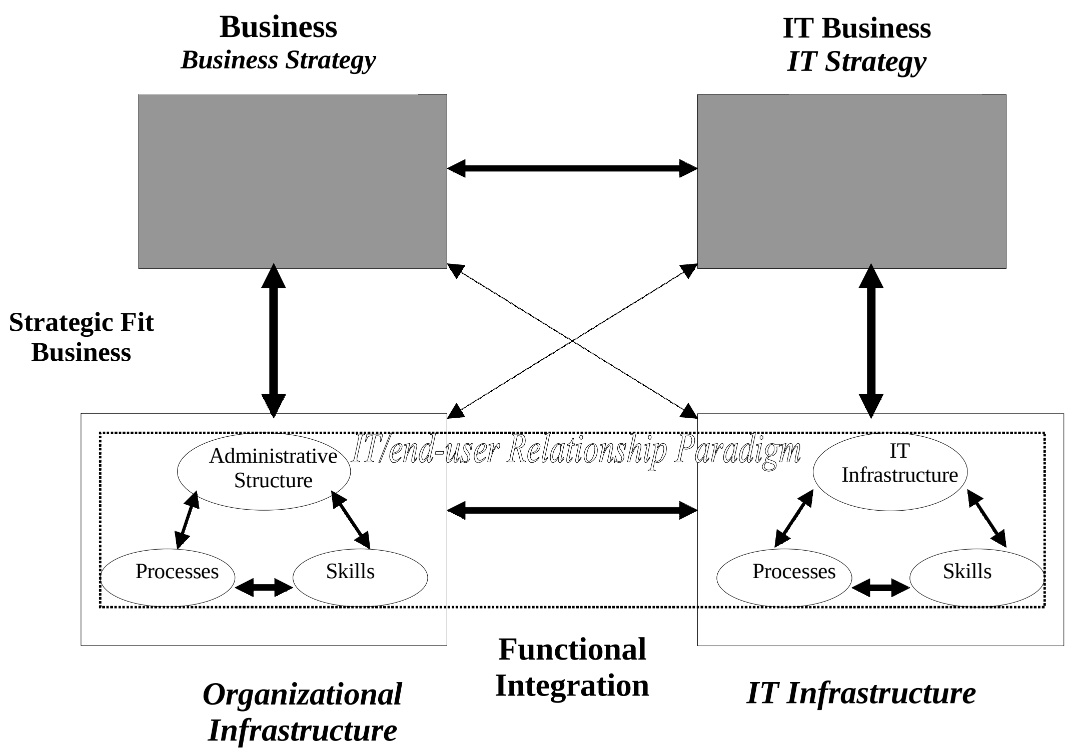
- They are dynamic: The nature of the relationships between the IT department and its end users will, amongst other things, depend upon the type of end user, as well as upon regarding the end user as a human being. According to Stokes (1991), when talking to end users, the IT professional should always bear in mind their concerns, problems, environment, and responsibilities in terms of opportunities for IT services and support.

Furthermore, he says, continuous contact with end users gives IT the opportunity to gain more insight into their problems.

- They are sensitive to change: Because of the social nature of relationships, any form of change initiated on either the IT or the end-user side may disturb a relationship. It is argued that any kind of change having an effect on any of the elements of both the physical and abstract dimensions of a relationship will in fact disturb the relationship because of its holistic nature, which will be described later.
- They have a knowledge base: The complex world of perceptions, attitudes and approaches towards developing software products by IT professionals for the end user forces us to a point where it can be said that in order to overcome the most serious problems during this communication process in a relationship, a knowledge base of some kind is required before entering a relationship.
- They have a supportive culture: In order for a relationship to be sound, continuous support and mutual understanding, amongst other things, need to be elements of such a relationship. According to Pheysey, a support-oriented organization has the elements of mutuality, belonging, and connection. Furthermore, an appreciative form of control should be applied, which means: “management is seen to be a process focused on maintaining balance in a field of relationships” (Pheysey, 1993).

- A co-operative behaviour pattern is followed by the participants: Cooperation is not a fixed pattern of behaviour, but a changing, adaptive process directed to future results. The representation and understanding of intent by every party is therefore essential to co-operation, and as such emphasizes the importance of communication during co-operation (Clarke & Smyth, 1993). Co-operation can also create new motives, attitudes, values and capabilities in the co-operating parties, which will help create and maintain a supportive culture.
- They have a holistic nature: The important elements making up a relationship between the IT department and its end users at a given time should be organized together as a whole. If any of these elements are disturbed in a negative sense, the whole relationship between the IT department and its end users is undermined. In other words, the relationship as a whole is more than the sum of its elements and therefore one can say that it has a holistic nature.
- Sustainability: A most obvious characteristic of the abstract dimension is its sustainability over a period of time. In this regard time refers to the life span of an IT/end-user relationship. One can therefore argue that out of an information systems viewpoint, a relationship of this kind will only last until the product or service reaches the end of its life cycle. In this regard, Introna (1994) states: "Structures as relationships are contingent, it appears and disappears. It could be brief (a few seconds) or long lasting (several years)."
- Commitment: Kinlaw (1989) states that one of the primary tasks of a manager is to create commitment and focus in employees. He furthermore states that managers who help employees increase their knowledge, skill and experience also are building employee commitment. In this regard it is important that managers should take note of the four sturdy supports of commitment, namely: (a) clarity of goals and values; (b) employee competencies that ensure success; (c) the degree of influence that employees have; and (d) the expressed appreciation given to employees for their contributions. Commitment should be seen as a solid block that rests on these four sturdy supports or legs (Kinlaw, 1989). Commitment has been defined by Newman and Sabherwal (1996) as a state of mind that holds people and organizations in the line of behaviour. It encompasses psychological forces that bind an individual to an action. Commitment has been argued to greatly affect the persistence of behaviour (Salancik, 1977, cited in Newman & Sabherwal, 1996).

Figure 2. Role and impact of IT/end-user relationships in the alignment of business and IT departments (based on the work of Henderson & Venkatraman, 1992)



All the elements described previously form important sub-dimensions of the physical and abstract dimensions. Each of these elements plays a specific social role in an IT/end-user relationship environment, which impacts on the soundness of such a relationship as well as the success of alignment between IT and the business. The way in which the application of this paradigm could enhance alignment is addressed in the following paragraphs.

ALIGNMENT MODEL FOR APPLYING THE IT/END-USER RELATIONSHIP PARADIGM

The theoretical construct of strategic alignment (Henderson & Venkatraman, 1992) indicates that in terms of alignment there are two distinct linkages, namely a strategic fit and functional integration. According to the model, strategic fit is the vertical linkage concerned with the integration of the external environment in which the firm competes (e.g., partnerships and alliances) and the internal environment, which focuses on administrative structure (e.g., human resources and product development). Functional integration, according to the model, is the corresponding horizontal link between business and IT. These two linkages are used to determine the relationships between IT and business (Papp, 2001).

It is clear that the paradigm of IT/end-user relationships, which is based on two dimensions, namely the physical and abstract dimensions (as described earlier), addresses the two lower domains indicated by the dotted rectangle in Figure 2. In other words, the paradigm enhances alignment in terms of organizational infrastructure and processes, and IT infrastructure and processes. The physical dimension addresses structures, skills, and processes whilst the abstract dimension addresses all the soft issues required to ensure that relationships prevail. Therefore, it is argued that if the paradigm of IT/end-user relationships is applied when service and support activities1 are performed by IT professionals, it will enhance the functional integration between IT and the business. This is the case because all the elements of the physical and abstract dimensions are of a sound nature, which directly impacts on structures, processes and skills in the infrastructure domains of the alignment model in Figure 2.

FUTURE TRENDS

Theories in terms of how relationships between an IT department and its end users could be managed are scarce. Those who do address issues in this regard (Beard & Peterson, 1988; CSC research foundation, 1994; Wike et al., 1984) do not look into soft issues, nor do they give substance to the contents of such relationships. Furthermore, none of these theories deal with the important issue of how to understand and manage the soft issues involved during the establishment and maintenance of sound IT/end-user relationships.

Managing relationships and alignment is especially critical in the outsourcing of information technology services or extending of business applications to systems in other enterprises in order to form extended enterprises. It is clear that in the future much more research needs to go into the management of relationships and service level agreements to ensure that sound relationships and alignment will be maintained.

CONCLUSION

In this article the paradigm of IT/end-user relationships was defined in terms of its physical and abstract dimensions. It was argued that these two dimensions enable one to fully describe the holistic nature of such relationships. Furthermore, in terms of business IT alignment, it was argued that the paradigm applies in the infrastructure domains (both IT and the business) and will therefore enhance alignment in terms of functional integration.

Umbaugh, R.E. (1991). Handbook of IS management (3rd ed.). Boston: Auerbach Publishers.

KEY TERMS

Abstract Dimension: The abstract dimension describes the soft issues of such a relationship.

Commitment: A state of mind that holds people and organizations in the line of behaviour. It encompasses psychological forces that bind an individual to an action.

Culture Gap: It should be seen as a gap of misunderstanding in the sense of two different organizational cultures that coexist in most organizations. The two cultures under discussion here are the culture of the IT profession and the culture of the rest of the organization.

Holistic Nature of an IT/End-User Relationship: The important elements making up a relationship between an IT professional and its end user(s) at a given time should be organized together as a whole. If any of these elements are disturbed in a negative sense, the whole relationship between the IT professional the end user(s) is undermined. In other words, the relationship as a whole is more than the sum of its elements.

IT/End-User Relationship: A relationship between IT and the end user consists of two dimensions, namely a physical dimension and an abstract dimension. The physical dimension describes those elements that are necessary in order to enable contact between IT and its end users, whereas the abstract dimension describes the soft issues of a relationship.

Physical Dimension: The physical dimension describes those elements that are necessary in order to enable contact between IT professional and its end users.

Social Dimension of an IT/End-User Relationship: Refers to all the elements in the abstract dimensions. Each of these elements plays a specific social role in an IT/end-user relationship environment, which impacts on the soundness of such a relationship as well as the success of alignment between IT and the business.

ENDNOTE

The Organizational Context in the Use of a Workflow System

Anabela Sarmento
ISCAP/IPP, Portugal and University of Minho, Portugal

INTRODUCTION

Organizations try to implement technological solutions that will improve the handling of relevant information in order to be able to respond more effectively to the opportunities and challenges presented by the environment, as they are aware of the importance of learning and knowledge management. Among the solutions offered to achieve this improvement are workflow systems (WS). The adoption of a new technology always means change but the implementation of the same information system (IS), by different organizations, does not usually result in the same changes. This implies that there are some factors that mediate the relationship between the adoption of an IS and the organization where it is implemented.

This article begins with a brief description of WS, their major characteristics and potentialities. Secondly, it describes the main organizational factors that might mediate the relationship between the technology and the organization where it will be implemented. This is followed by the description of a case study conducted with the intention of understanding, in depth, the influence of the organizational factors identified. Finally, we draw some conclusions and point up some future research trends.

BACKGROUND

Workflow Systems

WS are defined as proactive systems that manage the flow of work, during which documents, information or tasks are passed from one participant (persons, other systems, departments or even enterprises) to another, according to predefined procedures, which constitute the tasks (Plesums, 2002; WfMC, 2003). The main focus of these systems is the way the work usually evolves, that is, the *process* and not the specific information that may be contained in it (or in the documents used as a support that circulate in the process).

There are several types of WS. The categories most commonly used are: i) Production WS (these support rigid predefined rules and are used in critical processes where nothing should be allowed to fail); ii) Administrative WS (mostly based in electronic mail systems, characterized by the routing of reports, adequate for routine and low value processes), and, finally, iii) Collaborative WS (these focus mostly on the sharing of information and therefore allow joint working, used in areas with more creative needs).

Companies are especially interested in these systems because they enable changes in several organizational domains, namely: I) Economic, ii) Process Management and iii) Knowledge and Organizational Learning (see Table 1) (Hales, 1997; List, Schiefer & Bruckner, 2001; Orlikowski, 1996; Plesums, 2002;Sarmento, 2002).

These changes, although presented in isolation, should be seen as interconnected. For instance, the automatic routing of forms and documents (coordination) helps reduce task completion time (productivity). Also, the standardization of procedures and the capture and the performance of tasks according to predefined rules (coordination) contribute to the reduction of the number of mistakes (productivity), since all possible situations are analyzed and allowed for in the system.

Organizational Factors

The adoption of a new technology is usually mediated and conditioned by several organizational factors, namely technological, structural, social and individual, political and cultural (Bertrand & Guillemet, 1988; Bolman & Deal, 1997). These factors are summarized in Table 2.

The adoption of a new technology is a continuous process, as not all organizational factors have the same influence at the same time. Furthermore, all the factors mediating the adoption of a technology interact with each other, influencing the effects of the adoption and use of new IT. Thus, the complex relationships between these factors must be analyzed in a dynamic way. A new technology changes the organization (its structure and/or the individual roles and tasks) through the new technological characteristics it conveys and helps to establish new power relations. However, these changes themselves are also conditioned by the characteristics of the existing structure and the individuals who will regulate the choice of the technology.

Table 1. Synthesis of the most important changes due to WS, in the different organizational domains

Domains		**Changes**
Economic	Productivity	• Reduction of task accomplishment time, number of mistakes, costs, paper volume • Better product and information quality
Process Management	Coordination / control	• Automatic routing • Division of work • Standardization of procedures • Performance of tasks according to predefined rules • Decentralization • Control improvement • Monitoring
	Collaboration	• Possibility of collaboration, amongst distant participants, in time and space • Possibility of working from home
	Communication	• Elimination of time and geographic constraints • Elimination of human barriers • Computer mediated communication
Knowledge and Organizational Learning	Knowledge	• Capture rules and procedures of processes and tasks • Gather, process and distribute information • Make quality information available • Contribute to the constitution of a partial organizational memory • Help update organizational memory easily

Table 2. Summary of the organizational factors able to influence the use of an IS

Technological factors	Characteristics of the technology to be adopted and the technology already existing in the organization
Structural factors	Organizational design, the complexity, the number of hierarchical levels, the number of departments, the centralization or decentralization of power and decision making, the coordination of tasks, the formalization of procedures, the design of tasks and jobs and the degree of specialization
Social and individual factors	Multidisciplinary work teams, their distribution in time and space, their education, training, work satisfaction, skills and individual characteristics
Political factors	Who decides on the kind of technology to adopt, its design and implementation, who is going to use it, its purposes and objectives
Cultural factors	Culture, norms, rules and the reaction to change, knowledge and organizational learning capacity

LESSONS FROM A CASE STUDY

We have conducted a case study with the aim to identify changes that occurred due to the adoption of a workflow system and the organizational factors that enabled and constrained such changes. Results are summarized in Table 3.

As already stated in the introduction to this article, organizational changes that occurred due to the adoption of a workflow system are influenced either by the characteristics of the organization itself and the nature of the technology adopted, or by the relationship that is established between all the factors involved that can act as constrainers or enablers. The following paragraphs describe and discuss the role of the organizational factors that acted either as constrainers or enablers of changes.

Constrainers

The use of the WS in this organization was not implemented entirely without problems. For instance, there was an employee that had difficulties in using the system, as her computer crashed constantly due to system overload. Besides, this person also had some difficulties in understanding the functioning of the system at the beginning. Especially problematic was the system requirement of formally finishing any purchase process by expressing satisfaction. This step, although relatively simple, was, in fact, creating some difficulties, and was seen as unnecessary.

The educational background of the employees, as well as the state of their previous knowledge of how to operate computers may also have constrained the use of the

Table 3. Organizational impact due to the adoption of a workflow system

Domains		**Changes**
Economic	Productivity	• Some users consider that the system helped to shorten the process-accomplishment time; others consider that the time of the process increased (tasks are not the same for everybody; we can have different perspectives in the process). There was also a reduction in the paper volume circulating.
Process Management	Process Management (general)	• No changes in the process design. The new system was applied over the existing flow of work. However, some tasks performed before were eliminated (were seen as redundant). Tasks are performed from just one place. The support document used became electronic (instead of paper)
	Coordination/ Control	• Employees can check the status of the orders placed electronically. Forms became standardized. The number of exceptions was reduced.
	Communication and Collaboration	• Computer now mediates communication. Employees do not have to move physically from one department to another to deliver papers. The number and the frequency of informal contacts were reduced.
Knowledge and Organizational Learning	Knowledge	• The system helped to build an organizational memory easy to update and always updated. Information gathered in the system is available to all the staff members.

system. The members of staff who experienced more difficulties in adapting to the new system were also those with fewer schooling years. We cannot say for sure that their difficulties were due to lack of a college education background, as the data available do not allow for such extrapolation. However, the fact that those with a college degree had fewer problems in using the WS does corroborate this hypothesis, which in turn seems to point to the possibility that a college education may help develop some competencies and skills that are easily transferred whenever changes and obstacles have to be dealt with.

Finally, some characteristics of tasks may constrain the use of the system. In this case, the process where the WS was implemented was rather simple, not a crucial one and not performed regularly. Tasks were done sporadically, and this fact hinders the acquisition of a work routine. Thus, the obstacle is not the actual filling in of the document – a very straightforward procedure – but remembering all the steps needed to perform the task.

Enablers

In spite of the difficulties described previously, there were some factors that seemed to facilitate the use of the system. One of these factors is the educational background of the staff members. Most of the employees have a college degree. We would like to suggest that their educational background seems to allow them to develop some skills and competencies that helped to adapt and respond positively to the new system.

Individual personalities may also play a role in the successful adaptation to the use of the system. Although there were employees who experienced difficulties in using the system, at least one of them tried to overcome those difficulties and expressed interest in knowing and in exploring the system, without being told to do so.

Another aspect that seemed to enable the use of this system was the fact that the WS adopted runs on a Web-based platform. To use it, employees only need to know how to navigate on the Internet.

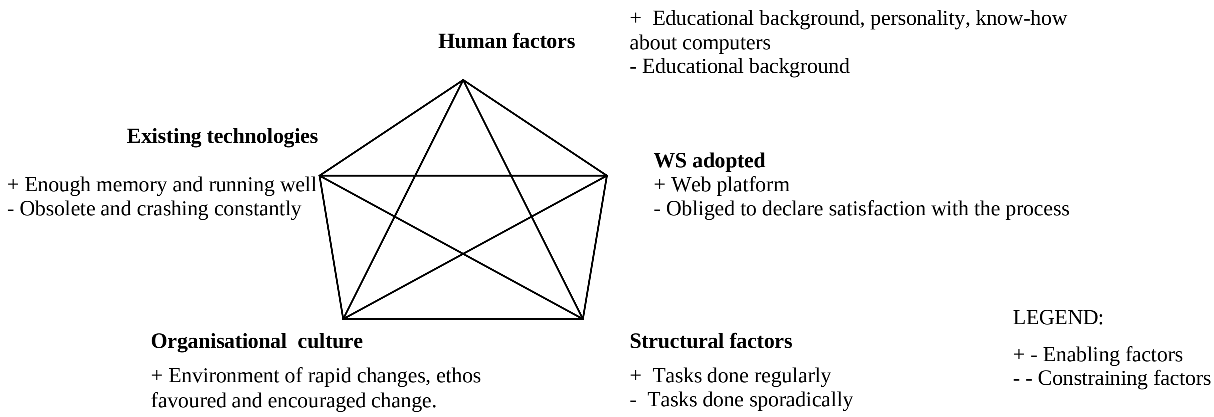
It was mentioned previously that the sporadic nature of the tasks does not help the acceptance of the system. Conversely, regular tasks enable the use of the system. So, those employees who used the system regularly became experts in the use of the WS. Interestingly, these members were also those who experienced more difficulties at the beginning of the process.

Finally, one should refer to the culture. This enterprise works in a market where changes are rapid, which means constant updating in order to remain competitive. So, changes are not unusual, but rather inevitable. And this situation might have helped the organization (and the employees involved) to better accept the new system and the changes that occurred.

Figure 1 summarizes the findings described previously.

The factors described earlier are not isolated, but interdependent. We also cannot say that one is more important than the other, as they interact constantly and simultaneously. For example, although some of the existing technologies were crashing, constantly preventing the employee from performing her job adequately, she was curious and committed enough to overcome her difficulties, even though her educational background is not as good as that of some of her colleagues. On the other hand, even those with a degree experienced some difficulties in

Figure 1. Summary of the organizational factors that enabled or constrained the use of WS



performing their tasks and learning how to use the application, probably because these tasks were infrequent. Moreover, the ethos of the company favored and encouraged change and a willingness to adopt the new system. Any expressed dissatisfaction was counteracted by the unanimous recognition that the new WS did reduce paper volume, a welcome change.

FUTURE TRENDS

The adoption of a WS in an organization should take into consideration not only the virtues and potentialities of the new system, but also consider the organizational reality of where it is going to be implemented. These characteristics of the organization are precisely what will mediate and condition those changes that might occur. Only a complete and profound knowledge of potential effects and organizational factors involved will allow a correct vision of changes caused by these systems. Furthermore, such knowledge will no doubt contribute to a better management of the process of change.

In this article we have only described a case study of an organization with particular characteristics. Also, the WS adopted was an administrative one, belonging to a specific producer. We recommend that other case studies, with different organizations and categories of WS, should be done in order to identify all the constrainer and enabler factors.

Management and application of knowledge are essential elements in the innovation process. The organizational knowledge domain is particularly important when considering the adoption and implementation of a WS. In this context, it is necessary to examine the flow of work through groups and organizations and explore how knowledge is or could be captured, managed and shared. Moreover, with the advent and expansion of e-business, another important area of research is the exploitation and use of workflow systems in the automation of business processes via the Internet. New implementation strategies are already emerging that offer e-commerce trading partners the opportunity to communicate and share information directly.

CONCLUSION

This article briefly explored workflow systems and described the application and use of such systems.

As these systems have an impact on the organization in the domains discussed earlier, we believe that future research will include the following: (1) the development of applications to be used in the different types of processes (production, administrative and collaboration/ad hoc) and (2) the exploitation of the different ways in which these systems might contribute to a better management of organizational knowledge. Some of the organizations that are concerned with these subjects and are exploring, developing and discussing issues related to workflow systems are WARIA - Workflow and Reengineering International Association (http://www.waria.com/), WfMC - the Workflow Management Coalition, (*http://www.wfmc.org/*) and the AIIM – Enterprise Content Management Association (*http://www.aiim.org/index2.asp*).

KEY TERMS

BPR – Business Process Reengineering: Analysis and redesign of workflow within and between enterprises.

Case Study: A detailed analysis of a person or group from a social, psychological or medical point of view. A careful study of some social unit (a corporation or a division within a corporation) that attempts to determine what factors led to its success or failure.

Content: Corporate knowledge stored in any form (paper, data, reports, correspondence, e-mail, multimedia, etc.).

ECMS – Enterprise Content Management System: It can be defined as an integrated approach to managing documents, Web content and digital assets. It combines the capabilities of enterprise document management system (EDMS) and content management systems with the ability to manage the full content life cycle across a growing assortment of content types.

EDMS – Enterprise Document Management System: Programs, procedures and/or software that manage, control and provide access to electronic documents.

Knowledge: Knowledge can be perceived as a discrete, objective, largely cognitive entity, susceptible of being classified as tacit and explicit, or it can be considered as a process or practice of knowing, being socially constructed and embedded in practice.

Knowledge Management: An organization that considers knowledge as a discrete entity will develop knowledge stores (repositories) and will try to capture the organization's knowledge by software. An organization that puts in perspective knowledge as something social will consider that knowledge resides in the minds of employees and cannot be captured. And thus, managing knowledge means managing people and the interactions among them.

Workflow: Term used to describe the tasks, procedural steps, organizations or people involved, required input and output information, and tools needed for each step in a business process. The workflow management focuses on processes rather than documents.

The Past, Present, and Future of End-User Performance

I. M. Jawahar
Illinois State University, USA

INTRODUCTION

Over the last decade, end-user computing has become an integral part of the organizational landscape. The emergence of end-user computing can be attributed to the necessity to manage and to effectively use information to function in a knowledge-based economy. Because of the increased organizational computing needs, computer literacy requirements have skyrocketed for clerical and support staff and for many middle and senior management positions (Bowman, Grupe, & Simkin, 1995). The proliferation of microcomputers and the availability of sophisticated user application tools (Shayo, Guthrie, & Igbaria, 1999) have facilitated the widespread implementation of end-user computing technology.

End-user computing has the potential to enhance productivity. However, for this potential to be realized, end users must learn EUC skills and perform at high levels. Given the significance of end-user performance to organizations, literally hundreds of studies have examined factors with potential to influence end-user performance. The purpose of this review is threefold: to review what we know about end-user performance, discuss some of the limitations of research on end-user performance, and to offer suggestions for future research on end-user performance.

BACKGROUND: FACTORS KNOWN TO INFLUENCE END-USER PERFORMANCE

Research in the areas of psychology and organizational behavior has clearly established that characteristics of the individual and the environment influence behavior and performance (e.g., Terborg, 1981). This approach, labeled the interactional approach, is an effective framework to review the factors that influence end-user performance (Jawahar, 2002).

Characteristics of End Users

To be sure, research has examined a variety of individual difference factors with potential to influence end-user performance. For instance, previous research has investigated the influence of attitudes (e.g., Jawahar & Elango, 1998; Kernan & Howard, 1990; Szajna, 1994), aptitudes (e.g., Evans & Simkin, 1989), learning styles (e.g., Bohlen & Ferratt, 1997), cognitive styles (e.g., Davis & Davis, 1990), self-efficacy (e.g., Jawahar & Elango, 2001), goal setting (e.g., Jawahar & Elango, 2001), experience (e.g., Dambrot, Silling, & Zook, 1988), education (e.g., Davis & Davis), age (e.g., Czara, Hammond, Blascovich, & Swede, 1989), and sex (e.g., Harrison & Rainer, 1992) on end-user performance. Organizations and managers can influence some of these individual difference factors, such as attitudes, aspiration or goals, and self-efficacy, more than other factors (e.g., aptitudes, learning/cognitive styles, and demographics). Therefore, this review focuses on the former set of factors.

Attitudes. The preponderance of research on end-user performance has focused on attitudes toward computers to predict end-user performance. However, these studies have generally reported inconsistent results. About one half of the studies that examined the relationship between attitudes and end-user performance have reported a relationship. While some of these studies reported a positive relationship (e.g., Nickell & Pinto, 1986), others have reported a negative relationship (e.g., Hayek & Stephens, 1989). Alternatively, roughly one half of the studies failed to find a relationship between attitudes and end-user performance (Kernan & Howard, 1990; Szajna, 1994). After reviewing these studies, Jawahar and Elango (1998) attributed the inconsistent results to the fact that many of these studies had *incorrectly* used the constructs of computer anxiety and negative attitudes toward computers interchangeably (see Kernan & Howard) and had relied on global attitudes to predict end-user performance.

Drawing on Ajzen and Fishbein's (1980) behavioral intentions model, Jawahar and Elango (1998) theorized that behaviors or outcomes could be best predicted by attitudes that specifically relate to those behaviors than by more global and general attitudes. They proposed that attitude toward working with computers is much more specific and relevant to performance of tasks which require the use of computer skills than the more general attitudes toward computers. Individuals who hold favorable attitudes toward working with computers are more likely to practice and learn end-user computing skills, and evidence higher levels of performance on tasks that require the use of those skills than those who hold less favorable attitudes. As expected, Jawahar and Elango found that attitudes toward working with computers but not attitudes toward computers explained unique variance in end-user performance. These results were replicated in a follow-up study (Jawahar & Elango, 2001). These two studies together with previous research indicate that attitudes that are specific to the task of working with a computer or a particular software package or packages are more likely to be predictive of end-user performance.

Goals. The positive effect of goal setting on task performance is one of the most robust and replicable findings in the psychological literature (Locke & Latham, 1990; Locke, Shaw, Saari, & Latham, 1981). Literally, hundreds of studies have been conducted on goal setting in a variety of settings and with a wide range of subjects including managers, engineers, and scientists (Locke & Latham). Research on goal setting has documented that specific and difficult or challenging goals lead to higher levels of performance than the absence of goals, easy goals, or "do your best" goals (Locke et al.). Locke and Latham have shown that goal setting, when combined with feedback or knowledge of results, leads to high levels of performance. Thus, goal setting is most likely to improve task performance when the goals are specific and sufficiently challenging, and feedback is provided to show progress in relation to the goal. In a series of two studies, Jawahar and Elango (Jawahar, 2002; Jawahar & Elango, 2001) found that end users' goals to learn and master a software package is in fact strongly related to their performance with the software package.

Self-Efficacy. Self-efficacy is the belief in one's ability to effectively complete a task or exhibit a specific behavior (Bandura, 1982). Theory and research on self-efficacy suggests that, in contrast to individuals with low levels of self-efficacy, the highly efficacious are less apprehensive of change, set more challenging goals, exert more effort, persist in the face of difficulty, and achieve higher levels of performance (Jawahar, Stone, & Cooper, 1992). Prior research has also documented that self-efficacy influences diverse behaviors and performance on various tasks including tasks involving end-user computing (e.g., Gist, Schwoerer, & Rosen, 1989; Jawahar, 2002; Jawahar & Elango, 2001; Stajkovic & Luthans, 1998). For instance, in one study, Gist et al. studied managers and administrators undergoing two types of training in the use of computer software. Trainees with higher self-efficacy prior to training performed better than their low self-efficacy peers on a timed computer task at the end of training. In another study, Jawahar and Elango reported that self-efficacy explained more unique variance in end-user performance than attitudes and goals or aspirations of end users. Enhancing self-efficacy of end users might very well be the single most effective approach to enhancing end-user performance.

Characteristics of the Environment

In contrast to the voluminous research on end-user characteristics, very little research has focused on characteristics of the environment. Even so, several different characteristics have been studied. In deciding which characteristics to include in the review, I relied on two criteria: the quality of research support for the characteristics and/or the relative ease with which organizations and managers can change the characteristic.

End-User Training. Several scholars have acknowledged end-user training as an essential contributor to the productive use of computer systems in organizations (e.g., Compeau & Higgins, 1995). The practitioner literature also supports the view that training is essential for effective use of computer technology (Finley, 1996). Because training can affect the success or failure of end-user computing in organizations (Bostrom, Olfman, & Sein, 1990; Rivard & Huff, 1988), training employees to use information technology productively has become a high priority in many organizations (Aggarwal, 1998). It is now well established that training end users enhances their performance (e.g., Gist et al., 1989). The next step, then, is to identify characteristics of training that facilitate end-user learning and performance.

Opportunity to Practice. Opportunity to practice in the training environment and in the posttraining environment is likely to affect how well trainees learn and use their newly acquired skills to perform their jobs. While the importance of practice for learning new skills is widely acknowledged (Tannenbaum & Yukl, 1992), training and work environments differ in the extent to which they provide trainees opportunities to practice newly acquired skills. For instance, Ford, Quinones, Sego, and Speer (1991) studied Air Force technical trainees after they completed training and found significant differences in opportunity to apply the training; they also noted wide variations in the lengths of time before trainees first performed the tasks for which they had been trained. Opportunities to practice newly acquired skills are likely to strengthen learning and influence how well trainees use those skills. In a study of IRS managers, Pentland (1989) found that attempts to practice trained computer skills immediately upon returning to the job had a major impact on long-term retention. These studies suggest that the opportunity to practice trained skills will significantly influence how well trainees learn and perform with those skills.

Time Constraint. In one study, Peters, O'Connor, and Rudolf (1980) used the "critical incidents" method to identify environmental constraints relevant to performance outcomes. In that study, 62 participants employed in a wide variety of jobs identified situational variables that adversely affected performance. Peters et al. identified time availability as a potent constraint. Trainees are likely to become frustrated and not learn as well when they are expected to learn and become proficient in new skills in a short amount of time. The time allotted to learn and become proficient in new skills is likely to affect how well trainees learn and use their skills. Consequently, trainees who perceive time constraints are likely to evidence lower levels of performance relative to those who do not perceive such time constraints. In a recent study, Jawahar (2002) reported that the perception of time constraint had a negative effect on end-user performance.

SHORTCOMINGS OF RESEARCH ON END-USER PERFORMANCE

The use of user satisfaction as a surrogate of end-user computing success and the lack of systematic research on characteristics in the end users' environment are two of the most obvious limitations. Because these two limitations are likely to limit the usefulness of research findings for researchers and practitioners, they are discussed next.

Surrogate Measures of End-User Performance. To date, user satisfaction has served as the most popular measure in the literature for measuring end-user computing success (Mahmood, Burn, Gemoets, & Jacquez, 2000; Munro, Huff, Marcolin, & Compeau, 1997). Use of user satisfaction as the primary measure of end-user computing success is based on the implicit assumption that satisfied users perform better than dissatisfied users (Amoroso, 1992). Unfortunately, evidence to support this assumption is lacking. Equating user satisfaction with end-user computing success is problematic because it does not tell us anything about productivity. Munro et al. aptly noted that a better measure of end user computing success than user satisfaction is necessary to justify the substantial investments in end-user technologies and in end-user training. Given that the primary reason organizations computerize their operations is to improve productivity, competitiveness, and profits, unless end users learn the skills and utilize those skills to improve their job performance, the expected benefits of end-user computing are unlikely to accrue. While perceptions of end-user satisfaction is an important measure, it is not equivalent to end-user performance, and therefore, future research should not use end-user satisfaction as a surrogate measure for end-user performance.

Characteristics of End-Users' Environment. Characteristics in the end users' environment could directly, or indirectly through their effects on characteristics of the end user himself or herself, influence end-user performance. After all, the prediction that inhibiting situational conditions could adversely affect performance is straightforward and has been expressed in several models of performance (e.g., Peters & O'Connor, 1980; Terborg, 1981). Situational factors that restrict or constrain performance are referred to as situational constraints. These include factors beyond the control of individual employees (e.g., faulty equipment, lack of resources, time constraints) that restrict the range of individual performance. Research has reported the existence of situational constraints (e.g., Peters, O'Connor, & Rudolph, 1980), and the adverse effects of situational constraints on performance is well documented (e.g., Hatcher, Prus, Englehard, & Farmer, 1991).

However, prior research has relied almost exclusively on characteristics of end users to predict end-user performance even though several models suggest that both person and environmental factors influence behavior and performance. For instance, in one study, Jawahar (2002) found that the variance in end-user performance explained by characteristics of end users reduced from 32% to 23% when they were faced with situational constraints. These results highlight the importance of examining the influence of characteristics in end users' environment with potential to influence their performance.

FUTURE RESEARCH ON END-USER PERFORMANCE

First, as noted above, studies should investigate the influence of both characteristics of the end user and the environment on end-user performance. Characteristics of end users' environment that merit research attention include attributes of the training (e.g., user friendliness of the training itself), software packages used (e.g., user friendliness, tutorials provided), and availability of posttraining support. Second, most research on end-user training has focused on training provided by the organization. Most learning, though, occurs on the job and with help from peers. The extent to which peers play a role in an end user's performance needs to be investigated. Third, not all end users are the same. Twenty years ago, Rockart and Flannery (1983) provided a framework for classifying end users. Unfortunately, many previous studies do not adequately describe the participants, making it difficult to ascertain the population to which results might generalize. It is critical that studies adequately describe the participants with reference to

Rockart and Flannery's framework. Finally, research that is likely to be of most theoretical and practical significance is research focused on the construct of end-user performance itself. For instance, it is one thing to show that X, Y, and Z factors influence performance on end-user computing tasks in a training environment or in the (end user's) job environment. What is more important is to examine if an end user's performance on computing tasks in the job environment enhances his or her overall job performance. Demonstrating the latter is likely to serve as not only the best justification for investments in end-user computing technology, but is likely to ensure organizational competitiveness, which after all, is the most important and primary reason for the emergence and need for end-user computing.

CONCLUSION

The primary purpose of introducing end-user computing technology is to improve performance and productivity, and to obtain a sustainable competitive advantage. This article reviewed research on factors that are known to influence end-user performance, discussed two significant limitations of extant research, and pointed out fruitful areas for future research. It is hoped that future research will overcome the limitations identified and address the important concerns offered as suggestions for future research on end-user performance.

KEY TERMS

End-User Performance: Performance of end users

End Users: Individuals who use software packages or computer systems that do not require programming

End-User Training: Teaching end users to learn and use organizational computing technology

Environmental Constraints: Factors in the environment with potential to inhibit or constrain one's behavior and/or performance

Interactional Approach: An approach that acknowledges that both characteristics of the personand the environment influence behaviors and outcomes.

Self-Efficacy: The belief in one's ability to successfully complete a task or execute a behavior

Sustainable Competitive Advantage: Achieving and maintaining an advantage over other competing firms

T

The Social Contract Revised

Robert Joseph Skovira
Robert Morris University, USA

INTRODUCTION

Corporate and personal behaviors express responsibility and obligation in doing business. Usually, accountable and obligated actions are explicitly given in legal contracts. The legalized versions that enforce responsibility and obligation are dependent upon moral expectations framed by a social contract.

Obligations and responsibilities influence and frame our everyday experiences. While some obligations and responsibilities are shaped into legal contracts, many of the obligations and responsibilities that govern our daily situations never see the light of day except in felt senses of duty and concerns under girding actions. Obligations and responsibilities are localized social and moral constructs arising from a communal sensibility of people in the ebb and flow of everydayness. Obligations are norms that structure human interaction and locate human relationships within a moral universe of discourse. Obligation is doing one's duty in the face of situational demands. Responsibility is owning up to the effects and consequences of actions in a social situation. Responsible behavior is local and personal.

Responsibility, also, is related to a constellation of supporting values, of which accountability and privacy are significant in their social reach. Accountability works best when private and confidential arenas of action are recognized. Being responsible carries an expectation of privacy. Other constellated expectations are access to information, freedom of speech, and information ownership, both physical and intellectual (Dhillon, 2002).

Obligations and responsibilities are social expectations framing relationships. These social relationships are based on a silent and intuitive communal agreement, the social contract. A social contract is implicit to any society and culture. Although the foundation for many written social and legal documents, the social contract is never written. It is a set of common understandings and assumptions framing situational behavior. A social group is an eventful result of a social contract: A social contract entails association. There are three great theorists on the social contract: Hobbes, Locke, and Rousseau.

BACKGROUND

Previous Ideas on the Social Contract

Hobbes

The social contract for Hobbes is a tacit affair that allows a communal association to form. Community is a natural restraint on humanity's natural perversity and propensity to selfishness and conflict. The social contract is the basis of societal authority, or the power of a society to sanction behavior. The social contract is a restraint on humanity's Darwinian-like tendency to reduce all interactions to power relationships and to coercion (Hobbes, 1988). The social contract confers the rights of citizenship and the duties—being responsive (responsible) to the now common or mutual interests (Halverson, 1972; Hobbes; Solomon, 1992, 1993).

Locke

Persons begin, for Locke, with the freedoms to act, to do what they will with their property, and to live as they see fit. All people are equal to one another. This is a natural state; it rests on natural law. The mutual agreement to join together as a community and political body rests on a social contract (Kendall, 1959; Locke, 1960). The social contract for Locke is based on natural law which argues that persons have certain rights. The notion of the social contract, according to Locke, is expressive of the values of freedom and fairness (Barker, 1970).

Rousseau

For Rousseau, each person naturally tends to self-preservation and maintenance of personal concerns. Socially agreed-upon norms are the basis of any authority within any group. The social contract is conventions of association; it is a solution to situations created when people join together to defend self and property (Rousseau, 1998). Individuals establish a society by agreeing to give up any natural rights for rights based on the collective. Individuals are dependent upon the community; the common will overrides individual will (Crocker, 1968).

Information Technology as a Frame for E-Social Contract

Information technology is a metaphor of hardware and software applications to informational situations and flows, that is, information systems, corporate or personal. Technology is an ideological stance that argues that all solvable problems are defined within technological space (Barbour, 1993; Postrel, 1998). Responsible living in today's world requires understanding technology (Monsma, Christians, Dykema, Leegwater, Schuurman, & van Poolen, 1986). Information technology enhances accountability or responsibility in business affairs (Galvin, 2000; Stoll, 1999).

Views of IT

There are several different views of information technology. These views frame our sense of the social contract. Information technology insinuates itself into our social existence and affects the nature of the social contract (Friedman, 2000). One approach sees information technology as a mere tool, a subsystem within its sociocultural environment. Societal members use information technology framed by the cultural sensibilities of the users. This view considers information technology to be value neutral. A second frame is that information technology is the culture which orients the person and the society. Information technology is the world in which we live, by which we live, and through which we live. Our mode of being in the world is technological; everything is technique. Information technology provides a new context for living. This frame changes the notion of the social contract. This paradigm is the foundation of the information society. A third sense, a hybrid, is that information technology contributes in major ways to how we understand and live in the world, but it is only one aspect of our experiences. In different ways, and to varying degrees, these perspectives frame how we are in the information society.

The Internet and E-Everydayness

The Internet and the World Wide Web are manifestations of information technology as cultural paradigm. Where there is a culture, there is a morality. Where there is a moral sense, there are obligations and responsibilities. The World Wide Web is a digital society that is intentionally created by its users. Users of the World Wide Web must be self-regulators according to accepted standards and rules (Berners-Lee, 1999; Chapman & Dhillon, 2002; Stoll, 1995). The Internet is viewed as a society of multiple local communities. These local communities encapsulate social and ethical values. The Internet is based on a social contract of sorts. The Internet expresses a normative architecture. It is a structure for responsible self-governance. The architecture is made up of free choice, free speech, honesty, and openness or disclosure (Dyson, 1997; Negroponte, 1996; Rheingold, 1993). The information highway, the Internet and World Wide Web, reflect a new social contract (Gates, 1995). The new social contract is digital and its major foci are about decentralization and globalization (Negroponte, 1995; Poster, 1995).

Information Society and E-Lebenswelt

The information society is a significant context for understanding social contract. The information society shows up in the Internet and the World Wide Web (Webster, 1995). The information society is the global connectivity of commercial interests, governmental venues, as well as individual and personal ways of being linked together globally (Friedman, 2000). The information society shapes and frames not only sociocultural environments, but also human thinking (Webster, 1995).

The information society reduces the physical social aspects of human interaction to nothing more than individuals and information flows (Borgmann, 1999). The information society is nothing but information and people. Ultimately, even people exist as information entities. Information is the focus of everything; it is everything. Because informational flows are the basis, society is not centralized; there is a diffusion of information (Brown & Dugwid, 2000). Worldwide connectivity is the information society. Contemporary life for citizens in the information society is digital behavior. Cultural behavior in the information society is the semantic behavior based on digital existence (Borsook, 2000). Information society is a cultural force, a shaper of obligations manipulating the social fabric; its foundation is the e-social contract.

MAIN THRUST OF CHAPTER

The E-Social Contract

The e-social contract is a digital affair. Cyberspace revises the social contract. The digital social contract resides in the expectations, assumptions, and constraints of online actions, such as conversations carried on in e-mails, chat rooms, and instant messaging services. The e-social contract resides in guest books and other forms of relationship building on the Web. The e-social contract informs behavior on the Internet; these are the tacit conventions of right or appropriate behavior at the right times in the right places to the right people. The digital social contract assumes a virtual trust of others encountered in cyberspace. This revision of the social contract in cyberspace as the e-social contract has at least three different faces to show the world, virtual though it may be. They are virtual communitarianism, virtual radical individualism, and virtual social capitalism.

Virtual Communitarianism

Virtual communities are communities of practice which are constituted by a set of expectations. These expectations are the values of reciprocity and trust (Blanchard & Horn, 2000; Stoll, 1995). Davenport (2002) argues that anonymity does not lead to responsible behavior. Responsibility maintains claims of rights and freedoms. The consequences of anonymity are inappropriate behaviors that take advantage of the situation. Responsible behavior is trustworthy because it is public or visible behavior. Public behavior is framed by the purpose of public space (or the virtual community or cyberspace) and what the public space has been created for (Erickson, Halverson, Kellog, Laff, & Wolf, 2002). Each virtual community generates its own set of sanctioned online behaviors and underlying policies which are expressions of the e-social contract. A virtual community has jurisdiction only over individuals who freely elect to join the group. Such normative prescriptions freely entered into have more moral force than civil governments. Communal norms or rules are tacit and implicit in the relationships that create the group and remain so until individuals abuse them or raise issues, which make the normative structures visible (Dyson, 1997). The Internet constructs a social contract for the empowering of individuals (Kinney, 1995).

Virtual Individualism

The new virtual individualism, or e-individualism, is a radical individualism and libertarian in its approach. It is a form of neo-Darwinism. This neo-Darwinism is digital in nature. Digital Darwinism is an approach that argues that the economic, biological, and Internet environments influence one another. This is a philosophy that is the ideology of technolibertarianism. The worldview of the individualist or the technolibertarian holds human nature to be a model of rational economic behavior that is always guided by enlightened self-interest. The individual is responsible or accountable for holding his or her way within the virtual marketplaces and locales in cyberspace. Digital existence is a matter of being able to compete, that is, to innovate and adapt to the situation. This worldview rejects an implicit social contract, electronic or otherwise, unless you count enlightened self-interest. Technological adaptation to its environment means pushing individual adaptation in societal and economic spheres. These spheres of influence are evolutionary. Evolutionary change is a consequence of technological change (Borsook, 2000; Schwartz, 1999; Kinney, 1995; Stewart & Williams, 2000).

Virtual Social Capital

Virtual social capital refers to an implicit willingness of individuals to work together in online settings. An important element that shows up is trust. Virtual social capital maintains digital communal behavior. A commonality of purpose is the stuff of virtual social capital. Commonalities of purpose show up in the interrelationships among virtual individuals on the Internet. Such interrelationships are social networks; they are cooperative relationships (Preece, 2002). The e-social contract is the structure of virtual social capital. Virtual social capital is the stuff of communal relationships in cyberspace. A sense of community implies that trust is an important element of social association. The unspoken and unwritten obligations of social living online show up in common trust and loyalty. Societal endeavors are grounded in shared beliefs, mores, and collaborative activities. The virtual community of practice (the basis for virtual social capital) demands adherence to its worldview. This is apparent even in cyberspace. Virtual social contract shows up in a common semantic universe and worldview. This worldview and its common senses are grounded in the e-social contract, which is a tacit set of reciprocal expectations and commitments among individuals in cyberspace. The e-social contract is the tacit set of presuppositions grounding appropriate virtual behaviors, commonly held beliefs, and expectations of benefits in the interactive settings of cyberspace (Cohen & Prusak, 2001; Dyson, 1997; Preece, 2002).

FUTURE TRENDS

As with any social setting, the tenuous and intuitive frame of the e-social contract will continue to bound and channel what is considered to be proper behavior in cyberspace. Where rifts and breaks happen in the delicate social fabric woven out of the e-social contract, the cybercitizens will strive to patch the tears in the online social cloth. This patching logically will be in the guise of generating formal codes of ethics and laws. Much of this has happened already, even from the beginnings of human interaction in cyberspace. Because of the dialectic between virtual individual actions and virtual communal sensibilities, need for articulated formal boundaries (and interpretations of the e-social contract) will continue.

CONCLUSION

This discussion has looked at the foundational contexts of behavioral expectations of travelers of the Internet and the World Wide Web. The journey in this essay began with a discussion of responsibility and obligation. These ideas are framed by the ideas of the social contract, information technology, and the information society. Information technology as a cultural frame of reference is discussed as a ground for the e-social contract. The essay sees the Internet, cyberspace, as an electronic *lebenswelt*.

KEY TERMS

Digital Darwinism: An ideology framing economic and social situations that argues that only the economically and socially fit will survive because of their ability to adapt to the digital world.

E-Social Contract: Tacit set of conventions underlying the information society and any kind of digital interaction across the Internet and the World Wide Web.

Information Society: Communal interaction based on the global informational systems of the Internet and the World Wide Web. Social relationships are informational flows and people are informational entities or links.

Information Technology: Hardware and software that constitute informational systems, as well as techniques for handling informational content and flows.

Obligation: The moral construct or concept of duty framing intentional behavior and its effects in communal situations.

Responsibility: The moral construct or concept of taking ownership of acts and the consequences in social situations.

Social Contract: Tacit and assumed set of conventions about human social involvement that frames all communal associations.

Technolibertarianism: A companion political ideology to digital Darwinism that argues in an age of global connectivity for radical individualism and no governmental regulation of digital life.

The Software Industry in Egypt

Sherif Kamel
The American University in Cairo, Egypt

INTRODUCTION

During the 1960s computing was introduced to Egypt. Its use and applications were limited to the government and the public sector. During the 1980s the introduction and diffusion of computing was widespread following the global personal computer evolution. Personal computers effectively impacted organizational development and growth due to the continuous developments in the information technology industry and caused by hardware penetration, software innovations, and the build-up of the telecommunications infrastructure. This article assesses the software industry in Egypt as a major building block of the information technology industry and a possible active contributor to business and socioeconomic development at large.

BACKGROUND

Although computing started in Egypt in the 1960s, it was only in 1985 that the active role played by the government caused a change in the way information technology was perceived as a vehicle for socioeconomic development and a tool to improve the decision-making process (Kamel, 1999). This change was accelerated by the continuous development of new tools and techniques that had direct and concrete effects on socioeconomic development. Therefore, it is perceived that the way developing countries will manage the computer driven process of change will influence whether their development goals will be promptly achieved. This will be bound to the continuous ability to invest in emerging technologies, the provision of skilled human resources and state-of-the-art information and communication technology infrastructure. Many researchers have identified information technology as the combination of information, computing and communication technologies.

Today, with the evolution and diffusion of the Internet, the integration of these technology elements is invaluable to societies around the world and is strongly contributing to globalization. The importance of information technology has been greatly emphasized in most developing countries in a deliberate effort to ensure that they do not lag behind. In most developing nations, the government has played the most important role in the diffusion of information technology, being the largest user of computers (Moussa & Schware, 1992), and through its policies, laws and regulations it still exerts the largest influence on the diffusion of information technology throughout different organizations (Nidumolu & Goodman, 1993).

In Egypt, since 1985, the driving force for the diffusion of information technology has been the government-private sector partnership. A large number of informatics projects were formulated targeting the use of information technology to leverage managerial and administrative performance in the government. These projects targeted key sectors such as education, health, employment, trade and local administration with a focus to introduce computer-based technologies with its different building blocks, including human and information resources, software, hardware, and networking resources to contribute to socioeconomic development (American Chamber of Commerce in Egypt, 2001).

A COUNTRY PROFILE

Egypt is the cradle of an ancient civilization dating back to 3000 B.C. With a population of about 70 million, it is the most populous country in the region (*www.mcit.gov.eg*). About 28% of its population is enrolled in education programs (schools and universities education) and 19 million represent its workforce (*www.idsc.gov.eg*). Egypt is trying to expand its industrial base and modernize itself technologically, with agriculture accounting for 17% of the gross domestic product, industry for 32% and a large service sector (51%) mainly built around tourism and transportation. A comprehensive economic reform program was implemented that enabled its current economic growth rate to stand at 5.7% annually with an inflation of 6% (*www.economic.idsc.gov.eg*). Estimates show that unemployment is standing at 8% and the labor force is growing at around 2.7% annually (ITU, 2001). The government of Egypt is more determined than ever to build up the national infrastructure and keep pace with the IT evolution worldwide. In October 1999, the government established a ministry for communication and information technology to embark on a master plan to build Egypt from an information and communication technology perspective that is based on the fact that as an emerging market, Egypt has already made considerable achievements in terms of economic development and is ready to move aggressively into the global market, and the only vehicle to realize that objective is through a state-of-the-art information and communication technology infrastructure (Osman, 2000).

THE SOFTWARE INDUSTRY

The software industry in Egypt is still in its infancy stage. However, it is diverse and heterogeneous in nature, with the presence of local vendors and multinationals like most mature markets. Most of the software development companies provide training services to support their products and clients. The software industry is divided into four categories, including (a) software tools, (b) packaged applications, (c) tailored applications and multimedia applications and (d) Arabization of applications. The total number of staff employed in the industry in October 2000 was estimated to be around 6,000, including managers, programmers and project managers mostly involved in the development and delivery of information systems to local and international markets (Osman, 2000). However, the figure excluded IT support staff working in the industry, the government and the private sector, which was estimated to be around 1,000 and an additional 1,000 experts and consultants in the IT training field. Software companies range in size between one to five staff members in start-ups, through to relatively mature firms with around 50 to 150 employees. The majority of firms are located in and around Cairo or Alexandria. However, recently, some of the new start-ups were located in the new industrial areas to benefit from the tax holidays they offer.

Software is the fastest growing segment of the IT industry. It represented 14% of the total market in 2000. The industry was valued at 105 million US dollars with 27% growth rate from 82.75 million US dollars in 1999 (American Chamber of Commerce in Egypt, 2002). Moreover, exports from the industry were valued at 50 million US dollars and are expected to reach 500 million US dollars by 2005 (American Chamber of Commerce in Egypt, 2001). The number of companies having software development as part of their activities is estimated to be 300 (*www.expolink.org.eg*). While these numbers are not impressive if compared with more developed software industries, they do provide a foundation from which to start a serious development of the industry. Moreover, the ministry of communication and information technology has embarked since May 2000 on a plan to train 5,000 fresh graduates annually on the recent IT and communication applications. The plan aims, over the next five years, to train 25,000 fresh graduates that could represent the core of the development of a high-tech industry (Osman, 2000). The expectation for growth in the domestic marketplace for IT products and services is expected to be in the range of 35% for services and products. Imported software accounts for 55% of software market revenues while the remaining sales comprise 19% for locally developed software, 16% for tailored software and 10% for Arabization (Osman, 2000). The market for Arabized software is large in Egypt but there is also a great potential elsewhere, with 300 million Arabic speakers in the Arab countries and worldwide to be served with language-specific software produced in Egypt.

The industry distribution channels in Egypt are still relatively underdeveloped, with around 63% of software sales without intermediaries; 50% of tailored applications are sold bundled with niche products and services. Moreover, software sales through system integrators are low because of limited subcontracting, technical cooperation and interchange of skill and specializations between local companies. Finally, function-oriented software is sold primarily through dealers. With regard to software demand, the government purchases generate 25% of total software revenues, making it the largest demand segment, with two major purchase determinants, which are quality and after-sales service for fear of system failure with cheaper systems (American Chamber of Commerce in Egypt, 1998). However, only 6% of revenues are from sales to small office and homes, which is in part due to the widespread piracy rate of 86% that plagues this segment. This figure is gradually decreasing due to the newly introduced laws against violators of software piracy laws. Also, the number of software applications sold to households is increasing due to the boom in PC sales for household usage and the spread of Internet among younger generations. The competitive advantages of Egypt's domestic software production environment have attracted numerous international producers to subcontract programming of tailored applications. Currently, 6% of subcontracting carried in Egypt is destined for export, and 15 to 20 companies are currently considered active exporters (IDSC, 2000). With the presence of over 50 Internet service providers; there is an expected significant growth in services and software applications that are Internet-based. Additionally, there is an expected increase in the development of applications of a number of key sectors in the economy, including the financial, petroleum, tourism and health sectors (Loch, Straub & Kamel, 2000).

SOFTWARE SWOT ANALYSIS

The software industry in Egypt is better analyzed through a SWOT analysis to be able to understand where it stands and where it is heading with an overview on its strengths and weaknesses and an identification of the opportunities available and the threats faced. Table 1 demonstrates the software industry in Egypt SWOT analysis.

FUTURE TRENDS

Based on the assessment of the software industry in Egypt, an action plan needs to be formulated to attempt to capitalize on the opportunities available and overcome the challenges in the market. The plan can assist Egypt in improving its software industry performance and could include (a) identifying and penetrating international target markets to realize growth, (b) investing in people to leverage the capacities of the key building block in the industry, (c) introducing incubator programs to link the industry to educational institutions and the government, (d) improving the infrastructure to ensure that firms have the vehicle to operate their business; and, (e) increasing government support role to demonstrate the value of software to Egypt's future (Kamel, 2003).

Table 1. Software industry in Egypt SWOT analysis

Strengths	**Weaknesses**
▪ Growing generation of well educated fresh graduates interested in the fields of information technology. ▪ Accumulated, though limited, experience, technical skills and capacities in the industry. ▪ Young, educated and competitive workforce with required knowledge. ▪ Low and competitive labor costs. ▪ Good command of English for dealing with overseas customers. Other languages are also learnt, such as French and Spanish. ▪ Same time zone advantage with Europe and provides a second shift for the United States. ▪ Geographically well located for most African and European cities and some Asian countries. ▪ No shortage of entrepreneurs willing to take risks in the development of their businesses. ▪ Encouragement of the government by facilitating procedures and logistics related to the software industry.	▪ Technical skills are too broad and thin. ▪ Lack of sufficient expertise in any one technology. More focus needs to be achieved ▪ Software companies spend around 6 months to turn graduates into productive contributors. ▪ Lack of skills related to project management, marketing and managing start-ups. Skills are purely related and oriented to software development. ▪ Domestic demand for software is small. ▪ Lack of management recognition to the value of using IT as a business vehicle. ▪ Minimal government role over the last decades. Some changes are starting to be introduced; however, the impact would need some time to become effective. ▪ Infrastructure level and cost is high compared to the capacities of manufacturers and beneficiaries. ▪ Corporate tax rates are high as well as taxes on print and TV advertising for promotional and diffusion purposes.
Opportunities	**Threats**
▪ Creation of software business incubators such as the smart villages' model. ▪ More proactive role played by educational institutions and training centers. ▪ Internships and scholarships from software vendors both local and multinationals. ▪ Promotional role played by software associations to activate the role of software development companies. ▪ Government support role needs to be more at the macro and micro levels. ▪ Changes in tax treatment, reduction on telephone tariffs and the introduction of new IP laws. ▪ Penetration of PCs in homes and businesses.	▪ Copyright violations. ▪ Piracy rates are relatively high. ▪ Government regulations need to be firm and enforced. ▪ Perception that software has little intrinsic value among commercial and government customers. ▪ Lack of understanding for software products and their implications on business development. ▪ Lack of market research in domestic and overseas markets that Egyptian companies could target. ▪ Lack of financial support to the industry. ▪ Limited distribution skills to serve the international software market.

CONCLUSION

Egypt has an excellent opportunity to develop the ingredients of a small but effective software industry. The level of effort and support given by government and supported by industry, finance and education will ultimately determine the level of success of the industry, making the industry profitable and contributing to business and socioeconomic development. There is a wealth of opportunities for Egypt to improve all aspects of development for the software industry. Egypt could dramatically increase the level of revenue and growth in the software business with a relatively small investment and focus to be able to attain the levels of achievement realized in nations such as Ireland and India.

KEY TERMS

Arabization: The transformation of software applications into the Arabic language in terms of usage as well as interface to be able to cater for a community that stands in 2003 at around 300 million people.

Building Blocks: Reflects all the critical success factors of the information technology industry that include: hardware, software, human resources "humanware," networking and information.

Diffusion of Information Technology: Reflects the spreading of information technology concepts among the society of implementation, whether within an organization or within the community at large.

Government-Private Sector Partnership: The teaming of different entities in the government and the private sector to realize a change and a transformation in the development of information technology at large and in the software industry in specific.

Incubator Programs: A form of collaboration usually between the industry, corporations, and the business community and the educational sector aiming at identifying industry and market needs, catering for these needs and creating employment opportunities for the society, especially young graduates.

Informatics Projects: The projects that involve in any way possible the use, design, delivery, implementation and management of information technology irrespective of the element involved, including software, hardware, and so forth.

Information Technology Industry: The accumulation of all elements of information technology design, delivery and management.

Software Industry: Focuses on the needs of the software development industry in terms of infrastructure, know-how, capacities, and development.

Tailored-Applications: Applications based on industry or organizational needs to complement the off-shelf software applications available in the marketplace.

Theoretical Framework for CRM Outsourcing

Babita Gupta
California State University Monterey Bay, USA

Lakshmi S. Iyer
The University of North Carolina at Greensboro, USA

INTRODUCTION

Customer service is emerging as a key differentiator among competitors as the explosive growth of e-commerce is changing the nature of competition among companies. This has changed the customer-related business requirements for all types of companies. With firms increasing their online operations, customers now have the ability to contact organizations through a variety of interactive and noninteractive means (such as e-mail, fax, call centers, FAQs, online chats, newsletters, snail mail, retail stores, and Web-based forums). This has led companies to consider customer relationship management (CRM) as an important part of their competitive strategy. As the focus is shifting to retention rather than acquisition of customers, companies are looking for ways to identify and engage their most profitable customers.

CRM is generally stated as a strategy that companies use to identify, manage, and improve relationships with their customers. Thompson (2001) defined CRM as a company's activities related to developing and retaining customers through increased satisfaction and loyalty. *eCRM* is a term generally used when a company's customer service operations are online. According to Cahners In-Stat Group (2001), worldwide revenues from CRM software application will increase from $9.4 billion in 2001 to approximately $30.6 billion in 2005.

CRM initiatives have high costs of implementation, typically $1 million, as well as high failure rates, estimated to be in the 55–75% range (Ericson, 2001). For large-scale CRM implementations at very large businesses, reported spending on CRM software, hardware, services, internal labor, and training have been as high as $30–90 million (Young, 2001).

For effective CRM, companies must generally adopt a customer-centric philosophy to achieve goals, such as increases in sales, customer loyalty, customer service and support, and better and effective distribution of products. CRM can produce additional profits for firms through cross selling, up selling, reduced product marginal costs, and lower customer acquisition costs (Winer, 2001). CRM applications must be designed to integrate all the customer communication points across various functional areas of a company. CRM products are generally classified into three categories (Karimi, Somers, & Gupta, 2001). These are as follows:

1. *Operational:* For improving sales, marketing, and customer service efficiency through marketing campaign management, service request management, and automation that integrate with existing processes and infrastructure.
2. *Analytical:* For collecting better customer data that contain customer buying histories and demographics data, mining this data to generate customer profiles and anticipate their needs, and thus formulating more effective customer-centric strategies.
3. *Collaborative:* For integrating communications across various channels to improve information sharing across the organization to build an integrated view of the customer, ensuring consistency of message to customer; for eCRM, one-to-one personalized Web marketing, customized product and services offerings for individual customers, etc.

Despite the rise in popularity of CRM outsourcing, there is little literature in information system (IS) outsourcing specific to CRM functions. This article presents an integrated framework of resource dependence, transaction cost economics, and social exchange theory. This framework is used to study CRM outsourcing partnerships and is an extension of the work of Grover, Cheon, and Teng (1996) and Lee and Kim (1999). This framework could be used to evaluate how these companies select a CRM vendor, how they adopt and integrate CRM technologies into their existing infrastructures, and what factors affect CRM outsourcing success.

OUTSOURCING OVERVIEW

Outsourcing is more a reflection of the strategic partnerships in the digital economy. While there are many definitions of IS outsourcing in the literature, there are three common components to these definitions, as stated in Yang and Huang (2000): "first an external provider takes over part or all of an organization IS functions; second, external provider should take the responsibility; and third, customers transfer IS functions to external provider as well as employee and part of computer facilities" (p. 227).

The nature and extent of IS outsourcing have evolved over the past few decades. IS functions of increasingly high asset specificity involving responsibilities for not just the technology but also for the business processes are being outsourced (Grover, Cheon, & Teng, 1994; Grover et al., 1996; Gurbaxani, 1996; Nam, Rajagopalan, Rao, & Chaudhury, 1996; Lee, Huynh, Chi-wai, & Pi, 2000). The reasons cited for widespread use of IT-enabled outsourcing by large U.S. companies are: slowing domestic economic growth, need to conserve costs, ability to focus on core capabilities and providing bottom-line benefits (Banking on Outsourcing, 2003).

Increasingly, the nature of the client–vendor relationship has shifted from just a contractual relationship to a tightly integrated partnership relationship for mutual benefit between the vendor and the outsourcing firm, as firms consider outsourcing a key strategic choice (Grover et al., 1996; Lee & Kim, 1999; Lee et al., 2000).

CRM implementations require far more coordination among functionally disparate organizational units, including IT and senior management involvement in IT planning, organization, control, and integration (Karimi et al., 2001). Because CRM initiatives are not confined to a particular function but rather cut across various functions of an organization, the process of CRM implementation through outsourcing becomes complicated. Because of the complex technologies involved in CRM, companies are choosing to outsource to vendors that specialize in CRM. IDC research shows that the worldwide CRM services market will increase from $19.4 billion in 2001 to $45.5 billion in 2006 (Morphy, 2002).

Outsourcing offers various strategic, technological, and economic advantages to a firm (Grover et al., 1996; Smith, Mitra, & Narsimhan, 1998; Lankford & Parsa, 1999; Ngwenyama & Bryson, 1999; King & Malhotra, 2000; Lee et al., 2000; Yang & Huang, 2000). These are as follows:

- *Strategic benefits* by allowing a firm to focus on its core competencies by outsourcing routine IT functions, being able to acquire state-of-the-art knowledge that the firm otherwise would not have the resources to acquire and improve IS service quality.
- *Technological benefits* through acquisition of complex technologies through an external vendor that otherwise would have high internal acquisition and coordination costs, high obsolescence risks, and longer time-to-market.
- *Economic benefits* through reduced costs and improved efficiencies in the long term by utilizing external vendors' expertise and economies of scale, and through favorable allocation of fixed costs.

Cost reductions through outsourcing to external vendors result through two primary approaches. One approach is adversarial, involving bidding among competing vendors to drive down prices. The other approach is through collaboration between the vendor and firm to lower transactional costs (Canon & Homburg, 2001). Outsourcing strategies involve contracting with either a single vendor or multiple vendors, though developing a relationship with a single vendor is more cost effective and leads to better outsourcing performance over the long term (Ngwenyama & Bryson, 1999).

Notwithstanding the advantages, outsourcing IS functions may fail due to complexities involved in managing long-term relationships with its vendor, resulting in loss of control of organizational assets, loss of firms' internal IS expertise and capacity to learn new skills and technologies, threat of opportunism from vendor, uncertainties and lack of decision models in choosing outsourcing vendor, and loss of morale and performance among firm's employees (Rao, Nam, & Chaudhury, 1996; Ngwenyama & Bryson, 1999; King & Malhotra, 2000). High-asset-specific IS outsourcing may also result in competitive threat from the vendor, and in addition, a firm may lose out on future business opportunities if the skills and competencies being outsourced appreciate in value (King & Malhotra, 2000).

CRM OUTSOURCING FRAMEWORK

While there are a number of studies for evaluating outsourcing of IS functions (Grover et al., 1996; Lee & Kim, 1999; Maltz & Ellram, 1999; King & Malhotra, 2000; Kini, 2000; Lee et al., 2000; Yang & Huang, 2000), there is very little literature specific to the outsourcing of CRM functions. This framework contributes to the IS field by studying CRM outsourcing partnerships through an integrated framework of resource dependence, transaction cost economics, and social exchange theories.

Resource-dependency theory refers to outsourcing to external vendors to fill resource gaps within the firm for the purpose of providing the firm with strategic competitive advantage (Lee et al., 2000).

Transaction cost theory provides an economic viewpoint to outsourcing via a set of principles for analyzing buyer–supplier (outsourcer–vendor) transactions and determining the most efficient mode of structuring and managing them (Nam et al., 1996; Ngwenyama & Bryson, 1999; Lee et al., 2000). Yang and Huang (2000) considered five factors—management, strategy, technology, economics, and quality—when determining the outsourcing benefits to the firm.

Social exchange theory is used to explain the close partnership style of an outsourcing relationship between the firm and vendor by taking into account prior relationships, trust, and culture, and their effects on an ongoing outsourcing relationship (Lee & Kim, 1999; Lee et al., 2000; Yang & Huang, 2000). Trust is perceived as the firm's belief that the vendor has in mind the best interests of the firm and will perform accordingly to achieve desired goals for the firm (Lee & Kim, 1999).

MEASURING CRM OUTSOURCING SUCCESS

The model (Figure 1) proposes to study the relationship between the level of CRM outsourcing and its success, how the CRM outsourcing success is influenced by the quality of service provided by the CRM vendor, and the partnership quality between the outsourcing company and the external vendor.

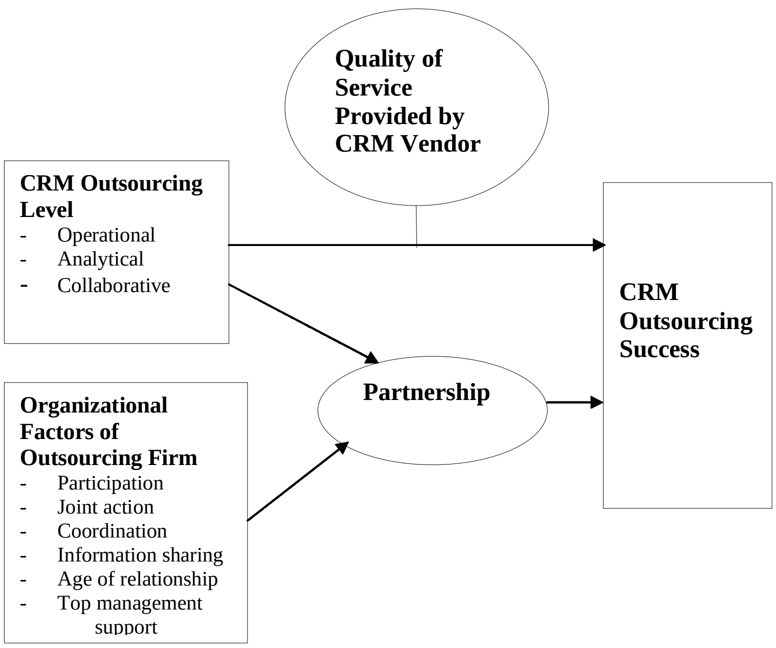
Generally, partnership relationship between vendor and firm is categorized as being of either transactional or partnership style. A transactional-style relationship is well specified in its contractual obligations. In contrast, the partnership-style relationships include sharing risk and benefit with a view to establish long-term commitment (Henderson, 1990; Lee & Kim, 1999; Lee et al., 2000).

The model also considers the effect of internal management issues and other organizational factors of the outsourcing company on the partnership quality and the success of CRM outsourcing. We consider prior outsourcing experience of an outsourcing firm, as this may affect outsourcing decisions (Nam et al., 1996; Lee & Kim, 1999; Lee et al., 2000).

MODEL CONSTRUCTS AND PROPOSITIONS

1. *CRM outsourcing level:* We adopt the classification of CRM products into three levels—operational, analytical, and collaborative (Karimi et al., 2001) and explore the relationship between level of CRM outsourcing and outsourcing success.
2. *Quality of service provided by CRM vendor:* The relationship between CRM outsourcing level and CRM outsourcing success will be stronger if service quality is higher. We adopt and adapt the two dimensions of the SERVQUAL instrument construct used in the Grover et al. (1996) study, tangibles and reliability, and add a new one, CRM technology, that pertains to product features, does one vendor provide better fit with the outsourcing company's existing technology than others, etc.
3. *Partnership:* We treat partnership as an intermediate variable. To evaluate the company–CRM vendor partnership relation, we use four dimensions: communication, trust, cooperation, and satisfaction (Grover et al., 1996; Lee & Kim, 1999).

Figure 1. Research model to measure the success of CRM outsourcing



4. *Organizational factors of outsourcing firm:* These include internal management issues that influence partnership quality, which in turn, affects outsourcing success (Lee & Kim, 1999).
5. *CRM outsourcing success:* High partnership levels between the CRM outsourcing company and the CRM vendor will help achieve the organizational objectives and provide a competitive advantage. The dependent variable, success of CRM outsourcing, is measured by using the widely used concept of satisfaction due to benefits gained by the CRM outsourcing company from a business perspective (Grover et al., 1996; Chin & Lee, 2000; Lee et al., 2000).

SUMMARY

We present a theoretical model that examines the relationship between CRM outsourcing levels, organizational factors of the outsourcing firm, partnership quality, and the success of CRM outsourcing from a business perspective. The model considers how quality of service provided by a vendor influences CRM outsourcing success and seeks to answer questions like how companies select CRM vendors, how they adopt and integrate CRM technologies into their existing infrastructures, and what factors affect CRM outsourcing success.

KEY TERMS

Customer Relationship Management (CRM): This is a strategy that companies use to identify, manage, and improve relationships with their most profitable customers to create long-term value for the firm.

Data Mining: Process of using statistics, artificial intelligence, and sophisticated algorithmic techniques to discover useful hidden relationships or patterns in large amounts of data.

eCRM: This is a strategy that companies use to identify, manage, and improve relationships with their most profitable online customers to create long-term value for the firm when a company's customer service operations are on the Internet, using e-mail, fax, Internet call centers, FAQs, online chats, and Web-based forums.

Information System Outsourcing: It is defined as transfer of an organization's IS function(s) to an external provider who takes the responsibility for managing these functions on behalf of the organization.

Resource-Dependency Theory: This refers to outsourcing of a firm's IT operations to external vendors to fill resource gaps within the firm for the purpose of providing the firm with strategic competitive advantage.

Social Exchange Theory: It is used to explain the close partnership style of outsourcing relationship between the firm and vendor by taking into account prior relationships, trust, and culture, and their affect on ongoing outsourcing relationships.

Transaction Cost Theory: It provides an economic viewpoint to outsourcing via a set of principles for analyzing buyer–supplier (outsourcer–vendor) transactions and determining the most efficient mode of structuring and managing them.

Transferring Technology to the Developing World

INTRODUCTION

The potential for technology growth in lesser developed countries (LDCs), particularly within the Arab World, is enormous (Loch, Straub, & Kamel, 2003). Within the Middle East, the projected demand for information technology hardware and services will be $8.9 billion by 2005 (Pyramid Research, 2001). Yet, in spite of this significant promise, information technology transfer (ITT) has been slow in this region. Clearly, there is more than money at issue in diffusing computing and the Internet throughout the Arab world, and the less developed world in general.

What are the reasons for this? As with most LDCs, resources for purchasing systems may be scarce, both for businesses and individuals. The public infrastructure for electricity and telecommunications may be lacking. Political instability, disease, and warfare may limit the ability of a people to absorb and effectively utilize technology, especially in many African countries.

Yet these reasons are not sufficient to explain the slow growth of IT in developing and least developed countries. There must be something more at stake. The scientific literature, although not as extensive as work in the developed countries, suggests several explanations for this phenomenon.

First, it is clear that much of the research related to IT has taken place in developed countries, primarily in North America. But as the business environment becomes more global, it becomes increasingly important to examine the influence of IT in other contexts and cultures (Checchi, Hsieh, & Straub, 2003). Naturally, countries that are less developed economically do not invest heavily in information infrastructure, limiting a country's ability to make efficient use of resources and effective choices for investments opportunities (Checchi, Sevcik, Loch, & Straub, 2002). Evidence is mounting, however, that other reasons may affect ITT in developing countries (Straub, Loch, & Hill, 2001). Loch, Straub, and Sevcik (2000) offer two reasons why the transfer of IT is difficult in the developing countries and in the Arab world:

- Cultural differences affecting system development and implementation
- Government policies influencing ITT

BACKGROUND

Before examining the transfer of IT to the Arab world, it is important to understand the impact of culture on IT. Identifying the culture of a nation is difficult; therefore, culture is often defined by national boundaries. However, the distinction between cultures is more sophisticated than geography. Researchers have defined culture based on shared values, problem solving and outcomes, and general, all-encompassing definitions, but culture is a complex, multi-layered phenomenon (Straub, Loch, Evaristo, Karahanna, & Srite, 2002). To classify culture, Ein-Dor, Segev, and Orgad (1992) identified factors, or "constants", that influence the culture and are consistent over time. Examples of constants identified by Ein-Dor et al. (1992) include geography, language, social norms, and traditions. Factors that change over time, "changeables", include technology, GDP, and level of education. Understanding the impact of the constants on IT solutions is critical for system architects as technology becomes implemented worldwide.

The Arab world consists of over twenty countries and 200 million people; therefore, it is difficult to definitively define the culture of such a large population. Within the Arab world, there are many subcultures; however, there are several characteristics that span across sub-cultural boundaries (Hill, Loch, Straub, & El-Sheshai, 1998). Barakat (1993) found several social characteristics that traverse the entire Arab culture, such as patriarchal family structures, pyramidal class structures, and expressive social interactions. Yet, he also found conflicting values within groups of the Arab world. He acknowledges that the dominant values of the Arab world include conformity, collectivism, and obedience, among others, but subgroups within the culture are emphasizing creativity, individualism, and rebellion. The social characteristics, dominant values, and emerging contradictory values are critical in shaping the Arab culture as we know it today (Barakat, 1993). According to Hofstede's (1980) work, Arabs have a strongly collectivist culture compared to the individualist North American culture. In addition, the Arab world is characterized by large power distance and high uncertainty avoidance. Regarding the position of the Arab culture on the masculine/femininity scale, the culture is considered moderately masculine. Examining the Arab world using the works of Barakat (1993) and Hofstede (1980) yield insight into the Arab organizational culture and the response towards technology transfer.

Research has shown that culture impacts the acceptance of technology. By understanding the effect of cultural beliefs and attitudes toward technology, it can be adapted to a group's behavioral patterns (Loch et al., 2000). Kransberg and Davenport (1972) argue that "an advance in technology not only must be congruent with the surrounding technology but *must also be compatible with…existing economic and other cultural and social institutions* [italics added]."

Although culture is considered to be a powerful force in ITT, much of the research on factors affecting ITT is related to economic issues and characteristics of the organizations implementing the system (Hill, Straub, Loch, Cotterman & El-Sheshai, 1998). While the economic state of a country does affect ITT, for many countries within the Arab world, cost is not an issue. For economically developed countries, such as Saudi Arabia and Kuwait, the adoption of IT has still been slow (Straub, 2003), suggesting that other factors, such as culture, are important.

DEVELOPMENT AND IMPLEMENTATION OF SYSTEMS

System implementations are difficult across cultural boundaries. Technology designed and created in developed countries has cultural-biases embedded within the system (Escobar, 1994). Cultural-specific beliefs can inhibit ITT in developing countries and within the Arab world. Typically, when implementing systems, the national culture is not taken into account and no adaptation occurs (Hill, Straub, Loch, Cotterman, & El-Sheshai, 1994). Two examples of cultural differences that impede system implementation in the Arab world include differences in leadership style and perception of time.

Cross-cultural conflicts between the styles of western and Arab leadership affect the system development process (Straub et al., 2001). Within the Arab culture, there is a preference within organizations for face-to-face meetings and family-like environments (Straub et al., 2001). These cultural preferences lessen the impact of groupware and e-mail technology within these countries. Practical implications of these cultural-specific beliefs of ITT within the Arab world suggest that managers should ensure top management support, even more so than in developed countries, before introducing new technology (Rose & Straub, 1998). In addition, technology such as e-mail or groupware should not be used to replace face-to-face meetings, but rather serve as a supplement to information exchange (Straub et al., 2001).

Another difference between cultures that affects the implementation of systems within the Arab world is the perception of time. The task-oriented, linear view of time that is found in Western culture is monochronic. The polychronic view of time found in Latin America and in the Arab world suggests that events unfold in parallel (Straub, 2003). These differences have strong practical implications. First, the Arab culture focuses less on long-term planning and forecasting than in western cultures (Straub et al., 2001); therefore, planning systems may be less accepted within the Arab world as compared to their western counterparts (Loch et al., 2000). Second, those in monochronic cultures tend to focus on one task at a time; however, people that are part of polychronic cultures often perform several tasks in parallel (Rose, Evaristo, & Straub, 2003).

With the explosive growth of the Internet and the supporting infrastructures, companies that are marketing globally must take into account other factors than language and currency. Research by Rose et al. (2003) has found that in monochronic cultures, long download times of a Web site lead to a negative attitude about the delay in viewing the content. But they also found that polychronic Web users, such as most Arabs, had more tolerance for long download times. For Web-based companies that are targeting people from polychronic cultures, it is not as important as in monochronic cultures to have an infrastructure and Web site design that reduces download time. Lower cost servers can be installed in these countries without having a negative effect on the attitude toward the website.

Although cultural factors can influence the ability to implement systems across national and cultural boundaries, technological culturation can offset this effect (Loch et al., 2000). Acculturation is an anthropological concept in which characteristics of one culture are assimilated into another culture. People in less developed countries may implement IT systems with cultural bias themselves if they either work for international companies or have spent time in developed countries, such as the U.S., Western Europe or Japan (Straub et al., 2001). People that have become technologically culturated are often more accepting of IT (Loch et al., 2000). Straub et al. (2001) confirmed this linkage between acculturation and ITT within the Arab world, and advised that firms in developing Arab countries should expose their employees informally to high technology cultures.

IT POLICY AND DIFFUSION OF IT

In addition to the cultural differences affecting systems development and implementation, a second determinant of ITT within the Arab world is the national IT policy executed by the government. IT policies influence the development of information systems based on the level of support a government provides within a given country (Loch et al., 2000). Governmental IT policy strengthens economic development in that higher-quality information can be used by both public and private sector organizations to more effectively use national resources (Checchi et al., 2002).

The influence of national IT policy on ITT can vary dramatically between countries. Checchi et al. (2003) noted several differences in the impact of policy on the diffusion of IT. First, in the least developed countries, regional or international agencies play a more important role in creating the IT infrastructure than the national government. In less developed countries, the private sector and individuals have little involvement in the process of developing IT capabilities. In these countries, the government is the most active in influencing ITT. Table 1 summarizes the differences in policies between developed and less developed countries.

Singapore is a success story where ITT occurred more easily across segments of the population because the government played an active role and encouraged ownership and investment in technology (Loch et al., 2000). Ireland is another example of a country that has been successful at implementing national IT policies to promote economic and technological development. By educating the workforce in technology and system programming, Ireland has been able to bypass an industrial revolution and progress straight to the information age (Straub, 2003). Other countries have failed to implement effective ITT policies due to lack of training, top management support, and user acceptance of technology (Loch et al., 2000). Some countries have made the mistake of relying too strongly on foreign assistance or focus on the consumption rather than the production of IT (Checchi et al., 2003). Having a national IT policy is not enough to ensure technological advancement. Table 2 lists successful and unsuccessful factors in national IT policies.

According to Al-Abdul-Gader (1999), there are several problems that governments within the Arab world need to address to ensure information technology transfer among its people. Similar to the active role that the Singapore government played in ITT, his recommendation is that an administrative body is needed to address these problems. Some issues this administrative body would address include:

- Creating and executing a national technology plan;
- Supporting collaborations of information systems across nations and regions;

Table 1. Differences with respect to IT policy setting (Checchi et al., 2003)

Policy Intervention Component	***Developed Countries***	***Less Developed Countries***
Initiator for policy making (mostly)	Domestic government	Regional or international agencies
Attitude of the government	Proactive	Passive or reactive
Investment purpose	Invest in both research knowledge and IT infrastructure	Invest mostly in IT infrastructure
Typical capabilities of the government	Has both technical and financial capabilities	Lack of technical skills, financial limitations
Position with respect to standards	Standard setting	Standard following

Table 2. Success factors in IT policies (Checchi et al., 2003)

Successful IT Policies	*Unsuccessful IT Policies*
Long-term oriented	Short-term oriented
Capability-building	Resource-consumption
Adaptive	Less-responsive
Collaborative	Non-collaborative

- Adopting a plan to develop and implement standards for information systems;
- Promoting the use of the Arabic language in technology applications; and
- Preparing and training the workforce in technology.

Many studies have concluded that ITT is in its infancy within the Arab world, and government policy needs to be more proactive in addressing these issues. Learning from Ireland, the countries within the Arab need to better train the workforce and prepare them for the diffusion of information technology (Al-Abdul-Gader, 1999).

FUTURE TRENDS

This review of literature suggests that there are two primary factors that affect ITT to the Arab World. They are: cultural differences affecting the implementation of systems and governmental policies that encourage or discourage the diffusion of IT. While these factors are critical in transferring information technology to the Arab world, little research has been devoted to fully examining these topics. More work is needed to better understand and distinguish between the subcultures within the Arab world. While there are shared characteristics across the region, understanding the sub-cultural differences could improve ITT. Additionally, prior research on governmental policies has been almost exclusively at the national level (Checchi et al., 2003). Future work should examine the interactions between policies at the national, international, and regional levels to determine the impact on economic and technological development.

CONCLUSION

The factors influencing the transfer of information technology to the developing world and to the Arab world in particular are more complex than simply language, geographical, and currency differences. Another misconception about the lack of ITT is related solely to the monetary investments needed for infrastructure and systems development and implementation. These misconceptions divert attention from other important factors that affect the diffusion of IT in the developing world, namely, cultural differences and governmental policies. A better understanding of these two important factors and implementing the findings into practice will aid in improving ITT to the developing world in the future.

KEY TERMS

Acculturation: The process by which a person adopts and assimilates characteristics of another culture into one's own culture

Arab World: An area of 5.25 million square miles, with a young population of 200 million people that encompasses 21 states. The countries of the Arab world include Algeria, Bahrain, Egypt, Iraq, Jordan, Kuwait, Lebanon, Libya, Mauritania, Morocco, Oman, Palestine (including the West Bank, Gaza, and East Jerusalem), Qatar, Saudi Arabia, Sudan, Syria, Tunisia, United Arab Emirates, and Yemen.

Culture: A set of multi-layered characteristics, beliefs, and values shared by a group of people that are consistently held over time.

Information Technology Transfer (ITT): The movement of information technology from creators to users.

Lesser Developed Countries (LDCs): Classes of countries in developing, emerging markets with a least developed status; older and more politically incorrect terms for these countries include second and third world and underdeveloped/undeveloped.

National IT Policies: Technology policies that influence the development and diffusion of information systems in a country.

Western Culture: The set of beliefs and values that are found in North America and Europe, that are typically characterized by higher levels of individualism and lower levels of uncertainty avoidance.

Translation of Natural Language Patterns to Object and Process Modeling

Alexandra Galatescu
National Institute for R&D in Informatics, Romania

INTRODUCTION

In order to shorten the engineering period of the complex information systems (ISs), the *integration of the models* is needed for uniformly: (1) traversing all phases of ISs' lifecycle (analysis, design, coding, testing), and (2) representing object, functional, process and organizational models on the business domain.

The seamless integration of the four models has not yet been a satisfactory solution from the conceptual, notational, semantic and logical viewpoints. The existing tools direct the designers to object-oriented modeling, possibly combined with "use case" and "state transition" diagrams. But, the functional, process and organizational models are not well and completely integrated with the object models. Moreover, using the agent-based technology for IS implementation, the knowledge modeling and integration will be necessary.

The integration solutions proposed in important methodologies like UML (Unified Modeling Language) (OMG, 2003) and IDEF (KBSI, 2000) (for object, functional and process models) or Workflow Reference Model (WfMC, 2003) (for organizational, process and functional models) mainly merge the models. Their conceptual integration is devolved to the developers of CASE tools or to the human designers and is accomplished during the coding phase. The existing methodologies, usually relying on the symbolic notation, do not provide the seamless and explicit (outside the code) integration of the object and activity-like symbols, from the semantic and logical viewpoints.

The integration abilities of natural language (NL) appear from the observation that people describe in NL any kind of information about objects, processes, information flows, the organization of their life and work, their knowledge, belief, intention, rationale and so forth. The universality and syntactic stability of a linguistic model is supposed to facilitate the communication among distributed ISs and users.

In computational linguistics, the main objective is to solve NL ambiguities (when more than one meaning is possible in a sentence) and to correctly identify the syntactic categories. Some NL analyzers build models for knowledge representation (logical models, semantic networks, frames, conceptual dependencies, conceptual graphs, etc.).

Instead, the discourse in the conceptual models (CMs) is a priori considered unambiguous and is expected to have a sound theoretical background. The objectives of NL analysis for model integration should be: (1) a linguistic theoretical foundation to the modeling interface, and (2) a uniform translation of NL to all types of CMs, without information loss. This article will focus on the second objective.

BACKGROUND

This section gives technical reasons for the research on natural language (NL) translation to conceptual models (CMs) (basically for model integration purpose) and a review of the state of the art and of the basic concepts and problems in this domain.

The complexity of information system (IS) representation comes from the complexity and diversity of the concepts it should integrate, defined in object, functional, process and organizational models. The integration of these models should be accomplished during the IS analysis or design phase.

These models result from the abstraction of the IS requirements, expressed by the analysts in NL. A comparison between the NL model (Allen, 1995; Sag, 1999), and the existing CMs reveals the conceptual relationships between NL and conceptual modeling. The most important relationships are:

- Between *categories* in CMs and NL. For example, between objects and nouns, activities and verbs, object attributes and adjectives, activity attributes and adverbs. Also, the noun and verb determiners/ modifiers/substitutes in NL have counterparts in CMs.
- Between *semantic relationships* in CMs and NL. For example, between object aggregation/fragmentation and noun meronymy/holonymy; between object specialization/generalization and noun hyponymy/hypernymy; between functional composition/decomposition of processes and verb meronymy/ holonymy, and so forth.
- Between *syntactic roles* in NL (subject, predicate, direct/indirect/prepositional object, complement,

adverbial modifier) and primitives in CMs. For example, the predicate is represented by an activity/event; the subject in active voice is the object-like sender of the message or initiator of an activity; the direct, indirect, prepositional objects are object-like parameters in activity execution; and so forth.

- Between *structures* in NL and CMs. For example, the simple sentence in NL is represented by the activity signature (list of object-like parameters that participate in the activity execution); the complex sentences are represented by (sub)process diagrams, and so forth.

Lately, the *co-references* between concepts in two or several sentences and the *ellipses* in NL are also represented in CMs.

This similarity made the researchers think that conceptual modeling could be as powerful as NL for representing the reality. But, the translation of NL patterns into a CM that integrates the four models is still an open problem.

NL-CM translation has been tried in several research domains: linguistic interpretation of the models (mainly, entity-relationship and object-oriented models), semantic integration of the conceptual schemas, modeling the systems' dynamics, human-computer interaction, requirements engineering, organization modeling, knowledge representation, formal ontologies and their application to the search on Web, business communication modeling based on speech act theory, and so forth.

The most important results have been obtained for the translation of NL to object and event models. Among the *NL-oriented representations* of these models, the most important are the functional grammar (FG) and the semantic networks (especially, conceptual dependencies and conceptual graphs). They propose the representation of the object models by syntactic categories and rules.

Functional grammar represents the functional aspects in NL, by the description and classification of predicate frames. FG has been further used for defining CPL (conceptual prototyping language), which focuses on NL simple sentences (the intersentential relations are not explicitly revealed). Also, CPL does not approach general semantic relationships inside the lexical categories (e.g., noun/verb synonymy, antonymy, homonymy, etc). COLOR-X (Riet, 1998) can be considered the most important application of CPL and practical result for CMs' integration. It integrates static object and event models of information and communication systems, abstracted from their textual descriptions. It relies on OMT (object modeling techniques). Like in any object-oriented model, the processes merely trace events that compose scenarios, similar to use case diagrams. Lately, the textual requirements are transformed into UML-schemata, for example (Fliedl, 2000).

The *conceptual dependencies* and, lately, the *conceptual graphs* (CG) (Sowa, 2000) are other linguistic representations for CMs. The syntactic categories are suggested by their roles to each other (meaning relationships between nouns and the verb that governs them in a simple sentence, e.g., agent, patient, instrument, recipient, location, time, source, destination, etc). A similar representation is the frame description in FrameNet (Filmore, 2002). But, all these representations are data-centric (ISs' dynamic behaviour is not important as a modeling goal).

The translation of NL to organizational models (workflows) has been obtained mainly with respect to the modeling of the business communication (e.g., Steuten, 2000). The theory of communicative actions and, lately, the *speech act theory* (Johannesson, 2001) are the main linguistic representations of the communication aspects in ISs.

The globalization of the organizations has a great impact on IS representation, especially with respect to the common vocabularies and the interoperability between distributed and heterogeneous applications. In this context, the conceptual modeling must step into a new era and intersect a new field: formal *ontologies*. A first benefit from ontologies for IS representation is that they describe, categorize and constrain concepts and relationships at the development time (Guarino, 2000). Using CMs, the constraints are basically imposed at run time. Another benefit is that the ontology specification is outside the code, while many object-oriented modeling specifications (especially constraints) are implemented inside the code.

Unfortunately, for the conceptual integration and for the representation of the ISs' dynamics, the existing ontologies have the same limits as the CMs. Most of them are object-oriented, relying on OKBC (open knowledge base connectivity) specification. For building business process ontologies, PSL (process specification language) (initiated by NIST) is recommended (e.g., Gruninger, 2003), mainly because it can be logically integrated with KIF (knowledge interchange format), appropriate for object and knowledge description and exchange.

For *ontology integration*, two alternatives can be considered: (1) by an upper-level ontology, able to represent all aspects in the real world, or (2) by a translation and correlation algorithm between the concepts and rules in different ontologies. Such an algorithm is mostly encoded and the ontology integration is recommended to be accomplished at the development time. So, the first alternative appears as a better solution. For the conceptual integration of all aspects in the real world (and, implicitly, in ISs), *upper-level linguistic ontologies* have been proposed (see next section), with benefits for ontology integration as well.

MAIN THRUST OF THE ARTICLE

This section first gives the limits in the existing research on natural language (NL) translation to conceptual models (CMs) and, lately, to ontologies. Then, the representation of the linguistic meta-models or upper-level ontologies is briefly analyzed from the syntactic and semantic viewpoints.

Most important *limits* of the existing translations of NL patterns to object and process modeling and the basic *open problems* are:

- NL translation only deals with the object-oriented aspects of the real world (RW). The functional, process and organizational aspects are not retrieved or are not well integrated in the translation results. Also, the correlations between the concepts resulted from translation usually confine to the inter-object relationships. The inter-activity ones and the system's dynamic behaviour are not properly treated.
- NL translation of different aspects in RW is accomplished with different software tools and results in different NL-oriented representations (languages). For example, the object-oriented aspects are translated into functional grammar structures or semantic networks and the communication aspects are translated into communicative acts (proposed in the speech act theory). The resulted Iss' representation is still not integrated from the conceptual, notational, semantic and logical viewpoints. The only benefits from the translation are: the automated abstraction of RW from textual requirements; and, a user interface closer to human reasoning and understanding, because it is closer to NL.
- Impossible use of the concepts resulted from NL translation for the expression of coherent and unambiguous ideas on any aspect in RW and IS, mainly because these concepts are heterogeneously represented (see previous). The brainstorming is going to become important in business management (several arguments are in Galatescu & Greceanu, 2002). Today, its automation for a virtual organization confines to the exchange of ideas in NL, by the electronic mail or chat, substantially increasing the virtual traffic. The communication by structures of ideas or modeling structures, issued during brainstorming sessions, and the automated comparison of these structures, must be other objectives of NL-CMs translation.

  Other reasons that make difficult the coherent expression of the modeling ideas using NL translation results are: (a) the intersentential relations in complex sentences and many semantic relations in NL are usually not considered; (b) the resulted concepts representing objects and processes are not stable and general enough. Also, many of them are not known at the development time.
- The logical consistency of the resulted IS representation from NL translation is hardly and incompletely verified at the development time, mainly because of the varied representations and implicitly, formalizations of the different aspects in ISs. This consistency is a pre-condition for the further automatic reasoning, simultaneously on objects, processes, workflows, and so forth.

  The logical consistency of the results from both NL-object model and NL-process/workflow model translation is, generally, proved using the first or higher-order logic or their variants (especially sorted, prepositional, modal, temporal logics). The logical consistency of the resulted process models is incompletely verified at the development time, because the logic of the procedural aspects cannot be represented with these formalisms.
- The meaning of the objects/activities and of the relationships between them in the resulted models from NL translation is, usually, incomplete and is not represented outside the code. This limit impacts on the epistemological aspects of ISs that, lately, are going to be conceived as multi-agent systems. NL translation is mainly concerned with NL syntax and only partially with its semantics.

The *linguistic meta-models* or the *upper-level linguistic ontologies* appear lately a solution to the model (or ontology) integration. Two research directions are important for their representation:

- The abstraction of NL s*emantics*, using a predefined *taxonomy of universal types* of objects, processes, activities and so forth (and relationships among them). This taxonomy is supposed to allow the subsumption (from the semantic point of view) of the words found in NL expressions, belonging to any category (noun, verb, adjective, adverb).
- The abstraction of NL *syntax*, using predefined rules for building *sentence-like structures*, that stylize the NL (simple, compound or complex) sentences and comply with NL syntax. These structures are supposed to be used for the unambiguous

description of any type of object, process, activity and so forth, in the modeled reality, as well as for the representation of coherent and unambiguous ideas about them.

These two directions are complementary and should be both considered in the definition of a linguistic meta-model or ontology.

From the semantic viewpoint, there are several proposals for taxonomies of the concepts in RW. They are compared in Bateman (2003). As *linguistically oriented taxonomies,* the most important are proposed in Oltramari (2002) and Sowa (2000).

From the syntactic viewpoint, the limits (emphasized in the previous section) of the functional grammar, conceptual dependencies and conceptual graphs, used today for NL translation to CMs, impose an improvement with respect to the model integration. Based on activity-oriented conceptual graphs, a new linguistic representation is proposed in Galatescu (2001, 2002), mainly for the model integration purpose. The same representation has been used as an upper-level linguistic ontology for the integration of three ontologies (re-engineering, domain and communication ontologies) and for the ideas expression (Galatescu & Greceanu, 2002).

FUTURE TRENDS

Related to the limits and existing solutions sketched in the previous sections, the *expected results* from the future research on natural language (NL) translation to object and process modeling should be:

- the translation *from textual requirements to* a *uniform representation* of all aspects in information systems (ISs), both externally (during the analysis and design phases) and internally (during the coding phase);
- the unification of all existing proposals for NL abstraction from the semantic point of view and the standardization of a unique *universal taxonomy* for all concepts in the real world and NL;
- the *automatic subsumption* of the words found in the textual requirements (and belonging to any syntactic category) inside a universal taxonomy of the concepts in the real world;
- *ontology-driven modeling* (i.e., based on concepts in a minimal upper-level ontology) (Guarino, 2000), expected to help for the globalization of the modeling activities and for the modeling completeness at the IS analysis or design time;
- the *integration* of the object, functional, process, organizational and epistemological views on organizations by means of linguistic meta-models or upper-level ontologies;
- the linguistic *representation of the epistemological and communication aspects* in IS multi-agent architectures. This representation should be integrated with the linguistic models for objects, processes, workflows and so forth; and
- the *multi-lingual* representation of IS. In this case, a problem in the abstraction of NL syntax will arise and must be solved, due to the differences in the syntactic rules of various languages.

The expected results enumerated previously will have an important impact on the IS lifecycle and on the developers' performance.

With respect to the future *technological means and user interface* for the linguistic conceptual modeling, new aspects should be considered:

- the interfaces of the CASE tools should become natural, close to human understanding. This means a shift from the exclusive symbolic notation to a notation that abstracts NL syntax and semantics; and
- the natural language processing (NLP) technology should be more deeply involved in the resolution of the problems in the conceptual modeling, as a basic translation technology; and
- the future CASE tools should involve practical and theoretical results from other domains, at least from NLP and linguistic ontologies.

CONCLUSION

This article has motivated the research on natural language translation to conceptual models and has reviewed the main limits of the existing models, the open problems and the expected theoretical and practical results (seen as future research trends).

The presentation has focused on the need for the conceptual integration of the existing models and for their representation outside the code. In this respect, as a requirement imposed by the globalization of the organizations, a recent trend was mentioned: the use of linguistic ontologies, able to represent all aspects in the real world (in particular, in any type of organization).

The limits and expectations enumerated for both domains (linguistic modeling and linguistic ontologies) lead to the conclusion that these domains are in an incipient stage, far from results that can be standardized and used in commercial products. The convergence and the integration of research activities and results in several fields (at least, conceptual modeling, NLP, and ontologies)

T

appear necessary for obtaining, as soon as possible, the expected results.

KEY TERMS

Business Process: The sequence of activities, the people and the technology involved in carrying out some business or achieving some desired results in an organization.

Category in NL: Noun, verb, adjective, adverb. Nouns are described by noun head, substitute, determiner, and modifier. Verbs are described by verb determiner/ modifier.

Conceptual Model: Abstraction of the real world/ domain and a mechanism for understanding and representing organizations and the information systems that support them. The most important *types of models* are:

- *object model*: describes objects by data and operations on the data. The object's identity encapsulates its state (attributes and relationships with other objects) and its behaviour (allowed operations on/with that object).
- *process model*: describes (sub)processes by the activities they involve, the activity order, decision points, pre-/post-conditions for the activity execution;
- *functional model*: describes the information flow and transformation, as well as the constraints and functional dependencies among the activities in a process;

- *organizational model*: describes the workflow (activities for the creation and movement of the documents) within an organization, the people's roles and the communication among people for performing the activities.

Object: An entity (e.g., "person") or a value (e.g., "phone number"). In object-oriented models, it is the instance of a class.

Ontology: Hierarchical structuring of knowledge about things by subcategorizing them according to their essential (or at least relevant and/or cognitive) qualities. Practically, a *vocabulary* used to describe a certain reality, plus a set of *explicit assumptions* regarding the intended meaning of the concepts in the vocabulary. The relations between concepts allow inferences (e.g., information interpretation and the derivation of new information/knowledge). The explicit axioms allow the approximation of the term meaning and the validation of the ontology specification at the development time.

Semantic Relationship in NL: Relation between the words in the same category (mainly, noun and verb category). Some relationships are bi-directional. Most important relationships are: *noun* or *verb* meronymy/ holonymy, hyponymy/ hypernymy, synonymy, antonymy, homonymy; *verb* troponymy or entailment; cause-effect relations between verbs (see the glossary of terms for WordNet, at *http://www.cogsci.princeton.edu/~wn/man/ wngloss.7WN.html*).

Sentences in NL: *Simple sentence***:** built around the static or dynamic action of the verb; *compound sentence*: joins independent simple sentences by conjunctions; *complex sentence*: composed of subordinated sentences (subclauses) correlated to a main sentence (clause).

Structure in NL: *Sentence* (simple, compound, complex); *phrase* (e.g., verb, noun phrase, adverb, prepositional, adjectival phrase); *clause* (noun, adverbial, relative, appositive).

Traversal Pattern Mining in Web Usage Data

Jenq-Foung (J.F.) Yao
Georgia College & State University, USA

Yongqiao Xiao
SAS Co., USA

INTRODUCTION

Web usage mining is designed to discover useful patterns in Web usage data, i.e., Web logs. Web logs record the user's browsing of a Web site, and the patterns provide useful information about the user's browsing behavior. Such patterns can be used for Web design, improving Web server performance, personalization, etc.

BACKGROUND

Pattern discovery applies methods and algorithms from different fields such as statistics, data mining, machine learning, etc., to the prepared data. By applying the statistical techniques to the Web usage data, some useful statistics about the users' browsing behavior can be obtained, e.g., the average view time of a page, and the most frequently accessed pages, etc. By applying clustering (a.k.a., unsupervised learning) to the usage data, groups of users which exhibit similar browsing behavior can be found. Such knowledge is useful for market segmentation and personalization. The focus here is on discovering traversal patterns from the Web usage data.

A traversal pattern is a list of pages visited by a user in one session. Several different traversal patterns and the corresponding methods of discovering them have been proposed in the literature, namely, Association Rules, Sequential Patterns, Frequent Episodes, Maximal Frequent Forward Sequences, and Maximal Frequent Sequences. The details about each type of traversal pattern are described in the following section.

TRAVERSAL PATTERNS AND DISCOVERING METHODS

Association Rules

Association rules were originally proposed for market basket data (Agrawal et al., 1993; Agrawal and Srikant, 1994). Association rules describe the associations among items bought by customers in the same transaction, e.g., 80% of customers who bought diapers also bought beer in some store.

To mine association rules from the transactions, there are two steps: first finding the frequent item sets, and then generating association rules from the frequent item sets. Since the second step is straightforward compared to the first one, the research focus is on the first step. An item set (or itemset for short) is frequent, if the support for the itemset is not less than some predefined threshold. The support for an itemset in a database of transactions is defined as the percentage of the transactions that contain the itemset.

Sequential Patterns

Sequential patterns (Srikant and Agrawal, 1997) were also originally proposed for market basket data. For example, customers buy a digital camera, then a photo printer, and then photo papers. Such sequential patterns capture the purchasing behavior of customers over time.

Sequential patterns have also been applied to Web logs (Buchner et al., 1999; see also Spiliopoulou, 2000; Pei et al., 2000). The sessions are ordered by the user id and the access time. As for association rules, the duplicate pages are discarded. Then for each user, there is a user sequence, which consists of all sessions of the user. A sequential pattern is a maximal sequence of itemsets whose support is not less than some predefined threshold. A sequence is maximal if it is not contained in any other sequence. The support of a sequence is the percentage of user sequences that contain the sequence.

Algorithm AprioriAll was proposed in Srikant and Agrawal (1995) for finding all sequential patterns given some support threshold. AprioriAll was then improved by Generalized Sequential Patterns (GSP) (Srikant and Agrawal, 1996). Traversal patterns were generalized to allow time constraints, sliding time window, and user-defined taxonomy.

Frequent Episodes

Frequent episodes were originally proposed for telecommunication alarm analysis (Mannila et al., 1997). Episodes are collections of events, which occur together within some time window. In general, they are partially ordered sets of events. There are two special types of episodes: parallel episodes and serial episodes. They differ in whether the events in the episodes are ordered. In parallel episodes the events are not ordered, while in serial episodes the events are ordered sequential. An episode is frequent if it occurs in the event sequence not less than some predefined threshold.

Frequent episodes were also applied to Web logs (Mannila et al., 1997). The clicks (pages) correspond to events. They are ordered by the access time, and usually the users need not be identified, i.e., there are no sessions.

Maximal Frequent Forward Sequences

Maximal Frequent Forward Sequences (MFFS for short) were proposed in Chen et al. (1998) Notice that MFFS was referred to as large reference sequence in Chen et al. (1998). An MFFS describes the path traversal behavior of the user in a distributed information-providing environment like World Wide Web. There are two steps to mine MFFSs from the sessions. First each session is transformed into maximal forward sequences (i.e., the backward traversals are removed). The MFFSs are then mined using level-wise algorithms (Park et al., 1995) from the maximal forward sequences.

In the raw sessions, there are often backward traversals made by the user. A backward traversal means revisiting a previously visited page in the same user session. It is assumed that such backward traversals happen only because of the structure of the Web pages, not because the user wants to do this. When a backward traversal occurs, a forward traversal path terminates. This resulting forward traversal path is called maximal forward sequence. It then backtracks to the starting point of the next forward traversal and resumes another forward traversal path.

An MFFS is a traversal sequence (consecutive subsequence of a maximal forward sequence) that appears not less than some predefined threshold in the set of maximal forward sequences. The pages in an MFFS are required to be consecutive in the maximal forward sequences, and an MFFS is also maximal, which means that it is not a subsequence of any other frequent traversal sequence.

Maximal Frequent Sequences

Maximal Frequent Sequences (MFS) were proposed in Xiao and Dunham (2001). In contrast to maximal frequent forward sequences, MFSs do not remove backward traversals from the sessions. It was argued in Xiao and Dunham (2001) that such backward traversals are useful for discovering the structures of the Web pages. For example, if a pattern <A, B, A, C> is found frequent, it may suggest that a direct link from page B to page C is needed, while the resulting maximal forward sequences <A, B> and <A, C> lose such information.

An MFS is a traversal sequence (consecutive subsequence of a session) that appears not less than some predefined threshold. Since the backward traversals are kept in the sessions, a traversal sequence may occur in a session more than once. In order to measure the actual number of occurrences of a traversal sequence, the support of an MFS is defined as the ratio of the actual number of occurrences to the total length of all sessions. The length of a session is the number of clicks in the session. The pages in an MFS are required to be consecutive in the sessions, and an MFS is also maximal.

Summary

Table 1 compares the different types of traversal patterns by the following features:

- Ordering: the pages in a traversal pattern can be ordered or not.
- Duplicates: which indicate whether backward traversals are allowed in the traversal pattern.
- Contiguity: the page references in a traversal pattern may be contiguous or not.
- Maximality: a frequent pattern is maximal if it is not contained in any other frequent pattern. A pattern could be maximal or not.

Notice that for frequent episodes, parallel episodes are not ordered, while serial episodes are ordered and the general episodes are partially ordered. Due to the different features of the traversal patterns, the support for each type of pattern is defined quite differently, which is also shown in Table 1.

These features used by different patterns can be used for different purposes. Backward traversals capture the structure information of the Web, and therefore can be used to improve the design of Web pages by adding new links to shorten future traversals. The maximality feature can reduce the number of meaningful patterns discovered. The contiguity and the ordering features could be used to predict future references and thus for prefetching and caching purposes.

These traversal patterns uncover the associations or sequences among the Web pages browsed by the user. They can be used together with other data mining techniques, such as classification and clustering, to further

Table 1: A comparison of traversal patterns

	Ordering	Duplicates	Contiguity	Maximality	Support
Association Rules	N	N	N	N	freq(X) / # sessions
Sequential Patterns	Y	N	N	Y	freq(X) / # users
Frequent Episodes	Y	N	N	N	freq(X) / # time windows
MFFS	Y	N	Y	Y	freq(X) / # maximal forward sequences
MFS	Y	Y	Y	Y	freq(X) / # clicks

facilitate Web usage mining as shown in Tan and Kumar (2002). In that paper, the authors used traversal patterns and classification to distinguish human sessions from robot sessions.

Pattern analysis is to analyze the patterns to the needs of the application. It includes filtering uninteresting patterns, visualization, etc. The Web Utilization Miner (WUM) system (Spiliopoulou and Faulstich, 1998) provides a mining language, which allows an analyst to specify characteristics of the patterns that are interesting.

Web usage mining has been applied to many applications (Srivastava et al., 2000), e.g., personalization, system improvement, Web design, business intelligence, etc. Specifically, the traversal patterns have been used for site evaluation (Spiliopoulou, 2000), prefetching (Lan et al., 1999; Pandey et al., 2001) network intrusion detection (Lee and Stolfo., 1998; Dokas et al., 2002), fraud detection (Colet, 2002), etc. Interesting results might be obtained from a comparison study among these different patterns.

FUTURE TRENDS

One interesting future research topic is to mine traversal patterns with Web document structure also captured. All the above traversal patterns ignore the document structure of the Web site, which is essentially hierarchical (a tree) or a graph. Techniques for tree mining or graph mining can then be adopted.

Other interesting work could include improving sessionizations, clustering of the traversal patterns, etc.

CONCLUSION

Five different types of traversal patterns that can be mined in the Web usage data, namely, Association Rules, Sequential Patterns, Frequent Episodes, Maximal Frequent Forward Sequences, and Maximal Frequent Sequences are described. These patterns are compared and contrasted in four aspects, i.e., ordering, duplicates, contiguity, and maximality. They can be used for different purposes.

KEY TERMS

Cleansing: To filter the irrelevant entries in the Web log, such as graphics files. The HTTP protocol is stateless, which requires a separate connection for each file that is requested from the Web server. Therefore, several log entries may result from a request to view a single page, since the files for the graphics embedded in the page are automatically downloaded from the Web server. Such filtering can be done by checking the suffixes of the URI name such as jpg, gif, etc.

Extraction: To select the related fields from the Web logs. Traversal patterns typically require the three fields: IP address, access time, and the page accessed. Other fields, such as referrer and user agent, can be used in cleansing and sessionization.

Preprocessing: The tasks of preprocessing for Web usage mining include extraction, cleansing, transformation, sessionization, etc.

Server Session: A collection of user clicks to a single Web server during a user session.

Sessionization: Identifying the sessions (server sessions) from the Web logs, called sessionization and is not a trivial task. It has two subtasks: user identification and session identification. A common way is to use the IP address to identify the user, i.e., all entries with the same IP address belongs to the same user.

Transformation: To convert the fields to the format required by specific pattern discovery algorithm.

User: An individual that is accessing the Web through a browser.

User session: A delimited set of user clicks across one or more Web servers. A click corresponds to a page on the Web server, which is uniquely identified by an URI (Universal Resource Identifier).

T

Trends and Perspectives in Online Education

Bruce Rollier
University of Baltimore, USA

Fred Niederman
Saint Louis University, USA

INTRODUCTION

Although the Internet has been in existence since 1969, it was not widely used for educational purposes in its first two decades. Few students had access to e-mail, and few educators could visualize its value as a teaching tool. Programs to serve students from remote locations, often called "distance education," became popular; these were generally delivered synchronously through television broadcasts and did not involve the Internet. When the World Wide Web was created in the early 1990s (Berners-Lee, 1999) and the first browsers became available (Waldrop, 2001), the enormous potential for education began to be recognized. New global users came online at a fantastic pace, and the value of all this connectivity was increasing even more rapidly in accordance with Metcalf's Law (Gilder, 1996). Nearly all students used e-mail regularly, and college professors were putting syllabi and course assignments online and creating Web pages with increasing sophistication. Soon entire programs were offered completely via the Internet, with students from all over the globe taking courses together.

According to a major survey conducted by Allen and Seaman (2003), there were more than 1.6 million students who took at least one online course during the Fall 2002 semester and 11% of U.S. higher education students took at least one such course. These numbers were projected to increase rapidly, and most institutions considered online education as a critical long-term strategy.

BACKGROUND

At first, online courses tended to be offered sporadically, often by a few technically savvy faculty members exploring how best to use the Web. Developing the courses to fit this new medium was difficult and time-consuming, and these professors began to demand some recognition for their efforts. Soon, university administrators noticed that the online courses were very popular, that they could attract students from distant locations, and that programs in other institutions were proliferating. The need for uniform policies was recognized. What is a reasonable class size? Should development of a new Web course count toward promotion and tenure? Should Web courses be taught the same way as face-to-face classes?

It soon became clear that there were major differences between face-to-face classes and online classes in providing high quality instruction. Online, at least with the currently available technologies, must be almost completely asynchronous, whereas face-to-face is primarily synchronous. The term "virtual university" (Morrissey, 2002; Schank, 2002; Stallings, 2001) has recently come into vogue, but with varying meanings. The term is often applied to an institution with no physical campus and that is completely online; Jones International University, Cardean University, and University of Phoenix Online are examples (Mason, 2000). These are usually for-profit companies and may be spin-offs from private universities. The term can also signify an institution that has a large physical campus but that has a coordinated approach to online education and devotes significant resources to its online programs. Some of the largest of these include Penn State's World Campus and the University of Maryland's University College (Stallings, 2001). There are also a large number of Virtual University Consortiums (VUCs) that have been formed to offer online programs in multi-institutional partnerships. A recent study identified 63 of such consortia, primarily state-based (Twigg, 2003).

There are many reasons for the rapid growth of VUCs. In many countries, including the U.S., governmental funding of education has decreased in recent years, forcing universities to look for new markets and new sources of revenue (Mason, 2000). Lifelong learning has become much more critical for the workforce as skills and careers become obsolete at a rapid clip. There is high demand from adult learners for retraining for new careers or for upgrading of skills, and online programs are ideal for this.

Twigg (2003) lists several factors motivating the growth of VUCs and other online programs: increased demand for adult education and training; the educational needs of underserved communities; coping with the increasing frequency of interuniversity transfers; streamlined access to the state's institutions via a portal; providing increased variety of degrees; lowering costs, and "overcoming the possibility that the state's institutions will be left behind in the new, highly competitive online environment" (p. 5). She comments that most states have decided that "stand-alone virtual university initiatives are too expensive to initiate and sustain both fiscally and politically" (p. 7). Most VUCs do not offer degrees because that would put them in direct competition with the other state institutions. Instead, they have adopted the collaborative model, which can mean anything from a passive posting of available courses or library sharing to a fairly aggressive stance as an alternative degree path.

Twigg notes that the most successful VUCs have adopted the following policies (2003, p. 10): (1) focus on increasing access for new students that might not otherwise attend; (2) find out what students need and create a viable response rather than merely aggregating what the member institutions can offer; (3) do not get involved in irrelevant higher education policy issues; (4) create a business plan for long-term viability without reliance on state aid, and (5) use a cost-effective development and delivery model.

Morrissey (2002, pp. 460-461) cites the following conflicts which may inhibit achieving the virtual university's full potential: compensation and ownership issues; lack of recognition for course development; poor course support; push for large classes, which may result in fewer faculty positions, and possible adverse impact on research.

ISSUES OF QUALITY

The societal benefits of a first class online education program are obvious, in providing quality instruction for those in remote locations or the physically handicapped or those whose daily responsibilities do not permit them to attend on-campus classes. It is not clear that the programs are being established for such altruistic objectives. Schank (2002) is skeptical, and suspects that Web courses are developed primarily for revenue and academic prestige. He also believes that courses are being modeled to fit existing programs and are not taking advantage of the unique characteristics of the Web.

Are online courses equivalent in quality to courses in face-to-face classrooms? Quality is of course dependent on many factors, and each medium has both advantages and disadvantages. A major difference is synchrony; physical classes are largely synchronous, and current virtual courses are almost completely asynchronous. This characteristic severely limits student interaction and team activities. Chat rooms are synchronous, but quickly become confusing. On the other hand, asynchrony makes it possible to maintain availability 24 hours a day, seven days a week (Pittinsky, 2002). Schank (2002) argues that Web courses would be superior to face-to-face if the design were less dependent on our current concepts, such as performing tasks rather than listening, and length of course and material covered based on student need.

Spicer (2002) warns university presidents that they must be prepared to expend significant resources over long time periods to maintain high quality and avoid shortcuts. The view of online education as a source of revenue and profit is misguided, and costs are typically underestimated (Niederman & Rollier, 2001). Teaching Web classes is difficult and labor-intensive, and huge classes are not feasible if quality is to be preserved. The required faculty skills are not the same as in the classroom, and the necessary faculty development is often overlooked (Agee, Holisky & Muir, 2003). Procedures must be established and controls enforced to ensure that instructors are responding quickly to student needs and evaluating student learning effectively (Hall, 2002; Stein, 2001).

FUTURE TRENDS

Market share is much more important on the Web than in traditional businesses. A large firm has a major marketing advantage, especially in advertising. The largest virtual universities of the future will offer programs in almost every discipline, at every level, and will compete for students in every locality and most languages. The competition is global; note that the largest distance education institution in the world is in China (Dunn, 2000). These schools will gradually lose their identification with a particular country. Most universities will adopt a niche strategy, competing in those markets for which they perceive a competitive advantage, or markets thought to be underserved.

With continuing advances in technology it seems likely that Web teaching techniques will change greatly. Online education will continue to be basically asynchronous, but with the availability of synchronous capabilities to provide far more interaction. When a critical mass of online students has access to broadband, the instructor will be able to see the students on screen, and the students to see the instructor. Highly interactive group assignments will be possible. The instructor will be able to demonstrate concepts and skills visually and audibly rather than just describing them. Examinations can be monitored visually. Although keyboards may still be necessary, voice will be the primary means of communication, thus reducing the importance of typing skill. Simulations and virtual reality will be widely employed for user interaction and feedback (Morrison & Aldrich, 2003).

Wireless will be a major communications technology (PriceWaterhouse Coopers, 2001), greatly increasing flexibility of location. Internet2 will make digital video available, bringing large-scale indexed video archives and digital-video conferencing. As Tsichritzis (1999) points out, professors can deliver lectures to more than one university at the same time with little additional overhead. Universities may become increasingly like brokers, providing facilities for buyers and sellers of educational services to meet virtually.

Mergers, joint ventures, and strategic alliances will be increasingly common (Makri, 1999). A growing number of states are centralizing services for distance education (Morrissey, 2002), claiming that such collaborations save money and provide more choices for students. Collaborations between universities in different countries can provide obvious benefits to both. There is an increasing trend for students to take courses at more than one university, and online education seems likely to accelerate that trend. Such alliances will lead to an emphasis on standardization of curricula and on ease of transfer between institutions.

Peter Drucker (2000) has said: "Online Continuing Education is creating a new and distinct educational realm, and it is the future of education" (p. 88). If high quality can be maintained and innovative approaches are developed to take advantage of the wealth of resources available on the Web, the chief beneficiary may be society itself, and particularly the Third World societies. Quality education at reasonable cost can be made available virtually anyplace in the world. As the population ages in the wealthier countries, a steady supply of skilled workers will be needed, but an increasing proportion of younger workers will be from economic classes whose members do not traditionally attend college. At the same time, most of the fastest growing occupations require an increasingly high level of education (BLS, 2004). In Third World countries, there is a critical need for an educated workforce and for high quality instruction and effective educational materials. Online education can potentially provide all of these elements.

CONCLUSION

Online education is here to stay, and seems certain to be an increasingly important component of every university's future. It will also be increasingly competitive, and to survive in this market institutions will have to invest significant resources to achieve high quality and favorable name recognition. The ultimate arbiters of success will be the global employers of college graduates. If the online students prove to be competent employees with knowledge and skills equivalent to the graduates of traditional programs, the students will land good jobs and others will flock into the online programs. If the online graduates are seen as weak, this will have a disastrous effect on program success. Skimping on quality would be a huge mistake.

Surveys such as that of Allen and Seaman (2003) indicate that the perception of quality is high among the institutions who offer the programs, but this is weak evidence; student and employer perceptions are much more significant. Research is critically needed to determine whether the necessary quality is being achieved, whether the students are being prepared for successful careers, whether some students are better candidates for online education than others, and whether college courses are equally adaptable to online delivery.

It should not be assumed that the courses will be taught the same way in the future as they are today. Wide availability of broadband and more sophisticated software will make possible much greater interaction among students and between students and instructors. Successful programs will incorporate the best blend of synchrony and asynchrony. Staying competitive may prove to be very expensive, and less well-endowed institutions may be wise to seek out strategic partnerships for sharing of faculty and other resources.

KEY TERMS

Asynchrony: A condition whereby events occur that are not coordinated in time. In online education, asynchrony makes possible performing course tasks at the most convenient time, not tied to a schedule.

Distance Education: A somewhat broader term that includes online courses but also classes that involve broadcasting from a television-like facility, often transmitted via satellite.

Metcalf's Law: The "value" or "power" of a network increases in proportion to the square of the number of nodes on the network.

Online Education: Instruction conducted on a network, usually the Internet, for students separated geographically. Sometimes called *distance education*.

Synchrony: Simultaneous occurrence of two or more events. Synchronous features would make it possible to perform lectures, demonstrations, and group activities in real time.

Virtual: Being such in force and effect, though not actually or expressly such.

Virtual University: A loosely defined term, but usually refers to a large, coordinated, degree program offered by one institution or a consortium in which students can take classes at any time and from any global location.

Virtual University Consortium (VUC): A group of higher education institutions, usually sponsored by the state, who have formed a strategic partnership to jointly offer online programs.

Trends in Information Technology Governance

Ryan R. Peterson
Information Management Research Center, Spain

INTRODUCTION

Information technology (IT) *governance* has been a perennial item on the corporate agenda of many organizations. Ever since IT proved to be more than an administrative tool, researchers and practitioners have pondered its governance. Defined as the locus of IT decision-making authority (Brown & Magill, 1994; Sambamurthy & Zmud, 1999), discussions concerning IT governance have flourished for more than four decades across research communities and boardrooms. Posed as a question of *centralization* during the 70s, IT governance drifted towards *decentralization* in the 80s, and the recentralization of IT decision-making was a 90s trend.

Today, IT governance is experiencing yet another transformation, and persists as a complex and evolving phenomenon (Grembergen, 2003). As business environments continuously change and new technologies evolve rapidly, how to govern IT effectively remains an enduring and challenging question. This chapter discusses past developments and the present status quo of IT governance, and outlines several critical questions, which are pending future investigation.

BACKGROUND

Traditionally, three IT governance models have been distinguished (Brown & Magill, 1998; Sambamurthy & Zmud, 1999). In each model, stakeholder constituencies take different lead roles and responsibilities for IT decision-making across the *IT portfolio*. In the centralized model, corporate IT management has decision-making authority concerning *IT infrastructure* and *IT applications*. In the decentralized model, division IT management and business management have authority for IT infrastructure and IT applications. In the *federal* model, corporate IT has authority over IT infrastructure, and (either or both) division IT and business-units have authority over IT applications.

In general, it is argued that centralization provides greater efficiency, control, and standardization, while decentralization improves business ownership, flexibility, and responsiveness (Brown, 1997; Rockart, Earl, & Ross, 1996). Literature suggests that the federal model provides the benefits of both centralization and decentralization (see Table 1). Research indicates that organizations adopt a federal model when pursuing multiple

Table 1. Drivers and design of IT governance (Adapted from Hodgkinson, 1996; Peterson, O'Callaghan, & Ribbers, 2000; Sambamurthy & Zmud, 1999)

Model / Drivers	Centralized IT Governance	Decentralized IT Governance	Federal IT Governance
Synergy	+	-	+
Standardization	+	-	+
Specialization	+	-	+
Customer responsiveness	-	+	+
Business ownership	-	+	+
Flexibility	-	+	+

competing objectives involving a simultaneous focus on cost-efficiency and business-flexibility (Peterson, O'Callaghan, & Ribbers, 2000; Sambamurthy & Zmud, 1999).

MAIN THRUST

While the federal model seems to be the dominant configuration in contemporary firms (Peterson, O'Callaghan, & Ribbers, 2000; Sambamurthy & Zmud, 1999), empirical studies regarding the complexity of this configuration are sparse. Specifically, *allocation of IT decision-making authority does not resolve the need for effective coordination between corporate IT, division IT and business-unit management*. Continuous differentiation leads to fragmentation, unless a corresponding process of integration complements it. The problems reported in practice and research regarding the lack of, for example, IT prioritization, top management IT commitment, IT management business understanding, business management IT responsibility, and IT value generation, are symptomatic of this fragmentation and are typically encountered in the federal IT governance model (Peterson, 2001; Weill & Broadbent, 1998).

In order to provide direction and achieve organizational effectiveness, differentiation begets integration (Daft, 1998; Galbraith, 1994; Lawrence & Lorsch, 1967). Designing effective IT governance is dependent on both the *differentiation* and *integration* of decision-making for IT across the portfolio of business IT investments and processes (see Figure 1).

Whereas differentiation focuses on the distribution of IT decision-making rights and responsibilities among different stakeholders in the organization (i.e., the locus of IT decision-making), integration focuses on the coordination of IT decision-making/-monitoring processes and structures across stakeholder constituencies. Organizations thus need to consider and implement integration mechanisms for the effective governance of IT.

FUTURE TRENDS

Integration mechanisms for IT governance can be classified according to two dimensions (Peterson, 2003). Vertically, integration mechanisms focus either on integration structures or integration processes; whereas horizontally, a division is made between formal positions and processes, and relational networks and capabilities. Col-

Figure 1. Differentiation and integration IT decision-making (Adapted from Weill & Broadbent, 1998)

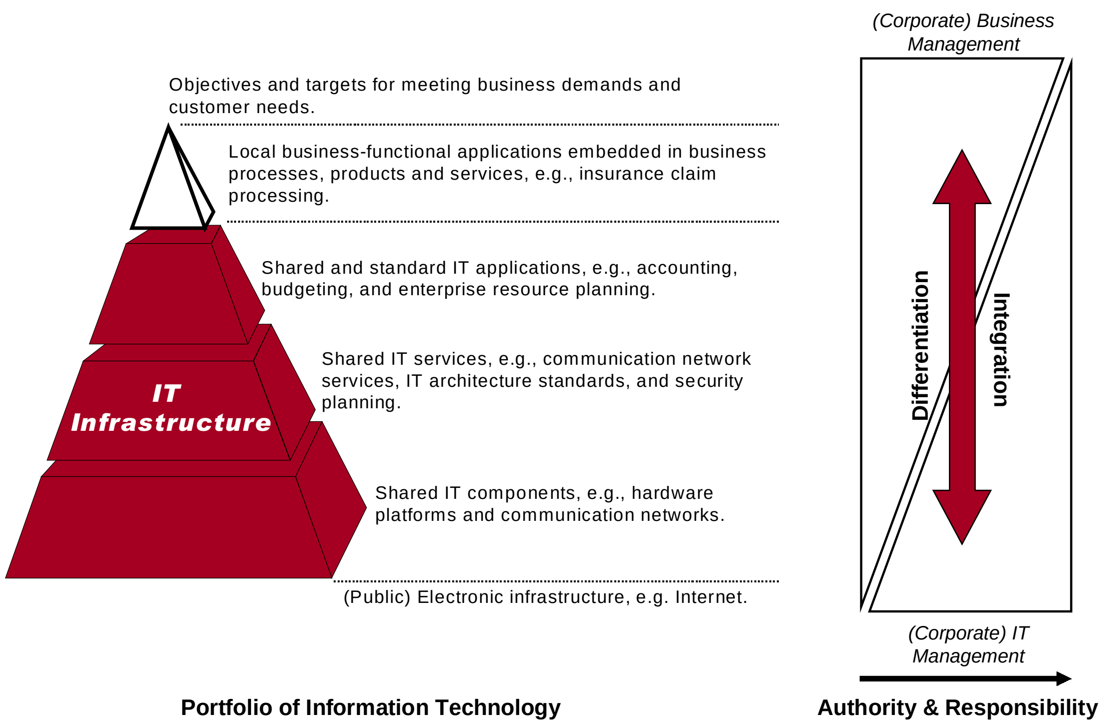

Figure 2. Generic integration mechanisms for IT governance (Adapted from Peterson, 2003)

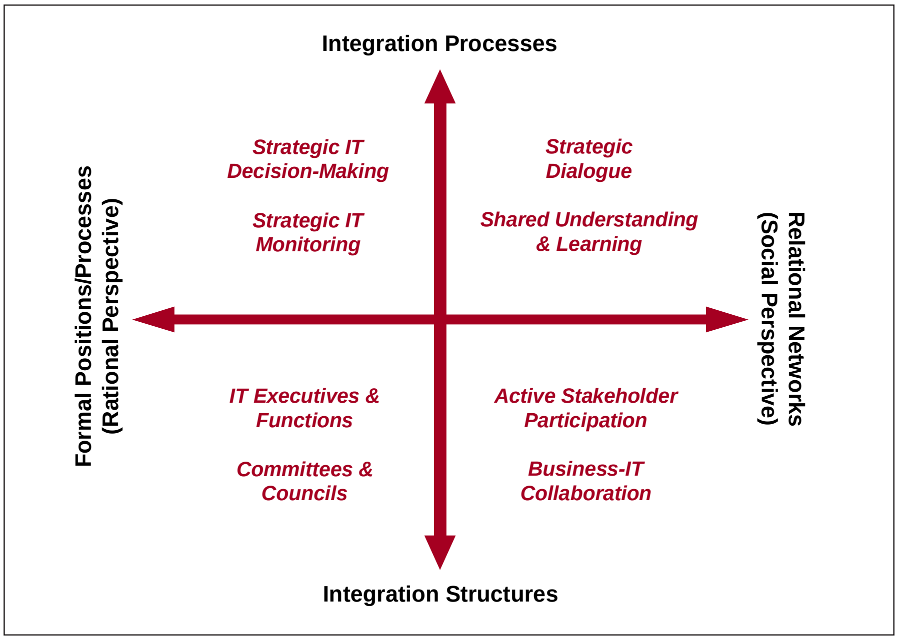

lectively, this provides four types of generic integration mechanisms for IT governance (see Figure 2).

Formal integration structures involve appointing IT executives (e.g., CIO) and IT functions (e.g., client-account and user relationship managers), and institutionalizing special and standing IT committees and councils. Committees and/or executive teams can take the form of temporary task forces (e.g., project steering committees), or can alternatively be institutionalized as an overlay structure in the organization in the form executive and/or IT management councils. Formal integration processes describe the formalization and institutionalization of IT decision-making-/monitoring procedures and performance. Formal integration processes vary with levels of IT governance *comprehensiveness*, *formalization*, and *integration*.

Whereas the foregoing formal integration mechanisms tend to be mandatory and tangible, relational integration mechanisms are "voluntary" and "tacit" actions, which cannot be programmed and/or formalized. While formal integration mechanisms are necessary, they are insufficient for designing effective IT governance in competitive environments (Peterson, O'Callaghan, & Ribbers, 2000).

Relational integration structures involve the active *participation* and *collaboration* between corporate executives, IT management, and business management. Central to relational integration is the participative behavior of different stakeholders to clarify differences and solve problems in order to find integrative solutions. The ability to integrate relationally allows an organization to find broader solutions, and unleashes the creativity involved in joint exploration of solutions that transcend functional boundaries and define future possibilities. Relational integration processes describe strategic dialogue and *shared learning* between principle business and IT stakeholders. Strategic IT dialogue incorporates a wide range of initially unstructured business perspectives and IT views, and involves rich conversation to resolve diverging perspectives and stakeholder conflicts. Shared learning describes the co-creation of mutual understanding by members of organizational sub-units of each other's goals and objectives.

In summation, formal and relational structures and processes collectively constitute and determine the integration capability of IT governance, and underscore the importance of flexible management systems in complex and uncertain environments. The organizing logic is characterized by a collaborative network, where communication is more likely to be lateral, task definitions are more fluid and flexible (i.e., related to competencies and skills, rather than being a function of position in the organization), and where influencing of business-IT decisions is based on expertise, rather than an individual's (or group's) position (Peterson, 2003).

Table 2. Future research

Suggested Research Questions	Suggested Research Design and Methodology
What types of integration mechanisms are used in conjunction with different IT governance models? Do certain IT governance *gestalts* exist that combine IT governance differentiation and integration mechanisms?	A quantitative approach (large scale survey) to identify and validate patterns of IT governance differentiation and integration. Multiple case studies can also be used to explore and discover new patterns.
What are the most effective integration mechanisms under different IT governance models?	A quantitative approach (large scale survey) to identify effective integration mechanisms for IT governance. Multiple case studies can be of value when considering the business and industry context.
How do integration mechanisms moderate the relationship between IT governance and IT business value?	A quantitative approach (large scale survey) to measure and validate the moderating impact of integration mechanisms on IT business value realization
How do organizations design and implement integration mechanisms for IT governance?	A longitudinal research design involving field-research and multiple case studies. A single in-depth case study can also provide rich (theoretical) insights.
What are the (inter-) dependencies between integration mechanisms? Do companies follow a specific path when developing and implementing integration mechanisms (e.g., do they start with positions, the processes and finally relationships?)	A longitudinal or retrospective field-study on the development and evolution of integration mechanisms in certain companies
Are certain drivers (e.g., standardization, responsiveness, flexibility) related to the use (or non-use) of specific integration mechanisms? How do the competing drivers of efficiency and flexibility impact the adoption and usage of integration mechanisms?	Both surveys and/or case studies can be used. A (quantitative) survey would identify empirically significant relationships amongst certain drivers and integration mechanisms. Multiple case studies would help explain why and how these (competing) drivers lead to the adoption and usage of integration mechanisms

CONCLUSION

Amidst the challenges and changes of the 21st century, involving hyper-competitive market spaces, electronically-enabled global network businesses, and corporate governance reform, IT governance has become a fundamental business imperative. IT governance is a top management priority, and rightfully so, because it is the single most important determinant of IT value realization (Mata, Fuerst, & Barney, 1995; Peterson, 2001; Rockart, Earl, & Ross, 1996; Sambamurthy & Zmud, 1999; Weill & Broadbent, 1998).

More than simply assigning and allocating IT decision-making authority, IT governance is the system by which an organization's IT portfolio is directed, and describes the distribution of IT decision-making rights and responsibilities among different stakeholders in the organization, and the rules and procedures for making and monitoring decisions on strategic IT concerns. These rules and procedures address the integration mechanisms, which are fundamental to effective IT governance.

Nevertheless, research has only recently focused on the use and effectiveness of integration mechanisms for IT governance. More research is definitely and urgently required in this area (Table 2). It is only through empirical investigation of these and other related research questions that we will be able to advance the current body of knowledge and understanding in the area of IT governance.

KEY TERMS

Centralized Model: The concentration of decision-making in a single point in the organization, in which a single decision applies.

Collaboration: A close, functionally interdependent relationship, in which organizational units strive to create mutually beneficial outcomes. Collaboration involves mutual trust, the sharing of information and knowledge at multiple levels, and includes a process of sharing benefits and risks. Effective collaboration cannot be mandated.

Decentralized Model: The dispersion of decision-making, in which different independent decisions are made simultaneously.

Differentiation: The state of segmentation or division of an organizational system into subsystems, each of which tends to develop particular attributes in relation to the requirements posed by the relevant environment. This includes both the formal division, as well as, behavioral attributes of the members of organizational subsystems.

Federal Model: A hybrid configuration of centralization and decentralization, in which decision-making is differentiated across divisional and corporate units.

Integration: 1) The process of achieving unity of effort among various subsystems in the accomplishment of the organizational task (*process focus*). 2) The quality of the state of collaboration that exists among departments, which is required to achieve unity of effort by the demands of the environment (*outcome focus*).

IT Applications: Local business-functional applications embedded in business processes, activities, products and/or services.

IT Governance: 1) Locus of IT decision-making authority *(narrow definition)*. 2) The distribution of IT decision-making rights and responsibilities among different stakeholders in the organization, and the rules and procedures for making and monitoring decisions on strategic IT concerns *(comprehensive definition).*

IT Governance Comprehensiveness: Degree to which IT decision-making/-monitoring activities are systematically and exhaustively addressed.

IT Governance Formalization: Degree to which IT decision-making/-monitoring follows specified rules and standard procedures.

IT Infrastructure: The base foundation of the IT portfolio, delivered as reliable shared services throughout the organization, and centrally directed, usually by corporate IT management.

IT Governance Integration: Degree to which business and IT decisions are integrated administratively, sequentially, or reciprocally.

IT Portfolio: Portfolio of investments and activities regarding IT operations and IT developments spanning IT infrastructure (technical and organizational components) and IT applications.

Participation: Process in which influence is exercised and shared among stakeholders, regardless of their formal position or hierarchical level in the organization.

Shared Learning: The co-creation of mutual understanding by members of organizational sub-units of each other's goals and objectives.

Triangular Strategic Analysis for Hybrid E-Retailers

In Lee
Western Illinois University, USA

INTRODUCTION

For traditional retailers, the success of an e-channel lies largely in formulating and implementing a sound e-channel strategy that leverages their resource base. Numerous evidences show that poorly developed e-channels have added little value to retailers (Huang, 2003; Prencipe & McCarthy, 2002). Some of the poorly developed e-channels have had a negative impact on business performance due to an excessive investment, disappointing sales, and low margin (Nataraj & Lee, 2002). The poor performance arose from focusing on the Internet as a separate channel not affected by the activities in other existing channels (Kannan, 2001). For many traditional retailers, their costly and frequent e-channel reorganizations could have been avoided if they had adequately analyzed the strategic fit between their external environment and e-channel organization.

There has been no universally applicable business strategy for e-channels. For many retailers, the right mix of the traditional channels and e-channel is critical to their business success (Gulati & Garino, 2000). Despite the strategic value of the e-channel, there have been only a paucity of frameworks that help managers initiate and formulate the e-commerce strategy (Allen & Fjermestad, 2001; Lee, 2001). A number of strategic analysis models such as SWOT analysis, five forces model, resource-based view, and critical success factors have been applied to the e-commerce strategy development. These models attempted to formulate a business strategy from different perspectives of a business organization, but have not been fully integrated with each other. Formulating a business strategy based on the analysis and integration of multiple perspectives will result in a more competitive strategy than those of a single perspective.

Based on a number of e-channel case studies and strategic management theories, this short article presents (1) an overview of a triangular strategic analysis and (2) an example application of the triangular strategic analysis with an Office Depot case study. Data on the Office Depot's e-channel strategy and implementation were collected through secondary sources such as trade journals and Office Depot's official publications. The triangular strategic analysis consists of (1) competitive forces analysis, (2) resource base analysis, and (3) critical success factor analysis

BACKGROUND

To capture the ever-increasing B2C population, retailers have experimented with a variety of B2C business models (Gulati & Garino, 2000). Some of the widely used e-commerce models include auction models (e.g., eBay.com), reverse auction models (e.g., Priceline.com), portal models (e.g., Yahoo.com), stand-alone e-retailer models (e.g., Amazon.com), and hybrid e-retailer models (e.g., Walmart.com). While B2B e-commerce applications such as e-procurement systems and the Internet-based supply chain management have brought significant benefits to business organizations, many B2C business models have failed to generate sustainable long-term profits.

In the late 1990s, most stand-alone e-retailers of commodity type products suffered the hardest hits due to low margin, rising customer acquisition cost, and the lack of financial support of investors (Stockport, Kunnath, & Sedick, 2001). Numerous stand-alone e-retailers such as Garden.com, Boo.com, and Petopia.com were consolidated with traditional retailers or liquidated (Kujubu & Martin, 2001). These failures were attributed to the poor business plan, weak complementary resources in distribution network and customer services, lack of brand name recognition, and low entry barriers.

Evidence shows that a misdirected e-channel development leads to costly and frequent revisions of e-commerce strategies. Kmart and Wal-Mart experienced a costly revision of their e-channel strategies. Kmart initially created a spin-off entity, BlueLight.com, in December 1999 as a joint venture between Kmart and Softbank Venture Capital. After Kmart withdrew from a planned initial public offering (IPO) for BlueLight.com in 2000, it acquired all of the interests of BlueLight.com in 2001. Walmart.com is another example of the costly revision of an e-channel strategy. Walmart.com was established in January 2000 as an independent company operating as a joint venture between Wal-Mart and Accel Partners. In 2001, Wal-Mart acquired all the minority interest in Walmart.com in order to establish the tight integration between its e-channel and physical stores.

Since each organization is uniquely positioned in a market with a different set of competitive forces, critical success factors, and capabilities, no single e-channel strategy would be suitable for all organizations. The successful deployment of an e-channel requires a thorough review and analysis of all major business activities, including business strategies, processes, functions, and vendor/customer relationships. For traditional retailers, poorly deployed e-channels without cross-channel coordination and integration mechanisms in place cannot create competitive advantages. These e-channels may also have a negative impact on other channels by losing customers who value a seamless cross-channel experience. The triangular strategic analysis will provides managers with a unified view of a business organization by combining and presenting multiple organizational perspectives.

TRIANGULAR STRATEGIC ANALYSIS FOR HYBRID E-RETAILERS

The purposes of strategic analysis are to examine the current and future business environments, to identify new business opportunities and threats, and to develop strategies to counter competition and achieve strategic goals. A number of strategic analysis models have been developed with the emphasis on different perspectives of a business strategy development. Table 1 summarizes major strategic theories/models, their purposes, advantages, and disadvantages. Based on the complementarities of these models, we utilize three analysis models in an e-channel development framework. The triangular strategic analysis consists of (1) competitive forces analysis, (2) resource base analysis; and (3) critical success factor analysis. While each of these strategic analysis methods

Table 1. Summary of major strategic management theories/models

Major Theories/Models	Proponents	Characteristics
Five Forces Model of Industry Competition	Porter (1980)	His basic theory was that dynamics of five competitive forces determine the nature of competitiveness in an industry and influence the strategies available to firms in the industry. The competitive forces are: (1) threat of new entry into an industry; (2) intensity of rivalry among existing competitors; (3) pressure from substitute products; (4) bargaining power of buyers; and (5) bargaining power of suppliers.
Resource Based View (RBV)	Wernerfelt (1984)	RBV suggests that firms compete not just in terms of final products, but more fundamentally in terms of the underlying “resources” which make production and product diversification possible. From a resource-based view every firm has a unique set of resources that the firm can leverage to exploit opportunities and counter threats.
Core Competence	Prahalad and Hamel (1990)	Core competencies are the collective learning in the organization that gives the company a unique advantage over its competitors. Core competence can manifest itself in many ways. Core competence is communication, involvement, and a deep commitment to working across organizational boundaries. It is the skills of individuals who can blend their expertise with that of others in new and interesting ways.
Balanced Scorecard (BSC)	Kaplan and Norton (1996)	The Balanced Scorecard is a method for turning a company’s vision and strategy into a coherent set of performance measures distributed among four perspectives: Financial, Customer, Internal Business Processes, and Learning and Growth. The framework provides a balance between short- and long-term objectives, financial and nonfinancial measures, and external and internal performance indicators.
Critical Success Factor (CSF) Analysis	Rockart (1979)	CSF analysis is a method developed to guide businesses in creating and measuring success. CSFs are key areas where satisfactory performance is required for the organization to achieve its goals. Rockart provided the following as an example of the CSFs: new product development, good distribution, and effective advertising - factors that remain relevant today for many firms.

Table 2. Impacts of e-commerce on competitive forces' threats and firm's opportunities from retailers' perspective

Competitive Forces	Threats	Opportunities

was developed in isolation of the others, they contribute unique yet complementary perspectives on the development of the business strategy. The integration of three analyses implicitly subsumes the essence of the core competence analysis. The balanced scorecard model can be used in parallel with the triangular strategic analysis or in the subsequent planning stage, and later in evaluating the organizational performance.

Competitive Forces Analysis

Porter's Five Forces Model (1980) has been widely used in analyzing competitive forces that would shift an organization's strategic position in the industry. The components of the model include: (1) the traditional competitors, (2) the bargaining power of the customers, (3) the bargaining power of the suppliers, (4) the potential threat of new entrants, and (5) the threat of substitute products/services. The competitive forces analysis presents a picture of where the company's current strategy stands against competitive forces and a road map of where it should go for the success in the competitive environment. The emergence of e-commerce has changed the ways all competitive forces perform businesses in the industry. E-commerce provides customers with opportunities to comparison-shop and thereby raises the bargaining power of customers. E-commerce also provides suppliers with opportunities to disintermediate retailers. Traditional competitors establish e-commerce Web sites to enter into the e-marketplaces.

The competitive forces analysis provides managers with vital information on the opportunities and threats arising in the e-commerce market. Table 2 summarizes the opportunities and threats introduced by the e-commerce from the retailers' perspective. While the competitive forces analysis is effective in understanding external environment, some researchers have pointed out its limitations (Luffman, Lea, Sanderson, & Kenny, 1996). The analysis has not explicitly addressed what the critical factors are and what resources are needed for a successful execution of a business strategy. The following resource base analysis utilizes the results obtained from the competitive forces analysis and determines what resources are needed and how they are used in the execution of an e-channel strategy.

Resource Base Analysis

Many researchers have indicated that the resource-based view of a firm is the most important theory of sustainable competitive advantage (Conner, 1991). The fundamental logic of the resource-based view is that the desirable outcome of a business strategy is a sustainable competitive advantage. Since not all resources are equal in creating sustainable competitive advantage, many researchers focused on identifying advantage-creating resources. Barney (1986, 1991) suggested that the advantage-creating resources must be firm-specific, rare, and difficult to imitate. The resource-based view of a firm was applied to understand how the superior IT resources of organizations render the cost and value of IT innovations different from competitors (Bharadwaj, 2002). In a changing environment, firms must continuously invent and upgrade their resources and capabilities if they are to maintain a competitive advantage and growth. The sequential development of resources and capabilities can make a firm's advantage inimitable (Barney, 1991; Lado, Boyd, & Hanlon, 1997).

Each retailer has a different set of firm-specific resources to utilize, and an addition of an e-channel can be

Table 3. E-commerce analysis matrix of competitive forces and resource base: Office Depot's case

Competitive Forces	Suppliers		Traditional Competitors		New Market Entrants		Customers		Substitute Products/ Services

Distribution Centers	●		●		●	
Database	●		●			
Integrated Information Systems	●	●	●		●	
Skills and Knowledge of Employees		●		●		●
Organizational Culture and Trust		●	●		●	●

viewed as a unique resource utilization and development process in achieving sustainable growth. The mapping between the competitive forces and the resource base provides answers to two important questions: (1) what kinds of existing resources a retail organization can leverage and (2) what resources it needs to differentiate itself from the competitors. While strong resources are leveraged to survive, weak or non-existent resources need to be critically examined for the future resource development and sustainable competitive advantage. Traditional retailers' resources include physical stores, distribution centers, patent, trademark, brand, reputation, enterprise-wide database, integrated information systems, skills and knowledge of employees, and organizational culture and trust. Some of these resources are more difficult to imitate and more valuable as a source of competitive advantage than others. In general, intangible resources would be more difficult to transfer and imitate than tangible resources.

Table 3 shows the e-commerce strategy matrix of the competitive forces and the resource bases of Office Depot. The rows list two types of resources: strong resources (sustaining resources) and weak/non-existent resources (developmental resources). Certain weights can be assigned to the competitive forces based on their importance to prioritize the resource allocation and development activities. The analysis of Office Depot suggests that the existing integrated information systems can be leveraged to counter the threat of the suppliers' e-commerce and to benefit from the growth of the customers' online purchases.

The matrix needs filling of e-commerce strategies and projects in relation to resources, threats and opportunities. Threats posed by new market entrants may force a retailer to choose the e-channel introduction as a strategic option. If a retailer has a strong resource base in support of an e-channel, then an immediate introduction of an e-channel may be feasible with little developmental resources. Overall, the e-commerce strategy matrix of the competitive forces and the resource base provides a conceptually grounded framework for assessing sustainable and developmental resources, and enables these resources to be examined in terms of the opportunities and threats for establishing sustainable competitive advantages.

Critical Success Factors Analysis

Once the previous analyses lead to an e-commerce strategy, critical success factors (CSFs) analysis decides what the most important determinants are in achieving strategic goals (Rockart, 1979). The successful execution of CSFs requires resources. Identifying a match between the firm's resources and the critical success factors in the industry is a demanding task, and the success of the match is a function of the accuracy of managerial expectations about the value of the strategy (Barney, 1986).

The e-commerce success factors for retailers include efficient business process, integrated distribution systems, multi-channel coordination and integration, customers' trust, strong brand recognition, superior customer service operations, financial stability, effective online technologies, and strategic alliances. Table 4 shows a matrix that develops matches between the Office Depot's resources and the critical success factors. For example, the business process redesign requires the integrated information systems, skills and knowledge of employees, and organizational culture and trust as critical resource bases.

The matrix helps managers determine what existing resources can be leveraged or what new resources are needed to achieve the CSFs and ultimately the business strategies. To successfully achieve e-channel strategic goals and sustain competitive advantages, retailers need to monitor the performance of these CSFs with a measurable objectives and metrics. Once CSFs and metrics are defined, a detailed e-channel plan should be developed to achieve these critical success factors and business strategies.

FUTURE TRENDS AND CONCLUSION

The rapid penetration of the World Wide Web and the explosion of e-commerce startups have changed the dynamics of the competitive forces across all industries. Due to the explosion in e-commerce competition, the e-channel has become a critical factor in the strategy development by the hybrid e-retailers. While managing the e-channel is one of the most important tasks for marketing managers, many managers are still unclear about e-channel strategies and lack core e-channel knowledge needed to analyze business environments, to develop strategies, and to evaluate alternative e-channel solutions. Empirical evidence shows that experimenting with different types of e-channels is very costly. Some retailers such as Kmart, Wal-Mart, CVS, and Staples experimented with spin-offs. These retailers later struggled to retrofit the spin-offs into their parent companies.

A number of strategic analysis models such as SWOT analysis, five forces model, resource-based view, and critical success factors have been applied to e-commerce strategy development. However, there has been little effort to integrate these models for e-channel strategy development. These models attempted to formulate a business strategy from different perspectives of a business organization, but have not been fully integrated with each other. The analysis and integration of multiple dimensions will result in a more comprehensive strategy than those of a single dimension. To develop a comprehensive e-channel strategy, the triangular strategic analysis attempted to integrate three well-known analysis models: competitive forces analysis, resource base analysis, and critical success factor analysis.

The triangular strategic analysis provides managers with a unified view of a business organization by combining and presenting multiple perspectives of an organization. The unified view will enhance managers' ability to effectively identify their present strategic position, internal resources, and critical success factors, and decide upon the most appropriate e-channel strategy. As important, the unified view will allow managers to utilize the emerging opportunities of e-commerce and to prevent threats that would be posed by carelessly developed e-channel strategies.

The triangular strategic analysis was applied to analyze Office Depot's e-channel development strategy. The evaluation of Office Depot's e-channel development strategy suggests a number of its success factors that may be useful for other retailers' e-channel development: (1) Office Depot was an early adopter of an e-commerce technology, and continued to explore different e-commerce business models over time; (2) its e-channel was not only another distribution channel but also a service channel; (3) it also leveraged its own e-channel expertise and resources in office supplies in expanding to other markets; and (4) it treated an e-channel not as an independent entity but as an internal business unit in an integrated business organization; (5) its senior management supported an e-commerce project from a strategic point of view; and (6) it pursued a resource-based e-channel IT development.

KEY TERMS

Channel Conflict: Situation in which an e-channel creates a conflict with existing channels because of real or perceived damage from inter-channel competition.

Complementarities: Products or services that provide more value together than individually. For example, hybrid e-retailers can leverage complementarities by providing offline services to online shoppers.

E-Channel: An online marketing channel where companies and customers conduct business, no matter where they are. Since the e-commerce revolution, many brick-and-mortar businesses have expanded their marketing channel to include e-channel.

Hybrid E-Retailer: A click and mortar company which conducts retailing through e-channel as well as physical stores and other distribution channels. Compared to its pure e-commerce competitors, a hybrid e-retailer can leverage existing physical stores, brand recognition, distribution network, existing customer base, and so forth.

On-Demand Delivery Services: Express delivery of products made with highly efficient transportation systems after an online order is received.

Order Aggregation: A group purchase designed to achieve a volume discount by aggregating orders placed by individual buyers.

Reverse Auction: A fixed-duration auction hosted by a single buyer in which multiple sellers compete for business.

Sell-Side Forward Auction: An auction where a seller announces the items for quick sale and buyers bid on them.

Triggers, Rules and Constraints in Databases

Juan M. Ale
Universidad de Buenos Aires, Argentina

Mauricio Minuto Espil
Universidad Católica Argentina, Argentina

INTRODUCTION

Databases are essentially large repositories of data. Since the mid-1980s up to the mid-1990s, considerable effort has been paid to incorporate reactive behavior to the data management facilities available. Reactive behavior is characterized by variants of the event–condition–action model. Applications areas include checking for integrity constraints, system alerts, materialized view maintenance (especially useful in data warehousing), replication of data for audit purposes, data sampling, workflow processing, implementation of business rules, scheduling, and many others. Practically all products offered today in the database marketplace support complex reactive behavior on the client side. Nevertheless, the reactive behavior supported by those products on the server side is poor. Recently, the topic has regained attention because of the inherent reactive nature demanded in Web applications and the necessity of migrating many of the functionalities of browsers to active Web servers (Bonifati, Braga, Campi, & Ceri, 2002).

BACKGROUND

Several applications that support reactive behavior in the electronic commerce arena appeared recently, as is the case in the following: the Active Views system, described in Abiteboul et al. (1999); the event–condition–action (ECA) rule language for XML repositories, described in Bailey, Poulovassilis, and Wood (2002); and the set of classes for remote notification within a Web service environment, described in Bonifati, Ceri, and Paraboschi (2001).

Supporting reactive behavior implies that a database management system must be viewed from a production rule system perspective (Baralis, Ceri, & Paraboschi, 1996). An active database system must support the definition of production rules. Production rules are well known nowadays, in database terminology, under the name of active rules or, simply, triggers.

Active rules and integrity constraints are related topics (Ceri, Cochrane, & Widom, 2000). Database engines do not bring a full support of declarative integrity constraints in their kernels. When a complex constraint must be enforced on data, and the constraint cannot be declared, it must be emulated by means of triggers.

From a user's point of view, reactivity is a concept related to object state evolution over time. Dynamic constraints, constraints making assertions on the evolution of object states, may be needed to control changes in the states of data objects (Sistla & Wolfson, 1995b).

ACTIVITY WITHIN DATABASES

Usually, a database system performs its actions in response to requests from users in a passive way. In some cases, it is desirable that actions be taken with no human intervention, that is, automatic response to certain events.

Traditionally, the latter behavior has been obtained by embedding it into user applications; that is, the application software recognizes some events triggered by an user and performs some actions in response.

Because of the complexity in supporting reactive behavior, it would be desirable that the active functionality be provided by the database system. A database with a capability of reacting to external or internal stimuli is called an active database. An active database system can be thought of as coupling a database management system with a rule-based programming environment (Paton & Diaz, 1999). Among the applications that use active database systems nowadays, we can mention inventory control systems, online reservation systems, and portfolio management systems, just to name a few.

Knowledge Model

A central issue in the knowledge model of active databases is the concept of active rule.

An active rule is defined throughout three dimensions: event, condition, and action. In this case, this is termed an ECA rule.

An event is something that happens at a point in time. The source of the event may be transactional (an abort, commit, or begin transaction), operational (insert, delete, or update operations), temporal (clock signaling), or external (generated by the environment). An event can be classified according to its complexity as primitive or composite.

A condition, i.e., a predicate evaluated on data states, is the second component of an active rule. Moreover, because the state of data may change, before and after the occurrence of an event, the condition should be able to refer to previous and new states.

An action consists in a sequence of operations. There are several options for possible actions: the update of the contents or structure of the database, the call of an external procedure, the abort of the current transaction, or the notification about some unexpected situation.

Execution Model

The execution model for a set of active rules determines how the rules are managed at execution time. This model is strongly dependent on the particular implementation. However, it is possible to describe it in general using a set of common activities or phases: signaling, triggering, evaluating, scheduling, and executing.

How these phases are synchronized depends on the so-called coupling modes of ECA rules. The relationship among the aforementioned activities of the rules involves the concepts shown in Table 1.

Termination and Confluence

The behavior of active rules is hard to understand and control (Baralis, Ceri, & Widom, 1993). Rule interaction is one of the most important aspects related to rule set behavior. Two important properties related to this problem are observed: termination and confluence. It is said that a rule set is guaranteed to terminate if, for any database state and initial event, rule processing cannot continue forever. A rule set is confluent if, for any database state and initial event, the final database state after rule processing is independent of the order in which activated rules are executed.

Basic methods that perform termination analysis of a rule set have been discovered. However, because of the undecidability of the problem in general (Bailey, Dong, & Ramamohanarao, 1998), we cannot always decide whether a rule firing process is guaranteed to finish.

According to the time when those methods are applied, they can be classified as static, if the rule set is analyzed at compile time, or dynamic, if the rule set behavior is analyzed at run time. Deciding whether the condition of one rule is affected by the action of other rules, and when two rule actions commute, is known as the propagation problem. Propagation has been thoroughly studied (see Baralis & Widom, 2000). Propagation is the crux of static methods to determine confluence and termination (Widom & Ceri, 1996).

In the commercial systems side, an approach consists of imposing syntactic limitations, in order to guarantee termination or confluence at run time, although in some cases, counters are used to prevent infinite execution.

ACTIVE RULES AND DECLARATIVE CONSTRAINTS

Declarative constraints are user definitions specifying restrictions that the database states must satisfy. In a SQL-1999 (Standard Query Language-1999) compliant system, four classes of declarative constraints are supported: check predicate constraints, referential constraints, assertions, and view check options. Check predicate constraints aim at validating conditions against the actual state of *one* table in the database, and they include *primary key* and *unique* definitions, *not null* column definition, and *explicit check* clauses that validate general predicates on the values of some of the columns of the table. Referential constraints aim at guaranteeing that a many-to-one relationship holds on the actual state of two

Table 1. Concepts

• Activation time
• Transition granularity
• Net effect policy
• Cycle policy
• Consumption modes
• Rule execution ordering

Table 2. Why declarative constraints and triggers must be distinguished

• Declarative constraints should be processed after all changes are effectively applied.
• Inconsistent states would lead to unpredictable behavior when firing a trigger.
• Processing constraints and triggers together should be confluent.

tables: the *referencing* or *child* table, and the *referenced* or *parent* table. A many-to-one relationship ensures that the column values of a foreign key (a list of columns of the referencing table) match the column values of a candidate key (a list of columns of the referenced table). Assertions aim at validating general predicates on rows in *different* tables. View check options deal with the problem of admitting modification operations through cascade defined views, yet retaining the natural meaning of the operations. A declarative constraint can be declared as having a deferrable or a nondeferrable activation time.

In SQL-1999, an active rule defined by the user is called a trigger, which is a schema object in a database (Ceri et al., 2000). The trigger structure is defined as follows:

CREATE TRIGGER <*trigger_name*> [BEFORE | AFTER] [<*event*> | <*events* >] ON <*table*>
REFERENCING NEW AS <*new_value*> OLD AS <*old_value*>
NEW TABLE AS <*new_table*> OLD TABLE AS <*old_table*>
FOR EACH [ROW | STATEMENT] WHEN <*condition*> < *action* >

Events can be statements INSERT, DELETE, or UPDATE <*list*>; <*table*> must be the name of a defined base table or view name; and <*list*> is a list of column names of table <*table*>. From now on, a trigger event is, therefore, a modification operation on a base table. The activation time is specified by keywords BEFORE or AFTER, thus yielding before and after triggers. Before triggers fire immediately before the operation specified as the trigger event has been issued. The after triggers fire immediately upon operation completion. The referencing clause admits defining correlation variables for transition values and transition tables, which allow the trigger to access column values of the affected rows before and after the execution of the modification operation. The transition granularity is specified by clause ON EACH and can be set to either ROW or STATEMENT. Hence, row-level and statement-level triggers can be defined. Row-level triggers fire one instantiation for each row affected by the modification operation. Provided no row is affected, a row-level trigger is never instantiated. Statement triggers fire only once per statement invocation and are evaluated even in the case the event does not happen to affect any row.

A declarative constraint includes explicitly or implicitly the specification of repairing actions. Hence, declaring a SQL constraint may be thought of as entailing the activation of internal active rules that enforce repairing actions whenever the constraint is violated. (See Ale & Minuto Espil, 2003, for details.)

Up to this point, the reader may wonder if declarative constraints and triggers are the same. Despite their similarities, declarative constraints and constraint rules must be distinguished. Table 2 summarizes some of the reasons.

The considerations above imposed the obligation of producing a precise specification on how declarative integrity constraints and constraint rules should be integrated. An actual accepted specification has been produced by the SQL-1999 standardization committee and is based on a proposal submitted by a research group in the IBM Almaden Research Center (Cochrane, Pirahesh, & Mattos, 1996).

FUTURE TRENDS

A different question is as follows: Can active rules be regarded as constraints? The answer is affirmative. If a past temporal logic formula is derived from the event and condition part of the rule, and a present temporal logic formula that fixes the new state in the case of rule activation is derived from the action part of the rule, an implication of the latter from the first defines a constraint that restricts state transition. It defines the pairs of consecutive states that are admissible in an execution and the pairs that are not (Sistla & Wolfson, 1995a).

CONCLUSION

We presented a brief survey of the interaction between active rules and integrity constraints. We discussed the current proposed techniques for dealing with situations when both declarative static constraints and triggers are defined. The perspective of our treatment has followed the SQL-1999 Standard Committee point of view, which constitutes the state of the art in that matter.

KEY TERMS

Action: A sequence of operations.

Active Database: A database with the capability for reacting to stimula.

Condition: A predicate that evaluates a situation with respect to circumstances.

Declarative Constraint: A schema object in the database that defines whether a state of the database is consistent or not.

Event: Something that happen in a point of time.

Rule Activation Time: A concept that fixes the position of the signaling phase with respect to the event occurrence.

Rule Evaluation: An activity determining condition satisfaction.

Rule Execution: An activity running the corresponding action of an instantiated rule.

Rule Propagation: A property that determines how the condition of one rule is affected by the action of any other.

Rule Scheduling: An activity that determines the order of execution within a set of rule instances whenver they are fired simultaneously.

Rule Set Confluence: A property that indicates whether the final database state after rule processing is independent of the order of execution.

Rule Set Consumption Mode: Feature indicating how a set of rule instantiations is reduced as a consequence of execution.

Rule Set Cycle Policy: Feature indicating whether recursion must be applied when triggering a rule or rules must be instantiated only once.

Rule Set Net Effect Policy: Feature that indicates the relationship among event occurrences, rule instantiation and consumption modes.

Rule Signaling: An activity occurring when some source causes an event.

Rule Transition Granularity: A concept used in analyzing the relationship between event occurrences in rule instantiation.

Rule Triggering: Rule instantiation.

Trigger: A schema object in the database that defines the event, condition and action part of a production rule.

Trust in B2C E-Commerce for the New Zealand Mäori

Konrad J. Peszynski
Deakin University, Australia

INTRODUCTION

This study was performed to allow an understanding of some of the elements of trust that are apparent to encourage the Mäori Internet shopper to feel comfortable to shop online. Mäori arrived in New Zealand from the Pacific over 1,000 years ago. Since then, New Zealand was colonised by Europeans in the 19th century. As a result, the Mäori have become a minority (Belich, 1996). That is, their culture, language and values have become secondary to those of the dominant European culture (Liu, Wilson, McClure & Higgins, 1999). Mäori have been defined as including "all those who identify themselves as belonging to the New Zealand Mäori ethnic group, either alone or in combination with any other ethnic group" (Statistics New Zealand, 1998, p. 94).

An extensive selection of literature exists on trust and the Internet (Camp, 2000; McKnight, Cummings & Chervany, 1998). Few studies have examined the aspects of trust and the Internet for different cultures. Early studies, for example, by Jarvenpaa, Tractinsky, Saarinen and Vitale (1999), found that cultural differences do exist in Internet shopping. As a result, a gap in knowledge has been identified in terms of trust, Internet shopping and culture in New Zealand. This study has focused on Mäori, who, according to the literature have varying beliefs and values as opposed to the non-Mäori in New Zealand (Patterson, 1992).

This study will examine the issues that have helped or hindered the adoption of Internet shopping for the Mäori Internet user. From interviewee responses, a better understanding of current attitudes with regard to Internet shopping will be obtained. These responses will be linked to the various issues raised in this study. This study will therefore answer the questions set out as follows:

- What issues of trust are apparent to the Mäori Internet shopper?
- Does the current literature on trust and Internet shopping apply to the Mäori Internet shopper, and if so, how?

An attempt will be made to relate the literature reviewed and the conceptual framework developed in this study to the answers obtained via interviews in order to answer these research questions.

REVIEW OF LITERATURE

Through an investigation into the nature of business-to-consumer electronic commerce and the issues affecting the Internet customer, three key issues emerged: trust, risk and reputation.

Business-to-consumer (B2C) e-commerce is the trading and transactional relationship between an organisation's Web site and an end user (Lawrence et al., 2000; Schneider & Perry, 2000). Consumers are able to purchase goods and services such as books, computer products, and music at any time that is convenient to the consumer. Business-to-consumer e-commerce focuses on direct transactions between businesses and end consumers (Dedhia, 2001; Lawrence et al., 2000; Riggins & Rhee, 1998).

Business-to-consumer e-commerce involves smaller amounts of money in each exchange, whilst a greater volume of money is exchanged in the business-to-business (B2B) environment due to the volume of goods and services being transacted. Transactional relationships tend to be intimate for B2C e-commerce, as the objective is to satisfy customer preferences and shopping habits, but in the B2B setting, relationships are formal and impersonal (Ah-Wong et al., 2001; Lawrence et al., 2000; Riggins & Rhee, 1998).

There are factors that inhibit B2C e-commerce adoption. These factors include trust, risk and reputation. According to McKnight, Cummings and Chervany (1998, p. 459), trust is "an individual's beliefs about the extent to which a target is likely to behave in a way that is benevolent, competent, honest, or predictable in a situation." The consumer needs to believe that the Web merchant is trustworthy before he or she purchases online.

Factors that can increase the trust of an Internet consumer include assurance services such as those provided by MasterCard and TRUSTe (Cashell & Aldhizer III, 1999; Nöteberg, Christiaanse & Wallage, 1999), which permit a Web site to display their Web trust seal (a graphic) provided their "practices…[comply] with the

WebTrust principles and criteria for business-to-consumer e-commerce" (Cashell & Aldhizer III, 1999, p. 51). Web sites that show a seal are more likely to be purchased from than sites that carry no seal at all (Nöteberg et al., 1999). It made no difference as to which seal was displayed on the Web site, just as long as a seal was visible.

Another factor associated with inhibiting Internet customers from shopping online is risk. Risk is defined as the consumer's perceptions of the uncertainty and adverse consequences of engaging in an activity (Camp, 2000; Jarvenpaa et al., 1999, 2000). There is little assurance that the customer will get what he or she sees on the computer screen, in the quantity ordered.

It has been suggested that two types of risk are predominately associated with Internet shopping (Fram & Grady, 1997; Jarvenpaa et al., 1999, 2000; Lynch, Kent & Srinivasan, 2001). These risks are product category risk and financial risk. Product category risk is risk associated with the product itself and is the consumers' belief that the product will function according to their expectations. Financial risk refers to the risk associated with the Internet as a purchasing medium. Consumers are apprehensive about putting their credit card information over the Internet because it puts the consumer at risk of losing money via credit card fraud (Fram & Grady, 1997; Jarvenpaa et al., 1999, 2000).

The reputation and size of the Web merchant has also been suggested as factors that contribute to consumer trust in a seller organisation (Doney & Cannon, 1997; Ganesan, 1994). Reputation is the extent to which buyers believe that the selling organisation is honest and concerned about its customers (Doney & Cannon, 1997). Reputation requires a long-term investment of resources, effort and attention to customer relationships (Jarvenpaa et al., 1999). The better the seller's reputation, the more resources the seller has presumably committed to build that reputation. The perception of a large organisation implies that the merchant has significant resources invested in the business and has much to lose by acting in an untrustworthy way (Stewart, 1999).

MÄORI AND THE INTERNET

It is only recently that studies have been carried out on Mäori and their presence on the Internet (Kovacic, 2001; Smith, 1997; Smith & Sullivan, 1996). However, no studies examining the relationship between Mäori, trust and Internet shopping were found, indicating a gap in knowledge.

Jarvenpaa et al. (1999, 2000) and Lynch et al. (2001) found that trust varies across nationalities and cultures. Hofstede (1980) identified four constructs that have been the foundation of much cultural research: power distance, uncertainty avoidance, individualism and masculinity. Consumers coming from an individualistic culture may have greater trust and be more willing to base their trust in a Web site than consumers from a collectivistic culture (Javenpaa et al., 1999, 2000). The individualism/collectivism construct was the focus of this study.

According to Hofstede (1980), those in an individualistic society:

- Take care of him or herself and his or her immediate family;
- Have an "I" consciousness;
- Have a self-orientation; and
- Have greater economic development.

Those in a collectivistic society:

- Are born into extended families or clans, which protect them in exchange for loyalty;
- Have an emphasis on belonging to an organisation;
- Have a "we" consciousness; and
- Have less economic development (Hofstede, 1980).

A Mäori concept of community is based on collective strength, which includes sharing, nurturing, supporting and empowering of interdependent groups. The Mäori see community as a form of relatedness, in which people are interdependent (Gregory, 2001). An important method of communication for Mäori is through the *whanau* (family) structure (Light, 1999). That is, the connections are about relationships to people and to place.

Individualism tends to promote a trusting stance in an individualistic society (Jarvenpaa et al., 1999). As a result, one gets better outcomes assuming that others are reliable. Individualists are more likely to trust others until they are given some reason not to trust. By contrast, those high on collectivism are more likely to base their trust on relationships with first-hand knowledge. Members of collectivist cultures are less likely to trust someone who is not part of their in-group (Thanasankit, 1999; Yamagishi & Yamagishi, 1994).

The purpose of this study was to explore the issues of trust apparent to the interviewed Mäori Internet shoppers and see whether the current literature on trust and Internet shopping applies to the interviewed Mäori Internet shopper, and if so, how. Face-to-face interviews were performed with eight participants, all full-time professionals in either the public or private sector in Wellington, New Zealand. This allowed the researcher to identify Mäori perceptions of trust and Internet shopping. Because of the small sample size, results may only be generalised to a small population. However, Creswell (1994) and Yin (1994) claim that the result of case research is not to generalise to populations, but to generate a theory, which can be tested in future studies, or provide confirmatory evidence of existing theory. The data were analysed using a hermeneutic framework that enabled the identification of issues that arose in either the interview or the background literature review.

SOLUTIONS AND RECOMMENDATIONS

It was found that the current literature applied to the interviewed Mäori Internet shoppers to a certain extent. The use of assurance services has been noted in the literature as helping increase the trust of a consumer; however, those that were interviewed claimed to pay no attention to these Web seals. Participants claimed no knowledge of the groups or organisations supporting the Web seals or what they stand for.

In terms of risk and Internet shopping, respondents felt that financial risk is important and the same as what the literature states; however, the product category risk equally applies to the traditional "bricks and mortar" environment. Although the risk factor exists, the final purchase ultimately comes down to whether or not they want to take that risk. However, knowing the reputation of the organisation contributes to the trust in the trading relationship.

Reputation was a major theme that was apparent in most of the interviews; however, those interviewed tend to pay little attention to customer testimonials, particularly because they do not know if they are real or how the person who wrote the testimonial based their judgements. Respondents prefer to speak to someone they know that has visited that site to see how they found that site, rather than trust a total stranger.

Further questioning brought to light other factors such as the notion of anonymity; that is, no one knows they are Mäori, and as a result will not treat them any differently as opposed to non-Mäori, allowing them to shop with no discrimination. Photos of the people inside the organisation on the Web site can give the Mäori Internet shopper recognition that the organisation does exist and that they are not a faceless organisation. This also helps if the Mäori Internet shopper needs to call up for any reason, as they have a face to the name. Finally, the association of recognisable Mäori names to e-commerce sites could also make a difference, as there is that reputation or word-of-mouth notion that if other recognisable Mäori trust the site, then the Mäori Internet shopper should do so.

The framework developed in Figure 1 is an adaptation of the model created by Jarvenpaa et al. (1999, 2000). The difference is the extra step leading to reputation.

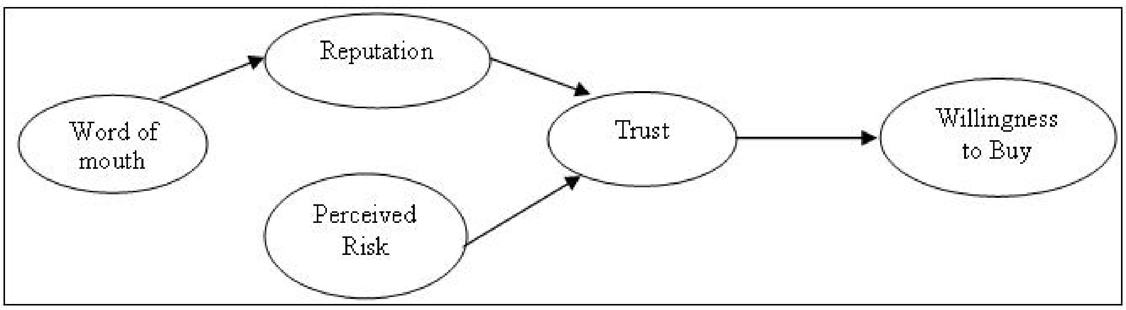
The creation of the extra parameter (word of mouth) leading to reputation has been introduced, as it has been found from the literature that because Mäori are part of a collectivist society, they are more likely to base their trust on relationships with first-hand knowledge. Mäori are also less likely to trust someone who is not part of their in-group (Thanasankit, 1999; Yamagishi & Yamagishi, 1994). That is, positive word of mouth about a Web site from someone in their in-group will increase the reputation of that Web site.

The information provided in this study can help New Zealand (and possibly international) e-commerce organisations, as it highlights some issues that Mäori have that either hinder them or assist them to purchase via the Internet. As Mäori are classed as being a collectivist society (Gregory, 2001; Light, 1999; Patterson, 2000), this information could also be applied to other collectivist societies.

One possible outcome of this study is the creation of a New Zealand Web seal. For example, a specific New Zealand organisation such as the Commerce Commission is seen as being a reputable source that those interviewed would trust. If New Zealand Web sites are registered with the Commerce Commission, then this could help increase the consumers' trust in the Web site and make them feel more comfortable to make a purchase.

The association of Mäori names with a Web site could also help the would-be Mäori Internet shopper trust the

Figure 1. Factors involved in increasing a consumer's willingness to purchase online



Web site and is linked closely to the previous suggestion of the Web seal. It is the recognition of a reputable association, and because the Mäori organisation (*iwi* (tribe), *hapu* (sub-tribe), *whanau* (family)) trusts that associated name, the Mäori Internet shopper should then trust the Web site.

Contact details should be made visible on the Web site, as one participant states: "I like the thought of it being on every page. You know, usually down the bottom they'll have all that information, the help, the contact details" (Participant Seven). Displaying contact details creates a professional image, and shows that there is the ability to contact the organisation.

FUTURE TRENDS

The study this article was based on also provides a base for future studies in the field of electronic commerce and cultural values. The first and foremost area is the New Zealand Mäori. The study was an introductory investigation into the cultural differences of Internet shopping for Mäori. As a result, possibly the first step for future studies is to investigate if and how the results of the current study compare to New Zealand Europeans.

Another extension would be to interview Mäori Internet shoppers in a New Zealand context, rather than a Wellington context. This would see if the results of this study are Wellington-specific, that is, only apply to Mäori Internet shoppers in the Wellington region. Another benefit of such an extensive study would create the ability to generalise the results New Zealand-wide, rather than concentrated on one specific city, Wellington. An investigation into other collectivist societies (Eastern countries,such as Japan, Thailand and China) could see if culture significantly influences the indigenous behaviours and attitudes of people.

CONCLUSION

The central concern of this study has been to gain some understanding of what issues of trust are apparent to make the Mäori Internet shopper feel comfortable to shop online. This study attempted to uncover some understanding of the associated factors that either help or inhibit Mäori from shopping on the Internet.

This study therefore tentatively suggests that trust for the Mäori Internet shopper in this demographic means that the Web site must have a good reputation, the ability to contact someone and the guarantee that the goods you order are actually the goods you receive in the delivery period as promised by the seller. There was also a sense of collectivism in the comment made. That is, participants want to see a contribution to Mäori society for any Mäori product they purchase.

Due to time and resource constraints, this study was restricted to a small number of interviewees. In improving on what has been done, it is suggested that conducting more interviews with the greater population of Mäori Internet shoppers within New Zealand could get more representative opinions about issues of trust and shopping on the Internet. Perhaps the adage "caveat emptor" is still applicable in this day and age when shopping via the Internet; that is, let the buyer beware.

KEY TERMS

B2C E-Commerce (Business-to-Consumer Electronic Commerce): Focuses on direct transactions between businesses and end consumers. Consumers are able to purchase goods and services such as books, computer products, music, at any time that is convenient to the consumer.

Collectivism: Concerned with group interest rather than individual interest (individualism). Collectivist societies support structures where people are born and live in extended families. The concept of collective strength includes sharing, nurturing, supporting and empowering of interdependent groups.

E-Commerce (Electronic Commerce): Usually refers to conducting business (electronically) with other businesses or consumers, but can be extended to include the inner workings within a business.

Individualism: Concerned with individual interest as opposed to group interest (collectivism). That is, everyone grows up to look after himself/herself. The relationship between superiors and subordinates is based on mutual advantage.

Reputation: The extent to which buyers believe that the selling organisation is honest and concerned about its customers.

Risk: The consumer's perceptions of the uncertainty and adverse consequences of engaging in an activity.

Trust: An individual's beliefs about the extent to which a target is likely to behave in a way that is benevolent, competent, honest, or predictable in a situation.

Trust in B2C E-Commerce Interface

Ye Diana Wang
University of Maryland Baltimore County, USA

THE NATURE OF TRUST

Electronic commerce (e-commerce) is changing the way people make business transactions, especially in the business-to-consumer (B2C) area, and it is becoming a significant global economic force. Since Internet technologies and infrastructures to support e-commerce are now in place, attention is turning to psychological factors that affect e-commerce acceptance by online users and their perceptions of online transactions. One such factor is trust, seen to be key to the proliferation of e-commerce.

Trust has existed as long as the history of humans and human social interactions, and it has been studied long before the emergence of the Internet or e-commerce. With respect to consumer behavior, studies have mainly focused on trust and trust relationships in the off-line world and have emerged from numerous disciplinary fields since the 1950s (Corritore, Kracher, & Wiedenbeck, 2001). These disciplines, including philosophy, sociology, psychology, management, marketing, ergonomics, human-computer interaction (HCI), and industrial psychology (Corritore, Kracher, & Wiedenbeck, 2003), have together contributed an extensive body of literature on trust in general, and therefore, they are important grounding points for the examination of trust in the online world. However, "trust is an extraordinarily rich concept, covering a variety of relationships, conjoining a variety of objects," as Nissenbaum (2001, p. 104) has pointed out. Due to the complex and abstract nature of trust, each discipline has its own understanding of the concept and different ways to conceptualize it according to the features of a particular context.

Even with the diverse trust research, researchers from every discipline do acknowledge the value of trust and generally observe and accept four characteristics of trust. First, there must exist two specific parties in any trusting relationship: a trusting party (trustor) and a party to be trusted (trustee). The two parties, comprised of persons, organizations, and/or products, constantly evaluate each other's behaviors. Second, trust involves vulnerability. Trust is only needed, and actually flourishes, in an environment that is uncertain and risky. Third, trust decreases complexity in a complex world and leads people to take actions, mostly risk-taking behaviors. "Without trust people would be confronted with the incomprehensible complexity of considering every possible eventuality before deciding what to do" (Grabner-Krauter & Kaluscha, 2003, p. 787). And fourth, trust is a subjective matter. It is directly related to and affected by individual differences and situational factors.

The previously mentioned characteristics of trust make it especially needed in e-commerce because people perceive economic transactions in a virtual environment as posing a higher degree of uncertainty than in traditional settings. Most e-commerce transactions are not only separated in time and space, but are also conducted via limited communication channels and impersonal interfaces, making trust a crucial facilitator for people to overcome fear, risks, and complexity. Therefore, online consumers need trust as a mental shortcut to reduce the complexity of conducting business transactions with online vendors (Luhmann, 1989). Such trust occurring in cyberspace is commonly termed "online trust," and we limit the scope to the online trust that is pertinent to B2C e-commerce, namely, the trust that occurs for an individual Internet user toward a specific e-commerce Web site or the online vendor that the Web site represents. Derived from the general definition for trust (Rousseau, Sitkin, Burt, & Camerer, 1998), online trust can be defined as follows: *an Internet user's psychological state of risk acceptance based upon the positive expectations of the intentions or behaviors of an online vendor*.

There are almost certainly many potential sources of influence that promote or hinder online trust. However, the current article focuses on the HCI or interface design perspective in inducing online trust, that is, to use what consumers can see on an e-commerce interface to affect their feelings of trust toward the online merchant that the e-commerce interface represents.

ONLINE TRUST IN THE HCI LITERATURE

Online trust is a relatively new research topic and has recently drawn great interest from researchers in HCI and human factors. There are several main themes that the majority of the existing studies can be divided into. First, some studies attempt to understand the online consumer's mind by investigating the underlying elements, antecedents, or determinants that are pertinent to the formation of online trust. For example, Gefen (2002) examined trust from a multi-dimensional perspective. According to the researcher, the specific beliefs of integrity, ability, and benevolence were seen as antecedents to overall trust. Other researchers, such as Corritore et al. (2003), also proposed that the consumer could perceive trust before, during, or after the online transaction, and they further concluded that online trust was characterized by its stage of development.

The second stream of studies focuses on conceptualizing trust into theoretical models or frameworks and dividing trust elements into various dimensions. For example, the Model of Trust for Electronic Commerce (MoTEC), is proposed by Egger (2001). The model consists of four components: the pre-interactional filters taking place before any online interaction, the interface properties of the Web site, the information content of the Web site, and relationship management. The Cheskin/Sapient Report (1999) focused on Web site interface cues and presented a model of six building blocks of online trust. These six building blocks were seals of approval, brand, navigation, fulfillment, presentation, and technology. The building blocks could be further divided into a total of 28 components to establish perceived trustworthiness. Such studies provide a theoretical account for exploring and enhancing trust in an online context and often take the effects of customer relationship management into consideration.

The third stream of studies aims to validate those conceptual frameworks or trust scales, often by analyzing data acquired directly from the consumers (e.g., Ba & Pavlov, 2002; Bhattacherjee, 2002). The main objective of these studies is to theoretically derive and empirically validate a scale that can be used to measure either individual online trust or the trustworthiness of an e-commerce Web site. In developing such an instrument, as for developing any other kind of scale, the researchers need to stress establishing its reliability, content validity, and construct validity. Factor analysis, structural equation modeling, and multiple linear regression analysis are some of the most commonly used statistical analysis methods in those efforts.

And finally, the rest of the studies suggest Web design guidelines that are intended to enhance consumer online experience and induce the feeling of trust from the consumers (Karvonen & Parkkinen, 2001; Kim & Moon, 1998; Neilsen, 2000). In other words, the main goal for the researchers of these studies is to explore Web interface design implications to maximize consumer trust or, more precisely, trust perception. A representative study of this kind is the Nielsen Norman Group Report (2000), in which explicit trust-inducing guidelines — including graphic design, surface cue, and Web usability features — are provided based on a large number of user testing observations carried out by experts.

These preceding studies provide important insights into trust in an online context. However, the research field of online trust is still far from maturity and expected to be significantly substantiated and enhanced. For example, the terms *element*, *antecedent*, *dimension*, *determinant*, and *principle* are sometimes used interchangeably due to the lack of agreement on a clear definition for each term among researchers in the field. Nevertheless, this is the current body of work from which any potential implementation is to be derived.

BUILD ONLINE TRUST BY WEB DESIGN

To initiate and build a consumer's online trust is inevitably a challenging task. Due to the nature of the Internet, people nowadays browse different e-commerce Web sites as fast as they switch TV channels. Consequently, to succeed in e-commerce, online vendors must be able to convey their trustworthiness to first-time visitors and effectively and efficiently build trust in the eyes of consumers. This requires online vendors to implement optimal electronic storefronts that can attract potential consumers and induce their trust. According to Ang & Lee (2000), "if the web site does not lead the consumer to believe that the merchant is trustworthy, no purchase decision will result" (p. 3). In other words, applying trust-inducing features to the Web sites of online vendors is the most effective method of enhancing online trust, given the current state of knowledge.

Efforts have been taken to establish a framework that classifies various trust-inducing Web design features into three broad dimensions: visual design, content design, and social-cue design (Wang & Emurian, in press). The framework is not exhaustive in the sense that it does not attempt to capture every possible trust-inducing feature that web designers can apply. It is focused on articulating the most prominent set of trust-inducing features and presenting them as an integrated entity that can be empirically evaluated and appropriately implemented in Web design. *Table 1* illustrates the framework in detail, including the explanations and design feature examples.

All the trust-inducing interface design factors that are identified in the framework have been illustrated on a synthetic e-commerce interface and evaluated by 181 survey respondents (Wang & Emurian, 2004). Along with identifying the three dimensions, the factors were found to significantly contribute to online trust ratings. This has confirmed what most HCI researchers believe — as Kim & Moon (1998) pointed out — that informative emotions such as trust can be triggered by the customer interfaces

Table 1. Framework of trust-inducing features

Dimensions	Explanations	Design Feature Examples
Visual Design	Defines the graphical design aspect and the structural organization of displayed information on the Web site.	• Use of three-dimensional and half-screen size clipart • Symmetric use of moderate pastel color of low brightness and cool tone • Use of well-chosen, good-shot photographs • Implementation of easy-to-use navigation (simplicity, consistency) • Use of accessible information (e.g., no broken links and missing pictures) • Use of navigation reinforcement (e.g., guides, tutorials, instructions, etc.) • Application of page design techniques (e.g., white space and margin, strict grouping, visual density, etc.)
Content Design	Refers to the informational components that can be included on the Web site, be they textual, graphical, etc.	• Display of brand-promoting information (e.g., prominent company logo or slogan, main selling point) • Up-front disclosure of all aspects of the customer relationship (company competence, security, privacy, financial, and legal concerns) • Display of seals of approval or third-party certificates • Use of comprehensive, correct, and current product information • Use of a relevant domain name
Social-Cue Design	Relates to embedding social and interpersonal cues, such as social presence and face-to-face interaction, into the Web interface via different communication media.	• Inclusion of a representative photograph or video clip • Use of synchronous communication media (e.g., instant messaging, chat lines, video telephony, etc.)

and further aid decision making while using e-commerce systems. It may also be concluded that the three dimensions of the framework can act together to promote online trust and reflect the different aspects of Web interface design.

The first two dimensions, which are visual design and content design, are seemingly straightforward, and they have been traditionally the focus of the research that aims to promote online trust by Web design. The last dimension, the social-cue design dimension, is a relatively new design strategy being suggested by numerous researchers (Riegelsberger, Sasse, & McCarthy, 2003; Steinbruck, Schaumburg, Duda, & Kruger, 2002; Wang, in review). This approach is aimed to remedy the prominent problem of e-commerce known as "lack of human touch" that eliminates online shopping for a considerable number of people.

At least two reasons, or disadvantageous characteristics of e-commerce, contribute to such a problem. First, e-commerce transactions are mostly separated in space and time. Second, a Web site is the only primary and direct "contact point" that online vendors can rely on to interact and communicate with their customers. While the face-to-face interaction can help to establish and stabilize consumer trust in off-line situations, the business transaction in e-commerce is deficient in the personal communication dimension. Therefore, there is need to bring e-commerce interactions closer to off-line shopping experiences by implementing social and interpersonal cues that moderate the disadvantages of an impersonal e-commerce interface and induce online trust. It is such an initiative that compels the social-cue design dimension of the framework.

The social and interpersonal cues, being investigated and embedded into e-commerce Web sites, refer to voice, gestures, appearance, and other communication cues that have been found to have a strong impact on triggering people's trust in face-to-face encounters. Using richer communication media has been seen as a valid means for facilitating the conveyance of these interpersonal cues and providing more opportunities for personal contacts between consumers and online vendors. With the advancement of technology and the increase of bandwidth, a huge collection of communication media is presently available. However, to choose suitable communication media for adding social or interpersonal cues in e-commerce Web sites, designers need to be aware of the different features of each medium, such as channel availability, synchrony, and channel symmetry (Greenspan, Goldberg, Wimer, & Basso, 2000). When implementing social cues, special care should also be taken, as advised by Riegelsberger et al. (2003), to prevent online shoppers from being disappointed by elements lacking functionality other than giving cues of social interaction.

The existing research on interpersonal cues and online trust still remains preliminary. Most research only focuses on examining the trust-inducing capacity of photography, which is the simplest form of communication media to be employed in e-commerce, and the outcomes are found to be somehow contradictory (e.g., Riegelsberger et al., 2003; Steinbruck et al., 2002). Therefore, empirical evidence and valid methodologies are in great need in this research area to address a number of intriguing research questions.

CONCLUSION AND FUTURE DIRECTIONS

As e-commerce gains widespread attention and rapidly emerges as a competitive business form, online merchants are facing an urgent challenge of building and sustaining consumer trust on the Internet. While the issue has initiated numerous investigations for valid research methods and effective solutions by researchers from multiple disciplines, this article shows the merit of an HCI approach in confronting the challenge. Adding trust-inducing interface features and interpersonal cues in Web design has been proposed as a fruitful strategy for building online trust.

Based upon the present overview, five potential areas of suggested research include (1) the effects of culture on online trust; (2) the effects of domain (e.g., .com, .edu, .org) on online trust; (3) the reasons for losing online trust and the ways to repair it; (4) the importance of civil remedies for consumers in case of violations of privacy laws; and (5) the transferability of online trust from the Internet to other activities. In addition, there is obvious need for further investigation on the effects of social and interpersonal cues on online trust, including both methodology development and experimental testing. Finally, it should be pointed out that while well-crafted Web interfaces can induce trust in those who intend to purchase online, online vendors should also pay attention to other methods, such as customer relationship management (CRM) and off-line marketing strategies, to obtain consumer trust and nurture strong business relationships (Tan, Yen, & Fang, 2002).

KEY TERMS

Channel Availability: A feature of any communication medium. A communication medium's channel can be contextual, audio, visual, or any combination of the three. For example, telephone is an audio-only communication medium, while videoconferencing is an audio-visual communication medium.

Channel Symmetry: A feature of any communication medium. A communication medium affords symmetry if the recipient of a message can respond with the same type of message. For example, telephone and e-mail tools are symmetric (two-way) communication media, while television and Web sites are asymmetric (one-way) communication media.

Communication Media: The methods or tools in which information can be exchanged and communication can be facilitated. Examples include telephone, television, e-mail, Web sites, video conferencing, and instant messaging, to name a few.

Customer Relationship Management (CRM): An approach that recognizes that customers are the core of the business and that a company's success depends on effectively managing its relationship with them. CRM is about locating and attracting customers and thereby building long-term and sustainable relationships with them.

Electronic Commerce (E-Commerce): An emerging business form in which the process of buying, selling, or exchanging products, services, and information is undertaken via computer networks, including the Internet.

Online Trust: An Internet user's psychological state of risk acceptance based upon the positive expectations of the intentions or behaviors of an online vendor.

Synchrony: A feature of any communication medium. A communication medium is synchronous if the recipient of a message can respond immediately. For example, telephone and instant messaging are synchronous communication media; while e-mail and voice mail are asynchronous communication media.

Trust-inducing Design: The application of empirically verified features of a Web site to enhance a consumer's perception that the online vendor is trustworthy.

Trustworthy Web site: A Web site that reduces a consumer's perception of risk and that increases confidence in the online vendor's integrity.

Trust in Knowledge-Based Organizations

Mirja Iivonen
University of Tampere, Finland

INTRODUCTION

The knowledge-based society of the 21st century is characterized by knowledge generation as the primary source of wealth and social well-being. As partly intangible in nature, increased understanding of knowledge and information as a resource is critical (Sveiby, 1996; Teece, 1998). Such intangibles are gradually replacing traditional elements of power in states (Rosecrance, 1999), also emphasizing the role of trust in the positive aspect of economic globalization.

This development is supported by the resource and knowledge-based views of an enterprise (e.g., Barney, 1991; Grant, 1996; Penrose, 1959) and the idea of organizational learning (Argyris & Schön, 1996). A holistic view of contextual factors and means, such as trust, is necessary for managing knowledge and information processes to enhance them as a resource, whose value is difficult to estimate in economic, quantitative terms (Yates-Mercer & Bawden, 2002). To combine human, technological and structural factors in a unique manner is critical to prolonging strategic capability and sustainability. Knowledge creation occurs by combining people's distinct characteristics with a particular set of activities. Moreover, the core capabilities are created through activities consisting of values and norms, skills, managerial and physical systems (Leonard-Barton, 1995, p.25; Prahalad & Hamel, 1990). These four dimensions also relate to social capital.

In this article, we seek better understanding of knowledge-related processes in respect to trust and social capital. The foci are on trust as related to organizational culture and climate and to collaboration enhanced by appropriate organizational structures.

BACKGROUND

It is demanding to define the concept of knowledge management (KM) due to the difficulty of defining the concept of knowledge and its relation to the concept of information (see, e.g., Wilson, 2002). The perception of KM as providing knowledge representations/artefacts stored for use in information systems is close to information management (IM) (Davenport & Cronin, 2000; McInerney, 2002), though information and knowledge are distinctive concepts. The goal of KM is to transform information into learning, insight, and commitment to action, which requires turning personal knowledge into corporate knowledge to be widely shared and appropriately applied (Choo, 1998; Skyrme, 1997).

Knowledge is often understood to consist of explicit, implicit and tacit elements. Nonaka's (1994; Nonaka & Takeuchi, 1995) theory of knowledge creation, the SECI model, popularized Polanyi's (1966) identification of the tacit nature of knowledge in the mid-1990s. However, many authors argue that tacit knowledge is understood too superficially in the conceptions of KM (Yates-Mercer & Bawden, 2002) when actually referring to implicit knowledge (Nahapiet & Ghoshal, 1998, p.246; Orlikowski, 2002; Wilson, 2002). Tacit knowledge is the most intangible and very personal form in organizations and thus difficult to articulate. Manifested in organizational practices, the constructionist viewpoint that regards knowledge as a social construct (e.g., von Krogh, 1998) may prove appropriate to understand this phenomenon.

ORGANIZATIONAL KNOWING

The social nature of knowledge and information calls for the concept of organizational knowing and its management (Brown & Duguid, 2000; Choo, 1998; Choo & Bontis, 2002). Cook and Brown (1999) claim that innovation as "a generative dance" is an outcome of the interplay of knowledge and knowing. Orlikowski (2002) views cognition and action as inseparable that makes articulation of tacit knowledge unnecessary. The concept of a community of practice has evolved as knowledge appearing as a collection of processes that allow learning to occur and knowing to be internalized (McInerney, 2002, p.1012). Blackler (2002) argues that the five types of knowledge (embrained, embodied, encultured, embedded, encoded) are insufficient to account for knowledge as a social process. Boisot's (1998) contention is that the evolution of knowledge forms a social learning circle: through the codification of shared experience, personal knowledge can become proprietary knowledge or the intellectual capital of an organization. Once externally scrutinized, this knowledge becomes public while widely internalized, it turns into common sense. The assumption that knowledge exists in people's minds makes it hard to manage causing much debate about the relevance of the concept of KM. The management of people is as crucial as the management of information when aiming at the strategic management of knowledge and information as a resource (Huotari & Iivonen, 2004). Thus, the structure of the organization itself becomes critical to sharing, based on trust, and re-creation of knowledge throughout the organization.

TRUST

Trust is based on expectations of other people's willingness and ability to fulfill our needs and wishes (e.g., Fukuyama, 1996). That presupposes similar or related worldviews and shared meanings. This refers to normative trust assuming that common values provide a frame of reference for social norms creating predictability and trustworthiness. "Trust is… an intersubjective 'reality' that cannot exist… unless the symbols used to signal trustworthiness have meaning for all parties." (Hardy, Phillips & Lawrence, 1998, p.70). However, this type of trust has been challenged, too (Lane, 1998, p.8).

Trust is manifested in people's behavioral patterns, and honesty and predictability build it up (e.g., Ciancutti & Steding, 2000; Shaw, 1997). Trust has been called a communicative, sense-making process in which shared meanings develop to bridge disparate groups also in interorganizational relationships (Hardy et al., 1998). As a social phenomenon, trust is therefore a highly desirable property that also affects the well-being of the work community, produces commitment and internalised accountability, and provides a way to cope with risk and uncertainty (Huotari & Iivonen, 2004; Lane, 1998).

FUTURE TRENDS

The major managerial challenge in the globalized economy is the pooling of the intellectual capital of collaborators in a partnership. Trust is the basis for and co-evolution of social capital and through it is manifest in the concept of intellectual capital. Social capital, in particular, whose foundation is human behaviour may gain more emphasis in the future. Because personal relationships provide the basis for unique, networked organizational activities differences in types and levels of developed trust may result in different levels of resource exchange and flows (Nahapiet & Ghoshal, 1998, pp.245, 255; Tsai & Ghoshal, 1998; see also, Adler & Kwon, 2002).

Organizational culture and climate are revealed by values which form the basis for social norms and refer to social capital. Normative trust is essential for organizational knowledge involving the creation and maintenance of trust, and the resulting norms of behavior, that are important for knowledge sharing, for example, in communities of practice (Tuomi, 2002; Wenger, McDermott, & Snyder, 2002). Such facilitators as boundary spanners or roamers are an important component of the infrastructure of communities of practice contributing to the diffusion of knowledge between communities (Davenport & Hall, 2002) thereby strengthening social capital.

The development of a knowledge culture may promote learning and sharing of what is known. Trust is a core organizational value allowing people to communicate openly and without fear of unethical conduct. Dialog can build a culture for the continuing creation and sharing of knowledge. Moreover, trust is fundamental in virtual communities (McInerney, 2002, p.1014; Sonnenwald, 2004).

Collaboration relates strongly to trust and networking and enables converting individual knowledge into organizational knowledge. It is a cornerstone of social capital and necessary for innovating and accomplishing tasks in knowledge-based organizations. Collaboration and trust have a two-way relationship (Huotari & Iivonen, 2004). Co-workers learn to trust each other, but swift trust is required when collaborating without a long history of working together (e.g., Davenport & McLaughlin, 2004). Networking requires that collaboration as a behavioral model is encouraged by appropriate strategies related to the communicative and sense-making processes to cross borderlines and bridge gaps. For example, the cognitive distance of network members inhibiting collaboration can be decreased by establishing so called "epistemic communities" of shared mental categories, meanings and interpretations (Nooteboom, 2002, pp.23-29). These strategies facilitate trust and can strengthen social capital.

Organizational hierarchy may also affect knowledge sharing and the type of trust or mistrust developing. A low hierarchy and open organizational culture enhances information flows whereas a strong hierarchy has a negative effect on knowledge sharing in a multiunit organization where units compete against each other. Informal lateral relations, in turn, have a positive effect on knowledge sharing among units that compete in the market place but not when competing for internal resources. Thus external market competition in particular influences knowledge sharing and allows units to accumulate social capital (Hansen, 2002; Tsai, 2002). Social capital facilitates the creation of intellectual capital (Nahapiet & Ghoshal, 1998, p.246). Social interaction and trust increase knowledge creation through resource exchange and combination having a positive effect on product innovations and enhancing trustworthiness. A shared vision, in turn, can influence resource exchange and pooling only indirectly via its influence on trust (Tsai & Ghoshal, 1998).

CONCLUSION

This article focused on the role of trust in managing the knowledge-based, networked organization. Knowledge as organizational knowing and the importance of understanding the impact of intangible and social factors on knowledge generation were emphasized. Trust was examined within the framework of social capital, whose relation to intellectual capital was highlighted. The foci were on the role of trust in the development of organizational culture and climate, structure and collaboration. Managing intangibles may challenge the organization in the future. Therefore, their impact on knowledge generation and human behavior should be examined in theory and practice.

KEY TERMS

Collaboration: Human behavior, sharing of meaning and completion of activities with respect to a common goal and taking place in a particular social or work setting (Sonnenwald & Pierce, 2000).

Information: A message, or data, which makes a difference. Information has meaning, and becomes knowledge when a person internalizes it.

Intellectual Capital: Knowledge that transforms raw materials (both tangible and intangible) thereby increasing their value. It can be divided into human, structural and customer capital. Human capital refers to the talent of employees. Structural capital involves intellectual property, methodologies, software, documents, and other knowledge artefacts. Customer capital refers to client relationships. By integrating organizational knowledge into intangible assets an organization aims to turn human capital into structural capital (Stewart, 2001).

Knowledge: From the cognitive viewpoint, is an individual's total understanding of himself/herself and the surrounding world at any given point in time, incorporating (sub)conscious memory, thinking and cognition, as well as emotional and intuitive properties (Ingwersen, 1992, pp.228-229). When communicated, knowledge becomes information and consequently the raw material of new knowledge.

Knowledge Management: Combines human resources management and information management, and is defined as the management of all processes concerned with the identification, acquisition, creation, storage**,** distribution, and use of information and knowledge (Huotari & Iivonen, 2004).

Organizational Culture: Embraces two levels: deep-seated ideas and beliefs, and espoused values that form part of the cultural knowledge embedded within organizations. It is reflected in the organizational climate.

The SECI Model: Assumes knowledge creation as an iterative process converting tacit and explicit knowledge through socialization, externalization, combination and internalization (Nonaka & Takeuchi, 1995).

Social Capital: The sum of the actual and potential resources embedded within, available through, and derived from the network of relationships possessed by an individual or a social unit. It includes:

- **The relational dimension** concerned with the behavioral embeddedness involving the nature of the relationships developed over time, including trust, norms, obligations and identification.
- **The structural dimension** related to ties of social interaction such as density, hierarchy, network configuration, and so forth, between actors.
- **The cognitive dimension** related to shared representations, interpretations and systems of meaning, for example, to a shared vision (Nahapiet & Ghoshal, 1998, pp.243-245).

Social capital focuses on networks and partly overlaps with intellectual capital, which covers other aspects as well.

Trust: Can be defined as follows:

- **Affect-based trust** has emotional connotations and is related to issues like care, concern, benevolence, altruism, commitment, mutual respect, and so forth (Scott, 2000).
- **Calculative trust** is based on the weights of the costs and benefits of certain actions, and on a view of man as a rational actor.
- **Cognition-based trust** is a rational view of trust and is associated with competence, ability, responsibility, integrity, credibility, reliability, and dependability.
- **Non-calculative trust** is based on values and norms (Lane, 1998; Nooteboom, 2002).
- **Normative trust** refers to common values that give a frame of reference to social norms creating predictability and trustworthiness.
- **Swift trust** coincides with risk and uncertainty. It is needed in circumstances where the history of working together is limited to learn trust.

Trust in Technology Partnerships

Kirsimarja Blomqvist
Lappeenranta University of Technology, Finland

INTRODUCTION

Technology partnerships are seen as a key element both in knowledge creation for technological development itself and in leveraging the value of technological knowledge (Bidault & Cummings, 1994; Teece, 1987; Ford, 1998). Complementary knowledge is generally regarded as a source for competitiveness (Doz & Hamel, 1998; Powell, 1998; Nahapiet & Ghoshal, 2000). Potentially, the focus on core competencies enables relatively stronger competitiveness (cumulative learning, focused use of critical resources) and ability to gain synergistic benefits and scale by leveraging different knowledge bases and networks (Miles, 2000; Blomqvist, 2002).

In the converging ICT sector, the technological discontinuities like the Internet bring new innovative players, which try to break the rules of competition and seek the niches not noticed by the incumbent players. For incumbents the discontinuities pose a threat that may be turned into an opportunity through cooperating with innovative players and learning from them. In technology partnerships, complementary companies are able to focus on their core competencies and simultaneously leverage external knowledge and resources to complement their knowledge and resource base.

According to a recent study, 94% of the technology executives believed that alliances and technology partnerships were becoming more critical to their strategy, yet every second alliance turns out to become a failure (Kelly, Schaan & Joncas, 2002). In several studies,, empirical trust has been identified as a key success factor for technology partnerships (Forrest & Martin, 1992; Bruce, 1995). The aim of this article is to increase the understanding of trust as a critical factor in technology partnerships. The empirical illustrations in this article are based on research on asymmetric technology partnerships, in which eight small software firms' partnerships with five large firms were empirically analyzed (Blomqvist, 2002; Blomqvist & Ståhle, 2003). The knowledge creation in technology partnerships between large and small firms, as well as the converging ICT market as an example of complex and dynamic business environment, make the context especially interesting from the point of view of trust. Perceived or assumed dissimilarities in complementary actors' values, goals, time-horizon, decision-making processes, culture, and logic of strategy can form barriers to cooperation (see Doz, 1988; Blomqvist, 2002). Rapid changes and high risks concerning technological success and economic rewards are typical.

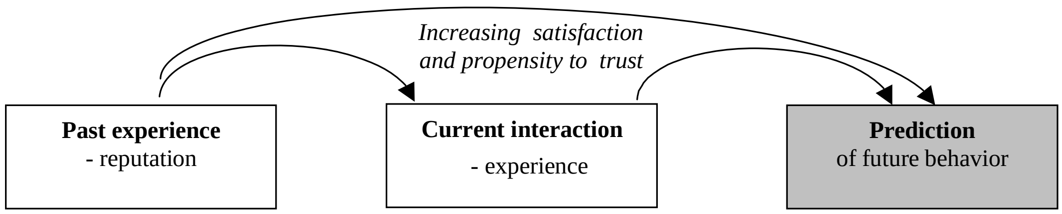
TRUST AND INTER-FIRM COLLABORATION

Trust has been identified as an important issue in partnerships and alliances (Håkanson, 1993; Parkhe, 1993, 1998; Das & Teng, 1998; Lazarec, 1998; Ariño, de la Torre & Ring, 2000) and supplier relations (Sako, 1998). It has been proposed that some *cooperative threshold amount of trust* is needed for cooperation to evolve (Dibben, 2001). For the context of asymmetric technology partnerships, based on an extensive literature analysis and conceptualization, Blomqvist (1997) has defined trust as the "*actor's expectation of the other party's competence and goodwill.*" This definition includes the dimensions of competence (i.e., technological capabilities, skills, and know-how) and the more abstract goodwill, which implies moral responsibility and positive intentions toward the other. Signs of *goodwill* and the related expectation of the partner's positive intentions are necessary for a partner to be able to accept risk and a potentially vulnerable position. It could be assumed that *competence* is a necessary antecedent for trust in the business context, especially in technology partnerships, where complementary technological knowledge and competencies are a key motivation for partnership formation (Blomqvist, 2002). Also Sako (1998) has included competence in his definition of trust.

There is a strong temporal dimension in trusting. Trust is seen as evolving from past experience and current interaction (Deutch, 1973). It is seen as an outcome of a process, that is, trust relationships develop gradually (see Figure 1).

Trust between partners can be said to be a bridge between past experiences and the anticipated future. In general, trust is believed to evolve slowly, through repeated interactions of increasing satisfaction (e.g., Blau, 1964) and through incremental investments and experiences. Reputation and experienced *similarity both in character and values* enhance the experience of trust

Figure 1. Trust as a prediction resulting from satisfactory interaction and past experience (Blomqvist, 2002)



(Zucker, 1987; Gulati, 1995; Jones & George, 1998) through the ability to predict the other's behavior.

THE CRITICAL ROLE OF TRUST IN TECHNOLOGY PARTNERSHIPS

Blomqvist (2002) has used interviews of business practitioners from large and small technology firms representing operative and strategic organizational levels in order to look deeper into the role of trust in technology partnerships. The components of trust were formed through interviews based on open questions: How do you evaluate your partner? What characteristics do you find important? What do you tell and highlight about you and your company when presenting yourself to a potential partner? The quotes in this article are drawn from these in-depth interviews.

The interviewed large firm managers, small firm managing directors, and other key persons very clearly saw trust to be critical for technology partnering. The interviews confirmed the two components of trust—capability and goodwill—that were brought up also in the literature review. However, the interviews included many viewpoints that could not be labeled under competence or goodwill, but dealt often with the other party's behavior, for example, what really happened in the cooperation. Already at the very first meetings, the behavioral dimension of trust is present in signs and signals, for example, what information is revealed and in which manner. Signs of goodwill are necessary for the trusting party to be able to accept a potentially vulnerable position. Through the partnering process (a long time), the actual behavior (e.g., kept promises) becomes more visible and easier to evaluate. This was highlighted for example as follows:

"I evaluate a potential partner with feelings anyway. It is the first couple of minutes...The first impression is important... how they present themselves, whether they are really interested, and whether they have a vision. I also look whether they are able to communicate their vision and have self-respect. It is the feeling…Yes, I don't know if I should have, but I don't have any systematic way of evaluating them. You listen to their story and evaluate whether it is credible or not." (Partner Director, Large ICT Company B)

"Communication is very critical…trust is created between individuals, not organizations. Individuals act like representatives of their organizations…You cannot trust a large firm's organization more than the small firm's organization." (Technological Expert, Internet Technology Net)

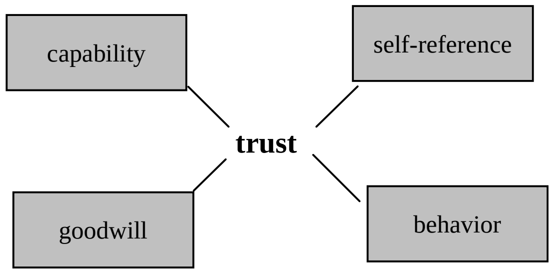
The interviews of large and small firm managers produced empirical evidence about the role of self-reference in asymmetric technology partnership formation. In technology partnerships the individuals and organizations can be referred to as self-referential, if they are aware of their identity, capabilities, and values. A self-referential actor has an ability of building relationships and is more willing to accept interdependency (double contingency). Some of the interviewed managers discussed self-reference as follows:

"First (when introducing your company to a potential partner) you need to have focused your business so that the other party understands that and sees it clearly. Then they can see my role, my firm's role, and how we and they will work together…and what they need and can get from my company." (Managing Director, Small Software Company Alpha)

"The ability to build trust comes from the ability to be humble. If you have been able to dictate what will be done…It will be a long drop and major change in the mental mode to actually listen to what the other person is after and what they want and to think of them as equals." (Partner Director, Large ICT Company)

As a result of the analyses of all the perspectives of the interviewees, two new components of trust—*behavior* and *self-reference*—were included. Subsequently the

Figure 2. Components of trust



concept of trust can be seen to include four components: capability, goodwill, behavior, and self-reference (see Figure 2).

Some factors related to each component were identified. In the technology partnership formation context, *capability* consists of *technological capability*, *business capability*, and *meta-capability to cooperate*. Capability is a necessary but passive component for trust in a technology partnership formation. Capability component can be explicitly emphasized and analyzed when negotiating for technology partnerships. Capability can be communicated as references of difficult projects, prizes for outstanding technology, first-to-market technologies, prominent members of the board, venture capital, and symbols like certificates and employee education.

Goodwill implies a more abstract, yet a very important component of trust in technology partnerships. It was defined earlier as the "partner's moral responsibility and positive intentions toward the other" (Blomqvist, 1997). Also Tyler (1996) and Sako (1998) have highlighted the trustee's intentions as a source of experienced trustworthiness. Experienced goodwill is a necessary and active component for trust in technology partnership formation. The goodwill component is more difficult to discern explicitly, but negotiating parties can both stress goodwill in their behavior and attempt to evaluate goodwill in other parties' behavior. Reciprocity, care, and concern, as well as social and characteristic similarity, may enhance feelings of goodwill. Expressed norms such as keeping promises and active consideration for mutual norms also build trust through goodwill (Blomqvist, 2002).

As the relationship is developing, the actual *behavio*r (e.g., that the trustee fulfills the positive intentions) adds to the trustworthiness (Bidault, 2000; Lazarec & Lorenz, 1998). Thus the capability and goodwill dimensions of trust become visible in behavioral signals of trustworthiness. Open communication, adaptation, and commitment are critical behavioral factors building trust (Blomqvist, 2002).

Clear self-reference enables the individual or organization to connect to other actors and to cooperate (Luhmann, 1979). At the corporate level, self-reference is the basis for strategy and business plans. At the individual level, the individual's clear identity and values form a basis for self-reference. Without clear self-reference, recognizing the right partners (strategic and cultural compatibility) and establishing partnerships is difficult. Self-reference enables the actor to trust, to be trusted, and to cooperate. It is proposed that an individual or organization with a strong self-reference is able to recognize, maintain, and develop the heterogeneous strength in its identity, yet connect and cooperate at an equal level with diverse and complementary actors.

Therefore, it can be summarized that in technology partnerships, *"Trust is an actor's expectation on the other party's capability, goodwill, and self-reference, which needs to be confirmed by experience."* Thus trust is increased by—and decreased by the lack of—these components in parties' actual behavior and communication.

CONCLUSION

In this chapter the concept and phenomenon of trust, with special focus on technology partnerships, has been examined. The basic conceptualization of trust was based on Blomqvist's research (2002) on trust in asymmetric technology partnerships, in which the conceptual analyses with the four components—capability, goodwill, self-reference, and behavior—was based on both literature and empirical data. Some empirical illustrations were shown to support conceptualization.

It has been shown that trust is a critical issue in technology partnerships. However, on the way toward methods and tools for trust building in partnership formation, we are only in the beginning (Blomqvist & Ståhle, 2003). It is believed that this research area with its multidisciplinary nature will be quintessential for technology firms competing in the dynamic business environment of today and the future.

KEY TERMS

Asymmetry: Here we use asymmetry to mean that parties are heterogeneous and possess diverse knowledge bases. Asymmetry manifests also in corporate culture and management. As a result of Blomqvist's study (2002), asymmetry will be defined as "difference in resources, capabilities, and power, as well as management and culture of actors."

Convergence: In the ICT industry convergence at the *firm level* means that firms cooperate to combine their different knowledge bases. Also industries, such as communications and media industries, can be said to converge if focal actors leverage knowledge from two previously separated industries.

Information and Communications Technology (ICT): Depending on the author, ICT equipment, network operation and network services, and digital content provision can be listed as *key industries*. *Related industries* (e.g., entertainment and traditional media or consumer electronics) are getting closer to the key industries by acquisitions, joint ventures, and established new business units. It is difficult to describe industry boundaries as clear-cut, as boundaries are blurring and actors are searching the best possible position in the value network.

Technology Partnership: In a technology partnership, the technology and a common objective are included in inter-firm collaboration. R&D collaboration is a typical example.

Trust: An actor's expectation on the other party's capability, goodwill, and self-reference, which needs to be confirmed by experience. In the context of technology partnership, formation capability consists of technological capability, business capability, and the meta-capability to cooperate.

Trust in Virtual Enterprises

T.T. Wong
Department of Mechanical Engineering, The Hong Kong Polytechnic University, Hong Kong

INTRODUCTION

For a virtual enterprise(VE) to be competitive and successful in a dynamic environment characterized by constantly changing customer demands and technological innovations, it must be capable of rapid adjustment in order to reduce the time and cost needed to deliver to the customer a quality product. The success in the agile competition naturally depends on the effective operation of the VE.

Trust has been recently regarded as the foundation of the digital economy (Keen, 2000; Stewart et al., 2002). The e-business environment is characterized by:

a) the impersonal nature of the online environment;
b) the extensive use of communication technology as opposed to face-to-face transactions;
c) the implicit uncertainty of using an open technological infrastructure for transactions; and
d) the newness of the transaction medium.

Given these attributes, trust development in VEs presents significant challenges because it is difficult to assess partners' trustworthiness without ever having met them (McDonough et al., 2001). Moreover, as the life of many virtual teams is relatively limited, trust must quickly develop (Jarvenpaa & Leidner, 1999). Yet, trust development is deemed crucial for the successful completion of virtual team projects (Sarker et al., 2001). The objective of this chapter is to identify the essential conditions for trust building in VE and to evaluate the likely impact of trust on the operations and management of VE. The study raises a number of issues to be explored by future research.

BACKGROUND

Trust encompasses constructs as diverse as ethics, morals, emotions, values, and natural attitudes. Further, trust spans interdisciplinary fields, including philosophy, computer science, economics, and organizational behavior. Consequently, there is a myriad of definitions of trust. Since the dyadic view of familiarity-based trust does not readily correspond to the reality of the VE environment, which involves a large number of potential partners, the author proposes to define trust as the expectation by one member of ethical behavior on the part of the other member in a joint VE project. This definition emphasizes the importance of trust in organizational relationships and includes the idea of a joint undertaking, implying that there is a level of understanding of shared business goals and practices between the partners. Another factor that is implicit in the definition is the role of ethical behavior. Any change in ethics will cause a change in actions and thus influence trust. Finally, the definition implies that the VEs will undertake jointly to contribute to the final outcome.

According to traditional studies, trust builds incrementally and accumulates over time. VE business relationships, however, are characterized by project-oriented relationships that may entail no past history nor any plan for future association. In these temporary relationships, time is a vital but often elusive component in the trust building process. This does not mean, however, that trust cannot be apparent in temporary groups. On the contrary, McKnigh et al. (1998) have shown that trust in initial relationships can often be high. Further, Jarvenpaa & Leidner (1999) argue that trust is maximally important in new and temporary organizations, because it acts as a substitute for the traditional mechanisms of control and coordination.

Creating a VE takes more than just information technology. A study on issues of information technology and management concluded that there is no evidence that IT provides options with long-term sustainable competitive advantage. The real benefits of IT derive from the constructive combination of IT with organization culture, supporting the trend towards new, more flexible forms of organization. Information technology's power is not in how it changes the organization, but the potential it provides for allowing people to change themselves. Creating these changes, however, presents a new set of human issues. Among the biggest of these challenges is the issue of trust between partner organizations in the VE (Wong & Lau, 2002). The following section identifies the essential conditions for trust development in a VE.

ESSENTIAL CONDITIONS FOR TRUST DEVELOPMENT

From the literature, the essential conditions for trust development in VE may be summarized as follows:

a) Common Business Understanding

Researchers such as Wigand et al. (1997) and Fuehrer & Ashkanasy (2001) note that an important element in any business cooperation is the establishment of common business understanding. An earlier work suggests that there are three specifications necessary for the establishment of a common business understanding in the virtual context. The first is a clear product specification: the design, quality, and functionality of the product or service. The second is a specification of the level of cooperation, which requires agreement about deadlines, liability, prices, profit allocation, and staff and resource input. The third is a formal specification of agreements between the virtual partners. In a virtual organization, these specifications need to be communicated clearly between the partners in order to achieve a common business understanding. There is always varying uncertainty between members, however. Therefore, the need to guard against opportunistic behavior varies between the partners (Wicks et al., 1999). This depends on the risk that the member is prepared to sustain as a potential loss, and also upon the partner's fear of opportunistic exploitation and the uncertainty of their behavior.

The three specifications (production, cooperation, and agreements between partners) can be achieved by negotiating relational contracts that guide the formation, operation, and dissolution of the virtual organization, thereby facilitating an increase in the level of collaboration-enabling trust. VEs, like other organizations, create fiscal and legal issues that must be clarified, but they lack a formalized legal framework (Fuehrer & Ashkanasy, 1998). Therefore, it is incumbent on the organization's members to develop their own guidelines for the operation of the enterprise. Such agreements may include clarification of members' tasks and responsibilities, agreement on contracts, allocation of funds, potential liability, and how members will contribute their expertise. In this sense, clear guidelines, spelled out in an early stage of the partnership, serve to reduce misperceptions and to foster the establishment of trust.

Other mechanisms to establish a common business understanding in VEs include development of an organization handbook, design of a mutual Internet site, chat room technology, and the use of team addresses for e-mail. A specific example is Livelink, a software selected by Siemens to enable the creation of a common business understanding through a standard computer interface.

The concept of common business understanding, therefore, shares similarities with organizational identity, which may be described as a set of distinctive and enduring traits that members associate with their organization. Scott and Lane (2000) have proposed further that identity is determined in part by the nature of stakeholder networks. Common business understanding, however, is more akin to Barney's broader concept of identity: "the theory organizational members have about who they are" (Barney et al., 1998, p. 103). In this respect, the author agreed with Gioia, Schultz, and Corley (2000) that organizational identity is not necessarily a stable phenomenon, but mutates to suit the prevailing environment. In the virtual context, therefore, a common business understanding may be defined as a transient understanding between network partners as to what they stand for, the nature of the business transactions that they engage in, and the outcomes that they expect—their "vision."

Scott and Lane (2000) emphasize that a common business understanding requires the creation of a shared vision, together with communication of mutual aims through a clear definition of the roles and expectations within the team, especially in the early stages of the partnership. In this respect, the process is typically initiated by agreement on a symbolic logo or design for a product or service, since understanding each member's role, together with group identification, determines critical behaviors such as willingness to cooperate with others, and willingness to engage in mutual goal setting. The VE partners thus rapidly need to establish group identity and an awareness of mutual needs and expectations, along with the clarification of tasks and responsibilities. In traditional partnerships, awareness and identity are in part shaped by the legal framework that regulates organizational relationships, as well as by networks, artifacts, and the organization chart (Scott & Lane, 2000). In the case of the VEs, however, mechanisms outside of the domain of traditional organizations need to be put in place to establish a common business understanding, which constitutes an important precursor of trust formation (Jarvenpaa & Leidner, 1999).

These examples illustrate how the creation of a sense of shared meaning, member identification, and mission identity, especially in an early stage of the partnership, facilitates collaboration at an individual level and the operation and productivity of the VE as a whole. As such, a common business understanding provides an essential condition for the development of trust within the organization. In effect, a common business understanding provides the virtual organization's members with an opportunity to share their perceptions of the organization's defined features, and creates a feeling of ownership and trust.

b) High Ethical Standards

Three factors uniquely characterize the virtual organization's position in regard to business ethics. First, VEs are rarely guided by pre-existing codified laws in which values and standards are written into legal systems enforceable in court. Since the organization's partners are not usually legally bound to the organization, any negative outcomes or perceptions attributed to poor business ethics could result in the organization's reputation suffering (Fichman, 1997). Second, because VEs like those created in our opening example are intrinsically temporary (Fuehrer & Ashkanasy, 1998), corporate ethics are difficult to develop because members will typically finish one virtual collaboration and enter into another. Third, VEs are intrinsically boundary spanning in nature, so that they must incorporate a diversity of culturally based values and morals.

Researchers focused on the notion of advances in ICT and the related effects on social behavior agree that unethical behavior in the virtual context is predominantly caused by technological changes and by the "inside keepers of the information systems" (Pearson et al., 1997, p. 94). They also agree that social behavior needs more than "new laws and modified edicts" (Johnson, 1997, p. 60) and that ethical issues will become increasingly important to enable business transactions to be carried out safely and securely. Although technology has been largely secured by advancing software and technology for virus detection, as well as encryption or decryption of information to ensure the security of business processes, Johnson (1997) notes that technology can never be sufficient to control all aspects of social behavior. Consequently, online behavior is predicated on an awareness and acceptance of ethical norms and behaviors. This can best be achieved through specification and clarification of the members' tasks, responsibilities, and agreed sanctions for proscribed behavior.

Johnson posits further that the "only hope to control online behavior is for individuals to internalize norms of behavior" (1997, p. 60) and suggests three rules for online ethics: (1) know and follow the rules of the forums; (2) respect the privacy and property rights of others (if there is any doubt, assume the user's desire for privacy and ownership); and (3) respect interacting partners by not deceiving, defaming, or harassing them. Not surprisingly, these rules for online behavior are essentially identical to rules for off-line behavior. Indeed, there is no reason why the same ethical guidelines that apply to regular behavior should not be employed in online behavior.

Pearson et al. (1997), reported on ethical standards for the IS profession that were proposed by three major professional associations in this field. These associations share an agreed set of behavioral obligations to society, colleagues, and professional organizations. The standards aim to promote the principle that individuals within the professions act in an ethical and responsible manner in order to influence the success of their organizations (Pearson et al., 1997). Clearly, similar standards can be developed for the operation of individual VEs specifying, for instance, the obligation to virtual organization members and clients.

Other possible mechanisms to promote ethical behavior in VEs include formal codes of ethics that comprise statements of prescribed and proscribed values or behaviors, and thus provide a strategic tool within organizations to inculcate and demonstrate ethical standards. Ethical standards also fulfill a strategic external role through recognition by government agencies and insurance companies. In the case of VEs, informal rules known as "netiquette" are usually in place, but a lack of a formal legal infrastructure means that a code of ethics is simultaneously both imperative and difficult to achieve. This is further compounded by different ethical standards and regulations between countries. Nevertheless, trust in interorganizational VEs clearly cannot be established until all members recognize that ethical standards are in place and are made aware of what the standards are.

c) Mutual Forbearance Between VE Partners

Some researchers approach the issue of trust by defining cooperation as coordination effected through mutual forbearance. Forbearance is refraining from cheating. Cheating may take a weak form (failing to perform a beneficial act for the other party) or a strong form (committing a damaging act). The incentives for forbearance arise from the possibility of reciprocity, leading to mutual forbearance. Parties that are observed to forbear may gain a reputation for this behavior, which makes them potentially attractive partners for others. The parties to a successful agreement may develop a commitment to mutual forbearance, which cements the partnership, and, in this way, mutual trust is created, which alters the preferences of the parties towards a mutually cooperative mode. Thus, short-term, self-interested behavior converts to cooperative trusting behavior.

d) Ability of VE Partners

In a VE, participants will be more willing to share knowledge when they trust others' abilities. It is only natural that participants want to converse with others who have the knowledge and skills regarding the topic at hand, since VEs almost always center around a common theme.

e) Effective Communication and Interaction between VE Partners

By communicating with people, we calibrate them, we get a better sense of them, and we understand their priorities. Members of VE therefore can increase the trust they are giving and the amount they will trust others by actively seeking opportunities to communicate with other members.

OPERATIONAL BENEFITS

Assuming that all of the above-mentioned conditions are in place, the likely impact on the functioning and management of VEs would include the following:

a) Favorable Trading Environment

In VEs, the risk that the Internet creates through identity and product uncertainty, physical separation, and the newness of the medium, has been attributed as an important barrier to online transactions (Bakos, 1998). Thus, perceived risk reduction is an important element that trust should influence. In addition, the success of online B2B marketplaces depends on transaction volume; hence, continuity is another crucial variable. Finally, satisfaction is an overall construct that describes the quality of the exchange relationship (Cannon & Perreault, 1999; Geyskens et al., 1998). In short, satisfaction, perceived risk, and continuity are posited as important success elements in online B2B marketplaces that could be influenced by interorganizational trust.

A recent research examines how institution-based trust develops in online B2B marketplaces to facilitate buyers' trust in sellers (Pavlou, 2002). This study proposes how specific institution-based structures help engender interorganizational trust and indirectly influence transaction success in B2B marketplaces. To assess the influence of the two dimensions of interorganizational trust—credibility and benevolence—in buyer-seller relationships, three trust outcomes are examined: perceived risk, continuity, and satisfaction.

Risk is a fundamental element of an organization's strategy because it has implications for performance. Since risk is difficult to capture as an objective reality, research has addressed the notion of perceived risk, which may be defined as the subjective probability of suffering a loss in pursuit of a desired outcome. Perceived risk has been negatively associated with transaction intentions (Jarvenpaa, 1999), interfirm partnerships, and joint ventures (Leverick & Cooper, 1998). Buyers' perceived risk in VEs mostly stems from the sellers' behaviors and not from the marketplace context. Most buyer-supplier transactions are characterized by information asymmetry, since the seller usually possesses more information than the buyer. Information asymmetry may give scope to opportunistic behavior and uncertainty. Although risk is inevitable in every transaction, trust reduces the expectations of opportunistic behavior and reduces perceptions of risk. Trust has also been shown to reduce the perceived risk of being taken advantage of by the other party. Following the trust literature, it is expected that both dimensions of trust should reduce perceived risk.

Continuity is defined as the perception of a buyer's expectation of future transactions with sellers in a B2B marketplace. There is significant evidence in the literature to suggest a strong association between trust and continuity; hence, it could be positively correlated with both dimensions of trust. Credibility allows buyers to concentrate on future transactions by reducing fears of short-term opportunism. Similarly, benevolence helps buyers to establish a long-term horizon, since they are confident that marketplace sellers will seek future transactions with mutual gain in the future.

The importance of satisfaction on business success has long been recognized. Cannon and Perreault (1999) posit that satisfaction with the relationship represents an important outcome of any business exchange. Satisfaction is the outcome of a trust-based relationship, since trust enhances satisfaction by reducing conflict (Geyskens et al., 1998). When buyers have faith in the credibility and benevolence of marketplace sellers, they are likely to be satisfied with their transactions, since conflict and fears of opportunism are diminished.

These findings provide evidence on how specific institutional mechanisms build trust in online B2B marketplaces, which in turn help to build a trustworthy trading environment for VE.

b) Reduction of Transactional Costs

The distinctive characteristic of a VE—shared ownership—is also its key problem. Shared ownership or control implies two or more companies deciding the strategic direction and operational issues of the joint subsidiary. Shared control brings with it increased transaction costs.

Transaction costs have both ex ante and ex post elements. Ex ante transaction costs include drafting, negotiating, and safeguarding an agreement. These costs can be quantified by examining actual costs (mainly management time) of the agreement process and examining the insurance costs of default. Ex post transaction costs include (1) the adaptation costs incurred when transactions drift out of alignment with the terms of the agreement; (2) the haggling costs incurred if bilateral efforts are made to correct ex post misalignments; (3) the setup costs and running costs associated with the governance structures (either in the courts or outside them) to which any disputes are referred; and (4) the bonding costs of securing partner commitments. Ex post costs are not easily quantifiable prior to the implementation of the agreement, because they include an element of uncertainty (How likely is it that the partner will default on the agreement?). This implicit probability exists in the minds of the executives entering into the agreement. It is difficult for the executives to articulate the complexity of these issues, and hence, "The transaction costs that are really there, in the sense that they determine the outcome are those transaction costs that are perceived by the managers who make the decisions" (Buckley & Chapman, 1997).

The impact of trust can now be seen in clear focus. Trust is a transaction cost-reducing mechanism that lowers the subjective risk of entering into an agreement. Both ex ante and ex post elements are reduced by trust. Costs of negotiating are reduced (perhaps legal trappings are replaced by "a gentleman's agreement"), and the subjective probability of ex post transactions failure declines when the parties trust one another.

c) Continuous Innovation in VE Products and Services

Rapid technological improvement means that continuous innovation in VE products and services is required to prevent users from switching to another system. To meet this challenge, VEs must possess state-of-the-art technological expertise. Trust is particularly important in a networked organization that requires constant and close attention to shared commitments, to safety and reliability, and to a shared willingness to learn and adapt. It has been suggested that trust permits a virtual organization to focus on its mission, unfettered by doubts about other members' roles, responsibilities, and resources, and that with trust, synergistic efforts in interorganizational missions are possible.

Trust plays an important synthesis role, as well. VE, with its flexible organizational structures, can leverage the ability and willingness to learn, thereby enhancing performance and attention to reliability over time. VEs with high levels of trust among their members can effectively utilize interactions and communication processes at their interfaces so members can learn together and develop shared mental models of reliability and a shared culture of safety.

d) Better Relationship Management

The strategic management literature often cites interorganizational systems (IOS)—automated information systems shared by two or more organizations—as examples of information technology used for competitive advantage. However, there is increasing awareness that IOS are becoming a strategic necessity and that their organizational impact demands attention. Examples show that IOS offer opportunities for enhanced organizational design. At the same time, however, IOS lead to mutual dependence between participating organizations, which potentially limits their adaptability. This makes management of relationships between IOS participants a key issue in establishing and managing successful IOS. To gain a better understanding of this issue, it is important to go beyond existing functional typologies of IOS. A framework of different contexts of IOS usage presented by Meier (1995) helps to assess the importance of relationship management between different groups of IOS participants. The framework classifies IOS contexts along two dimensions. First, does the system give the user a competitive advantage, or is it a strategic necessity for participating in the industry? Second, is the system an adjunct to the IOS provider's primary product, or does it constitute a stand-alone business? The author concludes that trust between IOS participants is essential for successful IOS. Analyzing IOS from the perspective of relationship management yields potential win-win outcomes amid all the rhetoric about the competitive battlegrounds.

e) Better Information Exchange

In the VE environment, one would expect that increased trust would result in increased information sharing and acceptance between members. It is important to note that information sharing occurs in both directions—giving information and getting information. These two are distinctly different behaviors, as getting information is the act of querying the members of the VE or searching the VE's conversation for items of interest, while giving information involves answering others' queries or volunteering comments or observations to the community. Additionally, giving information generally involves exposing oneself to a greater degree than just inquiring.

Trust in the benevolence and integrity of other members would increase the desire to get information, because the value of such information depends on the honesty of the person providing it and the person's willingness to help. It is hypothesized that this trust would make an individual more inclined to ask for information in the VE because the individual would know the provision of information is likely to be governed by these principles. In the same manner, members would only desire to give information when they trust in others' benevolence and integrity; otherwise, they would expose themselves to possible opportunistic behavior. Belief in the benevolence and integrity of others will also influence information exchange due to the reciprocal nature of communication that it implies. The VE will not survive if reciprocity does not exist; all must contribute reciprocal rewards and have a desire to do good to others. Individuals will be less inclined to share knowledge in the VE if they feel this adherence to benevolence norms is lacking. There are many indications in the literature that highlight the centrality of the reciprocal nature of communication in virtual enterprises.

f) Ownership Culture

An ownership culture exists in a VE where member organizations think and act like the core company. Building an ownership culture requires that member companies change the way they behave and move from conventional business patterns to challenging new roles. Members of the VE must trust one another, and, in particular, frontline partners must trust the core company before they will risk change. Trust is a prerequisite to building an ownership culture in a VE. It is commonly assumed that ownership primarily is an incentive that aligns financial interests of member organizations with the interests of the core company. To a great extent, this is true; this incentive plays an essential role in motivating partner companies because it gives each partner an individual profit motive to promote the success of the entire VE. The financial incentive is necessary, but the real power of ownership results from the trust effect. The trust effect is a deep connection to the VE, a relationship based on more than money. Ownership can give partners a reason to belong to the VE. The trust effect is the result of psychological ownership and only exists in VEs that actively nurture a sense of ownership throughout organizations in the network. Studies show that ownership and significant participation make it possible for a VE typically to have an advantage unavailable to their competitors.

FUTURE TRENDS

Current research on the impact of trust in VE has limitations. Most work was based on a limited number of case studies. These case studies cannot be considered representative of all VE because of their industrial and cultural biases. Because most of these models are longitudinal, for generalization purposes it is necessary to test them against the behavior of VE over time—a difficult, costly, and time-consuming exercise. A possible next step is to confront the above models with a richer, more widely dispersed set of cases, with more cultural and structural variety in the VE analysed in order to investigate its degree of robustness.

While some studies (Pavlou, 2002) posit positive relationships between trust and its consequences, these relationships are non-linear. Following Castelfranchi and Falcone (2001), buyers would only engage in a transaction if their level of trust exceeded their organization’s threshold, which depends on the importance of the transaction, the level of risk, and their individual propensity. Given a minimum threshold for trust to become effective, it is important to recognize this non-linearity.

Currently, a popular experimental paradigm employed by Human-Computer Interaction(HCI) researchers to assess trust between people interacting via computer-mediated communication, covers social dilemma games based on the Prisoner’s Dilemma(PD). HCI researchers employing this experimental paradigm currently interpret the rate of cooperation—measured in the form of collective payoff—as the level of trust the technology allows its users to develop. Some researchers argue that this interpretation is problematic, since the game’s synchronous nature models only very specific trust situations (Reigelsberger et al, 2003). Furthermore, experiments that are based on PD games cannot model the complexity of how trust is formed in the real world, since they neglect factors such as ability and benevolence.

Additionally, it is noted from the literature that little theoretical explanation exists in order to understand the impact of trust in various forms of VE relationships. It has been found that firms in horizontal alliances would display a lower level of organizational trust and a weaker relationship between interfirm cooperation compared to firms in vertical integration of alliances, and that trust is unrelated to cooperation in horizontal alliances (Rindfleisch & Moorman, 2001). It was suggested that this different impact of trust could be due to higher opportunism, lower interdependency, and stronger institutional linkages among horizontal collaborators compared to their vertical counterparts. If this finding is substantiated by future empirical research in the VE domain, researchers may need to reconsider the popular notion that trust is an essential component of all types of relationship exchanges in the VE.

CONCLUSION

Cooperative teamwork offers a greater chance for VE to be successful in today’s’ agile competition. Trust models based on traditional familiarity would not meet the special needs of the VE, which is having a short life cycle and involves a large number of partners who have never met before. Consequently, the VE partners must realize the need to effectuate this paradigm shift. This chapter identified five essential conditions needed for effective trust development in a virtual environment: a common business understanding, high ethical standards, mutual forbearance between partners, ability of partners, effective communication, and interaction within the VE. It is anticipated that the likely impact of trust would include a favorable trading environment, reduced transactional costs, continuous innovation in VE products and services, better partnership management, better information exchange among VE partners, and the development of an ownership culture.

KEY TERMS

Agile: Being agile means to be proficient at change, which allows an organization to do anything it wants, whenever it wants. Since virtual enterprises do not own significant capital resources of their own, it helps if they are agile, so they can be formed and changed very rapidly.

Benevolence: An act intending or showing goodwill and kindness.

Credibility: The quality of being believable or trustworthy.

Ethical: Conforming to standards of professional or social behavior agreed to by all members of a virtual enterprise.

Information Asymmetry: Condition in which at least some relevant information is known to some, but not all, parties involved. Information asymmetry causes markets to become inefficient, since all market participants do not have access to the information they need for their decision-making processes.

Ownership: Ownership of a business by the people who work for it (e.g., partners of a virtual enterprise).

Risk: A possibility of incurring financial loss.

Virtual Enterprise: A temporary business organization set up between trading partners operating from geographically dispersed sites, for the duration of a common project. The design and manufacture of new products or services frequently require the talents of many specialists. When many corporations combine their specialties to create a product or service, the result can be called a virtual enterprise. A virtual enterprise must be able to form quickly in response to new opportunities and dissolve just as quickly when the need ceases.

Traditional Familiarity: Traditional familiarity combines an assumption of continuity with the past experience of a partner. Traditional trust, therefore, relies on the fact that VE partners who could be observed as trustworthy in the past will display the same kind of behavior in the future.

Trustworthiness: The trait of deserving trust and confidence.

Trust Placement Process in Metateam Projects

Walter D. Fernández
Australian National University, Australia

INTRODUCTION

Metateams are temporary confederations of dislocated teams from different firms working on a single Information Systems (IS) development project. These teams (or groups) are linked by interdependencies and commercial agreements and use information and telecommunication technologies as the main media for their communication activities. Within these socio-technical systems, teams are members of *virtual teams of teams*, where key teams belong to different firms, each performing well-defined functions in accordance with its contractual role, with the objective of executing a single overarching project.

Metateams can bring expertise from multiple firms to the project while information and communication technologies facilitate the collaboration of their teams. However, managing metateams presents unique difficulties, as achieving effective metateam collaborations is both critical and difficult. Metateams are particularly exposed to the lack of common understanding of prime objectives and deficient pre-project arrangements observed in traditional IS project teams (Jiang, Klein, & Means, 2000); identity issues of autostereotype (how groups perceive themselves) and heterostereotype (how groups perceive other groups), arising from encounters of groups exhibiting organizational or national cultural differences (Hofstede, 1997); difficulties in successfully applying "foreign" management techniques to culturally heterogeneous groups (Trompenaars & Hampden-Turner, 1998); and, goal incongruence as a product of organizational fragmentation resulting from deregulation, privatization, or outsourcing (Berggren, Soderlund, & Anderson, 2001).

This overview, based on a theory-building empirical study, suggests that the effectiveness of the trust placement process—and not just exhibiting specific levels of trust— significantly impacts on project success. We focus on trusting behaviors, what we *do* when we trust or distrust others, and how our actions impact on the *quality* and *cost* of the metateam project.1

STUDY BACKGROUND: THE PROJECT AND ITS KEY PLAYERS

The SUN Project involved three key organizations – RedCorp, ITSP, and OSC – and dislocated teams from three countries (Figure 1). RedCorp was in charge of the total project. RedCorp and ITSP were linked by an information technology (IT) outsourcing agreement in which RedCorp was the client. OSC was working in partnership with ITSP on the SUN project.

SUN was a strategic multimillion-dollar IT development and implementation project. Due to its high priority, magnitude, and impact within the client company, SUN was highly visible at the top management level in all participating firms.

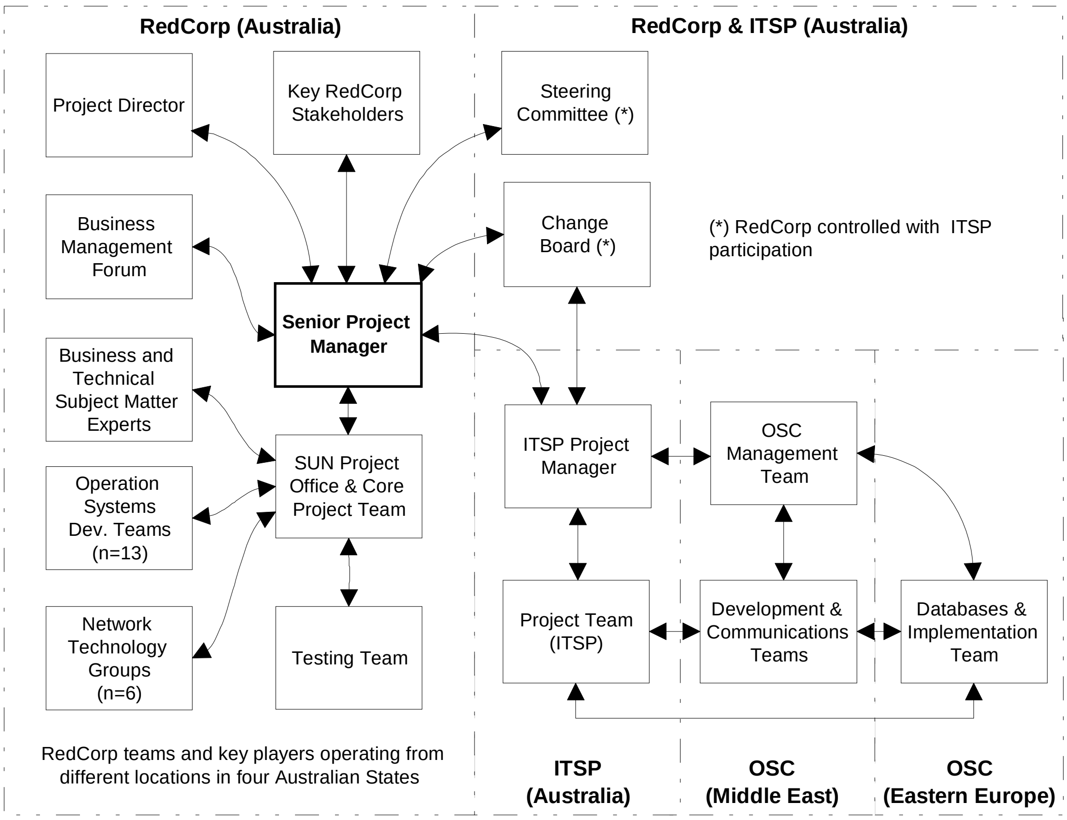
The case data included semi-structured interviews, observations, and access to project documents and electronic correspondence. The SUN Project provided rich documentary evidence; more than 4,000 e-mails and 800 project documents were available for the study. Grounded Theory Methodology (Glaser & Strauss, 1967 Glaser, 1978, 2001) was used to develop a conceptual account while the software package ATLAS.ti facilitated text analysis and management of research memos.

CONTEXTUAL ISSUES

Contextual issues are critical to understanding socio-technical organizations such as metateams; among others, the following aspects need to be briefly described:

- Metateams are organizationally fragmented systems where managers: (a) do not have the full range of options regarding project strategies and control mechanisms available to more traditional project organizations; (b) deal with teams from multiple firms having multiple mental models of what reality is or should be; and (c) may confront resentment as a consequence of anti-outsourcing sentiment.
- Metateams may be subject to unrealistic demands and expectations. Modern organizations, pushed by markets or regulators and competing in a fast-changing environment, may resort to metateams expecting to achieve the fastest project cycles and the lowest possible costs. In our study, the combination of high demands for rapid delivery and poor understanding of project complexity resulted in inadequate inter-firm agreements, which enforced rigidity when flexibility was required.
- Communication effectiveness and efficiency face multiple obstacles (e.g., miscommunication due to

Figure 1. SUN Project key players, their firms, locations, and formal communication channels.



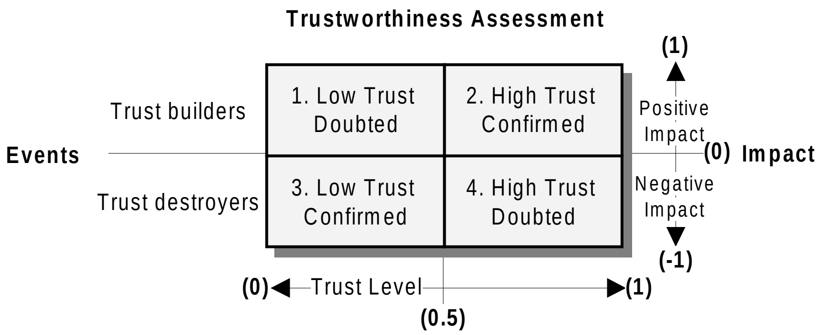
language barriers, message distortion; dogmatic approach; remoteness, inappropriate levels of trust). Additionally, it was observed that the quality of the inter-team communication was impeded, not only because of the "virtual" nature of their communication (as it is in the case of virtual teams), but also during face-to-face events due to diverging interests, urgencies, and priorities.

- Achieving a cohesive metateam is restricted by: multiple senses of identity; the magnification of the negative aspects of eliteness; the multiplicity of meaning regarding the "team product" and ownership of products and sub-products; and the often stressful nature of forced interrelations under low levels of trust.
- Goal incongruence can create different worldviews affecting teams and actors. Incongruent needs, wants, and perceptions can potentially lead to sub-goal strategies that are detrimental to successfully accomplishing the end goal. Goal incongruence is a default state of metateams, a consequence of imperfect contracting and imperfect cognition.
- While temporality is a condition of all project work, this condition is exacerbated in metateam. In traditional project teams, some level of expectation exists regarding the probability of team continuity; this probability is very low in metateams, reducing the perceived value of getting along with each and therefore adding more weight to the task-oriented, less personalized relationship.
- Although the higher level of experience required of team members is perceived as a critical asset, it also brings issues such as: allegiance to referential constituency versus project team allegiance; issues of replacement as top-level experts are more difficult to replace; and, skepticism inhibiting the beneficial effects of swift trust in virtual team formation.

TRUSTING OTHERS IN CONDITIONS OF UNCERTAINTY

Trust has been viewed as a lubricant to cooperation (Arrow, 1974; Misztal, 1996), as a product of cooperation (Axelrod, 1984) and as a way of dealing with imperfect knowledge and uncertainty about others' behavior (Gambetta, 2000). Therefore, we can expect trust to be relevant to those virtual team and metateam contexts exhibiting a high need for cooperation amid conditions of

Figure 2. Effect of project events on perception of trustworthiness (source: SUN Project-Data analysis)



uncertainty. Trust facilitates open communication, cooperative efforts, reduction of uncertainty, resolution of conflicts, common understanding, and control of transaction costs.

In our perspective, trust and mistrust are polar opposites in a conceptual continuum (a view supported by Gambetta, 2000; Giddens, 1990; and Rotter, 1967, among others). Therefore, trust is a threshold value between zero (complete mistrust) and one (complete trust). This threshold is a *subjective probability*, with which, according to Gambetta (2000), an agent assesses that another agent or group of agents will perform a particular action, both *before* he can monitor such action (or independently of his capacity ever to be able to monitor it) *and* in a context in which it affects *his own* action. p. 217

In trusting others, we take a risk because we expect certain outcomes with neither complete control of others' actions nor complete knowledge of their intentions, and because we are subject to the unforeseeable events of social reality (Lorenz, 2000; Misztal, 1996). Therefore, *trusting behavior* increases our vulnerability to another party and could make us regret our actions if that party abuses our trust (Lorenz, 2000).

In a metateam project, trust per se is neither good nor bad. Trusting behaviors, *when well placed*, have a lowering (positive) effect on the cost of inter-team transactions. Yet, when trust is misplaced, the effect on the project cost is detrimental due to the cost of opportunism. Thus, in metateams, trust is an economic asset that, when well placed, reduces the need for and, thus, the cost of controls. The importance of trust as an asset is given by the level of uncertainty in the metateam environment; where neither complete trust nor complete controls are possible due to issues such as organizational fragmentation, imperfect commercial arrangements, and diverging profit motives. In the following sections, we discuss how familiarity-building processes and the role of familiarity, exchange and reciprocity contribute to improve the quality of our trust placement, that is, economic decisions based on perceptions of others' trustworthiness.

Building Familiarity

Building familiarity is an interaction-based process that improves the quality of trust placement. By building familiarity, team members develop a grounded appreciation of others' trustworthiness and can reduce attribution errors (Cramton, 2002). Observable events such as project meetings, responses to deadlines, acceptance of deliverables, detected contract breaches, or joint conflict management and resolution efforts all provide opportunities to build familiarity and form the basis for *ex post* assessment of the trust placement's correctness. When significant, these events can modify the trust threshold, resulting in a new psychological state that is used to predict future events; using the lessons learned to look ahead, perceive possible hazards, and take *ex ante* inter-team hazard-mitigating actions (Williamson, 1985, 1996). Therefore, these events can either build or destroy trust. Figure 2 illustrates the effect of project events on trustworthiness perception.

In this evolving psychological process, project managers continuously conduct post-event evaluations. Trustworthiness evaluations involve an element of equivocality and non-rationality because they depend on availability of information and the belief that predictability is somehow possible.

Achieving greater familiarity in the SUN Project facilitated the actors' perception of hazards and the development of hazard-mitigating strategies. These strategies impact on transaction costs (immediate and/or future) and have potential long-term effects on the relationship between the client and the vendor. Yet, building familiarity in metateams can be difficult, as the next section explains.

Familiarity, Exchange, and Reciprocity in Metateams

The notion of building familiarity as a process based on metateam interactions aligns with Simmel's view of society as a number of individuals connected by exchange-based interaction, and that exchange and reciprocity are basic constitutive forms of relationships (Misztal, 1996). Exchange in this context is defined as "sacrifice in return for a gain," and it is "one of the functions that creates an inner bond between people – a society, in place of a mere collection of individuals" (Simmel, Bottomore, & Frisby, 1978).

A positive exchange occurs when the risks actors take in trusting their partners (sacrifice) return the benefits of effective and open collaboration (gain). Conversely, the outcome of the exchange will be negative when the expected gain is not realised (or is perceived as such by the actors). Unrealistic expectations, poor understanding of structural and situational drivers, opportunism, and lack of required skills or resources are some of the factors contributing to unrealised exchanges.

Because the metateam relationship is primarily task-based, the strength of the bond between teams depends on how these teams perceive the outcomes of their task-based exchanges. To expect an exchange, people in a particular team need to feel that other teams are (a) capable of doing the tasks they are contracted to do, and (b) able to understand why these tasks are important in a wider context (not just for their immediate goals), and to act according to that understanding. Therefore, expectations of exchange involve trust, as without trust an exchange cannot be rationally expected.

In the SUN Project, expectations of trustworthiness primarily resulted from evaluating other teams' contractual trust, competence trust, and goodwill trust, confirming Sako's (1998) assertions regarding the nature of trust in virtual teams. In other words, actors were concerned with questions such as: Are *they* going to respect the contract? Do *they* have the competence to deliver as promised? and Are *they* prepared to go beyond the letter of the contract to deliver on their promises?

THE HIGH PERFORMING METATEAM

We propose that effective and efficient metateam systems will (a) require appropriate controls, (b) allow flexibility, (c) foster cooperative conflict management, and (d) moderate extreme values of the trust-distrust continuum. To help in fulfilling these requirements, we need to improve the effectiveness of trust placement processes by, first, increasing awareness of the metateam's challenges among the team members and their organizations and, second, addressing key environmental issues.

Furthermore, we suggest that effective metateam controls need to be entrenched in *appropriate:*

- pre-project agreements and project agreements, and
- trust, congruency, and conflict-related processes.

By "appropriate," we mean agreements and controls *contributing* to the implementation of processes that are critical to the effective management of trust, congruency and conflict. Two key concepts—cognitive conflict embracement and trust processes and awareness—are briefly discussed next.

Cognitive Conflict Embracement

To embrace cognitive conflicts (rather than affective conflicts), we have to see them as opportunities to deliver what our customers want, to build relationship and to develop mutual knowledge. The continuous process of discovery and resolution of conflicts allows the project to move forward by building a shared mental model of the project that includes a more realistic view of its opportunities and risks.

Trust Processes and Awareness

Trusting other teams to conduct their work as expected considerably reduces the *perception* of need for interteam communication and controls. When high trust is justified, the project benefits. However, high trust is a double-edged sword that could save time and money but also result in costly disappointment when high-trust is placed on opportunistic partners, something that can only be known *ex post*. In metateams, project managers must balance the need to capitalize on the cost-saving properties of trust and the risk of trusting others in conditions of uncertainty. As trust shapes perception of relationship risks in metateams, the *trust placement process* has an important role in implementing effective hazard-mitigating strategies. To enhance the effectiveness of the trust placement process, organizations must:

1. Develop awareness of the trust placement process, of its nature and consequences. This awareness should help to assess trustworthiness and to generate conditions for trusting relationships.
2. Implement strategies to help metateam project managers to improve *ex ante* trust-based decisions by structuring their project in a manner conducive to building familiarity as early in the project as possible, i.e., using mini-milestone techniques allowing for early and frequent exchanges.

CONCLUSION

Trust plays an important role in the management of metateams. In deciding how much others can be trusted, actors make choices affecting the project's transaction cost, and thus they take risks. In this article, we presented contextual issues of metateams that must be considered when assessing project risks and strategies.

We perceive trust and distrust as opposite ends of the trust continuum. Trust has the power to shape perceptions of reality and therefore to influence the hazard-mitigating strategies actors adopt to achieve their objectives. We argued that trust is relevant to project success and that it affects the project's cost. Without trust, the interteam collaboration becomes difficult and carries a higher transaction cost due to (a) the need to implement additional controlling processes, and (b) less efficient conflict management processes requiring frequent escalation and causing delays. However, we also warned of the dangers of total trust in conditions of uncertainty and organizational fragmentation, and proposed that a balanced system of metateams will necessarily have to alternate between tendencies toward either end of the trust continuum.

Therefore, on the one hand, we believe that trust facilitates the relationship while, conversely, we are cautious in deriving a positive correlation between trust based behaviors and the success of the collaborative endeavor because *misplaced* trust is indeed detrimental to the success of the metateam collaboration. While trust is often seen as a lubricant for cooperation (Arrow, 1974), it can also be a cause of failure in major collaborative IT projects enacted by multiple teams. As our study shows, metateams exhibit both the need for and the risks of trust. Acknowledging the key role this ambivalence plays is critical to our understanding of metateams. Consequently, the key issue discussed in this article is the risk involved in placing trust; that is, trusting others and then discovering that the trust was misplaced or, in opposition, not trusting when we should and therefore introducing costly friction. As the effectiveness of the trust placement process increases the chances for project success, we argue that more effort (in research and practice) is required to improve this process.

We took an economist's view of trust, where the efficient building of a relationship through familiarity, exchange, and reciprocity serves the utilitarian purposes of cost minimization, effectiveness, and efficiency in major IT projects. We maintain that the economic value of creating trusting relationships outstrips the cost of doing so; consequently, we propose several areas to be considered when assembling and conducting metateam projects, including appropriate project agreements that align with critical needs for congruence building, conflict embracement, and effective trust placement.

Finally, metateams and virtual teams represent a revolution in the way we do IT projects and organize work. As the global business environment continues to demand innovation, flexibility, and responsiveness, the number of major IT projects using metateams will increase. The same demands for flexibility and responsiveness will further highlight the criticality of achieving project success; therefore, client and vendor organizations able to evolve and achieve effective metateam systems will thrive at the expense of those more inflexible and slow to adapt.

KEY TERMS

Affective or Relationship Conflict: "Incompatibilities among group members, which typically includes tension, animosity, and annoyance among members within a group" (Jehn, 1995, p.256).

Cognitive Conflict: Overt discrepancy among intervening parties about how a particular task or issue should be resolved and their subsequent engagement in action to redress the situation.

Major Projects: Multimillion-dollar IT development and implementation projects often defined as "*strategic*" due to their high priority and organisational impact.

Metateams: Temporary groups composed of two or more geographically and inter-organisationally dispersed teams, commercially linked by project-specific agreements and primarily enabled by electronic means of communication.

Virtual Teams: "Groups of geographically and/or organizationally dispersed co-workers that are assembled using a combination of telecommunication and information technologies to accomplish an organizational task" (Townsend, DeMarie, & Hendrickson, 1998, p.18).

Trust: A subjective *ex-ante* assessment of another party's ability and willingness to perform a particular action on which the assessor depends.

Trust Placement Process: The decision making process and the consequential actions resulting from trusting others under conditions of uncertainty and risk.

U.S. Disabilities Legislation Affecting Electronic and Information Technology

Deborah Bursa
Georgia Institute of Technology, USA

Lorraine Justice
Georgia Institute of Technology, USA

Mimi Kessler
Georgia Institute of Technology, USA

INTRODUCTION

The Americans with Disabilities Act (ADA) is the cornerstone legislation to address the civil rights of people with disabilities, including making products, services, and physical environments accessible to them. Almost everyone in the U.S. is familiar with the ADA, but designers of technology products and services need to be aware of accessibility standards that go beyond the ADA: specifically, Section 508 of the Rehabilitation Act and Section 255 of the Communications Act. These laws define accessibility standards and guidelines that impact the design of electronic, information, and telecommunication technologies, and they are intended to promote products and services that are as accessible to persons with disabilities as those without (Section 508, 1998). Furthermore, with the aging of the U.S. and world populations (Forrester, 2004), the number of people who want to use technology but cannot, because of disabilities, is on the rise. Designers of technology need to understand how modifications in traditional design will make products more marketable and usable by a wider range of customers. This article reviews important aspects of Sections 508 and 255, assistive technology and accessible design, and additional sources of information and training.

BACKGROUND

Key Implications of the Legislation

Section 508 of the Rehabilitation Act states that "each Federal department or agency, including the United States Postal Service…when developing, procuring, maintaining, or using electronic and information technology (EIT)…shall ensure…that individuals with disabilities…have comparable access" (Section 508, 1998). Section 508 required the Architectural and Transportation Barriers Compliance Board (also known as the Access Board) to develop accessibility standards for EIT, and it stipulated that the law applied to procurements after June 25, 2001 (Federal Acquisition Regulations, 2001).

The technology addressed in the Section 508 technical standards cover: "software applications; operating systems; Web-based intranet and Internet information and applications; telecommunications products; video and multimedia products; self-contained, closed products; and desktop and portable computers" (Federal Acquisition Regulations, 2001). The standards also address information and documentation including "product support in alternative formats, descriptions of accessibility and compatibility features in alternative formats, and product support services in alternative communications modes" (Access Board, 2001). Federal departments and agencies can be exempt from compliance only if they can show that compliance is an "undue burden" as a result of "significant difficulty or expense." Prior to the Section 508 amendments, Section 501 (federal employment) and Section 504 (federally funded programs and activities) of the Rehabilitation Act addressed accommodation of individuals. The amendments to Section 508 addressed the technology itself, that is, making it accessible to everyone right "out of the box" (although this does not necessarily eliminate the need for individual accommodation). It was thought that by making accessibility requirements a part of the federal procurement process, there would be financial incentives for companies to design products that meet these standards.

The Section 508 standards apply specifically to the United States government when purchasing, developing, maintaining, or using electronic and information technology. In addition, an increasing number of states purchase electronic products and services that conform to the Section 508 standards (or similar state-developed regulations or standards). Due to the complexity of the regulations and range of requirements, creators and vendors of technology products need information and training to ensure their products and services adhere to the 508 standards.

The Telecommunications Act of 1996, which was the first major overhaul of American telecommunications policy in nearly 62 years, added *Section 255* to the Communications Act of 1934. Section 255 requires telecommunications manufacturers and providers of telecommunications services to make their products and services accessible to and usable by people with disabilities if "readily achievable." The Federal Communications Commission (FCC) makes readily achievable determinations on a case-by-case basis, but generally, companies with more resources need to do more to make their products and services accessible to people with disabilities. When it is not possible to provide direct access, Section 255 requires manufacturers and providers to make their devices and services compatible with peripheral devices and specialized customer premises equipment (CPE) that are commonly used by people with disabilities, if readily achievable. Examples of specialized CPE include teletypewriters (TTYs) and assistive listening devices.

Section 255 also requires companies that develop telecommunications products and services to include the following activities as business practices:

- When the company conducts market research, product design, testing, pilot demonstrations, and product trials, it should include individuals with disabilities in target populations of such activities.
- Companies should work cooperatively with disability-related organizations.
- Companies should undertake reasonable efforts to test access solutions with people with disabilities. (Federal Communications Commission, 2002)

Unlike Section 508, Section 255 is not restricted to just the federal marketplace; it applies to telecommunications products and services purchased by anyone in the U.S. Section 508 covers a wide variety of disabilities: people who are deaf or hard of hearing, who have mobility or dexterity impairments, who have speech impairments, and those who have low vision or who are blind. Section 255 includes all of these impairments as well as cognitive disabilities. While the standards, guidelines, and directives associated with Section 508 and Section 255 may appear to complicate the product design process, often these challenges bring about innovation and new product ideas. In most cases, these innovations lead to product features that are desired by a customer market that is much larger than the disability community.

Disabilities and Applications

People with disabilities need different product and service features so they can access information and communicate with others at a level that is equal to those without disabilities. Often an assistive technology is needed by someone with a disability to overcome access barriers. For example, a text-to-speech software program, commonly called a "screen reader," is an assistive technology that allows someone who is blind to access electronic information, such as Web pages on the Internet. Designers of Web sites and software applications need to understand accessibility requirements so they can make their content accessible to users of screen readers. For example, Web sites and other software programs need to have text "tags" that describe every non-trivial image used in their applications. The screen reader reads these descriptions aloud so the user with low or no vision can understand the information being conveyed. These tags benefit sighted people too because the tag's text appears whenever they "mouse over" the image, which can help the users identify the function of an icon.

People who are deaf need visual assistance to access information that is typically delivered aurally. As a result of the Television Decoder Circuitry Act of 1990, televisions must now be manufactured with the circuitry necessary to show captioning. In this case, the viewer requires no assistive technology, and these caption-ready TVs are examples of making technology accessible "out of the box." Continuing the example related to Web site design, when sound is used to communicate information, there should be text to notify the user of the presence of sound and to describe the sound itself. Often the solution is as simple as a caption that says "music."

Another assistive technology is voice-to-text software, commonly called "voice recognition software," which assists those with motor or dexterity limitations to transmit information through speech. While this assistive technology was initially developed for people with disabilities, voice recognition is a popular feature for many technology products and is in high demand by the mass market.

Training for Accessible Design

Accessibility training is available to designers in several places around the country, and there is a wealth of information on the Internet. Web sites listed in the resources section of this article provide contacts for online training, courses, and conferences. Many of these courses are "hands on" so designers and information specialists can see the assistive technology software packages in action. Online training sessions are available through the national centers listed at the end of this article. Several centers have training materials that can be downloaded or requested through the U.S. Mail. Professional societies, such as the Human-Computer Interaction (HCI) group of the Association for Computing Machinery (ACM), American Institute of Graphic Arts (AIGA), and the Industrial Design Society of America (IDSA) include peer-reviewed papers and research on related topics.

FUTURE TRENDS

It is important for information providers and designers to know the requirements and guidelines of Sections 508 and 255 before they begin a project. If they include people with disabilities early in their user-centered design processes, they can avoid the cost of retrofitting later. In addition, increased software and hardware capabilities will ease compliance through software that easily converts information to text, or sound to image.

CONCLUSION

Section 508 of the Rehabilitation Act and Section 255 of the Communications Act are the two primary federal laws that directly affect the design of accessible electronic, information, and telecommunication technology in the U.S. These laws go beyond the Americans with Disabilities Act by defining specific standards and guidelines that address the accessibility needs of people with disabilities. Designers of technology, therefore, should understand and apply these principles when designing electronic and information technology that will be sold to the federal government (Section 508), or when developing telecommunications products and services that will be sold to the public (Section 255).

It would be a mistake, however, to assume that federal legislation is the only factor driving the need for more accessible technology. The U.S. population is aging, and with the years come age-related disabilities such as visual, hearing, and mobility impairments. The appeal of accessible technology, therefore, extends to a larger portion of the overall market, and accessibility requirements should become an essential consideration in the technology design process.

KEY TERMS

Accessible Technology: "[T]echnology that can be used by people with a wide range of abilities and disabilities. It incorporates the principles of universal design. Each user is able to interact with the technology in ways that work best for him or her. Accessible technology is either directly accessible—in other words, it is usable without assistive technology—or it is compatible with standard assistive technology" (Knowledgebase entry from University of Washington: www.washington.edu/accessit/articles?110).

Assistive Technology: Any item, piece of equipment, or system that is commonly used to increase, maintain, or improve functional capabilities of individuals with disabilities. Examples include screen readers, teletypewriters (TTYs), and Braille keyboards.

Disability: Under the ADA, an individual with a disability is a person who: (1) has a physical or mental impairment that substantially limits one or more major life activities; (2) has a record of such an impairment; or (3) is regarded as having such an impairment.

Rehabilitation Act: A federal law that was created to empower individuals with disabilities to maximize employment, economic self-sufficiency, independence, and inclusion and integration into society. It also was enacted to ensure that the federal government plays a leadership role in promoting the employment of individuals with disabilities. You can read the text of the act at www.ed.gov/policy/speced/leg/rehabact.doc.

Section 255: A part of the Communications Act. Section 255 requires telecommunications manufacturers and providers of telecommunications services to make their products and services accessible to and usable by individuals with disabilities, if readily achievable. For more information, see www.access-board.gov/telecomm/html/telfinal.htm.

Section 508: A part of the Rehabilitation Act. Under Section 508, agencies must give employees with disabilities and members of the public access to information that is comparable to the access available to others. The law applies to all federal agencies when they develop, procure, maintain, or use electronic and information technology. For more information, see www.section508.gov.

Telecommunications Act: The first major overhaul of American telecommunications policy in nearly 62 years. This Act added Section 255 to the Communications Act of 1934. See www.fcc.gov/telecom.html for more information.

Universal Design: "A process of creating products (devices, environments, systems, and processes) which are usable by people with the widest possible range of abilities, operating within the widest possible range of situations (environments, conditions, and circumstances), as is commercially practical" (Vanderheiden & Tobias, 2000).

Unified Modeling Language

Peter Fettke
Johannes Gutenberg-University Mainz, Germany

INTRODUCTION

Mature engineering disciplines are generally characterized by accepted methodical standards for describing all relevant artifacts of their subject matter. Such standards not only enable practitioners to collaborate, but they also contribute to the development of the whole discipline. In 1994, Grady Booch, Jim Rumbaugh, and Ivar Jacobson joined together to unify the plethora of existing object-oriented systems engineering approaches at semantic and notation level (Booch, 2002; Fowler, 2004; Rumbaugh, Jacobson, & Booch, 1998). Their effort led to the Unified Modeling Language (UML), a well-known, general-purpose, tool-supported, process-independent, and industry-standardized modeling language for visualizing, describing, specifying, and documenting systems artifacts. *Table 1* depicts the origin and descent of UML.

UML is applicable to software and non-software domains, including software architecture (Medvidovic, Rosenblum, Redmiles, & Robbins, 2002), real-time and embedded systems (Douglass, 1998), business applications (Eriksson & Penker, 2000), manufacturing systems (Bruccoleri, Dieaga, & Perrone, 2003), electronic commerce systems (Saleh, 2002), data warehousing (Dolk, 2000), bioinformatics (Bornberg-Bauer & Paton, 2002) and others. The language uses multiple views to specify system's structure and behavior. The recent version UML 1.5 supports nine different diagram types. *Table 2* and *Figure 1* overview the main concepts of each diagram, a more detailed description is given below. For a full description of all semantics see Fowler (2004), OMG (2003a) and Rumbaugh et al. (1998).

The specification of the UML is publicly available and maintained by the Object Management Group (OMG). OMG's standardization process is formalized and consists of several proposal, revision, and final implementation activities (Kobryn, 1999, p. 31f.). Modeling tools supporting the development of UML diagrams are available from a number of commercial vendors and the open source community (OMG, 2004; Robbins & Redmiles, 2000).

BACKGROUND

There is a great deal of terminological confusion in the modeling literature. A modeling language or grammar provides a set of constructs and rules that specify how to combine the constructs to model a system (Wand & Weber, 2002, p. 364). It can be distinguished between an abstract syntax and a concrete syntax or notation of a language. While the abstract syntax specifies conceptual relationships between the constructs of the language, the concrete notation defines symbols representing the abstract constructs. In contrast, a modeling method provides procedures by which a language can be used. A consistent and suited set of modeling methods is called a methodology. A model is a description of a domain using a particular modeling language.

The UML specification provides an abstract syntax and a concrete notation for all UML diagrams as well as an informal description of the constructs' semantics. The UML's language specification is independent of but strongly related to other OMG standards such as Common Data Warehouse Model, XML Metadata Interchange or Meta Object Facility. A modeling method or a modeling methodology is not defined by the UML standard. Hence, the language is process-neutral and can be used with different software development processes.

Conceptual modeling has a long history. Other modeling approaches that are to a certain degree accepted in practice, for instance the Entity-Relationship Model or flow charts, have a much more limited scope than UML. These approaches address just some aspects of systems' specification, namely data and process view. In contrast, UML supports the specification of static as well as dynamic aspects. Other approaches with a similar scope, for example, Open Modeling Language (Firesmith, Henderson-Sellers, & Graham, 1998), are not widely accepted in practice.

STRUCTURAL DIAGRAMS

Structural or static diagrams describe the objects of a system in terms of classes, attributes, operations, relationships, and interfaces.

(1) *Class diagram*. A class diagram can be viewed as a graph of several elements connected by static relationships. The main element is a class. Classes represent concepts within the system being modeled and are descriptors for a set of objects with similar structure, behavior, and relationships. An

Table 1. History of UML (Fowler, 2004, pp. 151-159; Kobryn, 1999, p. 30)

Version	Year	Comments
0.8	1995	Origin of UML, so-called “Unified Method”
0.9	1996	Refined proposal
1.0	1997	Initial submission to OMG
1.1	1997	Final submission to OMG
1.2	1998	Editorial revision with no significant technical changes
1.3	1999	New use case relationships, revised activity diagram semantics
1.4	2001	Minor revisions, addition of profiles
1.5	2003	Adding action semantics
2.0	2004 (?)	Planned major revision, deep changes to meta-model, new diagram types

Table 2. UML diagram types

Focus	Diagram	Purpose	Main Concepts
Static diagrams	Class	Object structure	Class, features, relationships
	Object	Example configuration of instances	Object, link
Dynamic diagrams	Use case	User interaction with system	Use case, actor
	Sequence	Interaction between objects emphasizing sequences	Interaction, message
	Collaboration	Interaction between objects emphasizing collaborations	Collaboration, interaction, message
	Statechart	Change of events during object’s lifetime	State, transition, event, action
	Activity	Procedural and parallel behavior	State, activity, completion, transition, fork, join
Implementation diagrams	Component	Structure and connections of components	Component, interface, dependency
	Deployment	Deployment of components to nodes	Node, component, dependency

object represents a particular instance of a class. Each class has a unique name among other classes within a specific scope (usually a UML package). A class can hold several attributes and operations. Attributes have names and belong to particular types that can be simple data types such as integer, string, and Boolean, as well as complex types (e.g., other classes). Operations are services offered by an instance of the class and may be requested by other objects during run-time. Different relationships between classes can be defined.

Figure 2 depicts a class diagram for banking systems. An account is described by the attributes “number” and “balance.” The operations “deposit,” “withdrawal,” and “freeze” are offered by an account. Each account is kept by a “branch” and is assigned to a “holder.” The classes “deposit account” and “current account” reuse the structure and behavior of the class “account” (inheritance relationship). In addition, the specialized account classes define further feature; for example, an object of the class “current account” is described by the property “overdraft facility” and offers an operation calculating the current debit balance.

(2) *Object diagram*. An object diagram is an instance of a class diagram and depicts the state of the system at a point in time (e.g., a particular configuration of several objects). It contains objects including their actual values of attributes and links describing object references.

BEHAVIORAL DIAGRAMS

Behavioral diagrams describe the dynamics between objects of a system in terms of interactions, collaborations, and state histories.

Figure 1. UML diagram examples

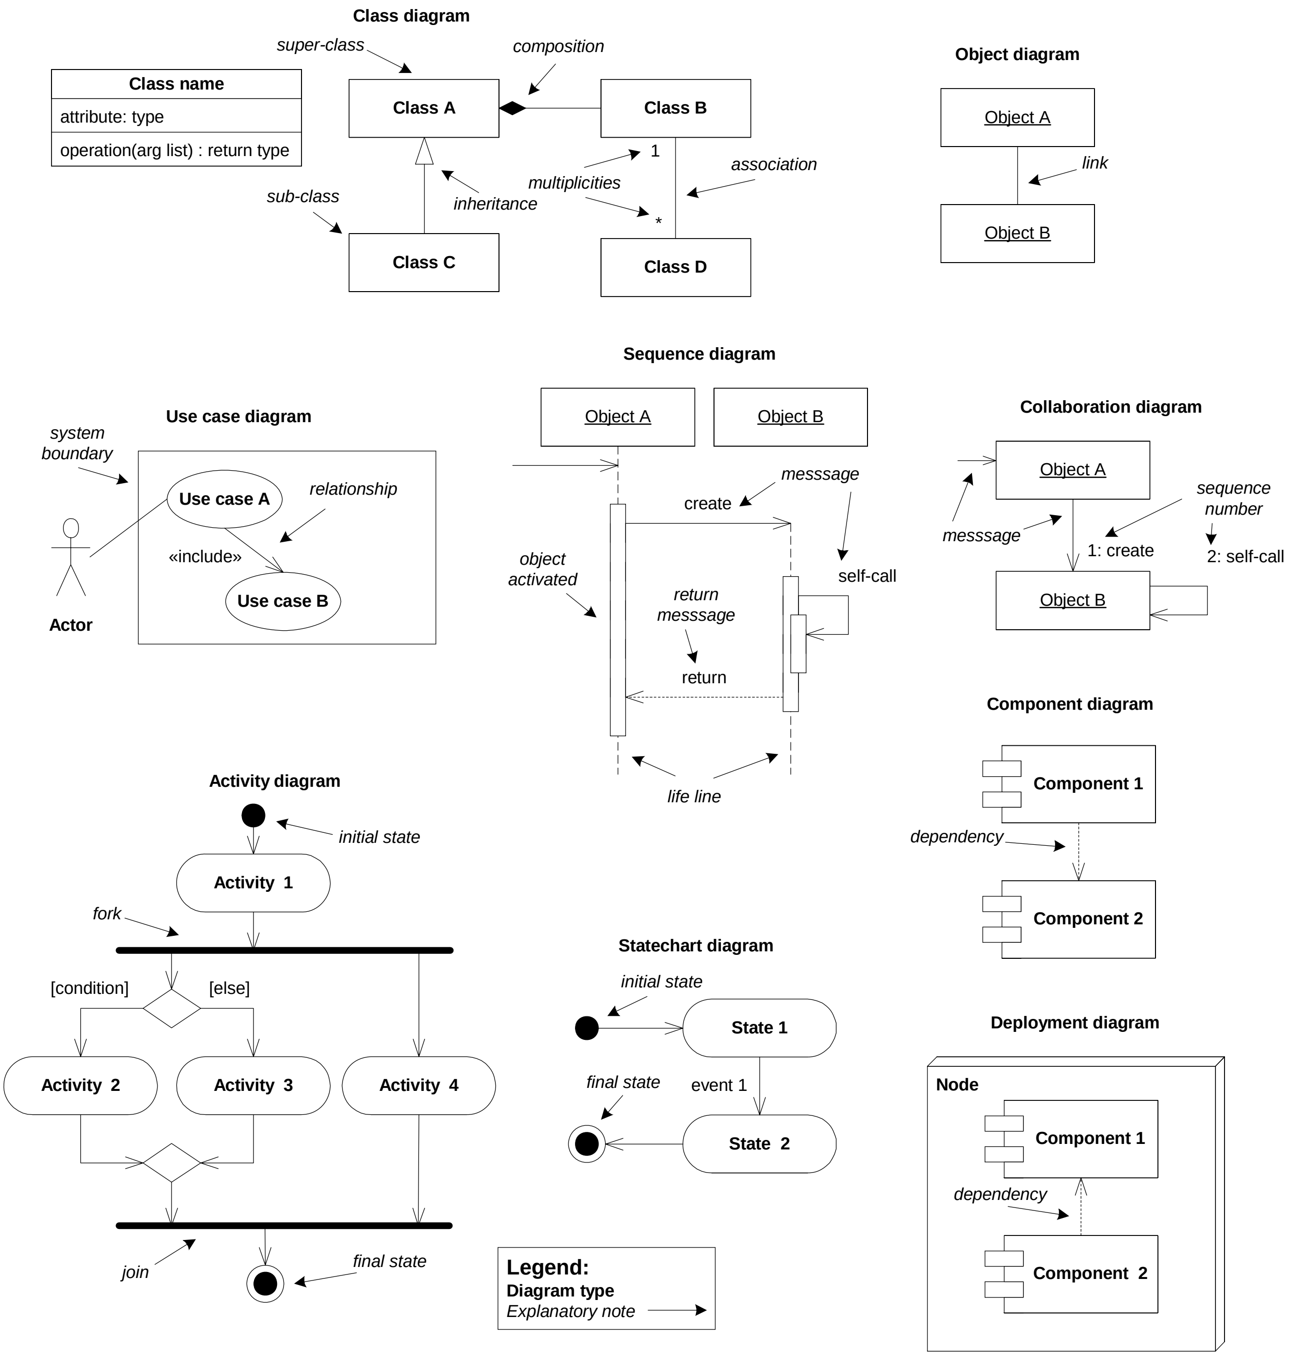

Figure 2. Class diagram for banking systems

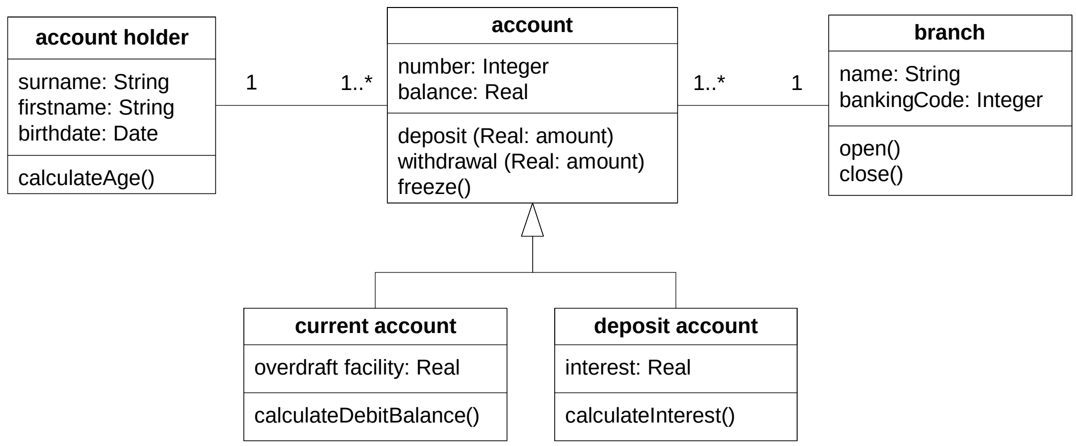

(1) *Use case diagram*. A use case specifies a complete set of events within a system to fulfill tasks or transactions in an application from a user's point of view. In a use case diagram, a set of use cases, actors, and relationships between these elements are depicted. Several use cases may optionally be enclosed by a rectangle that represents the boundary of the containing system. An actor describes a particular role of a human or non-human user of the system being modeled.

(2) *Sequence diagram*. Sequence diagrams describe interactions between different objects. An interaction consists of a partially ordered set of messages that are exchanged by the participants of that interaction. Sequence diagrams have two dimensions: the horizontal dimension represents the participants of the interaction; the vertical dimension represents the flow of time (usually time proceeds from up to down).

(3) *Collaboration diagram*. Collaboration and sequence diagrams use the same underlying information and can easily be transformed into each other. While sequence diagrams emphasize the sequence of communication between objects, collaboration diagrams show the roles of the participants of an interaction and their relationships. A sequence number specifies the flow of messages in an interaction, so no time dimension is needed in this diagram. Simple communication patterns can be depicted by collaboration diagrams; sequence diagram can better specify complex message exchanges or requirements for real-time systems.

(4) *Statechart diagram*. Object behavior is represented by statechart diagrams that can specify the behavior of an entire object or a single method. A state describes a condition during the lifetime of an object. Transitions are relationships between two states describing that an object's state can change from the first to the second state. The change of a state is triggered by an event that occurs in the modeled system. There are two special types of states: an initial state identifies the point at which behavior starts when an object is created, a final state identifies the point at which behavior ends (end of object's lifetime).

(5) *Activity diagram*. While statechart diagrams are used to specify the behavior of a single object, activity diagrams can describe behavior that crosses object boundaries. They are analogous to traditional flowcharts and are often used to document (business) processes or the dynamics inside a use case. So-called fork bars are used to describe activities that can be executed in parallel. Parallel activities get synchronized by so-called join bars. Guards are used to specify conditional forks that are only executed if particular conditions hold.

IMPLEMENTATION DIAGRAMS

Implementation diagrams capture the physical structure of a software system during build- and run-time.

(1) *Component diagram*. Components in UML are physical elements such as source, binary or executable modules and files respectively. Simple components can be aggregated to complex components to specify physical containment relations. Directed relationships between components specify that one component relies or refines the other. Such relationships are called dependencies.

(2) *Deployment diagram*. While component diagrams primary show build-time dependencies of components, deployment diagrams show a run-time configuration of the system's components. In addition, a deployment diagram uses nodes representing a processing resource, for instance a server or workstation that can execute system operations during run-time.

ADVANCED TOPICS

Object Constraint Language (OCL). There is often a need to capture unambiguously a system's semantics in a precise and rigorous way. OCL is used for that purpose. It is a formal textual language inspired by the "Design by Contract" concept and provides concepts for the definition of constraints such as invariants, pre- and post-conditions (Cengarle & Knapp, 2004; Warmer & Kleppe, 2003).

Language specification and meta-model. The UML itself is specified using textual descriptions and a four-layered meta-modeling approach (Atkinson & Kühne, 2002, pp. 291-296). In this approach, the semantic constructs at each layer are recursively refined. The top layer, the meta-meta-model (M3), provides a so-called Meta Object Facility (MOF) to specify meta-models on the next lower layer. The MOF is used on the meta-model (M2) layer to specify the concepts of UML diagrams,for example, class diagram and etcetera. The model (M1) and object (M0) layer are user-defined. The former specifies concrete UML models, the later instances of the former.

Extension mechanisms. So-called heavyweight extensions are supported by MOF and carried out on the meta-model (M2) layer. Such extensions have great impact on the language and are not performed by a particular modeler. User extensions are usually lightweight extensions that are built-in mechanisms of the UML. Lightweight extensions comprise constraints (OCL expressions), tagged values (attached additional information to model elements), and stereotypes [most powerful lightweight mechanism ranging from concrete syntax modifications to semantics redefinitions (Berner, Glinz, & Joos, 1999)].

FUTURE TRENDS

The forthcoming UML Version 2.0 (UML 2) was at first planned for 2001 (Kobryn, 1999, p. 30) but is until now (early 2004) not fully completed. In the meantime, a strong discussion about what UML 2 should and should not be evolved (Engels, Heckel, & Sauer, 2001; Miller, 2002). Currently, the UML 2 standard is voted to recommend by the OMG's technical board (OMG, 2003b) and is in its finalization phase. It consists of four separate documents (Kobryn, 2002). The UML 2 Infrastructure Specification is concerned with core language features. Advanced topics such as component and activity modeling are specified in the UML Superstructure Specification. The OCL and the Diagram Interchange Specification are two further separate UML 2 specification documents. This major revision mainly focuses on language extensibility, language specification, language precision and expressiveness. Although the complete language specification is almost fully rewritten, this revision will be primary an internal reorganization with just minor consequences for the end user. For example, the new diagrams mainly clarify and resemble existing diagram types.

Further trends include:

- *Model Driven Architecture* (MDA). MDA promotes modeling through the whole system's life-cycle (Frankel, 2003). Its objective is to fully automate the system's development process.
- *Executable UML*. Executable UML enriches modeling concepts with execution semantics (Mellor & Balcer, 2002). This opens the possibility of software development without "classical" programming.
- *Model libraries*. UML is used to standardize domain-specific models fostering the usage of reference models (Fettke & Loos, 2003a). Known reference models, for example, OMG's Business Enterprise Integration or Finance Domain Task Forces, they support model reuse.
- *Ontological analysis and semantics*. This research line evaluates UML from an ontological point of view and incorporates real-world semantics to UML constructs (Opdahl & Henderson-Sellers, 2002). The aim of an ontological evaluation is to examine if all constructs of an ontology can be mapped onto the constructs of UML and vice versa.
- *Component-based development*. UML is primary an object-oriented language. To fully support component-based development, some enhancements are needed (Dahanayake, 2003; Fettke & Loos, 2003b; Kobryn, 2000). Particularly, component descriptions must include dependencies on other components, quality specifications for needed and offered services, and domain-specific semantics.

CONCLUSION

Although almost everyone acknowledges the practical benefits of a standardized modeling language [e.g., protection of investments in technology, easier model exchange and reuse, better professional training (Frank, 1997, p. 13)], there are important opportunities that have to be challenged. UML's size (UML 2 has approximately 1,000+ pages) and complexity is overwhelming compared with other languages (Siau & Cao, 2001). Therefore users have difficulties in writing and reading diagrams (Agarwal & Sinha, 2003; Laitenberger, Atkinson, Schlich, & Emam, 2000) and tool venders have problems to fully support the UML standard. Furthermore, the maintenance of the standard is very expensive and error-prone, for example, Fuentes, Quintana, Llorens, Génova, & Prieto-Díaz (2003) identified several hundred errors in UML's meta-model. Other authors criticize UML for its semantic inconsistency, construct ambiguity, notation inadequacy, and cognitive misdirection (Champeaux, 2003; Frank, 1998; Henderson-Sellers, 2002; McLeod, Halpin, Kangassalo, & Siau, 2001; Shen & Siau, 2003; Thomas, 2002; Wang, 2001).

On the other hand, UML is the de-facto standard for object-oriented modeling and an important milestone in software engineering. Modeling of software systems increases the degree of abstraction during system development tremendously. This change is similar to the replacement of assembly languages by high-level languages in the 1960s and 1970s. Today, high-level languages are not used in all but most domains. We predict that, in the future, UML has an analogous position as high-level languages have today. Hence, UML continues to play a major role in systems development.

KEY TERMS

Conceptual Modeling: An action describing a domain with the help of some artificial or formalized language.

Meta-Model: A meta-model is a model of model.

Methodology: A consistent and suited set of modeling methods providing procedures to apply the constructs of a modeling language.

Model: A model is a particular product of conceptual modeling. It is a description of a domain using a particular language.

Object-Oriented Analysis and Design (OOA & OOD): Software engineering approach to constructing software systems by building object-oriented models that abstract key aspects of the target system.

Object-Oriented Programming (OOP): Object-oriented programming emphasizes the hiding or encapsulation of the inner state of objects and the specification of these objects by an interface. OOP languages support objects, classes and inheritance.

Reference Model: A reference model is a model representing a class of domains, for example, a reference model for production planning and control systems. It is a conceptual framework or blueprint for system's development.

Usability and Learnability Evaluation of Web-Based ODL Programs

INTRODUCTION

The rapid establishment of third generation distance learning environments, the so-called Web-based or tele-teaching environments, brought some problems with it. The main means for the delivery of the new educational approach is the World Wide Web, and there are some good reasons for it: It is easily accessible by many groups of learners. It supports multiple representations of educational material and various ways of storing and structuring this information. It is powerful and easy to use as a publishing medium. Additionally, it has been widely accepted that the hyper-medial structure of the Web can support learning. Some researchers characterize the Web as an active learning environment that supports creativity. In addition to this, the Web encourages exploration of knowledge and browsing, behaviors that are strongly related to learning. The associative organization of information in the Web is similar to that of human memory, and the process of information retrieval from the Web presents similarities to human cognitive activities (Tselios, Avouris, Dimitracopoulou, & Daskalaki, 2001). However, a hyper-medial space, like the Web, cannot be considered, only by these features, as an effective tutoring environment. It is rather more appropriate to think of the Web as a powerful tool that can support learning, if used in an appropriate way. This is because learning is a process (Duchastel, 2001) that depends on other features, such as learner's motivation, previous experience and learning strategies that the individual has been supported to develop, and so forth. Effectiveness of any educational environment cannot be considered independently of these aspects.

USABILITY VS. LEARNABILITY

To define the notion of "learnability", we must first answer the question, "what makes the (instructional) content of an environment easily learned?" The answer to this question defines in general the learnability of the environment. A more formal definition attempt would be the statement that it is *the set of the methods, the modes and the tools of the environment, which facilitate the acquisition of knowledge*. This work assumes that the notion of learnability embeds de facto the notion of the communication channel; it is impossible for someone to gain knowledge if the environment lacks the means to offer it. So, an evaluation of the learnability of the environment, evaluates hence the success rate of the established communication channel. Continuing on, the next question that emerges is the relation between usability and learnability and in how far one affects the other, which is a central question in this chapter. In more detail, we are interested if a usable environment facilitates the acquisition of knowledge, or, the opposite, if a less usable environment sets certain obstacles. And finally, this question transits to the question if one can heuristically assess the learnability of an educational environment. Heuristic evaluation, as described initially by Nielsen and Molich (1990) and following by Nielsen (1993), is a well-established, expert-based interface evaluation method for the evaluation of the usability of a particular interface. A set of interface experts is asked to judge the interface, based on a set of a few criteria, the heuristics.

What do we mean by the term "usability"? According to ISO-9241 (ISO, 1998) standard, we have the following definition:

Usability of a system is its ability to function effectively and efficiently, while providing subjective satisfaction to its users.

Usability of an interface is usually associated with five parameters (ISO, 1998; Nielsen, 1993), derived directly from this definition:

1. *Easy to learn*: The user can get work done quickly with the system;
2. *Efficient to use*: Once the user has learned the system, a high level of productivity is possible;

3. *Easy to remember*: The casual user is able to return to using the system after some period without having to learn everything all over again;
4. *Few errors*: Users do not make many errors during the use of the system or if they do so they can easily recover them; and
5. *Pleasant to use*: Users are subjectively satisfied by using the system; they like it.

To conclude, when the synergy between usability and learnability occurs, the use of the software can be thought of as "integrated", in that a seamless union develops between the use of the software and the learning process (Squires & Preece, 1996).

THE EDUCATIONAL EVALUATION

The evaluation methodologies applied in the field usually utilize questionnaires in the classroom, however most questionnaires embody closed-type questions, so they lack the opportunity to clarify some other aspects that could be of interest, have an impact on the environment and on the involvement of the software on learning. Moreover, closed-type questions do not take into consideration the individual differences of the students in learning. In general, quantitative approaches to evaluate an educational environment have been strongly debated as monosemantic approaches that must be supplemented by qualitative ones, which focus on *how* and *what* the student learns.

Other studies in the research field of the evaluation of a distance learning environment are the studies of Holmberg (1977), Saba and Shearer (1994), and Garrison (1993), however none of them deals absolutely in the field of evaluation of Web-based environments, as it is in the case of Makrakis, Retalis, Koutoumanos, and Skordalakis (1998) and Koutoumanos, Papaspyrou, Retalis, Maurer, and Skordalakis (1996). These are all user-based evaluation approaches, since they utilize more or less questionnaires that have to be answered by users.

THE HEURISTIC EVALUATION

Concerning the expert-based approaches, Jacob Nielsen and Rolf Molich (1990) started their research in 1988, and in 1990 they presented the "heuristic evaluation". The basic point was the reduction of the set criteria to just a few, at the same time being broadly applicable and generally agreed; simultaneously augmenting the evaluators' expertise, and consequently their reliability. These "heuristic rules" or "heuristics" derived from studies, criteria lists, field observations and prior experience of the domain.

The core point to evaluate in the initial approach is the usability of the interface. Based on the ISO principles about usability (ISO, 1998), Nielsen (1993) stated the following heuristics, slightly modified and reorganized by us:

1. Simple and natural dialog and aesthetic and minimalistic design;
2. Visibility of the system status – provide feedback;
3. Speak the users' language: match between system and real world;
4. Minimize the users' cognitive load: recognition rather than recall;
5. Consistency and standards;
6. Flexibility and efficiency of use – provide shortcuts;
7. Support users' control and freedom;
8. Prevent errors;
9. Help users recognize, diagnose and recover from errors with constructive error messages; and
10. Help and documentation.

The method refers mainly to traditional formative human-computer interface evaluation, yet a number of studies (e.g., Instone, 2000; Levi & Conrad, 1996) have proven its easy adaptability to the evaluation of Web sites as well.

LEARNABILITY HEURISTIC LIST

The next step one must perform is the construction of the heuristics for learnability. A good starting point provides the socio-constructivist view of instruction. Some studies in the field (e.g., Kordaki, Avouris, & Tselios, 2000) argue that an expert evaluator cannot predict the students' performance, although he/she can assess heuristically the learnability of the environment, however with mediocre results. The authors base their claims on the constructivist approach for open learning environments, also known sometimes as microworlds.

Squires and Preece (1999) proceed one step further: They do not make a combination, but a fusion of the Nielsen's heuristics with the five socio-constructivist learning criteria (credibility, complexity, ownership, collaboration and curriculum) providing thus a new list, which they claim to be a versatile tool to predictively evaluate educational pieces by their usability and simultaneous learnability.

1. Match between designers' and learners' mental models;

2. Ensure navigational fidelity;
3. Provide appropriate levels of learner control;
4. Prevent peripheral cognitive errors;
5. Understandable and meaningful symbolic representation;
6. Support personally significant approaches to learning;
7. Build strategies for the cognitive error recognition, diagnosis and recovery cycle; and
8. Match with the curriculum.

A PROPOSAL FOR A NEW LIST

Two studies performed by the authors (Karoulis & Pombortsis, 2001a, 2001b) based on the aforementioned approaches concerning usability and learnability. They concluded to a combined list of 10 heuristics axes to assess the usability and the learnability of an open and distance learning (ODL) environment. So, the proposed final heuristic list for usability/learnability expert-based evaluation of Web-based ODL environments is as follows.

1. *Content*: Is the quantity, quality and value of the content acceptable? Can one characterize it as "student centered" and "open"?
2. *ODL adaptation and integration*: Does the program provide spatial freedom and temporal flexibility? Are the principles of ODL concerned?
3. *User interface*: Are Nielsen's usability heuristics concerned?
4. *Use of technologies*: Does the environment make full use of the potential of the underlying system, without hampering the students' performance in any way?
5. *Interactivity with the instructional material*: Is there navigational fidelity and correct multimedia elements? Is the environment adaptable, and does it support collaborative work?
6. *Students' support*: Is there adequate guidance and support for the student? Are the supporting elements easily accessible?
7. *Communication channel*: Is synchronous and asynchronous communication possible? Are there tutorial sessions and a tutor?
8. *Acquisition of knowledge*: Easily acquired knowledge and support of personal styles and cognitive levels. Support of authentication of the knowledge.
9. *Projects and "learning by doing"*: Are there enough exercises and hands-on practice? Is exploratory learning supported?
10. *Assessment and self-assessment*: Is the student assessed according to the principles of ODL? Are there self-assessment tools?

DISCUSSION

The general impression from the literature survey we presented in this article and the studies we have conducted is that the method is applicable and provides some great advantages as well, which are advantages of the heuristic evaluation in general: it is cheap, fast, easy to apply; the experts, despite the difficulty in locating them, are more easily brought together than the users; and it is very efficient, according to the problems it discovers in relation to the effort and the resources needed (Nielsen, 1993; Levi & Conrad, 1996).

However, there are some important concerns regarding the applicability of the method one has to keep in mind when working with it.

Maybe the most important concern is that the heuristic approach may sometimes not allow for usability issues that occur for specific tasks and users groups. It is also not able to identify and to take into consideration socially relevant issues (Hess & Azuma, 1991), such as the individual characteristics of ODL students, financial categorization, minorities and cultural differentiations, or the well-known problem of the harmonization of the ODL class, due to the observed student diversity. These issues could lead the evaluation of the usability and the learnability of the system to the edge, in the sense that any opinion of an evaluator could be rejected by an opposing statement of a second one; the paradox being in this case that both are right. This problem occurs in empirical evaluations as well; we presented it briefly as we mentioned the antagonistic studies published up to now on the domain. So, it is obvious that one has to make an assumption on the harmonization of the ODL class, a common profile of the students, which however has to be broad and flexible more than usual, to enclose as many of the characteristics of the "common ODL student" as possible, even if some researchers advocate that "the common user" doesn't exist.

FUTURE TRENDS

Concerning the delivery of information over the Web and the collaboration of many people over a network, socially relevant issues arise as well, such as the preservation of privacy (Bellotti & Sellen, 1993). Information technology can store, transmit and manipulate vast quantities and varieties of information. ODL environments are extremely prone to intrusions, due to their structure, and a clear way to be protected against intrusions has not yet been found. Future research about evaluation methodologies in a holistic manner, should take this point of concern into consideration as well.

CONCLUSION

We claim that expert-based methodologies in general and the heuristic evaluation in particular can be successfully applied in the evaluation of Web-based open and distance learning environments. Generally, many problems of the site under evaluation can be discovered, and the general impression is that with the results of the heuristic evaluation, one could propose many concrete improvements to the site under consideration, which finally is the aim of every evaluation.

Levi and Conrad (1996) argue that the final assessment of every system must be made according to its usability. Myers and Rosson (1992) calculated that 48% of the total code of every software concerns the interface; Avouris (2000) augments this number to 70% while Myers (1992) claims that in many cases the interface is the system itself. We do not entirely agree with this position; we rather believe that the heuristic methodology provides a powerful tool to evaluate the usability and the learnability of a particular interface; however, in the case of complex environments, like ODL environments, it must be combined with in-field evaluations. There is, more or less, a coincidence of the researchers in the field over this issue (Kordaki et al., 2000; Preece, Rogers, Sharp, Benyon, Holland, & Carey, 1994; Squires & Preece, 1999). So, we consider the heuristic approach as a powerful tool for the formative evaluation of the first design stages of the environment; however, as the system matures, it should fade out in favor of more user-centered approaches, which can provide an in-depth analysis of the system's usability and learnability. Yet, one must be aware of the constraints of the empirical evaluations, and, most of all, the problem in finding *real users* to evaluate the system under *real circumstances*.

KEY TERMS

U

Constructivism: An educational theory, arguing that the student "constructs" his/her own knowledge on the domain, rather than "acquiring" certain behaviors on how to interact with it.

Educational Evaluation: Assessment of the educational value of an educational software piece.

Empirical Evaluation: Evaluation methodology which employs users to interact with the system.

Expert-Based Evaluation: Evaluation methodology which employs experts, mostly from different cognitive domain, to assess certain system aspects.

Heuristics: Rules or criteria which derive directly from practice. Usually, they are not "proven" in a scientific way, yet they are broadly acceptable.

Learnability: The degree to which a system can transfer knowledge in a "natural" way. "Natural" in this context is "the way the user is used to acquire the knowledge."

Usability: The ability of a system to interact "natural" and "transparent" with its users. "Natural" in this context is "the way the user is used to act" and "transparent" means "not interfering with the performed task".

Usability Evaluation of Online Learning Programs

Bernard Blandin
CESI SAS, France

INTRODUCTION

Human activities are social activities, in essence. Evaluating or using a piece of software is a social activity, as well as a learning activity. Nonetheless, these activities are generally considered as relying upon universal and culturally neutral criteria or ways of achieving them. This chapter makes the case for an opposite viewpoint and aims to support the idea that "usability of online learning software" has to be considered as situated.

In its broad sense, "usability" addresses the relationship between tools and their users. From a designer's viewpoint, usability is seen as a relationship between a human being and an artifact that measures the productivity of a user using the artifact (Nielsen, 1994). Some authors consider an extended notion of usability that distinguishes clearly between two usability-related concepts, "ease of use" and "usefulness," but takes them both into account (Notess, 2001). This extended notion of "usability," which is the one supported by this chapter, has a strong dependence on social and cultural aspects, because the use of any object is a social activity, which implicitly implies social relations belonging to different registers (Blandin, 2002).

Therefore, the standpoint presented here is the following: usability evaluation should not be limited to consider "simply ease of use of a tool" criteria, but should also take into account all the conditions that lead a user to actually use a tool. When "learning" is the aim of the activity, underpinned by the use of the said tool, social, cultural, and context-dependent factors are driving forces that shape the action and that need to be taken into account within the evaluation process.

BACKGROUND

Usability, in its first sense in the field of software design and engineering, was synonymous with "ergonomical issues," though the sense of the word can now be broader and encompass "usefulness" or "utility" issues.

In its first, "historical" sense, the word "usability" intended to define rules to design the application to match users' habits, various types of equipments, various languages, etc. The basic principles of a good design for usability, still in use today (Notess, 2001), were, and are, those described in Norman (1988):

1. Provide a good conceptual model
2. Make things visible
3. Map the controls, their movements, and their results in the real world
4. Provide feedback for any action

Such principles apply to "usability engineering" (Notess, 2001) and are considered as good heuristics (Nielsen, n.d.) to design learning software. Their application may, in some conditions, facilitate the use of learning software.

A "good conceptual model" cannot be universal—it is related to a particular culture. If "learning" is concerned, even in a given culture, different "learning styles" and "learning cultures" exist that generate different appreciation of what a "good conceptual model" might be (Blandin, 2003).

It can also be argued that the same tools are used differently within different communities (Brown, Collins, & Duguid, 1989), which reinforces the need to take into account social and cultural aspects belonging to the world of the user.

Sociology of uses, which now relies on a large "corpus" of surveys published on both sides of the Atlantic (Martin, 1997), points out the fact that "usefulness" or "utility" is a precondition to use a tool. Research made to understand why tools or facilities, such as video recorder, a personal computer, or pay-TV, are not used lead to this evidence: "no need" is the main reason given to explain rejection of the tool (Punie, 1997). A recent two-year survey (Rouet, 2003) on the development of uses related to the Internet among a sample population representative of a French provincial area showed that the uses developed after two years are based on the applications that were considered useful at the beginning (e-mail, browser, search engine, etc.), and those not considered useful (chat, Webcam) remain unused. Utility does not spontaneously evolve.

This means that the first criterion of usability evaluation of an online learning program is that it has to be considered as useful by the user. Again, this is context dependent. As a result, the use of online learning programs appears dependent on what I called "social schemata of uses" (Blandin, 2002), which determine and format conditions for using tools as well as the ways the tools are used.

MAIN THRUST OF THE ARTICLE

For these reasons, factors describing the environment of uses need to be encompassed in any usability assessment. To take this into account, Blandin (2003) proposed the notion of "situated usability" to name a set of heuristics that account for describing how the environment impacts usability factors. These heuristics, as stated in Blandin (2003) are as follows:

1. **Social Schemata of Uses:** to be used within a given community, a tool should embed common Social Schemata of Uses of this community;
2. **Type of Action:** to be used in a given situation, a tool should correspond to user's need and purposes in this situation, and allow him/her to perform a given action;
3. **Culture of the Users:** to be used within a given community, a tool should convey representations and practices which are considered as "common sense knowledge" by the user;
4. **Culture of the Environment:** to be used within a given community, a tool should convey representations and practices which are considered as "common sense knowledge" by the community;
5. **Tool Efficiency in a Given Situation:** to be used in a given situation, a tool should have proved efficiency in such a situation;
6. **Ability of the User to Use the Tool:** to be used in a given situation, a tool must be mastered, to some extent, by the user; which also means that an object does not become a tool at hand;
7. **Motivation of the User to Use the Tool:** to be used in a given situation, a tool should interest enough the user to perform his/her action using this tool rather than in any other manner (pp. 319–320).

These heuristics are general and may apply to any type of tools. They could be refined in the case of online learning programs by identifying the "learning culture" of the user (Brown, Collins, & Duguid, 1989).

Following the principle used by Lakoff and Johnson (1999), four families of "learning cultures" can be considered, based on four different "learning metaphors," or four different "learning paradigms," built upon different learning theories throughout history (Table 1). These learning cultures still correspond to different communities of thinking within the educational world.

Some tools originated in, or better fit, with a particular learning culture. For example, mail and other written communication tools fit better with the Socratic paradigm, because they allow discussion; computer-based training programs originated from the Plato system, based on the work of renowned behaviourists, such B. F. Skinner (Dooijes, n.d.).

A typology of "formal learning systems," as presented in Blandin (2000) or in TTNET Dossier Number 4 (2001), will help to classify online learning programs according to the learning cultures. It is presented in Table 2.

It can be noticed that these four learning cultures do not allow for the implementation of all the "situated usability" heuristics presented above in the same manner, and some of the tools corresponding to Platonism, objectivism, and behaviourism might not always fulfill the requirements stated by heuristics (2), (3), (6), and (7).

One of the reasons why online learning programs are not used is because there is a "trench" (Brown, Collins, & Duguid, 1989) between the learning culture that they implicitly embed and the learning culture of the learner, or of the learning system in which they are inserted. This trench generates learning situations that are ill-formed, and thus inefficient, or that are rejected by one of the actors, either the teacher or the learner.

From current research, it appears that the learning culture might influence the use of online learning programs in the following ways (Blandin, 2003):

- There could be a mismatch between a teacher's learning culture and off-the-shelf programs, which

Table 1. Four learning cultures

The Learning Paradigm	The metaphor underpinning the learning culture
Platonism (Socratic)	Learning is remembering
Objectivism (Aristotelian)	Learning is recording
Behaviourism	Learning is training
Constructivism	Learning is building

Table 2. Four learning cultures and online learning programs (Source: Blandin 2003).

The Learning Paradigm	Type of online learning programs fitting with the culture
Platonism (Socratic)	Programs based on collaborative tools or communication tools (virtual communities, virtual campuses, etc.)
Objectivism (Aristotelian)	Poorly interactive and broadcast programs (information resources, Webcast courses and conferences), virtual classroom (audio or video real-time instruction)
Behaviourism	Interactive learning systems (computer-based training, Web-based training, computer-assisted instruction, etc.)
Constructivism	Interactive learning systems (simulators, virtual labs, micro-worlds, etc.), problem-based learning systems

leads to "no-use recommendations."

- Most current programs provided by online learning providers are of Aristotelian or Behaviourist style and, therefore, will not be used or recommended by teachers implementing the Constructivist paradigm.
- The use of online learning programs might be facilitated when the conditions to develop and promote self-directed learning are fulfilled. This supposes both to use the Constructivist paradigm and to implement the "seven pillars of self-directed learning" as described by Carré (2002, 2003).

From these findings, more specific usability criteria related to the use of online learning programs can be derived, such as the following (Blandin, 2003):

- Adequacy between the learning paradigm embedded within the learning program and the learning paradigm in use within the school or the university
- Adequacy between the content of the learning program and the course curriculum in which it is supposed to be embedded
- Adequacy between the content of the learning program and the way this content is taught by the teacher in charge of the course
- Adequacy between the learning paradigm embedded within the online learning program and the learning paradigm in which tutoring support is rooted
- Adequacy between the learning paradigm embedded within the online learning program and efficient learning strategies for such content for the learner
- Adequacy between the use of a given type of learning material, the learner's motivation, and his or her self-directed learning readiness
- Adequacy between the learner's ranking in the self-directed learning readiness scale (Guglielmino, 1977) and the kind of support provided
- Adequacy between the learning environment culture and supportiveness and the expected motivation of learners

These criteria correlate with the findings of recent research and can explain their results (Masie, 2001; Paxton, 2000; Quinn, 2001).

FUTURE TRENDS

From a broader viewpoint, this topic is a subpart of sociology of uses. Research in sociology of uses traditionally focused on uses "as they were" at a given time among a given population.

A more recent trend is illustrated by the "*100 fenêtres sur Internet*" survey in France: 100 people were given a computer with cheap Internet access over 2 years and, in counterpart, accepted to be questioned and observed four times, at the beginning and then every 6 months (Rouet, 2003). This research looked upon the evolution of uses over a 2-year period: uses are no longer considered "static."

But this is not enough. If we consider that uses have their own dynamics, it is important to start research on how uses are built and how they emerge. This will allow us to understand how a technology is accepted and how its "usability" is created.

Because this topic is a particular application domain, the processes that might result from the research described above will have to be specified to learning software and to educational contexts. Further research on learning cultures and their impact on the use of learning tools is needed in order to better understand such phenomena and to produce more criteria that will facilitate the implementation of "e-learning motivators" adapted to a given context.

CONCLUSION

The epistemological stance of the teacher or of the trainer; the motivation of learners; the learning culture of the school, of the university, or of the company; and context-related factors interact together to produce the conditions that will determine how a given type of learning material and, in particular, online learning programs, are used in the school, the university, or the company.

This is why usability has to be considered as "situated," and why a sociological standpoint is required to understand how a user uses a tool in a given context, and what factors are involved in influencing the relationship between the user, the tool, and the community to which they belong. Because the use of a tool is deeply rooted in users' cultures, and may be learned, usability has to take into account the social and material environments of the users.

KEY TERMS

Formal Learning System: This is a situation that is specially designed to facilitate learning. This situation takes place at a given time in a particular physical environment equipped with dedicated furniture and technical facilities.

Learning Culture: This is a particular way of considering the learning process, how it occurs, in what conditions, and so forth. It relies on an explicit or an implicit theory that provides more or less accurate representations of the learning process.

Learning Metaphor: This is an image representing the way the brain is supposed to process information to produce knowledge. This image is built according to the implicit theory in use or to the explicit theory espoused.

Learning Style: This is the preferred way a person collects, decodes, and processes information to produce knowledge.

Online Learning Program: This is a piece of software, running on an electronic network, that was explicitly designed to support a learning situation.

Sociology of Uses: This is a domain of Sociology that studies how a given population uses technical objects. Initiated by telecom operators in the second part of the 20^{th} century, the field of research has been enlarged to encompass the use of any type of technical object.

Usability: This is the capacity of an object to be used within a given course of action. It includes the "ease of use" of the object for the action and its "usefulness" or "utility" for the user to achieve the action.

Uses: These are the different ways a tool is used. Uses are highly cultural and depend upon the context of use and the culture of the social surroundings.

Utility: This measures the degree of usefulness of an object. Classical economical theories consider that the utility of an object and the available quantity of this object determine its price.

Usability of Online Learning Systems and Course Materials

Elizabeth Furtado
Universidade de Fortaleza, Brazil

INTRODUCTION

Human-computer interaction (HCI) aims to design and develop high-usability interactive systems (ISs) focusing on users' needs and ergonomic principles, among others. The usability of an IS refers to how easy it is to use and to learn. Similarly, software engineering (SE) aims to design and develop high-quality ISs focusing on schedule, budget, communication, and productivity. The quality of an IS refers to how satisfied the system clients and/or users are, verifying whether the system is performing exactly what was requested.

In order to achieve both IS usability and quality, it is necessary to integrate HCI concepts into an IS development method. HCI concepts can be characteristics of users (such as their preferences, language, culture, and system experience) and of their context of use (such as easy accessibility and good luminosity of the environment). In the online learning context, it is necessary to integrate HCI concepts into an online learning system development method. The pedagogic usability of an online learning system is related to how easy and effective it is for a student to learn something using the system. For these reasons, it is important not only to think about the IS quality, but about its usability as well. In this text, an online learning system on the Web is composed of a virtual learning environment (VLE), with tools to support a collaborative learning and online course materials available for the users through this environment. So, it is important not only to think about the VLE usability, but also about the online course material usability.

We have identified some problems to achieve a successful deployment of online learning systems (Furtado, Mattos, Furtado & Vanderdonckt, 2003):

- *Lack of learning quality:* Many academic staffs are not worried about the design of online course materials. The material of a face-to-face course is hardly ever adapted to online course material. Whenever a course is to be published on the Internet, it is important to envision the virtual course as the software. This way, it is expected that a course is to be developed with the same severity as the software is planned.
- *Lack of adaptive tools and guidelines:* Learning systems are very useful, but most of them are not adaptive and neither is the user model predefined (Gomes & Viccari, 1999). In addition, user interfaces of such systems are generally specified without taking into account guidelines (Eleuterio & Eberspacher, 1999).
- *Lack of training in collaborative technologies and methods:* Any academic staff (such as a teacher), as part of his/her professional development, needs continuous training. Such training is often carried out without using technologies that can deal with adaptive and collaborative processes. It is necessary to fulfill these needs by adopting an integrated pedagogical-technological content (Perrenoud, 2001).

All of these issues have a critical impact on the usability and quality of online learning systems. Thus, we developed a general architecture for such systems, which aims to show the concepts that must be considered to increase the quality of the learning process and to increase their user interface (UI) usability.

The remainder of this article is structured as follows: in the next section, we explain the main concepts that helped us to develop such general architecture. Then, we provide the best practices used in a development cycle of an IS, focusing on the usability issue. Finally, we summarize the main points of this text.

VLE AND ONLINE COURSE MATERIAL BACKGROUND

As we have mentioned before, an online learning system is composed of a VLE and online course instructional materials.

A VLE has to provide students with spatial freedom and time flexibility. It has to be flexible enough so that every student may profit from his/her own skills and abilities, use his/her previously developed idiosyncratic characteristics (cognitive, social, or emotional), and apply his/her previously gained experience and expertise

(Karoulis & Pombortsis, 2003). Some tools available in a VLE are the following: links to tutorials and course materials, collaborative tools (as discussion forums, chats), evaluation tools, and administrative tools.

The main focus in instructional material is on: content, exercises and solutions, and project and lecture notes. The online course material needs ad hoc preparation: target and expected results must be stated, keywords must be provided, and a review must be present at the beginning and at the end of each chapter. Some authoring tools allow teachers to develop their own instructional materials. Other tools, such as those for specific programming languages (HTML, FLASH, SVG), are only used by specialized teams.

BASIC CONCEPTS RELATED TO USABILITY IN ONLINE LEARNING SYSTEMS

The general architecture proposed here (see Figure 1) aims at the development of VLE and online course instructional materials, taking into account some concepts studied in different areas (human-computer interaction, cognitive sciences, ergonomic, artificial intelligence, and pedagogy).

According to this figure, an online learning system's usability can be assured when its components have been built with quality and when users' needs have been taken into account. Quality of a component means: (i) quality in the application corresponds to content, which refers to the information and knowledge involved in the system. Information (such as learning stories and objects) are related to the development of instructional materials, and knowledge (such as cases) are especially related to the collaborative practice in forums, for instance; (ii) usability in the UI, which refers to a good specification of the interactive information of the system (its windows, its buttons, etc.); and (iii) usability through interaction devices, which makes the interaction with different media (sound, text, image) possible through devices as cameras, microphones, and so on. The quality of the user refers to his/her ability to use new interaction devices and technologies, experience with computer-based systems, and acquaintance of the domain in question.

The concepts related to usability in an online learning system are the following:

- Utilization of ontology to assure the flexibility in modeling learning applications. The ontology notion comes from the artificial intelligence area where it is identified as the set of formal terms with one knowledge representation, since the representation completely determines what "exists" in the system (Guarino, 1995). During an application modeling, models (such as the user model), knowledge (such as cases studies), and learning stories and their learning objects associated to an instructional material can be represented using ontology. The advantage of using this representation is that the ontology can be defined once and used as many times as necessary (evolutionary approach). In addition, the ontology is useful to create learning objects and reuse them when a new course is initialized.
- Utilization of guidelines and human factors to assure learnability (effective interaction and maximum performance) and flexibility (multiplicity of ways the user and the system exchange information). Human factors, such as the teachers' beliefs, and guidelines related to graphic aspects and characteristics of the users and their context of use, must be considered. Guidelines are suggestions about the ergonomic aspects of the interfaces, such as showing only the necessary information or letting the user control the system dialog (Bastien & Scapin,

<tr><td colspan="3">Usability of the VLE</td></tr>
<tr><td colspan="4">Usability of the Overall On-line Learning System</td></tr>
</table>

1993; Bodart & Vanderdonckt, 1993). Taking into account guidelines during the interface design of a system allows the designer to determine the best way in which the information is to be provided to users and to ensure optimal accessibility of the system.

- Utilization of multimedia resources to improve interaction. The use of different interaction devices (such as microphone and video camera) makes it possible to provide a multimedia environment. Specify a multimedia-supporting system derives from the worldwide desire for non-textual information. Non-textual information characterizes systems that use different channels, and codes in their interactions with the user.
- Utilization of collaboration and communication mechanisms to assure the quality of the user and the continuous usability of the learning system. Some VLEs implement the collaborative aspect by allowing users to share an application (such as TELE (Neto, 2001)) and/or by using forums and chats. It allows users to share knowledge, when they are motivated to collaborate through principles of participation, for instance, in problem definition practical situations. There is a need to continuously assure usability of a system due to technological changes and to the evolution of users' needs. We believe instructional materials of a course should evolve from human interactions between students and teachers occurring within an online discussion forum (Mattos, Maia & Furtado, 2003). Hence, we believe in a collaborative process between users and designers to adjust accessibility, acceptability, and usability criteria of a system.

USABILITY OF ONLINE LEARNING SYSTEMS: THE BEST PRACTICES OF REQUIREMENTS ENGINEERING

In this section, the concept of usability (learnability, flexibility, and robustness) is related to some best practices of the requirements modeling and validation of an IS (see Table 1).

An IS must be developed with the participation of users throughout the development process, because it is easier for developers to define and evaluate the functional and non-functional (usability) requirements. The functional requirements of a VLE are related to the tasks that the user wants to perform (user tasks), for instance, to interact with other students and tutors, and to access the rules and regulations of the course. Usability requirements are related to users' satisfaction and the performance of the system. These requirements directly influence aspects of the system quality of use (e.g., never lose sight of navigational functions).

Sutcliffe (2002) gives practical guidance for requirements modeling and validation based on scenarios. A scenario represents a story or example of events taken from real-world experience. These stories are close to the common sense use of the word and may include details of the context of use for a system. These representations help users think about how the system would support their tasks.

During the material design, students must be able to inform their learning requirements, which are related to content (students must perform the study tasks for a particular unit). These requirements are usually represented in storyboard sketch or animated sequences. A storyboard represents a future vision of a designed material with sequences of behavior and possibly contextual description. These representations help teachers focus on the pedagogical functions of the material.

However, a single scenario or storyboard shows only some possible sequences of events among many possible sequences permitted during the interaction of a user with an IS. Interactive prototype is an interactive medium that allows the users to explore all alternative paths, and it gives a look and feel overview of the IS. Before doing prototypes, Constantine, Windls, Nolbe, and Lockwood (2003) suggest completion of an abstract content model, or an abstract prototype, because it facilitates creative thinking, leading to more innovative solutions instead of thinking over the real interfaces.

During a session of requirements validation, it is necessary to actively engage users in checking that the designed IS actually does what they want. If the IS developed is accepted by the user, we can say that its development process was user centered, according to their needs and suggestions. As we mentioned, the usability of an online learning system is not just the UI. The focus must also be on the support that the VLE or instructional material provides for its online students.

As requirements are so volatile, it is important to examine how they can be specified so software can evolve and adapt to the users´ needs. The evolutionary process involves continuous requirement adjustments in two points of view: (i) of the user—when using the system, his/her practices and working methods can be adapted to satisfy the evolving needs individually and/or collectively; and (ii) of the system—the system's behavior can be adapted. The evolution of users' needs can involve modifying a system's characteristics related to its design options, for instance. In order for an IS to be considered evolutionary, its quality must be continuously verified. In VLEs, this means that its functionalities must be changed (for instance, to realize that students would like to publish their work to be viewed by any of their tutors other than themselves). In course materials, the changes can require a definition of a new learning object from an existing one.

To develop an adaptive IS, the UI designer must consider guidelines that must conform to usability requirements defined previously and users' characteristics and their context of use. It is usual to gather users sharing the same value for a given set of characteristics into stereotype. The problem is there is no predefined information on the users to ensure that an IS has high quality of interaction to a stereotype of all users (Furtado et al., 2001).

Ontology can be used to represent a variety of parameters that are not necessarily identified nor truly considered in the requirements analysis. The notion of ontology allows the definition of the meta-models, which define the specification language with which any model can be specified. This resource makes it easier to consider new information in models (Vanderdonckt et al., 2004). In online adaptive learning systems, a flexible user modeling approach is very important. The ontology of a user model can be updated accordingly to consider more information.

So the success of an IS will depend on a complex trade-off between the classic view of requirements being satisfied by a design, but evolving, and the desired degree of satisfaction in acquiring the desired product (Sutcliffe, 2002).

These practices and the HCI concepts described here are more detailed in the description of the lifecycle called CONE (Furtado & Sousa, 2003). It provides the developers and users a new spatial organization, including the activities that must be performed according to these practices and using these HCI concepts and artifacts. This organization aims to facilitate the participation of users, clients, and development team members in monitoring any iterative and incremental process.

FUTURE TRENDS

The multidisciplinary dimension of this work is characterized by the studies done in diverse areas of knowledge, from human-computer interaction and software engineering to pedagogy. Distance learning adheres to a vision where online learning applications are developed for the widest population of users in the most varied contexts of use by taking into account individual differences. This population of users is being called "online community". To create an online community-centered design will be the best practice of the requirements engineering for developing the applications, which will be able to better support the collaborative learning. In addition, it will be possible to develop applications with adaptive user interfaces. These interfaces must be able to *adapt* themselves to the community and contexts of use characteristics.

CONCLUSION

From our experience with the community of students and teachers in the online learning systems and with the development of interactive systems, it was possible to establish the following conclusion about how to obtain more usable ISs: the main question for the success of learning processes for users through the Internet does not lie exclusively on the choice of pedagogical methodology and techniques. It lies, fundamentally, on three factors: i) the understanding of the needs of both teachers and students though a participatory design, ii) the transformation of such needs in a consistent UI and adaptive functions of a VLE and its available course materials; and iii) the need to continuously assure usability of a system through an extensible representation of requirements.

Table 1. Summary of requirements engineering practices to have usability

Usability of VLEs	**Usability of Course Instructional Materials**
Participatory design of users	Participatory design of students and teachers
User-centered design	Student-centered design
Focuses on the UI and pedagogical functions of the VLE	Focuses on the UI and pedagogical content of the material
Requirements are represented in scenarios and prototypes	Requirements are represented in storyboards and prototypes
Evolutionary and adaptive VLE	Evolutionary and adaptive material

KEY TERMS

CONE: A new life cycle in which development process occurs in iteration cycles, each one having many activities grouped together in phases.

Evolutionary System: Involves continuous adjustments of its functionalities and UI according to the user and/or technological changes.

Extensible Representations of Requirements: Ways to represent easy requirements that were not necessarily identified nor truly considered in the requirements analysis.

Pedagogic Usability of an Online Learning System: Related to how easy and effective it is for a student to learn something using the system.

Requirements Engineering: The human acts of identifying and understanding what people want from an IS.

Usability of an IS: Refers to how easy it is to use and learn the system.

Usability Requirements: Related to users' satisfaction and the performance of the system.

Usable M-Commerce Systems

John Krogstie
NTNU and SINTEF, Norway

INTRODUCTION

Today, the PC is only one of many ways to access information resources. On one hand, traditional computing technology is becoming more mobile and ubiquitous and, on the other hand, traditional mass media are becoming richer. Whereas information services related to interactive TV and ubiquitous computing are projected to become prominent in a few years, mobile computing is the most important current trend within information and communication technology.

According to Siau, Lim and Shen (2001), the essence of m-commerce and mobile information systems is to reach customers, suppliers and employees regardless of where they are located and to deliver the right information to the right person(s) at the right time. So far, relatively little attention has been paid to the user side of m-commerce systems. The ability to develop and evolve usable m-commerce systems may become an even more critical success factor for enterprises in the next few years than is their ability to develop and evolve usable e-commerce systems today.

BACKGROUND

M-commerce systems differ from more traditional information systems along several dimensions (Hirsch, Coratella, Felder, & Rodriguez, 2001; Krogstie, Brandtzæg, Heim, & Opdahl, 2003b; Siau et al., 2001). We have grouped the differences within the following three areas:

- User-orientation and personalization;
- Technological aspects including convergence and need for multi-channel support; and
- Methodology for development, evolution and operations to ensure organizational returns.

User-Orientation and Personalization

Mobile information systems often address a wide user-group, which means that user-interface aspects should feature prominently and early in the design process and often need to be very simple. Input and output facilities may be severely restricted (no keyboard, small screen-size, etc.) or based on new modalities (speech-recognition and synthesis, etc.). This means that individualization of mobile information systems becomes increasingly important, both at the individual level where user-interface details are tailored to personal preferences and hardware, and at the work-group level, where functions are tailored to fit the user's preferred work processes.

Individualization means information systems that both automatically adapt themselves to the preferences of the user and that can be explicitly tailored by users through a specific user-interface. The main goal is to achieve usability of the applications on all possible interfaces, based on adaptation to the different physical devices. This calls for intelligent, adaptive and self-configuring services that enable automatic context-sensitivity, user profiling and personalization.

Technological Aspects including Convergence and Multi-Channel Support

Mobile devices have limited processing, memory and communication capacities compared to other kinds of computers. Performance considerations, therefore, become increasingly important. Analytically-based predictive methods are necessary in order to assess a large number of alternatives during the design. Mobile information systems also pose new challenges to achieving information systems dependability. The new mobile devices provide integration and convergence of technologies into a wide range of innovative mobile and multimodal applications. Mobile and other new technologies provide many different ways to offer the same or similar services to customers. Novel approaches for the development and evolution of applications on and across different mobile and traditional platforms are thus needed.

Methodology for Development and Operations to Ensure Organizational Return

Mobile information systems are often radical and, therefore, reward an increased focus on idea generation early in the requirements and design process. Understanding the mobile users requirements for new services is thus of large importance. One would need both to be able to develop these systems and to address the major hurdles for the deployment of applications and services. Another effect of the radically new approaches is that the introduction of mobile information systems often spawns several other initiatives for changing other information systems within an organization. It is important to focus on the interoperability of services and seamless access to corporate and government resources from the mobile devices.

STATUS FOR MODEL-DRIVEN DEVELOPMENT AND EVOLUTION OF USABLE M-COMMERCE SYSTEMS

When speaking about *model*-driven system development, we refer to models developed in languages that have the following characteristics:

- The languages are diagrammatic, with a limited vocabulary (states, classes, processes, etc).
- The languages utilize powerful abstraction mechanisms.
- The languages have a formal syntax and semantics. The formal semantics is either operational enabling, e.g., generation of other models including executable programs or mathematical enabling advanced analyses.
- The languages are meant to have general applicability across problem domains.

Although most software developers are aware of model-driven methodologies, they are seldom followed in great detail in practice, and mostly only in initial development stages.

In general, a model-driven approach to information systems development has been found to provide the following advantages (Krogstie & Sølvberg, 2003b):

- Explicit representation of goals, organizations and roles, people and skills, processes and systems;
- An efficient vehicle for communication and analysis;
- Basis for design and implementation; and
- Readily available documentation as a basis for extensions and personalization.

One striking aspect in connection to contemporary information systems development and evolution is that there is an increasing demand for shorter development time for new products and services (Pries-Heie & Baskerville, 2001). This is specifically important for m-commerce systems, where the convergence of different platforms continuously creates opportunities for new functionality. Some would argue that this highly dynamic situation would make model-based approaches impractical. To the contrary, we claim that idea generation should not be limited by currently available technologies and that systems must be developed for change.

We can identify the following areas for potentially increased utility of techniques earlier developed as part of model-driven development:

User-Orientation and Personalization

Traditionally, support for workers performing nomadic processes has not been provided. Functions of the mobile information system should be tailored to fit the user's preferred work processes, which typically involve other persons. To support teamwork, raising awareness of the status of knowledge resources is increasingly important in a mobile setting. To enhance social mobility, organizations and industries need to develop "social ontologies", which define the significance of social roles, associated behaviors and context (Lyytinen & Yoo, 2002). Given that knowledge resources include both individuals and technology that can be mobile, one should look into interactive systems to improve group performance. Peter Wegner's interaction framework (Wegner, 1997) was triggered by the realization that machines that must interact with users in the problem solving process can solve a larger class of problems than algorithmic systems computing in isolation. The main characteristic of an interaction machine is that it can pose questions to human actors (users) during its computation. The problem solving process is no longer just a user providing input to the machine, which then processes the request and provides an answer (output), but rather is a multi-step conversation between the user and the machine, each being able to take initiative. A major research question in this area is how to specify and utilize interaction machines on a multi-channel platform. Process support technologies are a natural choice for enabling interaction machines. Such technologies are typically based on process models, which need to be available in some form for people to alter them to support their emerging goals. Thus, interactive models should be supported (Jørgensen, 2001). The outset for this thinking is that models can be useful tools in a usage situation, even if the models are changing and incomplete. The user is included as an interpreter and changer of the models. Emergent workflow systems (Colombo, Francalanci, Mecella, Pernici, & Plebani, 2002; Jørgensen, 2001) represent a different approach to static and adaptive workflow systems with respect to their use of models. They target very different kinds of processes - unique, knowledge-intensive processes where the structure emerges or processes with strong requirements for adaptation to the context during process execution

Technological Aspects Including Convergence and Multi-Channel Support

There is a multitude of competing technologies available for providing the underlying infrastructure and access devices for distributed and mobile applications. A central element when addressing this is the development of model-based specification techniques that are powerful enough to be used as a basis for the development of systems on a large number of technical platforms, but still general enough to represent the commonalties at one place only. A major initiative within Object Management Group (OMG) is on model-driven architectures (MDAs) where both platform independent and platform specific modeling notations including refinement techniques and mappings between platform independent and platform specific notations are specified. Meta-modeling techniques and domain-specific modeling (DSM) have found a special application for the design of mobile phone software (Kelly & Tolvanen, 2001). It could be argued that mobile information systems are a particularly good climate for using domain-specific modeling:

- The software (on the client side) is partly embedded and thus needs a higher reliability than traditional software and can be supported by restricting choices through the addition of modeling rules and code-generation.
- You need many very similar variants of the same application.
- There are a number of standards to adhere to, and the technology and standards change rapidly.

Model-based development can be used to support dependability analyses, that is, the use of methods, techniques and tools for improving and estimating dependability, such as risk analyses, probabilistic safety assessment, testing, formal walkthrough, simulation, animation, exhaustive exploration, and formal verification.

The new separation between content and medium found in mobile information systems serves as a major challenge. Generally, the context should be explicitly modeled to maintain an overview of, analyze, and simulate the multitude of possibilities open for adapting to the context and the use of context traces. For the more general use of mobile applications, it is also important to be able to adapt these systems to the user at hand, thus making a case for simple user-models to guide the adaptation. Banavar and Bernstein (2002) highlight the importance of semantic modeling in this respect.

Recently, work within user interface modeling has focused increasingly on mobile user interfaces (Eisenstein, Vanderdonckt, & Puerta, 2001). This is often done to facilitate some level of common models for both the mobile and more traditional user interfaces. A central element in this is the development of model-based approaches that are powerful enough to form the basis for the development of user-interfaces on the multitude of platforms needed, but still general enough to represent the commonalities in a single place. One approach is to define user-interface patterns with general usability principles as powerful building blocks (Nilsson, 2002).

Methodology for Development to Ensure Organizational Return

Siau et al. (2001) highlight as an important application-oriented research area the development of m-commerce business models. In order for m-commerce to succeed, it is vital to ensure that all of the related applications and services can be accessed with ease and at little cost. Thus, in addition to externalizing the business models in the manner of independent computing, it is important to integrate these models with the internal enterprise models and enterprise architecture in order to pinpoint the links to, for example, internal systems for the efficient billing of services provided

Mobile information systems are often radical and, therefore, reward an increased focus on idea generation early on in the development phase. This also means that services or situations in which to anchor problem analysis efforts such as using as-is analysis as a starting point for to-be design (Rolland & Prakash, 2000) do not always exist. Technology in the field still develops rapidly, which means that idea generation should not be limited by currently available technologies. One needs to enhance the techniques for modeling of scenarios to take this into account. Applications of the new technology call for highly distributed systems that comprise new user-interface systems on the client side, new and existing back-end systems, as well as new bridging systems (which port information between other systems). The new technologies, therefore, highlight the need for principled, long-term IS-architecture management and for integrating architecture management with software development methodologies. Often, there is a need to interface with existing enterprise systems and architectures to enable the new workflow. Another aspect is how to integrate the user-interface models discussed previously with other parts of the requirements and design model, for instance, the entity model, process model and goal model. On both the process and the user-interface side, the challenges can be attacked by extending existing approaches to modeling, although research is needed to investigate the techniques that should be extended and how they could be best adapted to the new problem areas. Looking at the architecture for the general existing mobile information systems framework and solutions (e.g., Celesta, 2001), we notice that the generic architecture is geared towards the modeling of data, business processes and tasks, events and behavior, rules, user interfaces and general context information

FUTURE TRENDS

The large-scale application of m-commerce is in its infancy and, unsurprisingly, limited work has so far been done on usable m-commerce systems or on model-based development and evolution of usable m-commerce systems. On the other hand, the upcoming, 3G- (UMTS-) infrastructure provides higher bandwidth and constant connection to the network from virtually everywhere, and the number of m-commerce applications is therefore predicted to explode as will the number of users of complex applications on a mobile platform. Thus, the need for evolving best practice within systems development will be increasingly important.

CONCLUSION

In this article, we have highlighted the need for adapting and extending modeling-based approaches to ensure usable m-commerce systems for the future. Obviously, we are not starting this work from scratch, it is possible to build on existing work within the usability, user interface and modeling fields, specifically on techniques for modeling of functional and non-functional requirements, process modeling, user-centered design, model-driven architectures, requirements specifications of web-applications, domain-specific modeling and dependability analysis.

KEY TERMS

M-Commerce: A technological approach to reach customers, suppliers and employees regardless of where they are located and to deliver the right information to the right person(s) at the right time.

Mobile Computing: The capability to physically move computing services with us.

Mobile Information Systems: Information systems that include end-user terminals that are easily movable in space, are operable independent of location and typically have wireless access to information resources and services.

Multi-Channel Information Systems: Information systems that are to be used by different types of end-user equipment such as traditional PC, PDA, and a mobile phone in an integrated manner.

Nomadic Computing: The use of computers while on the move.

Pervasive Computing: An environment where computers have the capability to obtain information from the environment in which it is embedded and utilize it dynamically.

Ubiquitous Computing: An environment where computers are embedded in our natural movements and interactions with our environments. Combines mobile and pervasive computing.

Use Cases and the UML

Jeffrey Parsons
Memorial University of Newfoundland, Canada

INTRODUCTION

The Unified Modeling Language, or the UML (Booch, Jacobson & Rumbaugh, 1999), has rapidly emerged as a standard language and notation for object-oriented modeling in systems development, while the accompanying Unified Software Development Process (Jacobson, Booch & Rumbaugh, 1999) has been developed to provide methodological support for application of the UML in software development. The UML is a non-proprietary modeling language managed by the Object Management Group, a not-for-profit consortium, which also manages several related modeling specifications. The UML has evolved from its initial version, with UML 2.0 formally adopted by the OMG in June 2003. This article is based on the UML 1.5 specifications (OMG, 2003), as those for UML 2.0 have not been finalized. However, the role of use cases appears to be essentially unaffected by the changes proposed for UML 2.0.

The term "use case" was introduced by Jacobson (1987) to refer to text document that outlines "a complete course of events in the system, seen from a user's perspective" (Jacobson, Christerson, Jonsson & Overgaard, 1992, p. 157). The concept resembles others being introduced around the same time. Rumbaugh, Blaha, Premerlani, Eddy, and Lorensen (1991), Wirfs-Brock, Wilkerson, and Wiener (1990), and Rubin and Goldberg (1992) use the terms "scenario" or "script" in a similar way. While use cases were initially proposed for use in object-oriented analysis and are now part of the UML, they are not inherently object-oriented and can be used with other methodologies.

BACKGROUND

A use case should have a clear goal and describe what should typically happen (but not how it should happen). Common examples would include a customer renting a video, purchasing an item, withdrawing funds from an account, and so forth. The use case also identifies the main "actors" involved, which, in these examples, could include the customer, employees (e.g., rental clerk), a device (bank machine), and so forth.

The use case differs from typical structured requirements analysis tools that preceded it in two important ways. First, the use case is largely text-based. Some refer to them as use case narratives to clearly distinguish them from use case diagrams, which provide an overview of the use cases and actors in the system. Together, they form the use case model. Structured analysis emphasized the importance of graphical tools, such as work flow and data flow diagrams. The UML has not abandoned diagrams; 13 are now included. The class, activity, communication (previously collaboration), sequence, state machine (previously statechart) and use case diagrams play important roles. But use cases are written in the customer's language, so that "users and customers no longer have to learn complex notation" (Jacobson et al., 1999, p. 38).

Second, use cases focus on complete transactions from the user's perspective. In particular, use cases have a goal, which comes from the goals of those who will be using the system (Cockburn, 2001). This also helps facilitate communication with the system's intended users. In UML terminology, a use case is initiated by an actor, usually a person in a particular role (e.g., cashier), but sometimes an external system. Other actors may be involved as well (e.g., customer). The use case provides a complete view of the transaction, from initiation to achievement of the defined goal.

Consistent with an object-oriented approach, use cases can also have generalizations and include/extend relationships. As with classes, generalization allows a child use case to override the behavior of its parent use case in certain situations. An include relationship is generally used when the same steps are required by several use cases, in order to avoid repetition. An included use case is dependent on base use cases and "never stands alone" (Booch et al., 1999, p. 221), although not everyone follows this convention. An extend relationship exists when a base use case incorporates another use case depending on certain conditions.

As discussed extensively in the next section, the content and format of use cases vary widely among published books and articles. In addition to the basic narrative, use cases may contain initial sections that specify assumptions, preconditions (that must be in place before the use case is applicable), and triggers that initiate the use case. At the conclusion, there may be specified postconditions (that must be true when the use case ends). Exceptions (or alternative paths) may also be documented along with relevant business rules that govern behavior within the use case. None of these are part of the UML 1.5 specifications (OMG, 2003), which contains no sample use cases or suggestions on format, but some or all of them may be useful in different situations.

ROLE OF USE CASES

Use cases have been all but universally embraced in object-oriented systems analysis and development books written since Jacobson et al. (1992). Despite this strong endorsement, there are many variations on Jacobson's original theme. First, there is a difference in content. Use cases, at least during the analysis phase, are generally viewed as a conceptual tool. The use case should emphasize "what" and not "how" (Jacobson et al., 1994, p. 146). This suggests use cases should not mention technology (e.g., Evans, 1999).

A review of use case examples shows that determining when the "what" ends and the "how" begins is not always easy. Brown (2002) interprets "what" to mean what the system will do rather than the internal implementation. Thus, his use cases include references to screen designs. So do those of Satzinger and Orvik (1996, p. 126). Others, such as Harmon and Watson (1998, p. 121) refer to specific technology (salesperson's laptop). And even Jacobson et al. (1992, p. 162) refer to a display "panel," "receipt button" and "printer" in one of their examples. Some use cases also include more detail on business rules. For example, the IBM Object-Oriented Technology Center (1997, p. 489) video store example includes the condition that customers who are not members pay a deposit of $60.00. In contrast, Kulak and Guiney (2000, p. 23, emphasis at source) state that use cases "should show the *what* exclusively," and their examples seem to follow this philosophy. However, as Larman (2002, p. 75) notes, use cases are not tied to object-oriented methodologies and thus are technology-independent in that sense.

Second, there are several variations proposed for use case formats. While the first use cases in Jacobson et al. (1992) were written as a paragraph of text, most others have adopted numbered steps. Soon after, Jacobson et al. (1994, p. 109) did so as well.

Third, the granularity of use cases also varies from coarse (few use cases) to fine (many). Most take a minimalist approach. Jacobson et al. (1994, p. 105) suggest that use cases should offer "measurable value to an individual actor". MacMaster (1997) argues that use cases be used only for main system functions. But White (1994, p. 7) states that "the collected Use Cases specify the complete functionality of the system". While Dewitz (1996) uses 11 use cases in her video store example, the IBM object-oriented technology center (1997) has 24. Kulak and Guiney (2000, p. 37) suggest that "most systems would have perhaps 20 to 50 Use Cases and some small systems even fewer". But, as they later point out (p. 88), "there are no metrics established to determine correct granularity". In contrast, Armour and Miller (2001, p. 244) claim that large systems may have hundreds of use cases.

Fourth, the level of detail within each use case also varies. For example, both Kulak and Guiney (2000, p. 125) and Armour and Miller (2001, p. 125) recommend limiting the length of the flow of events to two pages of text, but the latter also note that some practitioners prefer a few longer use cases to many short ones. Constantine and Lockwood (2000) distinguish between "essential" use cases, containing few if any references to technology and user interface implementation, and "concrete" use cases that specify the actual interactions.

Jacobson et al. (1999) advocate an iterative development approach in which both the number of uses cases and their level of detail increase as the life cycle progresses. They suggest that only the most critical use cases (less than 10%) be detailed in the first (inception) phase. As analysis progresses and requirements become firmer, additional use cases can be added and each can be expanded to include considerably more detail. The analyst could move toward concrete use cases or simply expand the detail within essential use cases. Some authors have become quite specific in describing the different levels. For example, Kulak and Guiney (2000) have identified four levels. However, knowing where to start, how far to go at each phase, and when to stop are clearly critical issues not easily resolved.

To further complicate the issue, some of those who favor fewer or less detailed use cases supplement them with "scenarios". Booch et al. (1999, p. 225) define scenarios as "basically one instance of a use case". "Add a customer" is a use case. Adding a specified customer with a particular name, address, and so forth is a scenario. Some references use scenarios to provide further detail on exception handling and other special cases, for example, customers with missing, improbable, or unusual data (Bennett, Skelton & Lunn, 2001; Lockheed Martin, 1996). However, the UML defines a scenario as "a specific sequence of actions that illustrates behaviors" (OMG,

Table 1. Summary of a research framework for studying the need for, and effectiveness of, use cases in the UML

Research Question	**Primary Independent Variable**	**Primary Dependent Variable**	**Methodology**
Do design/implementation details in use cases impede process redesign efforts?	Use case structure	Process innovation	Experiment; Case study
Can class diagrams be effectively extracted from use cases?	Use cases	Class diagram completeness	Case study; Developer surveys
Do use cases facilitate communication between developers and users?	Communication medium (use cases or class diagrams)	User understanding Domain coverage	Experiments; User surveys

2003, Glossary p. 13) with use case variants ("alternative sequences, exceptional behavior, error handling, etc.") handling other situations (pp. 2-136). While scenarios are commonly recommended for testing the completed system (e.g., Booch et al., 1999, p. 221), they can also be used to test the use cases themselves (Armour & Miller, 2001; Kulak & Guiney, 2000). How many scenarios, alternate paths and exception paths should be developed, and what their role should be in developing class and object diagrams, is not clear. A minimalist approach to use cases combined with extensive scenarios and paths may still result in a large and very detailed set of specifications.

While the general consensus seems to be in favor of a smaller set with relatively brief descriptions, "Use Case modeling concepts may be applied very informally and loosely or very rigorously and formally" (Armour & Miller, 2001, p. 70). The difficulty is determining when each is appropriate. Stories about organizations mired in hundreds or even thousands of use cases suggest that some limits need to be applied. Users will not read, or at least not properly understand, long and complex use cases. But a smaller set may be insufficient to develop the class diagram. Thus, the two key roles of use cases, to gather requirements and support development of the class diagram, may conflict somewhat and the ideal set of use cases for each role are perhaps quite different.

Fifth, and perhaps most important, the role of use cases varies among methodologies. Earlier work on the UML focused on the language itself, and was largely agnostic on issues of methodology. More recently, the UML specifications (OMG, 2003, p. 1-7) state: "The UML authors promote a development process that is use-case driven, architecture centric, and iterative and incremental." In particular, use cases provide "major input when finding and specifying the classes, subsystems and interfaces" (Jacobson et al., 1999, p. 34). In addition, they drive the development of subsequent behavioral models, including activity, sequence, and statechart diagrams (Masciaszek, 2001, pp. 133-150).

Schneider and Winters (2001), however, precede use case development by preparing a problem description and risk analysis, while Booch et al. (1999) include a vision statement (p. 344) containing a feature list and some risk identification. Why this document is not considered part of the UML is unclear, although it may be because projects have different starting points that are often outside the control of the analyst (Booch et al., 1999, p. 113). Armour and Miller (2001, pp. 48, 84) start with a vision document and business case, and then create a "system glossary" prior to use case development. Rosenberg and Scott (1999) suggest that "domain modeling" precede use case development. Blaha and Premerlani (1998, p. 49) state, "Once you have a sound object model, you should specify Use Cases." Schmuller (1999) starts with class diagrams and then moves to writing use cases. We have also seen organizations begin with class diagrams for pragmatic reasons, such as when the data structure is already largely defined by existing systems. Regardless of which is used, some clear understanding of the problem seems essential before use case writing begins.

FUTURE TRENDS

Use cases have generally been well received and are not only being used as part of the UML but also with traditional structured methodologies. While no major changes to the basic concept are foreseen, some resolution of the issues raised previously is likely as both researchers and system developers become more familiar with them.

Better tools may also change the ways in which use cases are written and used. Many developers are still relying largely on word processors to develop use cases. A closer integration with other UML diagrams would help ensure consistent specifications across all UML components and greatly facilitate changing the specifications when modifications are required.

There is considerable opportunity for researchers to examine the issues identified, particularly format, granularity, level of detail and usage. Perhaps the most fundamental issues deal with the effectiveness of use cases in their two key roles, communicating with users and supporting development of UML diagrams and particularly the class diagram. How effective are use cases in helping users find incomplete or incorrect specifications? More importantly, how effective are they at helping find better ways to do things? Do use cases support creative problem solving?

CONCLUSION

In summary, review of the literature shows extensive differences in how use cases are defined and used. This is not surprising, given the UML's relatively short history. But these differences can also be attributed to the lack of a theoretical foundation. The UML is promoted as the "culmination of best practices in practical object-oriented modeling" (OMG, 2003, p. xxv). This is a notable achievement, but there is little research to support claims of "best practices" beyond the claims of successful practitioners and the review contained here demonstrates that recommended practices are sometimes contradictory.

KEY TERMS

Actor: An actor plays one or more roles in relation to a set of use cases. An actor could correspond to a job title (e.g., purchasing agent, sales clerk) or can be non-human (e.g., another system or database). Each actor in a use case must be directly involved at some point and is not merely a stakeholder (someone or something that is affected by the success or failure of a particular transaction).

Use Case: Use cases are used during system analysis to help specify the behavior of a proposed system. A use case is a largely text-based description of a complete transaction as seen from the user's perspective. A use case should emphasize what the system will do, not how it will do it, and be written in the user's language. Thus, use cases are an important communication tool between developers of systems and the intended users.

Use Case Diagram: The use case diagram shows a set of use cases (by title) and the actors involved in them. This provides an overview of the use case structure and also shows how each actor is involved in a system.

Use Case Scenario: A scenario, as specified in the UML, is an instance of a use case that can help illustrate its use. For example, a use case (rent video) might have different scenarios for renting a video to a child, a new customer, an existing customer with overdue videos, and so forth. However, the term is also used in other ways outside the UML.

User Experiences of the E-Commerce Site with Standard User Interface

Shin-Ping Liu
JCC, USA

Dennis Tucker
Yaasuo Consulting Company, USA

INTRODUCTION

The future of economic competitiveness for most enterprises relies on entrance and active participation in the e-commerce market (Vestal, 1999). E-commerce offers speed, convenience and often cost-effectiveness for today's busy shopper, but most e-commerce sites are still too hard to use. Zona Research (1999) found that 62% of online shoppers had given up at least once while looking for products, and 42% had turned to traditional channels to make their purchases. These statistics are astounding. In addition, according to Nielsen and Norman (2000), users fail when they try to purchase products on an e-commerce site about a third of the time. In reality, what happens is not just that the user fails, but that the site fails and does not sell a thing. Is "lost-in-hyperspace" primarily a psychological or an engineering problem? In other words, is "lost-in-hyperspace" a problem for users, or is it a symptom of poor design, which itself may be a psychological problem for authors of e-commerce sites?

Traditional services design user interfaces to treat users as suppliants who will simply have to learn to ask the right questions to get the right answers (Gonzalez, 1999). This approach will not work for the world of e-commerce. Much like driving a car or talking on the telephone, e-commerce follows the same rules in that the users are not concerned with the inner workings, but with the end result. E-commerce will make significant advances as long as the interface is kept simple and can be used in the same context as telephones are used today, according to Gonzalez (1999).

The problem with e-commerce sites is that the controls and organization are different for each site. This study investigates how an individual's perceptions of key beliefs surrounding the use of the e-commerce site with the standard user interface would influence the individual's decision to accept these e-commerce sites for online shopping purposes. This study applies the technology acceptance model (TAM) identifying components of usefulness and ease of use that predict user attitude toward the usage of the standard user interface. The research uses a Web-based survey and employs TAM with path analysis to identify features of the standard user interface that might contribute to its usefulness and ease of use.

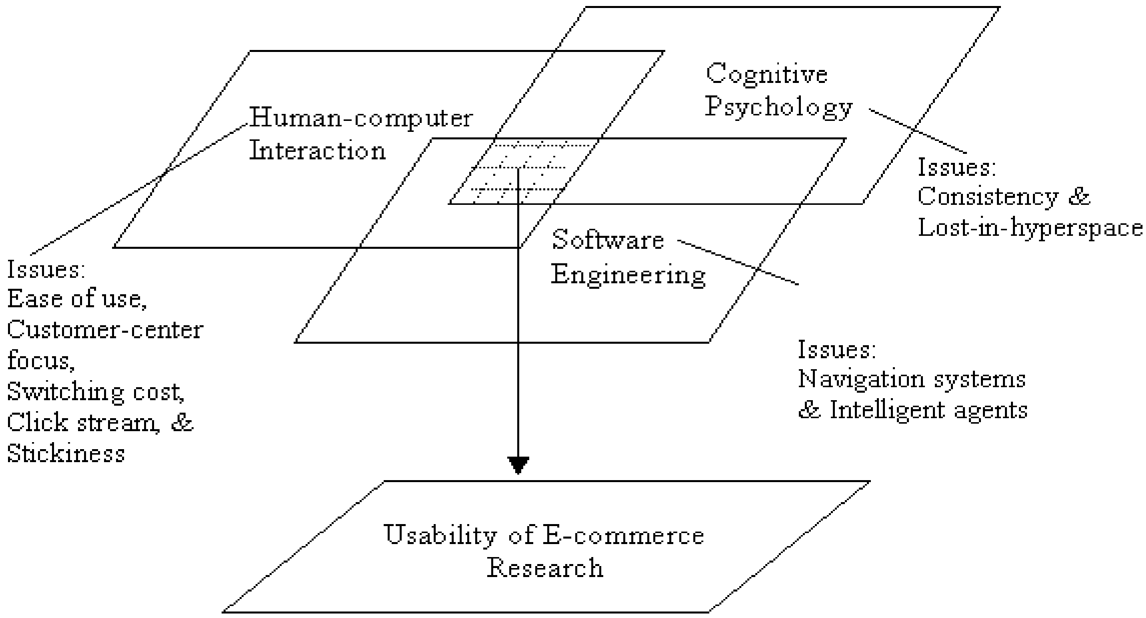
BACKGROUND

This study provides a review of the pertinent literature via an interdisciplinary approach integrating different disciplines into the usability of e-commerce research. In addition, to study user acceptance of e-commerce sites from an interdisciplinary perspective, TAM used by Davis (Davis, 1993; Davis, Bagozzi & Warshaw, 1989) is adopted to explain the usage of information technology.

Interdisciplinary Approach to E-Commerce Usability

An interdisciplinary approach integrates three disciplines of human-computer interaction, cognitive psychology and software engineering into the usability of e-commerce research. Theng and Thimbleby (1998) state that the human-computer interaction is typically grounded in empirical data from usability studies such as ease of use, customer-center focus, switching cost, click-stream, and stickiness. Cognitive psychology is typically grounded in models of human behavior and performance such as consistency and lost-in-hyperspace. Software engineering is typically grounded in sound engineering practice such as navigation systems and intelligent agents. Academic research may wish to promote a discipline-specific well without seeing the wider picture; for example, few software engineers are seriously concerned with usability (Theng & Thimbleby, 1998). This study is concerned with how the concepts, values, methods, and procedures from these disciplines can be integrated into the usability of e-commerce research; therefore, this study explores closely related literature in the areas of increasing the usability of e-commerce.

Figure 1. Interdisciplinary approach to the usability of e-commerce: integrating the disciplines of human-computer interaction, software engineering, and cognitive psychology into the usability of e-commerce research



Technology Acceptance Model (TAM)

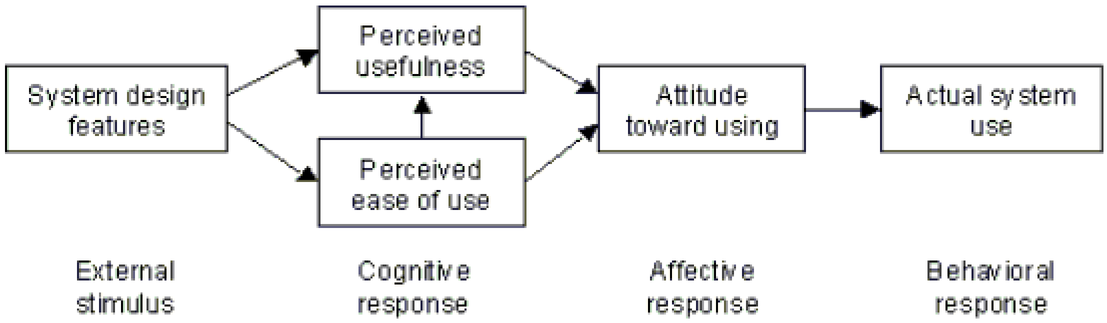
Several researchers have validated TAM using different applications including e-mail, voice mail, word processing, micro-computers, automated teller, spreadsheet, calculator, Web pages development software, among others (Adams, Nelson & Todd, 1992; Bagozzi, Davis & Warshaw, 1992; Chau, 1996; Davis, Bagozzi & Warshaw, 1989; Fulk, Schmitz & Ryu, 1995; Hendrickson & Collins, 1996; Igbaria, Guimaraes & Davis, 1995; Szajna, 1996; Thompson, 1998). Other researchers have recommended TAM for the investigation of Web user behavior (Shaw, Gardner & Thomas, 1997). TAM provides a foundation for research on why users accept or reject information technology and how to increase user acceptance by judicious choice of system design features (Davis, 1993). Davis's proposed TAM is shown in Figure 2.

A prospective user's overall attitude toward a given system is hypothesized to be a major determinant of whether the user actually uses it or not. The perception of the stimuli creates cognitive beliefs, which initiate an affective response. The affective response has an influence on consumer behavior. Attitude is determined by cognitive beliefs. Attitude toward use, in turn, is a function of two beliefs: perceived usefulness and perceived ease of use. Perceived ease of use has a causal effect on perceived usefulness. System design features directly influence perceived usefulness and perceived ease of use. System design features have an indirect effect on attitude toward use and actual usage behavior through their direct effect on perceived usefulness and perceived ease of use. Perceived usefulness refers to the degree to which a person believes that a particular information system would enhance his or her job performance by reducing the time to accomplish a task or providing timely information (Davis, Bagozzi & Warshaw, 1989; Lederer, Maupin, Sena & Zhuang, 1999). Perceived ease of use refers to the degree to which a person believes that using a particular system would be free of effort (Davis, Bagozzi & Warshaw, 1989).

METHODOLOGY

A Web-based survey study with two specific research objectives was conducted. The first objective was to explore the current usability problems of e-commerce sites and employ an artificial intelligence user interface

Figure 2. Technology acceptance model by Davis (1993)



agent to create a standard user interface for increasing the usability of e-commerce. The second objective was to examine the user acceptance of the e-commerce site with the standard user interface. Employing TAM, the study was designed to identify features of the standard user interface that might contribute to its usefulness and ease of use.

The Web-based survey instrument contains instructions asking respondents to compare an e-commerce site without a standard user interface to the same site with the standard user interface. Altogether the instrument contains 33 items, including seven demographic questions. A letter that solicits participation in the study was sent out via e-mail to students and faculty members listed on several mailing lists at a major university. All together a total of 2,946 potential participants were contacted.

Research Hypotheses

The hypotheses are adopted from the Davis study (1993). TAM is represented by the following structural equations

$$\text{Ease of Use} = \beta_{11}\ (\text{System}) + e_1$$

$$\text{Usefulness} = \beta_{21}\ (\text{System}) + \beta_{22}\ (\text{Ease of Use}) + e_3$$

$$\text{Attitude} = \beta_{31}\ (\text{Ease of Use}) + \beta_{32}\ (\text{Usefulness}) + e_3$$

$$\text{Usage} = \beta_{41}\ (\text{Attitude}) + e_4$$

H_1: Attitude toward use will have a significant positive effect on actual standard navigation usage.

H_2: Perceived usefulness will have a significant positive effect on attitude toward use, controlling for perceived ease of use.

H_3: Perceived ease of use will have a significant positive effect on attitude toward use, controlling for perceived usefulness.

H_4: Perceived ease of use will have a significant positive effect on perceived usefulness, controlling for system.

H_5: System will have a significant positive effect on perceived ease of use and perceived usefulness.

H_6: Perceived usefulness, perceived ease of use, and system will not have significant direct effects on actual standard navigation usage, controlling for attitude toward use.

H_7: System will not have a significant direct effect on attitude toward use, controlling for perceived usefulness and perceived ease of use.

Figure 3. Standard navigation in action

(Duncan, 1975). While "System" is a dummy variable taking on value 0 for an e-commerce site without the standard user interface and 1 for an e-commerce site with the standard user interface, "Usage" refers to intensity of the actual standard navigation usage, "Attitude" refers to attitude toward use, "Usefulness" refers to perceived usefulness, and "Ease of use" refers to perceived ease of use. Ordinary least-squares (OLS) regression is used to test this structural equation model.

The statistical significance of the proposed TAM relationships, represented in the following hypotheses, was assessed using the t-statistic corresponding to each estimated parameter. The hypotheses for this study are as follows: H_1-H_5. Furthermore, two more hypotheses (H_6 and H_7) are postulated to test whether the causal relationships implicitly hypothesized to be indirect have no significant direct effect or not. Hierarchical regression and associated F-tests of the significance of the increase in R^2 due to the additional variables were used for these hypotheses. In addition to testing for the significance of the hypothesized relationships, the data to estimate the magnitudes of the causal parameters are also analyzed. The estimates are the standardized regression coefficients, expressed as both point and confidence interval estimates.

Standard User Interface in E-Commerce Sites

One hundred and two e-commerce sites are evaluated that had been recognized as most popular with consumers by several independent polling organizations for several design criteria that may affect customer experience. From this evaluation of the 102 sites, 42 different features commonly used are identified and compiled to assist customers who browse e-commerce sites. Some of the most frequently used such features include contact information, privacy statement, company information, customer service/help, search engine, shopping cart, and security statement. Based on the list of features identified from the 102 e-commerce sites, a standard user interface that allows users to navigate was constructed. The idea behind the standard user interface is that all e-commerce sites should have some type of standard navigation to improve usability and functionality. Unfortunately, most e-commerce sites lack such standard navigational systems (Allum, 1998; Booker, 1997; Bort, 1999; Hoffman, 1996). In addition, based on the findings from the study of the 102 e-commerce sites, a menu bar as shown in Figure 3 was developed as the standard user interface to be used by study participants.

Then three example sites were selected from the list of 102 e-commerce sites to be used in this study. For each of the three e-commerce sites, two versions of the site are created—one with the standard user interface and another without. Figure 4 compares the two versions of one of the sites used in the study.

DATA ANALYSIS AND RESULTS

The survey produced 127 usable responses out of 2,946 students and faculty members at UNT for a 4.4% response rate. This response rate may be low in comparison to conventional paper-based postal surveys. However, the total number of subjects suffices for the analysis described in the following section. The testing of the TAM relationships then used a multiple regression model and a simple linear regression model to test the mean differences among various conditions. To examine the construct validity of the instrument, factor analysis was performed to test the factor loadings of the items on these constructs: usefulness, ease of use, and attitude toward use. The Cronbach model of reliability was used to assess internal consistency, based on the average inter-item correlation. Cronbach's alpha coefficients were 0.95 for the items used to measure of perceived usefulness, 0.85 for perceived ease of use, 0.83 for attitude toward use, and 0.87 for actual standard navigation usage.

Findings of the Study

The TAM motivational variables of perceived usefulness and perceived ease of use mediate the effect of system design features on the attitude toward use. The system characteristics appear to influence behavior through these motivational variables. The most significant finding is the direct effect of usefulness on attitude toward use. How-

Figure 4. E-commerce site without the standard user interfaces (left) and with the standard user interfaces (right)

ever, the fact that perceived usefulness exerts almost the same as the system design features do direct and indirect influence on attitude toward use. In addition, perceived usefulness exerts more than two times as much direct effect on attitude toward use as does perceived ease of use. Compared to perceived usefulness, perceived ease of use has a direct effect on attitude toward use, much smaller to affecting attitude indirectly via its relatively influence on perceived usefulness. In addition, the previous discussion has emphasized the importance of perceived usefulness, arguing the ease of use performs via this variable. Thus, the model views the standard navigation usage behavior to be intrinsically motivated; being driven by concern performance gains more than associated rewards. That is, people use systems in part because users who have more system familiarity or experience enjoy the process of using them per se, not just, because they are extrinsically rewarded for the performance impacts of usage.

FUTURE TRENDS

The future of economic competitiveness for most enterprises relies on entrance and active participation in the e-commerce market (Vestal, 1999). Bonisteel (2000) claims that, to be successful, sites have to be extremely intuitive and simple to use. The site's providers need to make navigation systems dramatically simpler. Bonisteel's (2000) advice for online retailers is to remove the obstacles consumers most often encounter while shopping online by improving search engines, information entry systems, and site navigation. Designers must start studying the trends of real people. Gonzalez (1999) states that answers to real trends are solutions that must be implemented onto the user interface. The designers no longer have full control, and the users are the ones placing demands on how things are to be done. Although shopping online by simply clicking a button is extreme convenience, users become more demanding as time passes and e-commerce becomes more and more popular. The success of e-commerce depends on the ability to attract non-computer-literate people through ease of use (Gonzalez, 1999).

CONCLUSION

Many designers believe that the key barrier to user acceptance is the lack of user friendliness and that adding a user-friendly interface to increase usability is the key to success (Branscomb & Thomas, 1985; Davis, 1993). Yet, the current results indicate that, although ease of use is clearly important, the usefulness of the system is even more important. Users who are familiar with the system may be willing to tolerate a difficult interface in order to access functionality that helps them on their online shopping, while no amount of ease of use can compensate for a system that does not do a useful task. Thus, the intention of this study is to test the behavioral constructs of perceived usefulness and perceived ease of use as predictors of usage acceptance of the standard user interface in e-commerce sites. The results show a strong relationship between users' perceptions of usefulness and ease of use about the standard user interface.

KEY TERMS

E-Commerce: Financial business transaction that occurs over an electronic network such as the Internet.

Navigation: The process by which a user explores all the levels of interactivity, moving forward, backward, and through the content and interface screens.

Perceived Ease of Use: The degree to which a person believes that using a particular system would be free of effort.

Perceived Usefulness: The degree to which a person believes that a particular information system would enhance his or her job performance by reducing the time to accomplish a task or providing timely information.

Standard User Interface: Even as implementation technology changes at any given time, usability is improved by following standards and conforming to user expectations, but over time, these standards and expectations have to evolve as the technology improves and new interface ideas are invented.

Stickiness: "Stickiness" of a site refers to the likelihood that visitors will stay on the site for a while and be inclined to return again and again.

Switching Cost: Refers to how much cost it takes to switch from one vendor to another.

Technology Acceptance Model: Describes the relationship between perceived qualities of a system's usage, affective attitude, and behavioral responses to the system.

Usability: How easy an interface design is to understand and use. A user-friendly document will let the user read or play any content at will; it will have unambiguous interactive controls and a clear navigational scheme.

User Interface: Controls how data and instructions are entered and how information displays on a screen.

User Perceptions and Groupware Use

INTRODUCTION

The increasingly complex, global nature of work tasks has led to increased interest in virtual teams that interact across space, time, and organizational boundaries to achieve organizational objectives (Bell & Kozlowski, 2002; Roebuck & Britt, 2002). One of the factors thought to contribute to the popularity of virtual teams is the availability of groupware systems (Townsend, DeMarie & Hendrickson, 1998). While some groupware systems, such as electronic mail, have become almost ubiquitous in many organizations, other groupware applications have not enjoyed similar acceptance (Briggs, Adkins, Mittleman, Kruse, Miller & Nunamaker, 1999; Orlikowski, 1993). Because of the importance of groupware to the success of virtual teams, it is important to understand *why* this innovation has not successfully diffused.

This article uses a diffusion of innovation (DOI) perspective (Rogers, 1995) to understand factors that impact intentions to use groupware technology. The Rogers' DOI perspective gives us a much richer set of factors than other technology adoption models, and should therefore better aid in understanding groupware adoption (Plouffe, Hulland & Vendenbosch, 2001). We surveyed 186 college students and found that intentions to use groupware technology are impacted by perceptions of: relative advantage gained from use of the groupware, amount of complexity in groupware use, compatibility with work practices, and demonstrable results. Suggestions for positively influencing these factors are offered in order to ensure more successful groupware implementations.

BACKGROUND

Group Support Systems

Groupware technology facilitates the work of groups by providing electronic means to communicate, cooperate, coordinate, solve problems, compete, or negotiate. While traditional technologies such as the telephone qualify as groupware, the term is ordinarily used to refer to a specific class of technologies relying on modern computer networks.

The origins of groupware technology are often traced back to the early 1980s, when academic researchers at the University of Arizona, University of Minnesota, and Southern Methodist University developed group "decision rooms" supported by group decision-making software (Power, 2003). With advances in telecommunications over the last two decades, groupware applications have expanded to include e-mail, audio/video/data conferencing, instant messaging, electronic meeting systems, and a host of Web-based collaboration tools. With approximately 130 million workers worldwide expected to telework in 2003, the integration of groupware into organizations is expected to grow rapidly (Roebuck & Britt, 2002).

The growth in virtual teams also reflects this change in work habits, as employees may be located anywhere around the world at any point in time (Townsend et al., 1998). Virtual teams use groupware to span geographic, temporal, and organizational boundaries. The sophisticated communication facilities of groupware facilitate

Figure 1. Groupware classification (source: Johansen, 1988)

	Same time "synchronous"	**Different time** "asynchronous"
Same place "co-located"	Group decision support systems, Voting, presentation support	Shared computers
Different place "distance"	Videophones, chat, instant messaging	Discussions, e-mail, workflow

frequent communication among team members, which is an important factor in creating a sense of identity in virtual teams (Kezsbom, 2000). In particular, asynchronous groupware helps overcome time-related barriers to distributed work (Kelly & Jones, 2001).

Groupware technologies are typically categorized along two dimensions, time and place (Johansen, 1988), as shown in Figure 1. Based on the time dimension, users of the groupware can work together at the same time or different times. On the other hand, the place dimension indicates that groupware users can work together in the same place or in different places.

Diffusion of Innovations

Diffusion of innovation (DOI) research is concerned with how use of an innovation spreads throughout a social system (Mahajan, Mueller & Bass, 1990). Diffusion theory has been applied to a wide range of technologies, including information and communication technologies such as groupware. Diffusion theory states that potential adopters' *perceptions* of an innovation's characteristics, rather than an objective assessment of how an innovation rates on these characteristics, impact the diffusion rate (Rogers, 1995). Rogers (1995) identifies five perceived characteristics of an innovation that influence its adoption: relative advantage, compatibility, complexity, trialability, and observability. Moore and Benbasat (1991) provide empirical support for breaking observability into two constructs: result demonstrability and visibility. Additionally, because use of innovations may be optional in some settings, the degree to which potential users feel that innovation use is voluntary has been found to be important in understanding innovation use (Agarwal & Prasad, 1997).

Other models such as the technology acceptance model, or TAM (Davis, 1989), have proposed characteristics that may influence adoption, including perceived usefulness and perceived ease of use, which are conceptually similar to relative advantage and complexity (Moore & Benbasat, 1991). However, this research uses Rogers' diffusion theory with the additional constructs noted previously. Reasons for this are two-fold: first, we seek a better understanding of the groupware technology diffusion process. As such, Rogers' model offers a richer set of potential factors than does the more parsimonious TAM model (Plouffe et al., 2001); second, we hope to provide guidance to managers to ensure successful groupware implementations. Again, Rogers' model provides us with more areas that can be influenced by management to create environments conducive to groupware adoption.

MODEL OF GROUPWARE TECHNOLOGY DIFFUSION

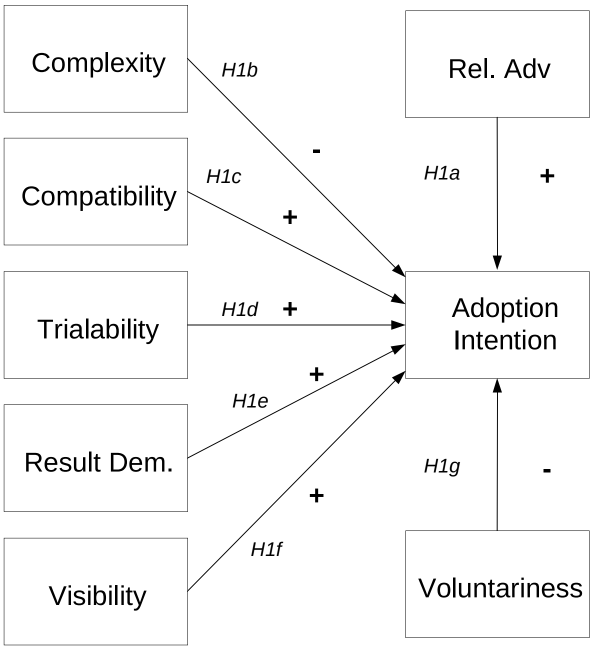
Based on the previous research, we propose the model in Figure 2 for understanding factors important to groupware technology diffusion. In general, the model suggests that users' perceptions of a groupware system influence their subsequent intentions to use the groupware system. Research indicates that these intentions are highly correlated with actual future use (Davis, 1989).

Validating the Model Using Domino

As a test of our model, we surveyed students at a major midwestern university. The students, primarily college seniors, were enrolled in courses where a groupware system, Lotus Domino, was made available to them for optional use in the course. The Lotus Domino Discussion database is an asynchronous groupware product designed to be used "any time and any place," placing it into the lower right-hand portion of the grid in Figure 1. The Domino groupware system was chosen because it supports student-centered, project-based courses, with faculty as facilitators of student learning, as opposed to providers of information. In our experience, Domino does help in achieving learning goals in such courses (Day, Lou & Van Slyke, 2004).

Users access Domino discussion databases and participate in group discussions over the Internet using a Web browser. Users have the ability to browse through or participate in discussion topics and responses contributed by others. The history of any discussion is pre-

Figure 2. Model for diffusion of groupware technology



served in the discussion database, and is presented as a discussion thread. Figure 3 illustrates a threaded discussion.

Findings

We used a regression analysis to test our data against the research model. Sixty-five percent of the variance in use intention is explained by the model variables (adjusted R^2 = 0.656). Results, summarized in Table 1, show that all but three perceived groupware innovation characteristics are important in predicting groupware use. Examining the significance values for each variable suggests that perceptions of relative advantage and compatibility are better predictors of subsequent use than are perceptions of result demonstrability and complexity. While examining the significance values allows us to detect probable phenomenon, an examination of subjects' comments regarding Domino confirms these findings and confirms the statistical results.

Several subjects mentioned the value of the frequent and timely instructor feedback via Domino, as well as the value of being able to post assignments to Domino, rather than having to travel to campus to hand them in. Others noted that Domino facilitated interaction with team members. These comments confirm the relative advantages of using Domino.

Also interesting are comments related to compatibility. Many subjects either praised the ability to work from home, or lamented the necessity to travel to a campus computer lab to use Domino. Further, while one subject stated, "It was easier to 'talk' about things without feeling put on the spot the way I sometimes feel in a classroom," others commented that they would rather interact face-to-face than through Domino. While these comments seem contradictory, they demonstrate the importance of groupware being compatible with the work and communication styles of the intended users.

Implications

Our study validated that groupware use is greatly influenced by users' perceptions of the technology. Thus it is important that efforts be taken to ensure potential users have positive perceptions of groupware. One aspect that

Figure 3. Discussion thread in a Domino discussion database

Construct	beta	Significance
Relative advantage	*0.383*	*0.001*
Complexity	*-0.170*	*0.035*
Compatibility	*0.335*	*0.001*
Trialability	0.012	0.824
Result demonstrability	*0.207*	*0.014*
Visibility	-0.027	0.601
Voluntariness	0.044	0.475

can have a negative impact on perceptions is a poorly functioning, unreliable groupware system. Having a sound technology infrastructure in place for the groupware system is critical. Adequately-performing servers and a fast, reliable network should be viewed as requisite for the use of groupware. If users have difficulty accessing the groupware system, it is likely that perceptions of relative advantage and complexity will be impacted in a manner that negatively influences use intentions.

In educational settings, it is important that instructors pay close attention to the quality and frequency of early, class-related discussion database postings by students. Encouraging students to make frequent, proper use of the groupware system is likely to increase perceived relative advantage for most users. The same holds, we believe, in non-educational settings. Organizational managers should encourage early and frequent use of groupware for team discussions. Offering incentives and showcasing teams that frequently and productively use groupware can serve to motivate others to increase their groupware use. If only a handful of users utilize the system, the value of this utilization is less than if a larger number of users provide meaningful postings.

Another factor that change agents should consider is their own use of groupware. For example, in an educational setting, it is important for instructors to make full use of the groupware system. In non-educational settings, it is likewise important for managers to model desired behavior by using groupware to, for example, solicit staff feedback on organizational issues, and perhaps supplement or replace regular departmental face-to-face meetings. If these efforts are not undertaken by change agents, a message is sent to other users that the system is not valuable, which is likely to have a negative impact on perceptions of relative advantage. If the instructor or manager makes use of the system, the opposite message is sent, increasing perceptions of relative advantage.

Providing users with an introduction to the groupware system may impact perceptions of complexity. For example, posting interesting, provocative topics to a discussion database may engross users in a discussion and help overcome any trepidation some users may have about their ability to use the system. Such playful use of an application may lead to learning that can be applied to other, more serious uses (Belanger & Van Slyke, 2000). Of course, providing training and technical assistance to users can also impact users' perceptions of complexity.

Perceptions of compatibility are also important determinants of use intentions. A consistent look and feel of the groupware system should be maintained for different applications. If a consistent look and feel is maintained across the applications, users with experience using one application of groupware are likely to feel that a new application is compatible with their past experience. Even something as simple as changing font styles or colors can have a negative impact on perceived compatibility.

Our study has confirmed that perceived innovation characteristics are important indicators of one's intention to use groupware technology. Further, our results also validate Moore and Benbasat's (1991) contention that the traditional innovation characteristic of observability is actually two constructs since result demonstrability is highly significant (p = 0.014), while visibility is clearly non-significant (p=0.601).

Interestingly, while we found perceived complexity to be a significant factor in predicting use, it had the weakest association with adoption intention. In the case of Domino, perceptions of complexity are less important than those of relative advantage, compatibility and result demonstrability. This result may be surprising to many who feel that user friendliness is *the* critical factor in determining use. The finding is particularly interesting in light of the much-studied technology acceptance model (TAM) (Davis, 1989). TAM in its basic form suggests that ease of use and usefulness determine intention to use. The results of this study suggest that the TAM may not be sufficiently detailed for some innovations. TAM does not consider other factors such as compatibility and result demonstrability. Using the richer diffusion of innovation theory as a framework allows researchers to better understand factors that influence groupware use.

FUTURE TRENDS

This research points to the need to manage the perceptions of potential groupware users to ensure successful groupware implementations. To this end, suggestions for influencing the perceptions of potential groupware users were offered in the previous section. This research also suggests other organizational factors that warrant examination in future groupware studies. For example, the degree to which the groupware software is available, reliable, and secure can have ramifications on the degree to which groupware technology is adopted. Future studies should examine the degree to which these infrastructure requirements impact the use of groupware systems.

Future studies should also explore the training aspects of groupware in more detail. While our research has clearly pointed to the need for technical training in order to decrease the perceptions of complexity of groupware use, other research has suggested that the *nature* of training in groupware situations should go beyond the technical aspects, and extend to "human" areas such as communications and diversity (Roebuck & Britt, 2002). These aspects of training should be explored further to see what impacts they have in groupware use, and in groupware effectiveness.

CONCLUSION

This article shows that groupware technology, while necessary for the success of virtual teams, needs to be appropriately implemented in organizations in order for intended users to adopt the technology. By focusing on improving team members' perceptions of the technology characteristics we have identified, more groupware systems can achieve widespread success in organizations.

While our study focused on the adoption of groupware in an educational setting, we feel the results of the study can be generalized to other settings where group communications are required or desired. In this research, student subjects were surveyed about a topic that had direct relevance to them (i.e., their use of Domino was directly related to their coursework). They were not asked to project themselves into an artificial role; they were asked their perceptions as students. Thus, it is reasonable to expect that any associations found between their perceptions and their adoption intentions are valid. Further, it should also be noted that many of the students in this study had work experience; the mean full-time work experience for the sample was 5.5 years. Yet statistical analysis indicated that the amount of work experience had little significance on their intentions to use the Domino groupware. Again, this lends support for the notion that the significant relationships found in this study between individuals' perceptions and intentions to use groupware would apply to those in actual working settings as well as educational settings.

In the future, the exact form and function-set of groupware is likely to change. We are already seeing this with the emergence of instant messaging software use in organizations. Whatever form the groupware of the future takes, one fact is likely to remain. Users' perceptions of the characteristics of groupware significantly impact its use. Those interested in promoting the use of groupware are well advised to carefully consider how the design and implementation of their systems might impact users' perceptions. Failing to do so may well lead to systems that go unused.

KEY TERMS

Adoption: The stage of technology diffusion in which an individual or organization decides to select a technology for use.

Compatibility: Degree to which an innovation is seen to be compatible with existing values, beliefs, experiences and needs of adopters.

Complexity: Degree to which an innovation is seen by the potential adopter as being relatively difficult to use and understand.

Diffusion: The spread of an innovation through a social system.

Groupware: Class of technologies that allow groups to communicate and coordinate activities. Typically network-driven software.

Relative Advantage: Degree to which an innovation is seen as being superior to its predecessor.

Result Demonstrability: Degree to which the results of using an innovation are perceived to be tangible.

Trialability: Perceptions of the degree to which an innovation can be used on a trial basis before confirmation of the adoption must occur.

Visibility: The perception of the actual visibility of the innovation itself as opposed to the visibility of outputs.

Voluntariness: Degree to which use of an innovation is perceived as being of free will.

User Spreadsheet Systems Development

Anders Avdic
Örebro University, Sweden

INTRODUCTION

In the early days of computers, expertise was needed not only to develop systems, but also to use them. As IT tools have become more powerful and user friendly, more and more people have been able to use computers and programs as tools when carrying out working tasks. Nowadays it is even possible for people without special IT training to develop information systems that only IT specialists could have done some years ago.

BACKGROUND

In this article the conditions and effects of user systems development (USD) using a spreadsheet program (SP) are discussed. USD is characterized as a sub-area of end-user computing. USD is performed by a user-developer, a person who acts both as a user and a systems developer. A typical feature of a user-developer is that he has a good knowledge of the business and the work related to the information system (IS) in question, which is called the user-developed application (UDA).

To a large extent USD is a question about learning. User-developed applications are often developed in order to learn and understand. In Figure 1 the difference between traditional systems development (TSD) (1) and USD (2) is outlined in order to demonstrate the nature of USD in contrast to TSD, since TSD is familiar to the IS community. To the IT specialist, knowledge about IS development tools (e.g., methods, program languages) (1a) is in primary focus when developing TISs (1c). This is the core of the user-developer's professional knowledge. Knowledge about business (1b) is of course essential, but not primary. To the user-developer knowledge about business (2a) is in primary focus and knowledge about IS development tools (2b) is just a means to accomplish business-oriented tasks, eventually by developing UDAs (2c). The IT specialist has access to knowledge about IS development tools that is hard to access for non-professionals. Some business knowledge is hard to access for the IT specialist, since this knowledge is not in the professional knowledge domain of the IT specialist. The user-developer on the other hand is the expert on business knowledge. His professionalism depends on his knowledge about business. No one can replace him in this matter. In order to perform USD, the user-developer needs some knowledge about IS development tools. It is not possible though to have access to as much knowledge about IS development tools as the IT specialist has.

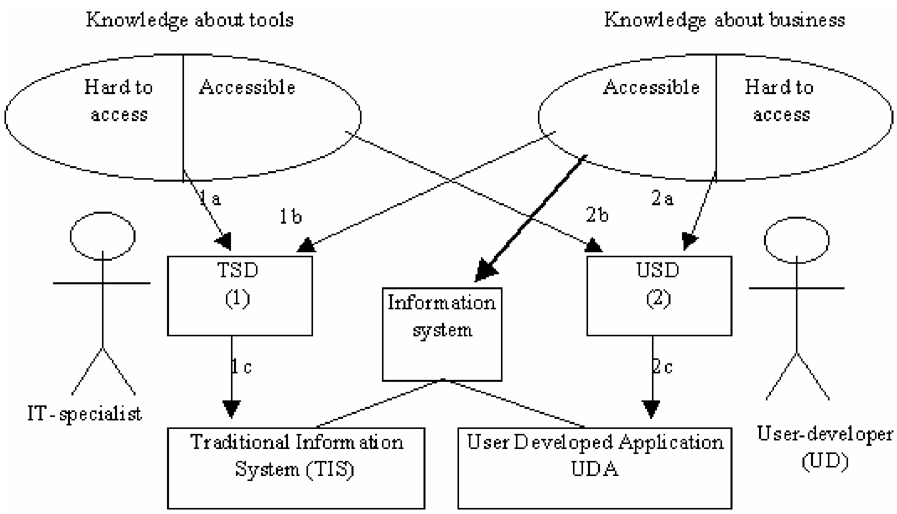
To both the IT specialist and the user-developer, both kinds of knowledge are to some degree necessary. In order to make an information system, the most important kind of knowledge is in general knowledge about business, since the information system is about the business. The thick arrow in Figure 1 demonstrates this circumstance.

In order to develop information systems, knowledge about business has to be transferred from business specialists to IT specialists. This transfer is problematic since people have different frames of references (Yourdon, 1989; Alter, 1996). The whole intention of the sender can therefore not be transferred to the IT specialist. The IT specialist cannot, on the other hand, fulfill the requirements since he cannot completely understand the business specialist. Complex systems development tasks still have to be performed through TSD, but as more powerful systems development tools are at hand, the possibilities to perform USD are enhanced from year to year. Spreadsheet programs have properties that give the user-developer access to IS development features without being an IT specialist. Of course there are other ways to overcome this gap, for example, by performing systems development with a participative approach like RAD (Tudhope, Beynon-Davies, Mackay & Slack, 2001). The systems discussed in this article are often small and local, and thereby often are not suitable for traditional systems development projects.

CONDITIONS AND EFFECTS OF USER SYSTEMS DEVELOPMENT

As a framework model, a modified version of the model of generic practice (the ToP model) (Goldkuhl & Röstlinger, 1999) is used to systemize empirical findings and related theory. The model can be used to specify the conditions and result of a specific practice, such as a controller practice or an IT specialist practice. The modified model consists of a set of conditional categories—*knowledge*, *norms*, and *tools*. The categories that express the specific practice are named *producers* (the user-developer) and their *actions* (user systems development). The last cat-

Figure 1. Relation between knowledge and development (Avdic, 1999)



egory is the *result* of the practice (the application). When a user-developer develops UDAs, he acts in at least two types of practices, the primary (e.g., controller) practice and the secondary (developer's) practice. Each practice is related to a profession, such as a controller and an IT specialist profession. The model makes it possible to separate the conditions of the different practices. It also makes it possible to discuss which parts of the developer's practice can improve the main practice without consulting an IT specialist. The use of the model makes it possible to show how different practices exchange conditions and effects. The result of user developer practice might, for example, be a condition of the controller practice. The model is described in Figure 2.

The ToP model is slightly related to the Work Systems model (Alter, 2002), in that the model focuses on practice without specific references to IT artifacts. The ToP model emphasizes knowledge aspects more explicitly, which makes it especially suitable to analyze the practice of user systems development. The nature of ToP model categories is described below.

Information Systems (Result)

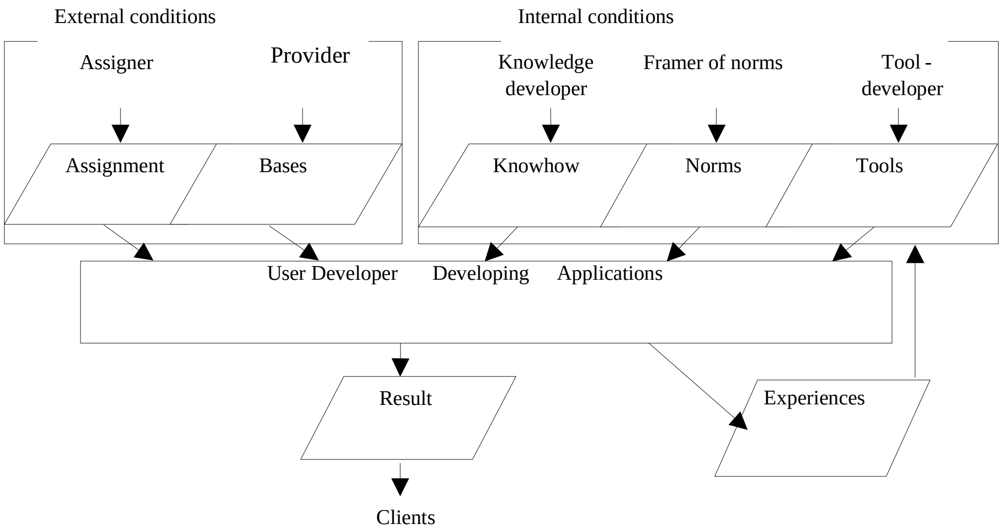
A UDA is an information system, and an information system is a result of systems development. The difference between a traditional information system (TIS) and a UDA is mainly a question of how it is built. UDAs are built by user-developers with a good knowledge of the business, while TISs are built by IT specialists.

User Systems Development (Actions)

Traditional systems development can be characterized by the notion of the 'Life Cycle', where tasks are specialized and activities are separated and systemized. USD and TSD are profoundly different in many ways. USD actions are seldom organized nor planned (Avdic, 1999). Specific work-related tasks or problems make the user-developer aware of some information need. USD is looked upon as work rather than systems development by the user-developer. From the user-developer's point of view, any tool is useful that might help him solve work-related problems. Compared to TSD, USD is characterized by integration rather than specialization. Where TSD professionals get specialized in programming, analysis, or database design, the user-developer integrates skills and performs the entire life cycle by himself.

Success factors of USD have been discussed in the scientific community for more than two decades. The reasons why USD is successfully adapted in an organization have been claimed to depend on the presence of informal channels of communication and how common training on USD tools is (Kruck, Maher & Barkhi, 2003; Brancheau & Brown, 1993). Basic conditions (suitable tasks, equipment, knowledge, and certain independence) must be fulfilled to make USD possible (Carlsson, 1993). If business and information needs are dynamic, USD can be justified. USD is appropriate when user-developers also have access to well-organized data, and get support from management and the IT department (Auer, 1998). Perceived importance is also claimed to be vital (Blili, Raymond & Rivard, 1998).

Figure 2. ToP model (Goldkuhl & Röstlinger, 1999)



When discussing how to manage and control USD, advocates of high control recommend (strict) organization of USD activities (e.g., Andersen, 1994). Advocates of low control consider USD as time saving and appropriate because of the lack of detailed monitoring (e.g., Speier & Brown, 1997).

The discussion of what factors determine successful USD is implicitly aimed at organizing USD activities with a certain degree of control. This discussion is not really relevant since the user-developers are professional in their respective professions. They use IT tools when they find it relevant in relation to their work tasks. Since they do not separate USD from running work, they have the same quality demands on the USD result as on the rest of their work. Contrary to some research (e.g., Teo & Tan, 1999), we claim that the risk of poor quality in UDA information output should be related to the user-developer's professionalism rather than to design methods or tool properties.

User-Developers (Producers)

A user-developer is a person with a good knowledge of the business who develops UDAs that support the user-developer in his work. The user-developer is primarily a professional (e.g., a controller) who integrates to some extent the role of one or more IT specialists when performing USD. The user-developer could have good knowledge about IS development tools. This does not disqualify him as a user-developer; it rather makes him even more efficient.

User-developers can be categorized in different ways. Commonly, categorization is done by knowledge of computing technologies. Rockart and Flannery (1983) and Govindarajulu (2003) are using the following types:

- Non-programming end-users, who are developing very simple applications and who are using a very limited set of tool functions.
- Command-level users, who are developing applications using declarative functions (e.g., formulas and functions).
- End-user programmers, who are developing applications that can be more complex (e.g., multi-user) applications using declarative as well as procedural functions.

With regard to the second and third types, the combination of deep knowledge about business and knowledge about IT tools makes it possible for the user-developer to perform systems development without engaging IT specialists.

Knowledge

When performing USD, knowledge is divided between the user-developer and the tool (SP). Certain kinds of (not too complex) knowledge are formalized into the SP and can be used in the SP-UDA. Other kinds can be formalized by the user-developer into the SP-UDA. Some kinds of knowledge (e.g., of critical evaluation of the relevance of formulas) cannot be formalized at all. Still, this kind of not easily formalized (sometimes tacit) knowledge can be taken into consideration when using the UDA, since the user-developer (with business knowledge) is the user of the system. We also claim that goals, not easily formalized, can be taken into consideration when performing USD.

Knowledge about tools can be used to deepen knowledge about business. User-developers can make tacit knowledge explicit when developing USD, which in turn makes it possible for others to evaluate and criticize the UDA and its output (Adam, Fahy & Murphy, 1998). The user-developers are conscious that an ongoing change in the company/authority's environment makes it important to develop not-yet-known knowledge about conditions and circumstances of their work. One important aim of the user-developer is to articulate knowledge about business and that the UDA is an important means to do this.

Norms

Norms and knowledge are closely related and sometimes hard to keep apart. One set of norms that are central is professional ethics. Professional ethics are crucial to the user-developer since the professionals' activities are monitored not by procedures, but by professional and business ethics. Professional ethics as well as professional tacit knowledge (see above) cannot easily be transferred to IT specialists in systems development projects. Therefore when USD is performed by user-developers, professional ethics and tacit knowledge can be taken into consideration in a way not possible in TSD. Ongoing questioning of business using UDAs can implicitly or explicitly challenge existing models as well as their norms.

Tools

USD tools are closely related to norms and knowledge, since norms and knowledge are implemented in tools. The main tool when performing SP-USD is of course the SP. The SP integrates functions for input, output, storage, processing, and presentation. This integration results in interactive development and use. The open nature of the SP can cause different kinds of errors (Panko & Sprague, 1998; Kreie, Cronan, Pendley & Renwick, 2000). Knowledge of business, tools, and design can prevent some of these errors. Lack of experience and training can also be a problem related to the tool (McGill, 2002).

FUTURE TRENDS

Since IT is becoming more and more common in different environments, it is likely that USD will also become more common. Rapid change in most aspects of everyday life and business contexts will make it more important to be able to deal with situations, questions, and specific information needs that are not anticipated in standard packages and systems developed years ago. The increased need of learning tools, eventually Web based, will therefore increase the need of flexible tools aimed at providing user-developers with learning possibilities. This way end-user computing and knowledge management will merge together and inspire future research.

CONCLUSION

SP-USD is characterized by integration, interactivity, and capacity of questioning. The notion of integration can be looked upon in several dimensions: 1) aspects of ISs (integration of collecting, storing, processing, and distribution of information), 2) roles (integration of developer, user, and manager roles), 3) roles of actors in systems development (integration of analyst, programmer, database, and designer roles), and 4) integration of processing functions of the IS. The integrated nature of USD results in interactivity. Interactivity means that the user-developer can change quickly between developing and using the SP-UDA. During the USD process the user-developer knowledge of the business and USD increases. This is actually the goal of the user-developer. Since the user-developer's knowledge of the business increases when performing USD, the user-developer can analyze and also question aspects of business (e.g., production measuring methods). The questioning aspect makes it possible to improve business.

SP-USD can be used as a means of controlling continuous changes in the environment of the organization by changing business with the help of USD (see Figure 3). A business analysis (1) can result in a revaluation of the business (2), which can result in a revaluation of its goals (3) (and norms), which can result in a revaluation of methods of measurement (4), which can result in new analytical models (5) (UDA), which can lead to a new business analysis (1), and so on. USD is discussed as one way to meet change as a permanent business condition, which differs from traditional methods for systems development.

This way of reevaluating organizational goals can be related to double-loop learning, as presented by Argyris and Schön (1996). This includes not only changes in behavior or strategies. It means that norms of the organization can be changed. The ongoing questioning of business practice that is performed through USD can imply this form of norm changing.

Figure 3. Continuous change and user systems development

KEY TERMS

End-User Computing: "…the adoption and use of information technology by personnel outside the information systems department to develop software applications in support of organizational tasks" (Brancheau & Brown, 1993, p. 437).

Information System: A system consisting of functions for input, processing, storing, output, and presentation of information.

Spreadsheet Program: The most common standard package next to word processors, suitable for user systems development.

Systems Development: A process where an information system is developed.

Traditional Systems Development: Systems development carried out according to the 'life cycle' model.

User Systems Development: Systems development initiated and performed by user-developers, who have good knowledge about and who are (partly) responsible for (part of) the organization the system is to serve.

User-Developed Application: An information system developed by a user-developer. The system is often small and dedicated to a specific task in the user-developer's working environment.

User-Developer: A person who develops UDAs that support the user-developer in his work. The user-developer has deep (often tacit) knowledge about, and is often (partly) responsible for (part of) the organization the system is to serve.

Uses and Gratifications for the World Wide Web

Thomas F. Stafford
University of Memphis, USA

INTRODUCTION

It has always been important to understand what motivates consumers to use the Internet, since network use is a critical precursor to electronic commerce (Eighmey & McCord, 1998; Lohse & Spiller, 1998; Schonberg, Cofino, Hoch, Podlaseck & Spraragen, 2000). Without Internet use, there is no e-commerce use; this is much the same sort of issue that retailers study when trying to determine issues that motivate store visits. Internet use motivations, then, serve an important purpose in the understanding of e-commerce activities (Stafford, 2003b).

Technically speaking, the Internet has always been a communication medium, so we understand much of its functionality from the standpoint of its telecommunications utility. As we strive to understand motivations for its use, it is important to realize that the Internet is far more than a computer network; as the Internet evolves to become not only a telecommunications network, but also a consumer entertainment source, it gains the potential uses of familiar entertainment and communications media such as telephones, radio and television. The Internet remains a network for the distribution of information and telecommunications services, but it also becomes a channel for the delivery of other, richer media. In this sense, it has become a medium of media, or *meta-medium* (Stafford, Stafford & Shaw, 2002). Thus, where understanding the motivations related to computer use once was sufficient to diagnose Internet user motivations, we must now consider a wider range of potential uses and motivating gratifications arising from use of this complex and rich medium.

Early work on the uses and gratifications for Internet use centered on the process of using the network and the gratifications related to the content that the network provided. However, recent work indicates that additional motivations exist for Internet use, and these are important for site and service operators to understand, if they wish to successfully motivate customer use of and loyalty to their resource. These new motivations are potential differentiators between operators *within* the Internet medium as well as *between* the Internet and conventional promotional media (Stafford, Stafford & Shaw, 2002).

BACKGROUND

It has been known for decades that individuals are motivated in their use of media; it is not a random or undirected activity (Katz, 1959), though it may occasionally seem so when one encounters the typical “couch potato” channel surfer or aimless “Web surfer.” Audiences are not passive consumers of media; they get involved (Katz, Blumler & Gurevitch, 1974; Rubin, 1981), which means that understanding the motivations that lead to media use also provides the basis for engineering more involved media use – an outcome that is surely beneficial to media operators and their commercial sponsors.

Media choice, being motivated by individual uses and related goals – something we characterize as “gratifications” (Lin, 1977) – is much like any other product or service that might be marketed to users. Consumers make choices about what to use, and in their media choices, users are both active and selective in choice (Levy & Windahl, 1984). This means that media operators dare not assume a captive audience, and this assumption applies equally well in the mass media world of television and radio as it does in the online world of the Internet and its rich media sites. For that reason, the robust theoretical perspective of uses and gratifications, which has been used to study media since before the advent of commercial television, is useful in investigating the Internet since our media knowledge in one context is often useful in another (Eighmey, 1997; McDonald, 1997; Newhagen & Rafaeli, 1996).

Uses and gratifications theory (U&G) has to do with what people do with media and why they do it. Classic applications of U&G theory have consistently identified only two key areas of motivation for media use: media content uses and motivations for use (*gratifications*, in U&G parlance), and media usage process gratifications. Content gratifications concern the *messages* carried by the medium (which could be informative, or entertaining), and process gratifications concern *actual use* of the medium itself (Cutler & Danowski, 1980). The modern analogies would be the Web surfer, who is clearly motivated by the process of using the Internet, versus the highly focused online researcher, who is engaged in searches for very specific message content to support information needs (Stafford & Stafford, 2000).

U&G UP-TO-DATE

In research that has spanned the course of the past five years, an emerging stream of literature documenting new Internet-specific U&G studies are now reaching publication. Previous Internet-related U&G research was useful, but authors had generally adapted measurement scales directly from television studies of uses and gratifications (cf., Eighmey, 1997; Eighmey & McCord, 1998; Rafaeli, 1988). The emerging stream of research began with the premise that motivations for Internet use might be different from the motivations that drive the use of other media, and that a new set of measures ought to be developed (e.g., Stafford & Stafford, 1998). This article documents some of the more prominent findings in the process of developing these new Internet-specific U&G dimensions.

The Initial Factors of Internet U&G

Stafford and Stafford (2001a) leveraged a qualitative study with HotWired site users into an AOL user survey to investigate the dimensionality of uses and gratifications for the Internet. Five Internet-specific U&G factors were identified: Searching, Cognitive, New and Unique, Social, and Entertainment. While searching certainly speaks for itself as an Internet activity, the cognitive factor was interesting, since it was characterized by descriptors related to learning: education, information, learning and research. The "new and unique" factor was characterized by descriptors such as ideas, interesting, new, progressive and relaxing; clearly a gratification factor, as opposed to a specific use. The social factor (chatting, friends, interaction, newsgroups and people) identified an exciting new possibility in U&G applications for the Internet, since previous U&G research had never identified a social motivation for media use. The entertainment factor (entertainment, fun and games) was clearly a content-based gratification related to having fun with Internet site content.

Applications of New Internet U&G Factors

With the interpersonal social factor identified as an aspect of Internet usage motivation, the Internet can be considered as both an interpersonal and a mass exposure medium, with simultaneous commercial and noncommercial opportunities to users (Stafford & Stafford, 2001a). Stafford's (2001) confirmatory analysis of emerging Internet U&G issues produced U&G factors that were applied in a study of Internet use and diffusion among the consumer market (Stafford, 2003b), examining differences between early and late Internet adopters; there were significant differences between each adoption category on specific Internet U&G factors. Internet laggards exhibited the lowest social gratification for online services, while Internet "innovators" (or, early adopters) exhibited the highest social gratifications. Innovators also produced significantly higher content gratification scores, as compared to laggards.

It began to appear, as a process of developing and applying specific U&G dimensions for Internet users, that the impact of social gratifications might be largely a function of user experience. A general expectation emerged which specified that heavy Internet service users are more motivated by social gratifications than light users (Stafford, Stafford & Shaw, 2002). To the extent that heavy users are desirable consumer targets for ISPs, verification of this supposition could have valuable implications for practice.

This presumption was tested in another AOL survey (Stafford, 2003a), and for all of the variables comprising both process and social Internet usage gratifications, heavy users scored higher than light users. Hence, heavy users can be expected to be more motivated in their Internet use specifically on the social dimension – a finding that resonates with unrelated Internet research on user demographics (e.g., Emmannouildes & Hammond, 2000) – but also any other U&G dimension, as well. Heavier users have more specific uses and find more enjoyment in the Internet usage process than do light users, it seems.

Internet U&G factors have also been applied to understand Web use in the distance education classroom (Stafford, 2003c; Stafford & Stafford, 2003). In this study of student motivations for use of distance course Internet resources, social gratifications were dominant, accounting for 70% of the variance. It is generally agreed that students on the remote end of a distance education teleconference feel somewhat socially removed and isolated from colleagues in the live origination section of the class (cf., Berger & Topol, 2001; Hamer, 2001). Internet technology has been shown to ameliorate the inherent social isolation of a distance course, and that consideration seems to be confirmed in the strong showing of the social factor in this specific distance education application (Stafford, 2003c).

Since much of the initial development of U&G dimensions for Internet use came from samples of AOL users, one recent study made an effort to understand specific characterizations of AOL users for their Internet activities. AOL users appear to be highly gratified by activities characterized by Web browsing and the guided search for information, and AOL users also appreciate communications-related Internet uses, and have clear social gratifications for Internet use. Interestingly, among all the potential indicators related to U&G factors examined in analysis, shopping as a specific activity does *not* appear to be highly gratifying to AOL users (Stafford & Gonier, 2004).

Further, while AOL users are certainly socially motivated in their use of the Internet, mean scores for the "chatting" component of the social gratification dimension were below the scale midpoint, suggesting that the explicit social activity related to Instant Messenger, chatting, was not prized as highly as other social activities available online. Light AOL users produced a "chatting" mean of 3.2 on a 7-point scale, while heavy users produced a mean of 3.9 (Stafford, 2003a), which suggests that AOL users in general are not overly enamored with chatting as a gratification for Internet use. One interesting aspect of the AOL user study was the potential dimensionality of social gratifications; in performing an oblique factor rotation, the list of social variables factored into a distinct communication factor, aside from the standard socialization factor that had been seen in previous analyses (Stafford & Gonier, 2004).

The communication factor referenced terms related to using the Internet as an interpersonal communications channel: access, answers, communication and e-mail. The reduced socialization factor was distinguished by what would appear to be the targeted use of the Internet as a communication channel (that is, the focus on the message receiver): chatting, friends, fun, interaction, newsgroups, people, relaxing. Analysis of variance was performed on the salient variables for each usage factor, and results show that heavy users score higher than light users on each of these variables (Stafford & Gonier, 2004).

Relationships between Internet U&G Dimensions

In a measurement study seeking to establish trait validity for U&G factors (Stafford, 2001), process and content gratifications were found to be highly related ($\Phi = .72$), but there were much weaker relationships between the social factor and the more traditional process and content gratifications, which tends to reinforce the multi-modal conceptualization of the Internet as providing both personal entertainment and interpersonal communications channels in one meta-channel. The process dimension was only moderately related to social gratifications ($\Phi = .38$), and the content dimension was also only moderately related to social gratifications ($\Phi = .34$), so social gratifications are distinct from (and not closely related to) standard process and content gratifications for Internet use.

The social gratification construct did display excellent measurement qualities, indicated by measurement model fit indices (GFI = .97, AGFI = .95, RMSR = .11, SRMR = .043, NFI = .96, CFI = .97), so social gratifications appear to be a distinct trait and a valid area of motivation for Internet use, if not directly related to the better understood process and content gratifications.

CONCLUSION

Given that they are derived and validated from a broad base of users, Internet social gratifications are worth considering as a key benefit sought by consumers using the Internet. Unlike other media studied in the past, where sought content and enjoyment of media usage processes were the defining factors of motivation, the Internet provides standard media gratifications along with interpersonal connectivity, giving it a multi-modal appeal and influence in human life.

Interpersonal communication and interaction with other people over the Internet seems to characterize the social Internet gratification. Site operators as well as Internet service providers can enhance this experience for users through the inclusion of Webmail, chat utilities, message boards and discussion groups. AOL already makes great use of this social dimension of Internet use in the way it leverages its Instant Messenger utility as a promotional tool for building the membership base and increasing online time among existing member (Stafford, 2001).

Regardless of the use or gratification a business may wish to impact in its provision of Internet service and utility, the important point is to realize that users actively interact with the medium, and that uses and gratifications is one of the best ways that exists in which to study active audience motivations for media use. Determining what audience members seek to do, and the benefit they expect to accrue from activity, is the important step in marketing and supporting Internet offerings.

A highly practical implication of what we know about U&G, in a business context, is that the Internet service providers will have more difficulties recruiting and motivating late adopters. Heavy users and early adopters are the *most motivated* of users, so perhaps efforts in the ISP business should focus on customer retention and current customer satisfaction, as opposed to new customer recruitment – to the extent that many of the new customers to be had in the current environment are late adopters and likely light users, if they are not already making use of the Internet and its functionality. For the purposes of e-commerce businesses, the implications that heavy Internet users are more motivated by social and process/content gratifications means that e-commerce sites must be both easy to use and appeal to the heavy user population. But it also means that heavy users can respond well to social utilities provided by Internet sites, so chat rooms and message boards dedicated to product users at a commerce site may have some attraction for the heavy Internet users of commerce sites.

U&G also reminds us to be customer-centric in our design and provision of products and services, keeping in mind that users want specific things because these things bring them enjoyment. Goal oriented activity is the lynchpin of motivation, and understanding the goals sought by our Internet customers will allow us to design and provide more compelling and satisfying offerings. Inevitably, business objectives will be more fully attained in a customer-centric approach to the Internet industry.

KEY TERMS

Active Audience: Uses and gratifications theory presumes media users are actively involved in selection and use of media, and are not passive recipients. This implies the need to specifically target media offerings to perceived user needs.

Content Gratification: Enjoyment of message specifics. Content can mean information, and often does, though it also includes entertainment in the form of medium-carried programming.

Gratifications: What people derive from use…the "why" of media use motivations.

Meta-Medium: A channel of channels, such as the Internet. This term conveys the sense of rich and complex media transmission across a multiplexed channel of conveyance. Numerous motivations for use could arise related to such a complex media venue.

Process Gratification: Enjoyment of media use, as distinguished from enjoyment of specific message content. This is much the same as channel surfing or Web browsing with no goal other than entertainment through engaging in the activity.

Uses: Things people do *with* media…the "how" of media use motivations.

Uses and Gratifications: Customer activities and the enjoyment that derives from such activities, particularly in a mass media context.

Using Geographic Information Systems to Solve Community Problems

Jane L. Garb
Baystate Medical Center, USA

Richard B. Wait
Baystate Medical Center, USA

INTRODUCTION

This article describes how the technology of geographic information systems (GIS) can be used as a tool to integrate various types of community-level data to address local problems. The purpose of the article is to present an approach that can be replicated by others. This approach is based on community-wide collaborative sharing of resources, data, and research applications with an aim to enhance the health and well-being of the local area population. Although the example used relates to health, the approach can be used to deal with any "event" or series of events in the community.

BACKGROUND

A GIS is a set of hardware and software for inputting, storing, managing, displaying, and analyzing geographic or spatial data or any information that can be linked to geographic location, such as events, people, or environmental characteristics (Bailey & Gatrell, 1995; Burrough & McDonnell, 1998). The advantages of GIS as an information system pertain to its ability to handle spatial data; integrate data from many sources; uncover spatial patterns and relationships by superimposing different data layers and viewing data at different levels of aggregation; and conduct spatial analyses to test hypotheses and make predictions. Significant advances in the field of GIS and spatial statistics in the last 20 years have enabled researchers to undertake a more extensive examination of the spatial component of a wide variety of applications. The visualization and analytic capabilities of a GIS enable the user to examine and model the interrelationship between spatial and nonspatial etiologic factors in a variety of events ranging from house sales to crime activity to breast cancer.

The American Community Survey (ACS; 2002) is an ongoing survey conducted by the U.S. Census Bureau. Data are collected monthly and are used to provide annually adjusted estimates of the current population based on an approximate 2.5% sample, with oversampling for small governmental units, such as American Indian Reservations. Full implementation of the survey will begin in 2004 (Census, 2003). ACS data forms the source of population data for the current study.

Despite the fact that ACS does not provide complete population counts, it can be used to derive community profiles, emphasizing relative proportions in each population subgroup. It can also be used as a mechanism for measuring changes and trends in the population in the interval between decennial census counts.

The Health Geographics Program at Baystate Medical Center in Springfield, Massachusetts, takes a comprehensive approach to the implementation of services, research, and community applications utilizing GIS. Because of its collaboration, giving access to community and hospital data, the program was contracted by the U.S. Census Bureau to undertake two case studies to demonstrate the utility of annually adjusted data from the American Community Survey.

The case study described here utilizes the ACS population and housing data in a GIS to improve breast cancer intervention programs. Previous research has clearly established that by lowering the rate of late-stage disease with increased mammography screening, breast cancer mortality can be reduced (Feig, 1988; Marchant, 1994). Furthermore, there is evidence that socioeconomic and cultural disparities in breast cancer screening exist (Katz, Zemencuk, & Hofer, 2000; O'Malley, Kerner, Johnson, & Mandelblatt, 1999; Phillips, Kerlikowske, Baker, Chang, & Brown, 1998). Several investigators have applied GIS and spatial analysis in the past to identify etiologic factors in breast cancer and late-stage breast cancer (Brody et al., 1997; Gardner, Joyce, & Melly, 1999; Kulldorff, Feuer, Miller, & Freedman, 1997; Lewis-Michl et al., 1996; Melly, Joyce, Maxwell, & Brody, 1997; Roche, Skinner, & Weinstein, 2002; Selvin, Merrill, Erdmann, White, & Ragland, 1998; Sheehan et al., 2000; Timander & McLafferty, 1998).

THE GIS APPROACH

The main functions of a GIS are *data integration*, *visualization*, *exploration*, *statistical analysis*, and *modeling* (Bailey & Gatrell, 1995). These functions can be combined in a systematic approach to solve problems. This approach can be outlined as follows:

1. **Integrate** data from multiple sources
2. **Visualize** the data with maps
3. **Explore** patterns further with spatial statistics
4. **Generate** hypotheses
5. **Test** hypotheses with mathematical modeling

We will describe how this approach was applied to the case study referred to above.

CASE STUDY: INVESTIGATING LATE-STAGE BREAST CANCER

The aim of the study was to create a profile of communities in Springfield in need of increased breast cancer screening. Specifically, we wanted to identify parts of the city with high rates of late-stage disease as well as identify socioeconomic and demographic factors in late-stage disease. This information would aid resource allocation by focusing intervention efforts on high-risk areas. Furthermore, it would allow the design of "culturally appropriate" (Healthy People, 2000) screening programs.

Applying the GIS approach, the first step was to gather and *integrate data* from three different sources. Geographic data were obtained from the City of Springfield Planning Department. This consisted of geographic boundaries and street locations that would be used in the geocoding process described later. ACS housing and population data provided aggregate information on demographic and socioeconomic characteristics of women over 40 by police sector (Table 1). Police sectors were used for this case study, because this was the smallest geographic unit for which ACS data were available. There are nine police sectors in Springfield. Breast cancer case data from the Springfield's two hospital oncology registries gave information on the dates and stages at diagnosis and home addresses for all patients diagnosed at these two hospitals. Together, these registries capture 95% of all cases of breast cancer in the city.

Cases were staged according to the American Joint Cancer Committee (AJCC; AJCC, 1997). Cases were defined as "late stage" if they were Stage 2 or greater. This definition captures all cases that should have been detected earlier had mammography been performed. A total of 891 breast cancer cases were diagnosed during 1995–1999, with 194 of these defined as late stage.

All data for the study were converted to dBASE IV format to be read into the GIS. Geographic data was in the form of ArcView (ESRI, 1999) shapefiles. Geographic and tabular data were imported into the GIS using ArcView. ArcView was used for all GIS functions. Geocoding of case locations was based on the patient's street address, using the City of Springfield streets shapefile as the reference database. Mapping of case locations was based on patient's home address. Mapping was done at a small enough scale so that individual patient addresses could not be determined from the map, in order to preserve patient confidentiality.

The next step in the GIS approach was to visualize the data. This was done by mapping the data in ArcView. We

chose a dot map to display the geographic distribution of cases of late-stage disease and indicate areas of concentration. This would show where raw numbers of cases were greatest and more resources were needed, e.g., where mobile mammogram units and educational or other intervention programs would be likely to have the highest yield. Visual examination of the map in Figure 1 reveals no apparent clustering.

Clustering can be formally tested in the next step, *exploring patterns* further with spatial statistics. In this study, we used the spatial scan statistic (Kulldorff et al., 1997; Kulldorff, Rand, Gherman, Williams, & DeFrancesco, 1998). This technique employs a systematic, iterative "searching" of space conceptually with overlapping circles, counting cases and people, and revealing areas of unusually high rates, or clusters. The software used to perform this analysis was SATScan, a free, publicly domain program (Kulldorff, Rand, Gherman, & DeFrancesco, 1998). Preliminary findings from this study showed no statistically significant spatial clustering of cases. From the results of this visual and statistical examination, we concluded that rather than concentrating resources in specific parts of the city, a more global approach to intervention seemed warranted.

We were also interested in whether the location of mammogram facilities influenced the rate of late-stage disease in the different police sectors. This has been shown to be a factor in screening (Athas & Amir-Fazli, 2000). Using ArcView, we overlaid a map of their locations onto the dot density map of cases (Figure 1). Although case location did not appear related to mammography facility location, we would later test this relationship with formal statistical modeling.

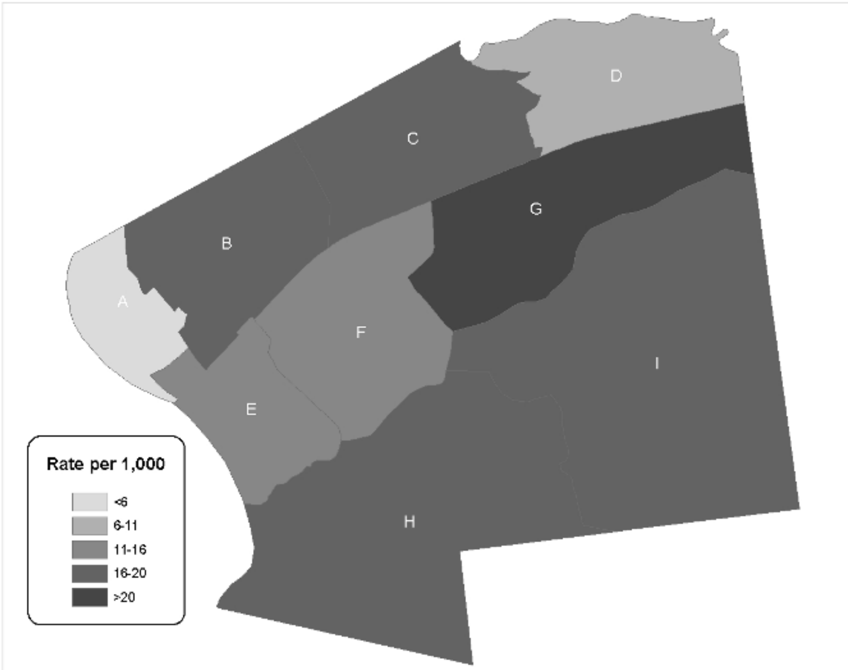
To estimate the risk of getting late-stage disease, case data were aggregated or summed to the police-sector level for which population estimates were available. The total number of cases of late-stage breast cancer for each sector were divided by the ACS population estimates for the total number of women over 40 (the population at risk for breast cancer) for that sector. This represented the prevalence rate of late-stage disease.

We mapped these rates in the GIS using choropleth maps to look for areas with unusually high rates. A choropleth map is used to display quantities for various geographic areas. Figure 2 shows the rate of late-stage breast cancer per 1,000 women over 40 in each police sector. Darker shades indicate police sectors with higher rates of late-stage disease. According to this map, Sector G has the highest rate. We needed to investigate what characteristics of this sector make women at higher risk for late-stage disease.

To *generate hypotheses* about etiologic factors in late-stage disease, the next step in the GIS approach, we compared the choropleth map of late-stage disease by

U

Figure 2. Choropleth map showing the rate of late-stage breast cancer per 1,000 women over 40 (darker shades indicate higher rates)



sector, with maps showing the distribution of various demographic and socioeconomic sector characteristics. Pattern similarities would indicate a possible relationship between these characteristics and the risk of late-stage breast cancer. Figure 3 shows the proportion of women over 40 who are married, receive public assistance, have a high school diploma, or are African American. Darker shades on the maps represent higher concentrations of these populations, and vise versa. Similar maps (not shown) were generated for other ACS demographic and socioeconomic variables listed in Table 1. The sector with the highest rate of late-stage disease (Sector G) had among the highest rates of African American or married women or those with a high school diploma or receiving public assistance. This generated the hypothesis that socioeconomic and demographic factors are related to late-stage disease.

The final step in the GIS approach was to use *mathematical modeling to test hypotheses* about cause–effect relationships. To accomplish this, a spatial regression was conducted to identify sector demographic and socioeconomic characteristics that made women at particularly high or low risk for late-stage disease. Spatial regression was conducted using the S-PLUS for ArcView extension (Insightful, 2000). This technique is helpful in sorting out the effect of various factors not necessarily apparent by mapping, and identifying characteristics of high-risk population subgroups. The unit of analysis for the regression analysis was police sector. The dependent variable was the rate of late-stage disease per thousand women over 40. Independent variables were the ACS estimates for sector population and housing characteristics from Table 1, as well as the number of mammogram facilities.

Four factors were predictive of late-stage disease: African American race, presence of a high school diploma, and foreign born or married status in women over 40. These factors were all positively related to the rate of late-stage disease: the risk of a woman's getting late-stage disease was greater in sectors with higher rates of African American, married, or foreign-born women, or those with a high school diploma. The number of mammogram facilities in a sector did not affect the rate of late-stage disease in that sector.

The results of this study can help in the allocation of resources and the design of culturally appropriate intervention programs. Areas of the city with high concentrations of cases or populations at highest risk of late-stage disease (e.g., African Americans or foreign born) can be targeted for increased resources for screening intervention such as education programs or mobile mammogram units. The fact that high school graduation was a risk factor in late-stage disease indicates that program materials should be geared to a higher educational level so as not to discourage more educated women from participat-

Figure 3. Rates of women over age 40 in Springfield, Massachusetts, according to various socioeconomic and demographic factors from the American Community Survey (darker shades indicate higher rates).

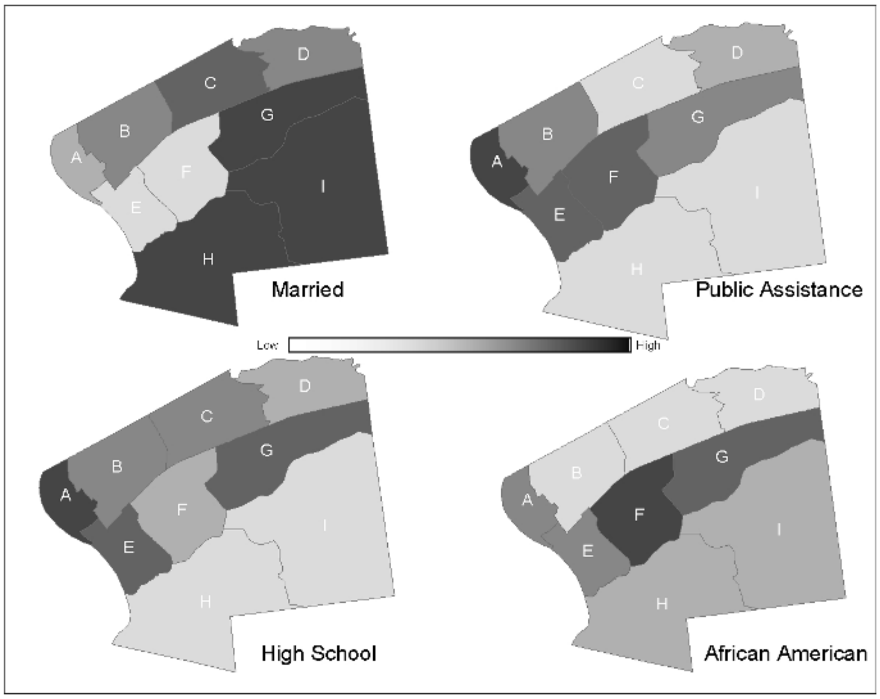


Figure 4. Three-dimensional map of locations of high-risk populations for late-stage breast cancer in Springfield, Massachusetts (darker and taller sectors are higher risk)

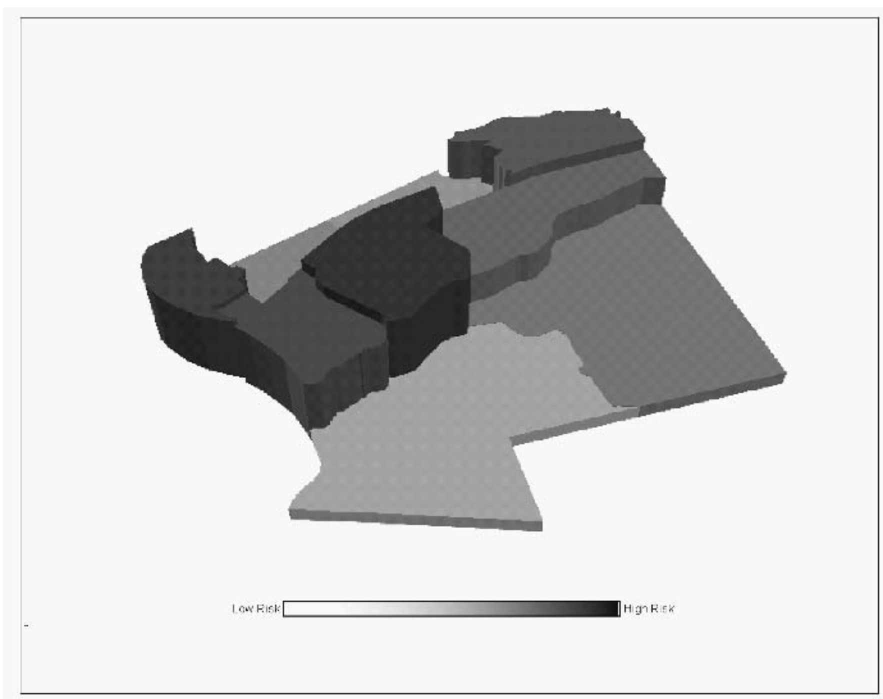

ing. The importance of foreign birth suggests potential avenues for reaching high-risk women through various national cultural organizations, such as the Greek Cultural Council in Springfield. The increased risk for African American women suggests working with African American organizations, many of which already target specific health problems.

Although the ACS data used are only preliminary estimates based on one year of survey data on a relatively small sample of the population, they demonstrate the importance of socioeconomic factors in the geographic distribution of late-stage disease, which is relevant to the design of intervention programs.

FUTURE TRENDS

With future advances in GIS technology, many of the functions of database management (such as importing data, joining tables, creating new variables, calculating new fields) as well as visualization (mapping) and analytic functions can be automated, and the entire process can be saved in the GIS for future use with updated or entirely different data sets. The ability to model the process described in this paper, then edit, save, and recall it is a new feature in the latest version of ArcGIS (ESRI, 2004).

Although not yet fully implemented throughout the country, the American Community Survey holds the most promise as a source of up-to-date U.S. population estimates for the type of application we have described. Data used in the present study were a special tabulation provided by the American Community Survey as part of our contract. However, the first data products for the smallest areas and populations throughout the United States will be available publicly in 2009. Once data products are produced for a population group or area, they will be updated each year (Census, 2003). The ACS will completely replace the Long Form of the next U.S. Decennial Census in 2010.

CONCLUSION

This article demonstrates how each of the main GIS functions outlined by Bailey and Gatrell can be implemented in an approach to address a particular community health problem. Geographic and population data can be used in a GIS to create a visual demographic profile of communities by providing denominators for the calculation and visualization of risks (incidence or prevalence rates), identifying the size and location of high-risk populations, and providing information on socioeconomic and demographic characteristics that can be used in analysis to identify risk factors for late-stage disease. It facilitates the design of culturally appropriate intervention and prevention programs. It enables the creation of community demographic profiles by identifying the size and geographic location of high-risk population subgroups. This is a tremendous aid for public health or other community agency planning and resource allocation.

The approach described here can be applied with any census geography (tracts, block groups, etc.) for which ACS or other population estimates (e.g., the Decennial Census) are available. This enhances its usefulness for a number of purposes and geographic scales. The broad utility of the ACS in providing accurate and timely data on the population and the economic environment in which it exists make it an essential tool in health care as well as other current community issues, such as homeland security. As ACS implementation continues to expand throughout the country, these benefits will become widely available to state and local public officials and agencies. Hopefully, this article will stimulate them to utilize these data in significant ways to improve and protect the health and well-being of our population.

KEY TERMS

ACS (American Community Survey): An ongoing survey conducted by the U.S. Census Bureau that collects detailed demographic and socioeconomic information on a sample of the population.

Choropleth Map: A color-coded map, also called a "thematic" map, in which geographic areas are portrayed in different hues or intensities according to their values on some quantities.

Culturally Appropriate: Refers to an unbiased attitude in organizational policy that values cultural diversity in the population served. Reflects an understanding of the diverse attitudes, beliefs, behaviors, practices, and communication patterns that could be due to race, ethnicity, religion, socioeconomic status, historical and social context, physical or mental ability, age, gender, sexual orientation, or generational and acculturation status. Includes awareness that cultural differences may affect health, and includes the effectiveness of health care delivery. Knowledge of disease prevalence in specific cultural populations, whether defined by race, ethnicity, socioeconomic status, physical or mental ability, gender, sexual orientation, age, disability, or habits (Healthy People, 2000).

Dot Map: A map in which the geographic locations of events, people, or other entities are depicted as points or dots.

Geocoding: A function of the GIS through which the geographic location of an address is given a set of geographic coordinates by reference to a standard geographically referenced database. These coordinates are then used for mapping.

Geographic Information System (GIS): A computer-based set of tools for capturing (collecting), editing, storing, integrating, analyzing, and displaying spatially referenced data (Bailey & Gatrell, 1995).

Late-Stage Breast Cancer: Breast cancer in an advanced stage, usually defined as involvement of regional lymph nodes or size larger than 2 cm.

Spatial Regression: A spatial analytic technique modeling the relationship of various factors to the geographical distribution of some attribute measured on a continuous scale.

Spatial Scan Statistic: A cluster detection statistic that uses a moving window to compare the number of events or case locations inside versus outside the window. This statistic can identify geographic clustering of disease cases or geographic areas with unusually high or low rates of disease.

Video Content-Based Retrieval Techniques

Waleed E. Farag
Zagazig University, Egypt

INTRODUCTION

Recently, multimedia applications are undergoing explosive growth due to the monotonic increase in the available processing power and bandwidth. This incurs the generation of large amounts of media data that need to be effectively and efficiently organized and stored. While these applications generate and use vast amounts of multimedia data, the technologies for organizing and searching them are still in their infancy. These data are usually stored in multimedia archives utilizing search engines to enable users to retrieve the required information.

Searching a repository of data is a well-known important task whose effectiveness determines, in general, the success or failure in obtaining the required information. A valuable experience that has been gained by the explosion of the Web is that the usefulness of vast repositories of digital information is limited by the effectiveness of the access methods. In a nutshell, the above statement emphasizes the great importance of providing effective search techniques. For alphanumeric databases, many portals (Baldwin, 2000) such as *google, yahoo, msn,* and *excite* have become widely accessible via the Web. These search engines provide their users keyword-based search models in order to access the stored information, but the inaccurate search results of these search engines is a known drawback.

For multimedia data, describing unstructured information (such as video) using textual terms is not an effective solution because the information cannot be uniquely described by a number of statements. That is mainly due to the fact that human opinions vary from one person to another (Ahanger & Little, 1996), so that two persons may describe a single image with totally different statements. Therefore, the highly unstructured nature of multimedia data renders keyword-based search techniques inadequate. Video streams are considered the most complex form of multimedia data because they contain almost all other forms, such as images and audio, in addition to their inherent temporal dimension.

One promising solution that enables searching multimedia data, in general, and video data in particular is the concept of content-based search and retrieval (Deb, 2004). The basic idea is to access video data by their contents, for example, using one of the visual content features. Realizing the importance of content-based searching, researchers have started investigating the issue and proposing creative solutions. Most of the proposed video indexing and retrieval prototypes have the following two major phases (Flinkner et al., 1995):

- **Database population phase** consisting of the following steps:
- **Shot boundary detection.** The purpose of this step is to partition a video stream into a set of meaningful and manageable segments (Idris & Panchanathan, 1997), which then serve as the basic units for indexing.
- **Key frames selection.** This step attempts to summarize the information in each shot by selecting representative frames that capture the salient characteristics of that shot.
- **Extracting low-level features from key frames.** During this step, some of the low-level spatial features (color, texture, etc.) are extracted in order to be used as indices to key frames and hence to shots. Temporal features (e.g., object motion) are used too.
- **The retrieval phase.** In this stage, a query is presented to the system that in turns performs similarity matching operations and returns similar data (if found) back to the user.

In this article, each of the these stages will be reviewed and expounded. Moreover, background, current research directions, and outstanding problems will be discussed.

VIDEO SHOT BOUNDARY DETECTION

The first step in indexing video databases (to facilitate efficient access) is to analyze the stored video streams. Video analysis can be classified into two stages: shot boundary detection and key frames extraction (Rui, Huang & Mchrotra, 1998a). The purpose of the first stage is to partition a video stream into a set of meaningful and manageable segments, whereas the second stage aims to abstract each shot using one or more representative frames.

In general, successive frames (still pictures) in motion pictures bear great similarity among themselves, but this generalization is not true at boundaries of shots. A shot is a series of frames taken by using one camera. A frame at a boundary point of a shot differs in background and content from its successive frame that belongs to the next shot. In a nutshell, two frames at a boundary point will differ significantly as a result of switching from one camera to another, and this is the basic principle that most automatic algorithms for detecting scene changes depend upon.

Due to the huge amount of data contained in video streams, almost all of them are transmitted and stored in compressed format. While there are large numbers of algorithms for compressing digital video, the MPEG format (Mitchell, Pennebaker, Fogg & LeGall, 1997) is the most famous one and the current international standard. In MPEG, spatial compression is achieved through the use of a DCT-based (Discrete Cosine Transform-based) algorithm similar to the one used in the JPEG standard. In this algorithm, each frame is divided into a number of blocks (8x8 pixel), then the DCT transformation is applied to these blocks. The produced coefficients are then quantized and entropy encoded, a technique that achieves the actual compression of the data. On the other side, temporal compression is accomplished using a motion compensation technique that depends on the similarity between successive frames on video streams. Basically, this technique codes the first picture of a video stream (I frame) without reference to neighboring frames, while successive pictures (P or B frames) are generally coded as differences to that reference frame(s). Considering the large amount of processing power required in the manipulation of raw digital video, it becomes a real advantage to work directly upon compressed data and avoid the need to decompress video streams before manipulating them.

A number of research techniques was proposed to perform the shot segmentation task such as template matching, histogram comparison, block-based comparison, statistical models, knowledge-based approach, the use of AC coefficients, the use of motion vectors, and the use of supervised learning systems (Farag & Abdel-Wahab, 2001a, 2001c).

KEY FRAMES SELECTION

The second stage in most video analysis systems is the process of KFs (Key Frames) selection (Rui, Huang & Mchrotra, 1998) that aims to abstract the whole shot using one frame or more. Ideally, we need to select the minimal set of KFs that can faithfully represent each shot. KFs are the most important frames in a shot since they may be used to represent the shot in the browsing system, as well as be used as access points. Moreover, one advantage of representing each shot by a set of frames is the reduction in the computation burden required by any content analysis system to perform similarity matching on a frame-by-frame basis, as will be discussed later. KFs selection is one of the active areas of research in visual information retrieval, and a quick review of some proposed approaches follows.

Clustering algorithms are proposed to divide a shot into M clusters, then choose the frame that is closest to the cluster centroid as a KF. An illumination invariant approach is proposed that applies the color constancy feature to KFs production using hierarchical clustering. The VCR system (Farag & Abdel-Wahab, 2001b, 2001c) uses two algorithms to select KFs (AFS and ALD). The AFS is a dynamic adapted algorithm that uses two levels of threshold adaptation—one based on the input dimension, and the second relying upon a shot activity criterion to further improve the performance and reliability of the selection. AFS employs the accumulated frame summation of luminance differences of DC frames. The second algorithm, ALD, uses absolute luminance difference and employs a statistical criterion for the shot-by-shot adaptation level, the second one.

FEATURE EXTRACTION

To facilitate access to large video databases, the stored data need to be organized; a straightforward way to do such organization is the use of index structures. In case of video databases we even need multi-dimension index structures to account for the multiple features used in indexing. Moreover, we are in need of tools to automatically or semi-automatically extract these indices for proper annotation of video content. Bearing in mind that each type of video has its own characteristics, we also need to use multiple descriptive criteria in order to capture all of these characteristics.

The task of the feature extraction stage is to derive descriptive indexes from selected key frames in order to represent them, then use the indexes as metadata. Any further similarity matching operations will be performed over these indexes and not over the original key frames data. Ideally, content-based retrieval (CBR) of video should be accomplished based on automatic extraction of content semantics that is very difficult. Thus, most of the current techniques only check the presence of semantic primitives or calculate low-level visual features. There are mainly two major trends in the research community to extract indices for proper video indexing and annotation. The first one tries to automatically extract these indices, while the second trend performs iconic annotation of video by manually (with human help) associating icons to parts of the video stream. One example of the latter trend uses a multi-layered representation to perform the annotation task, where each layer represents a different view of video content. On the other hand, works on the first trend, automatic extraction of content indices, can be divided into three categories:

- *Deriving indices for visual elements using image-indexing techniques.* For example, using the color and texture as low-level indices.
- *Extracting indices for camera motion* (panning, zooming, etc.). Generally, optical flow is used in such techniques.
- *Deriving indices for region/object motion.* One system detects major objects/regions within the frames using optical flow techniques.

Color and texture are commonly used indexing features in most of the above systems. Color feature extraction can work directly on the original decoded video frame or on its DC form. One technique converts the color space of DC video frames (YCbCr in case of MPEG) to the traditional RGB color space, then derives color histograms from the RGB space. Deriving the histogram can be done in many ways. An efficient technique uses some of the most significant bits of each color component to form a codeword. For instance, the most significant two bits of each color component are selected and concatenated to form a 6-bit codeword. This codeword forms a 64-bin color histogram that is used as the color feature vector. This histogram is a good compromise between computational efficiency and representation accuracy.

Many techniques are proposed in the literature to perform texture feature extraction. Some of them use auto-regression and stochastic models, while others use power spectrum and wavelet transform (Bimbo, 1999). The main disadvantage of these techniques is that they are computationally expensive.

THE RETRIEVAL SYSTEM

The basic objective of any automated video indexing system is to provide the user with easy-to-use and effective mechanisms to access the required information. For that reason, the success of a content-based video access system is mainly measured by the effectiveness of its retrieval phase. The general query model adapted by almost all multimedia retrieval systems is the QBE (Query By Example) (Yoshitaka & Ichikawa, 1999). In this model, the user submits a query in the form of an image or a video clip (in case of a video retrieval system) and asks the system to retrieve similar data. QBE is considered to be a promising technique, since it provides the user with an intuitive way of query presentation. In addition, the form of expressing a query condition is close to that of the data to be evaluated.

Upon the reception of the submitted query, the retrieval stage analyzes it to extract a set of features, then performs the task of similarity matching. In the latter task, the query-extracted features are compared to the features stored into the metadata, then matches are sorted and displayed back to the user based on how close a hit is to the input query. A central issue here is how the similarity matching operations are performed and based on what criteria (Farag & Abdel-Wahab, 2003d). This central theme has a crucial impact on the effectiveness and applicability of the retrieval system.

Many techniques have been proposed by various researchers in order to improve the quality, efficiency, and robustness of the retrieval system. Some of these techniques are listed below.

- *Relevance feedback.* In this technique the user can associate a score to each of the returned clips, and this score is used to direct the following search phase and improve its results.
- *Clustering of stored data.* Media data are grouped into a number of clusters in order to improve the performance of the similarity matching.
- *Use of linear constraints.* To come up with better formal definitions of multimedia data similarity, some researchers proposed the use of linear constraints that are based upon the instant-based-point-formalism.
- *Improving browsing capabilities.* Using KFs and mosaic pictures to allow easier and more effective browsing.
- *Use of time alignment constraints.* The application of this technique can reduce the task of measuring video similarity to finding the path with minimum cost in a lattice. The latter task can be accomplished using dynamic programming techniques.
- *Optimizing similarity measure.* By defining optimized formulas to measure video similarity instead of using the exhaustive similarity technique in which every frame in the query is compared with all the frames into the database (a computationally prohibitive technique).
- *Human-based similarity criteria.* This technique tries to implement some factors that humans most probably use to measure the similarity of video data.

Most of the above techniques end up with calculating the similarity between two frames. Below is one example of how similarity between the colors of two frames (*I* and *M*) represented by their color histograms can be calculated using the normalized histogram intersection. If *Sim* approaches zero, the frames are dissimilar, and if it is near one, the frames are similar in color.

$$Sim(I, M) = \frac{\sum_{i=1}^{n} \min(I_i, M_i)}{\sum_{j=1}^{n} M_j}$$

FUTURE TRENDS

Some of the important issues under investigation are surveyed briefly in this section. Efficient algorithms need to be proposed to parse video streams containing gradual transition effects. Detecting semantic objects inside video frames is also an open challenge that needs to be addressed. Moreover, multi-dimension indexing structure is one of the active areas of research that can be further explored. Determining the similarity of video data is another area of research that requires more exploration to come up with more approaches that are effective.

CONCLUSION

In this article, we briefly review the need and significance of video content-based retrieval systems and explain their four basic building stages. Current research topics and future work directions are covered too. The first stage, the shot boundary detection, divides video streams into their constituent shots. Each shot is then represented by one or more key frame(s) in a process known as key frames selection. The feature extraction stage, the third one, derives descriptive indexes such as color, texture, shapes, and so forth from selected key frames, and stores these feature vectors as metadata. Finally, the retrieval system accepts a user query, compares indexes derived from the submitted query with those stored into the metadata, and then returns search results sorted according to the degree of similarity to the query. At the end, we need to emphasize the importance of content-based video retrieval systems and assert that there is still a considerably large number of open issues that require further research to achieve more efficient and robust indexing and retrieval systems.

KEY TERMS

Content-Based Access: A technique that enables searching multimedia databases based on the content of the medium itself and not based on keywords description.

Key Frames Selection: The selection of a set of representative frames to abstract video shots. Key frames (KFs) are the most important frames in a shot, so that they can represent the shot in both browsing and similarity matching operations, as well as be used as access points.

Query by Example: A technique to query multimedia databases where the user submits a sample query and asks the system for similar items.

Retrieval Stage: The last stage in a content-based retrieval system where the extracted features from the query are compared to those stored in the metadata and matches are returned to the user.

Shot Boundary Detection: A process with the objective of partitioning a video stream into a set of meaningful and manageable segments.

Video Indexing: The selection of indices derived from the content of the video to help organize video data and metadata that represents the original video stream.

Video Shot: A sequence of contiguous video frames taken using the same camera.

V

Virtual Communities of Practice

Chris Kimble
University of York, UK

Paul Hildreth
K-Now International Ltd., UK

INTRODUCTION

When knowledge management (KM) began to emerge in the 1990s it was seen as an innovative solution to the problems of managing knowledge in a competitive and increasingly internationalised business environment. However, in practice it was often little more than information management re-badged (Wilson, 2002). More recently, there has been recognition of the importance of more subtle, softer types of knowledge that need to be shared. This raises the question as to how this sort of knowledge might be managed. Communities of practice (CoPs) have been identified as means by which this type of knowledge can be nurtured, shared and sustained (Hildreth & Kimble, 2002). Do CoPs offer a means of managing the softer aspects of knowledge and, if they do, are they applicable to today's increasingly "virtual" world?

BACKGROUND TO COMMUNITIES OF PRACTICE

The term communities of practice (CoPs) was coined in 1991 when Jean Lave and Etienne Wenger used it in their exploration of situated learning (Lave & Wenger, 1991). Although the examples they used (non-drinking alcoholics, Goa tailors, quartermasters, butchers and Yucatan midwives) were all based on what might be broadly termed an apprenticeship model, the concept of a CoP is not restricted to this form of learning.

Lave and Wenger (1991) saw the acquisition of knowledge as a social process in which people participated in communal learning at different levels depending on their authority or seniority in the group, that is, whether they were a newcomer to the group or had been an active member for some time. The process by which a newcomer learns by being situated in the group was central to their notion of a CoP; they termed this process legitimate peripheral participation (LPP).

LPP is both complex and composite; legitimation, peripherality and participation are each indispensable in defining the other. Legitimation is concerned with power and authority relations in the community but is not necessarily formalised. Peripherality is not a physical concept or a measure of acquired knowledge, but concerned with the degree of engagement with the community. Participation is engagement in an activity where the participants have a shared understanding of what it means in their lives.

For Lave and Wenger (1991), the community and participation in it were inseparable from the practice. Being a member of a CoP implied participation in an activity where participants have a common understanding about what was being done and what it meant for their lives and their community. Thus, it would appear that CoPs with their concentration on situated learning and the exchange of understanding might be well suited to the management of the softer aspects of knowledge: but can this idea be applied to the business world?

EXTENSIONS TO THE COMMUNITY OF PRACTICE CONCEPT

Interest in CoPs continued to grow throughout the 1990s and several attempts were made to re-define Lave and Wenger's (1991) original model to encompass new areas such as communities of circumstance, communities of interest and communities of purpose. In particular, several attempts were made to re-define CoPs in a way that was more relevant to the commercial environment (e.g., Seely Brown & Duguid 1991, 1996; Stewart 1996). One of the most popular work related definitions of a CoP was offered by John Seely Brown and Estee Solomon Gray in their 1995 article called "The People Are the Company":

"At the simplest level, they are a small group of people … who've worked together over a period of time. Not a team not a task force not necessarily an authorised or identified group … they are peers in the execution of "real work". What holds them together is a common sense of purpose and a real need to know what each other knows" (Brown & Gray, 1995).

In 1998, Wenger (1998) published the results of an ethnographic study of a claims processing unit in a large insurance company that described how employees exchanged knowledge during meetings and by the passing of handwritten notes. He proposed a view of the company not as a single community, but as a constellation of interrelated CoPs. CoPs arise out of the need to accomplish particular tasks and can provide learning avenues that exist within, between and outside organisations. CoPs are formed through mutual engagement in a joint enterprise and will share a repertoire of common resources (e.g., routines, procedures, artefacts, vocabulary) that members develop over time.

Thus, according to Wenger (1998) a CoP becomes defined in terms of:

- What it is about:

The particular area of activity/body of knowledge around which it has organized itself. It is a joint enterprise in as much as it is understood and continually renegotiated by its members.

- How it functions:

People become members of a CoP through shared practices; they are linked to each other through their involvement in certain common activities. It is this mutual engagement that binds its members together in a single social entity.

- What it produces:

The members of a CoP build up a "shared repertoire" of communal resources over time. Written files are a more explicit aspect of this, although less tangible aspects such as procedures, policies, rituals and idioms can also included.

Wenger (1998) also identified two key processes at work in CoPs: participation and reification. He described participation as:

"... the social experience of living in the world in terms of membership in social communities and active involvement in social enterprises" (Wenger, 1998, p. 55)

and reification as:

"... the process of giving form to our experience by producing objects that congeal this experience into thingness" (Wenger, 1998, p. 58)

Wenger emphasises that like LPP, participation and reification are analytically separable, but are inseparable in reality. Participation is the process through which people become active participants in the practice of a community and reification gives concrete form to the community's experience by producing artefacts. One is meaningless without the other and vice versa. In day-to-day work, people both negotiate meaning through participation in shared activities and project that meaning onto the external world through the production of artefacts.

Wenger's (1998) work with CoPs shows that the concept can be applied in a business setting. Since then, several other authors have identified the business benefits of CoPs (e.g., Fontaine & Millen, 2004: Lesser & Storck, 2001). However, almost all of the previous work on CoPs has described co-located communities. With the increasing globalisation of business and the heavy reliance on information and communication technology (ICT), the next question is "Can CoPs continue to operate in a modern business environment?"; that is, "Can a CoP be virtual?"

FUTURE TRENDS

Concerning the future of CoPs, and virtual CoPs in particular, two main issues must be considered. The first concerns the relationship between a CoP and its wider (electronic) environment; the second concerns the nature of the "work" that CoPs do; that is, do processes in a virtual CoP differ from one that is co-located?

CoPs in an Electronic Environment

Internet-based networking technologies, which can provide a single platform for groups or networks of groups to form within larger organisations, have led to the development of various forms of virtual groups and communities. Seely Brown and Duguid (2000) coined the phrase "networks of practice" (NoPs) to describe one type of virtual group. NoPs are composed of people who are geographically separate and may never even get to know each other, but who share similar work or interests. Thus, NoPs are organised more at the individual level and based on personal social networks than CoPs with their notions of mutuality and the collective social will of the community.

In a study of job seeking activity, Granovetter (1973) introduced the notion of strong and weak social ties. In terms of the previous description, CoPs are characterised by strong social ties, whereas NoPs are characterised by weak social ties. Within a wider network consisting of weak ties, an individual may act as a "local bridge" or broker that enables the network to react more quickly and provide a coordinated response. Nevertheless, within a network there is also a need for strong ties to encourage local cohesion and avoid fragmentation that would make knowledge sharing and the adoption of innovation more difficult.

CoPs can be seen in the role of hub for the wider network, providing a more tightly knit sub-network that serves as knowledge generating centres for the larger NoPs. CoPs can act as bridges drawing together different groups and combining knowledge in new ways. They can also provide the access points for individuals to engage with the wider network and to establish a local identity within the larger organisation. Previous research has shown that the most common distributed form of a "virtual" CoP has a co-located active core (Hildreth, Kimble & Wright, 1998), which tends to support this view of distributed working.

A more recent example was provided by Lundkvist's (2004) study of customer networks as sources of innovation. This case study was generated from a long-term study of the Cisco Systems newsgroup, which identified user networks as peripheral and yet vital sites of innovation. In this case, the co-located core of the network was provided by a group of university technicians.

Work in Virtual CoPs

How might the balance between reification and participation be maintained in virtual working? This issue was addressed in an earlier paper (Kimble, Hildreth & Wright, 2000) where we described how a geographically distributed CoP managed both hard (reified) and soft (social) knowledge. In this case, the CoP was made up of four members co-located in the UK, a group of five members in the USA and one member in Japan.

In this situation, it might have been expected that sustaining participation would be more difficult and therefore reification would play a greater role. However, the findings of the case study showed that this was not necessarily the case. Shared artefacts, such as a planning document, did play an important role but the importance of social relationships remained paramount. While the group was able to sustain itself using e-media, it was still dependent on the development of relationships in the physical environment through face-to-face meetings.

It is interesting to observe how artefacts such as a planning document (reification) were used not only as ways of projecting knowledge from within the CoP but were also instrumental in the process of creating it (participation). The document stimulated discussion, problem solving, innovation and further participation. It was used both to drive meetings and as the focus of meetings. During discussions based on the document, new and innovative ideas would be triggered that could form the basis for new projects. Thus, as well as acting as a stimulus for innovation, the document acted as a catalyst leading to further participation.

A similar account can be found in Bradshaw, Powell and Terrell (2004) that describes how a team of remote workers developed into a CoP. They describe not only how the group deploys a variety of technologies to maintain contact but also the efforts that went into building commitment, ownership, engagement and focus in the group. In this case, the members of the group were all engaged in collaborative research. Writing about their work and presenting papers for peer- review was seen as a key factor in maintaining cohesion and developing the community's shared understanding of goals, development of knowledge and sense of belonging.

CONCLUSION

Reporting on a recent case study of how CoPs translate to a geographically distributed international environment, Hildreth (2003) throws further light on a number of these issues. The study examines the work of an internationally distributed CoP that spans three continents. In particular, it highlights the role that shared artefacts play in the process of creating, sharing and sustaining both types of knowledge and highlights the role that the creation of artefacts plays in enabling and sustaining participation in CoPs. Hildreth (2003) observes that the process of creating the artefact and regular (although not necessarily frequent) face-to-face contact are instrumental in maintaining the relationships that allow a CoP to function successfully in a virtual environment. Thus, paradoxically, it appears that one of the keys to a successful virtual CoP is an occasional, non-virtual, face-to-face meeting.

However, the changes that are sweeping the corporate infrastructure mean that increasingly workers find themselves forced into one or another form of virtual working. Instead of inhabiting a world of fixed roles with easy access to co-located resources, today's workers are increasingly based in a world of weak ties where resources are only obtained through personal and individual relationships. Rather than being embraced by a collective CoP, workers often find themselves functioning as individuals and building up networks, one contact at a time. Again, paradoxically, as social networks such as NoPs become more important, the fundamental unit for many examples of virtual working is not the group but the individual. This is not to say that collective groups such as CoPs and teams have ceased to exist but simply that the difficulty of building and maintaining the strong social ties needed to build a sense of community in a virtual environment should not be underestimated.

KEY TERMS

Artefact: An artefact in the context of CoPs indicates objects, articles, and "things" which have been created by the CoP to assist the members in their work and which may have some of the community's knowledge embedded in them. Artefacts do not have to be concrete – a process or procedure may be an artefact.

Communities of Circumstance: Communities of circumstance are driven by position, circumstance or life experiences. Communities of circumstance are distinguished from CoPs in that they tend to be personally focused and are often built around "life stages," such as teenagehood, university, marriage or parenthood.

Communities of Interest: Communities of interest are groups of people who share a common interest. Members exchange ideas and thoughts about the given interest, but may know little about each other outside of this area. Participation in a community of interest can be compelling and entertaining but is not focussed on learning in the same way as a CoP.

Communities of Practice: Communities of practice are groups of people who have a common goal and who are internally motivated to reach the goal. The members have some form of common background and shared language.

Communities of Purpose: Communities of purpose form around people who are to achieve a similar objective. Such communities only serve a functional purpose. Members of the community can assist each other by sharing experiences, suggesting strategies and exchanging information on the process in hand.

Hard Knowledge: Hard knowledge is unambiguous and unequivocal, can be clearly and fully expressed, can be formalised and structured, can be "owned" without being used and is both abstract and static: it is about, but not in, the world.

Knowledge Management: Knowledge management is the means whereby an organisation "manages" and leverages its knowledge resources. This can include reports, databases and patents; it also includes people – identifying experts, sharing knowledge, and helping people learn.

Legitimate Peripheral Participation: LPP is the process by which a newcomer gradually works his/her way towards full participation in the community. Lave and Wenger's (1991) examples were based on the apprenticeship model, where a newcomer (the apprentice) was allowed to undertake basic tasks. As they became more experienced, they were given more complicated tasks until they could fully participate in the practice of the community and became old-timers.

Network of Practice: People who are not directly connected to each other but still engage in similar kinds of activities are said to belong to a network of practice (NoP). NoPs link local communities whose members have similar interests and give a minimal coherence to the network.

Soft Knowledge: Soft knowledge is implicit and unstructured, cannot be articulated, can be understood without being openly expressed, is associated with action and cannot be possessed, is about what we do and is acquired through experience.

Virtual Organization in the Human Mind

Jinyoul Lee
State University of New York at Binghamton, USA

INTRODUCTION

Virtual organization has been well documented as both a tool for organizations to seek further profitability through the removal of traditional barriers as well as a method to extend the provision of services to clientele in a manner previously achievable by only large, multinational corporations (Markus, 2000). The widespread implementation of information technology and its many applications in modern business have moved the act of management toward a virtual focus, where managers are able to complete tasks through the use of teams in varying physical locations, with members that may or may not be employees of that firm, sharing a wide variety of data and information. With so many companies now employing virtual organization techniques, referring to a company as "virtual" or to its components as possessing "virtuality" lacks the clarity and specificity needed when using these firms as examples for others. The variety of methods through which a firm can achieve virtuality represents a span nearly as wide as the business community itself.

BACKGROUND

The earliest definitions of a virtual organization appeared when the concept of virtuality was applied to studies of management before information technology existed in a refined state to support the theory. Giuliano (1982) saw that with the addition of telecommunications and networking technology, there was little need for work teams to assemble at the same time or even a contiguous location. A structured concept of virtual organization was formed by Abbe Mowshowitz (1994, 2002). He defined a virtual organization in previous work as a group of employees communicating and being managed electronically through *metamanagement*. This concept defines the way in which a *virtual task* is managed and further categorizes a virtual organization as a series of virtual tasks completed by virtual teams in strategic global locations. As each team has a certain commitment to the parent organization, the similarity in purpose and communication style allows for clear distribution of work across multiple groups of organizational members.

As with Net-enabled organizations, the concept of virtual organizations has gained prominence among researchers and practitioners. As shown by the recent work of Schultze and Orlikowski (2001), virtuality can be understood through the perception of time and space. This paper extends the scope of the virtual organization in terms of *virtual space*, a metaphor used in time and space (beyond the constraints of the actual location we belong to) dimensions (Allcorn, 1997). As opposed to the virtual organization, time and space dimensions are constrained in traditional or "real" organizations. Time constraints occur in real organizations due to the operational time dimension of such organizations, while the space dimension occurs due to constraints of location.

It is true that a virtual organization inherits the attributes of virtual dimensions—a newly defined concept of time and space. In other words, a virtual organization does not exist in our time and space, but rather exists only in virtual space (perceptual world), which is only a metaphor of our consciousness and not reality. A virtual organization, in this sense, is the metaphor of our designed and structured consciousness that exists in virtual space to perform the intended actions of interest. However, the most important thing in a virtual organization is to identify the role of human actors who get involved in both the physical and the perceptual world. We attempt to explain the relationships between the human actors, the real and virtual organizations, and our perceptions of these concepts.

DUALITY OF HUMAN IDENTITIES

Metaphors play a very powerful role in structuring virtual organizations because terms like virtual space and virtual organization originate from symbolic languages (Faucheux, 1997). These metaphors provide the meaning of existence, thus we can treat the organization like a real organization in virtual space. Continuous analogical processes between virtual and real organizations explain the existence of virtual organizations because there exist similarities and discrepancies in them (Ahuja & Carley, 1999). A virtual organization, operating within virtual-space imagery, exists in our consciousness while an actual organization physically exists in various forms (more tangible or definable manner) such as culture, politics, resources, and so forth (Morgan, 1986). Although a virtual organization exists in our consciousness, it is associated with its physical counterpart in the real world. Allcorn (1997) described this counterpart as a parallel virtual organization and bureaucratic, hierarchical organization counterpart. However, there is a possibility that in the near future, a real organization will exist only when its virtual counterpart exists in virtual space. Mowshowitz (1994, 2002) described this as "a dominant paradigm" of virtual organization due to its unique advantages in the efficiency, cost, and effectiveness of goal-oriented activity. Surprisingly, human actors manage to control these two opposing ideas of real and virtual worlds; thus, it becomes obvious that humans possess duality of existence in both the real and the virtual world.

This paper discloses the social aspects of a virtual organization and identifies the role of human actors in a virtual organization (or consciousness in Faucheux, 1997). This consciousness exists in the perceptual world that we create beyond the limits of time and space (Allcorn, 1997). However, its counterparts exist in various forms (entities) in the real world. To bridge the gaps between the consciousness and the entities, there exists a need for human interveners who possess dual identities in both virtual and real worlds. This research provides the meaning of virtual organization, and proceeds to explain the relationship between the consciousness (virtual organizations) and entities (real organizations) with human intervention (human players).

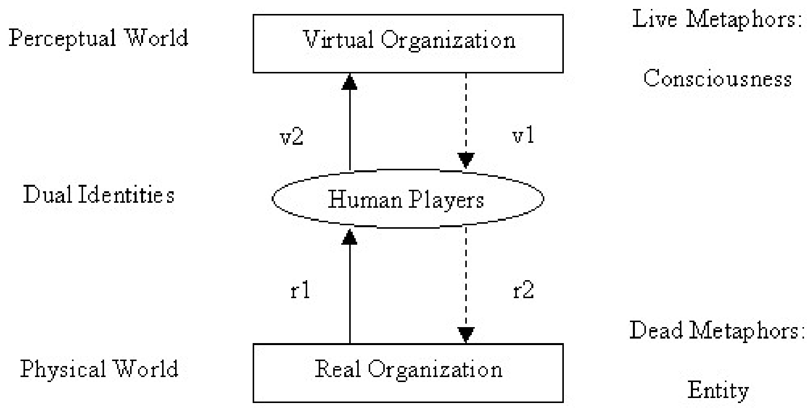
Schultze and Orlikowski (2001) examine rhetorical oppositions between real organizations and virtual organizations, and in doing so, apply metaphors to the discourse. The visions or views of two opposing elements are not divergent or dichotomous; rather, they offer substitutes for the opposition through a process referred to as dualism. As Orlikowski (1991) proposed in her earlier paper, "The Duality of Technology," this dualism is not mutually exclusive. The dualism originated from the admirable work by Giddens (1984), *The Constitution of Society*. Giddens' structuration theory integrated two main streams of sociology: objectivism and subjectivism. It appears that the structuration theory adopts the notion of phenomenology, as it seeks to make explicit the implicit structure and meaning in human experiences (Sanders, 1982). Phenomenology searches for the essence of what an experience *essentially is* and is the intentional analysis between objective appearance and subjective apprehension. Structuration theory (the process of structuration of an organization) seeks a complementary essence in the structure of organization science and in the process of struggles between objectivism and subjectivism. Interestingly, the conflict of objectivism and subjectivism was reflected in metaphors, as Lakoff and Johnson (1980, p. 189) stated:

Objectivism and subjectivism need each other in order to exist. Each defines itself in opposition to the other and sees the other as the enemy. Objectivism takes as its allies: scientific truth, rationality, precision, fairness, and impartiality. Subjectivism takes as its allies: the emotions, intuitive insight, imagination, humaneness, art, and a "higher" truth.… They coexist, but in separate domains. Each of us has a realm in his [or her] life where it is appropriate to be objective and a realm where it is appropriate to be subjective.

Human players have very important roles in both phenomenology and metaphors due to their valuable experience. The key differentiator between objectivism and subjectivism is always human experience. Another important fact (usually overlooked by researchers) is that the use of metaphors appears in both the physical world and in the perceptual world (Harrington, 1991) because the term organization itself results from "dead" metaphors. Tsoukas (1991) describes the process in which metaphors "have become so familiar and so habitual that we have ceased to be aware of their metaphorical nature and use them as literal terms." It implies that the metaphors of virtual organizations are "live" metaphors (Tsoukas) as we know "that these words are substitutes for literal utterances" that use dead metaphors (organization per se). Therefore, live metaphors are used to describe virtual organizations in another dimension, where we can do things that are not possible in the real world because the virtual world operates without the constraints of time and space, unlike the real world.

The process of structuration involves the reciprocal interaction of human players and institutional properties of organizations (Giddens, 1984); as Orlikowski (1991) pointed out, "the theory of structuration recognizes that human actions are enabled and constrained by structures, yet these structures are the result of previous actions." Because we live in both real and virtual worlds, we have both objective and subjective understandings of each world—dual identities. Figure 1 shows the relationship between real organizations and virtual organizations in the presence of human interveners. Both real and virtual organizations consist of rule resource sets that are implicated in their institutional articulation, thus these rule resource sets act as structures of the organizations (both virtual and real), where a structure is the medium and the outcome of organizational conduct. The structural properties do not exist outside of the actions of the organizational actors. Therefore, structural properties, related to space and time, are implicated in the production and reproduction of the organizations. In other words, both real and virtual organizations undergo structuration across the different sets of dimensions of time and space based on the perspectives of each human player.

Figure 1. Dual identities of human players in both real and virtual organizations



The above model, which is adopted from the duality of technology of Orlikowski (1991), depicts four processes that operate continuously and simultaneously in the interaction between human players and both real and virtual organizations. These processes include (a) institutional properties, represented by arrow r1 (objective appearance of the real organization) and arrow v1 (objective appearance of the virtual organization), which are the medium of human players; (b) structures, represented by arrow r2 (subjective construction of the real organization) and arrow v2 (subjective construction of the real organization), which are the product of human players; (c) the interaction of human players in both worlds and the resultant influences on the social contexts of the real organization within which it is built and used (the direction of arrow r1 and v2); and (d) how the virtual organization is built and used within particular social contexts in a real organization (the direction of arrow v1 and r2).

In Figure 1, there are two structurations from human players: one for the real organization and the other for the virtual organization. The realms of virtual organization and real organization are objective while the consciousness of the human player is subjective. The process of structuration (Figure 1) involves the reciprocal interaction of human players and institutional properties of organizations (Giddens, 1984). As Orlikowski (1991) pointed out, "the theory of structuration recognizes that human actions are enabled and constrained by structures, yet these structures are the result of previous actions." We have both objective and subjective understandings of each world (dual identities) because we live in both real and virtual worlds.

The maturity phase of the real organization (with its established tradition) and the fledgling state of the virtual organization (with its newly emerging phenomena) indicate that the objective appearance of the real organization (arrow r1) and subjective construction of the real organization (arrow v2) dominate the structuration process in modern organizations. Many observations show that the knowledge and experiences accumulated in a real organization enforce the formulation of the virtual organization in the abstraction process of efficient and effective goal-oriented activity (Mowshowitz, 1994). It is partly true that the creation of the virtual organization is only for the representation of the real organization in virtual space. A considerable amount of explanation arises from rethinking the basic assumptions of time and space. The real organization, whether tangible or intangible, is bound in time and space while the virtual organization, an imaginative concept established in computer hardware and software, is free from the constraints of time and space.

Barley and Tolbert (1997) defined an institution as "shared rules and typifications that identify categories of social actors and their appropriate activities or relationships." As they explained their recursive model (institutions and actions), institutionalization involves the behavior of revision or replication of organizational abstracts (work procedures) and entails objectification and externalization of behaviors. In this sense, the successful functioning of a virtual organization is reaching institutionalization in virtual space. Through this process, the virtual organization becomes stable and helps serve as the constitution where human players can follow their activities. Upon further inference, institutions from business processes of real organizations constrain human actors (constitutive nature, r1) who in turn construct institutions of virtual organization (constituted role, v2), and/or vice versa (from v1 to r2).

The above arguments provide complementary insights into the social process explained by the structuration theory (Giddens, 1984). In this theory, actions and institutions continuously interact, thereby determining the structure. The structuration theory lacks the explanation of how these interactions (revising and reproducing an institution or structure) are processed, although this is arguable as Giddens explains the role of reflection, interaction, and so forth. However, Barley and Tolbert (1997) clearly stated that their work, "the aim of institutional theory," is "to develop the implications of structuration theory for the interplay between actions and institutions and to address the practical problem of how to study institutional maintenance and change in organizations."

The authors believe that the results of this study are compatible with the belief of Barley and Tolbert (1997) that "the institutional perspective must come to grips with institutionalization as a process if it is to fulfill its promise in organization studies." The focus of this study is the explanation of what is going on in a virtual organization. The result revealed by this research is a rich description of theoretical induction. A limitation of this process is that it only reflects one part of the recursive model of institutional theory (Barley & Tolbert).

The approach of this paper is that organizational transformation is "the ongoing practices of organizational actors, and emerges out of their (tacit and not so tacit) accommodations to and experiments with the everyday contingencies, breakdowns, exceptions, opportunities, and unintended consequences that they encounter" (Orlikowski, 1996). The above statement is identical to the theoretical framework of this paper in that users of the system continuously interact with the system through producing, reproducing, and transforming work practices (Giddens, 1984).

Mowshowitz's (1997) depiction of a virtual organization is limited to a computer with a communication tool or computer network that increases the efficiency and effectiveness of organization performance (Mowshowitz, 1994). This paper complements the virtual organization as a social system giving the new meanings of time and space. This study rethinks the philosophy of the virtual organization, providing insight into the concept of the duality of human identity. It is not only a lens for understanding virtual organizations, but also a sociotechnical understanding of virtual organizations through structuration.

CONCLUSION

Organizations today are usually faced with a turbulent environment that requires flexible and dynamic responses to changing business needs. Many organizations have responded by adopting decentralized, team-based, and distributed structures. Advances in communication technologies have enabled organizations to acquire and retain such distributed structures by supporting coordination among people working from different locations (Abuja & Carley, 1998). Thus, virtuality plays an important role to achieve above goals of current business environments. The virtuality of a virtual organization can be seen as an "emptying" of the organization, where emptying of information and knowledge has occurred in current communication technology (Giddens, 1984, 1990). IT (or information systems) generates and stores information that helps in the emptying (separation) of information from organizations. Knowledge, a supposedly higher format of information, is managed by knowledge-management systems (KMSs), another evidence of the emptying of knowledge from organizations. Because data, information, and knowledge of organizations are emptying from their organizations (i.e., can be stored and manipulated in information systems), the separation of the organization from its four-dimensional entity (time factor and three location factors: latitude, longitude, altitude) can be achieved in the form of a virtual organization (Giddens) if the rest of the components of the organization are implemented in network.

KEY TERMS

Collaborative Culture: By their nature, virtual organizations foster camaraderie between members even in the absence of face-to-face communications. Since the built-in communications tools are so easy to access and use, relationships form between members who have not even met. A corporate culture forms out of friendship that produces a highly collaborative nature unlike traditional organizations where such extensive communicating is not required.

Complementary Core Competencies/The Pooling of Resources: The ease with which two members of a virtual organization can communicate allows them to pool their resources, even with members not directly involved in a specific project. Separate entities can quickly be called upon to provide secondary service or consult on a project via virtual channels.

Customer-Based/Customized Products: A virtual organization provides the unique opportunity to provide their customers with highly specialized products as per their specific needs. This can be accomplished through outsourcing work to a separate organization or through the use of a virtually connected interorganizational node located closer to the customer. Either way, it becomes simple to add a function based on the customer's request and seamlessly integrate that function into the existing framework.

Electronic Communication: A vital concept to the virtual organization is the ability to communicate through purely electronic means, eliminating the need for physical contact and allowing the geographical dispersion of organization members. Online collaboration via e-mail, discussion boards, chat, and other methods, as well as telephone and facsimile communications, are primary contributors to the removal of time and space in this new organizational concept.

Explicit Goals: Similar to metamanagement, each member of the organization is charged with an explicit task to complete as it relates to the overall function of the organization. Often times, after this single goal is completed, the link between the organization and the entity is dissolved until a further need for it is realized. At this point, the link is reestablished.

Flexibility: Virtual organizations are, by their nature, flexible. Traditional organizational structures are rooted in the physical world and rely on structures, unalterable networks, and specific locations to function properly. Because of this, when it becomes necessary to introduce change into a specific organization, a barrier is reached where further alteration requires physical, costly modifications. A virtual organization is unhindered by these problems. These structures are designed so that they can operate regardless of time or place, independent of existing physical realities.

Functionally or Culturally Diverse: The nature of global diversity and the ability to locate organizational functions across the globe creates a diverse environment for the entire organization. Since members are all in different locations and charged with different tasks, diversity exists that is only found in the very largest multinational corporations.

Geographical Dispersion: The combination of virtual organization with IT allows groups of employees to make progress on one project while working in tandem with another group in a distant physical location. Because information can be shared and meetings can be held with the use of high-speed networks and computers, tasks can be carried out in the location that is most appropriate and germane to that function.

IT: Information technology is the crucial component of a modern virtual organization. Without advances in technology, many of the realities of today's virtual companies would be merely science fiction. These components include the Internet, LANs (local area networks) and WANs (wide area networks) for business, e-mail and online chat and bulletin boards, and real-time video conferencing. These technologies allow smaller work groups as part of a larger company operate independently of each other across a room or the globe.

Open Communication: The foundation of a virtual organization is its communications components that exist in absence of face-to-face exchanges. A virtual organization can only survive if its members communicate freely through the provided channels between them, be they based on the Internet or more traditional telephone technologies. The organization cannot continue to function unless it is aware of what all its members are currently completing and often times, when communication is more closed, work that is being completed in tandem by more than one member can be hindered or brought to a halt.

Participant Equality: Each individual facet of a virtual organization is expected to contribute an equal amount of work toward a given goal, if appropriate. While the equality may not be measured best in quantity, it can be restated as effort and the successful completion of all tasks assigned to it, be they large or small. Since every task is considered to be essential as a part of the project, the equality comes in the addition of that piece to a larger puzzle.

Sharing of Knowledge: Members of a virtual organization collaborate to share their knowledge gained from individual activities performed. Since collaboration is facilitated through the communications channels that are afforded through the virtual organization, it is common to find "knowledge bases" or other database systems that contain information and documents pertaining to past experience.

Switching: The switching principle is a fundamental advantage that a virtual organization has over a traditional one. Because the links between organizational functions are largely electronic and nonphysical, it is easy to replace a weak component with a stronger one. Where this activity could be considerably expensive if the item in question was a physical supply chain, it may only be a change of suppliers for the virtual organization and can be made with a phone call and database edit, as opposed to a building project.

Temporary: Virtual organizations are often formed to fill temporary needs, only extending to the end of the specific project that is charged to them. In a manufacturing project, a virtual organization may be formed between the engineers who design the project, suppliers who provide the raw materials, and the factory who processes those into finished goods. At the end of that particular project, those alliances are dissolved as they are no longer necessary to benefit the three independent groups.

Trust: The lack of physical interaction places a higher regard to the trust that exists between each entity involved in the organization. Since fewer "checks and balances" can be placed on appropriate departments, management and other entities trust that they will complete the appropriate work on time or be straightforward about delays or problems. If two entities working on a project together separated by thousands of miles are unwilling to trust each other, the work slows and suffers to a critical point.

Vague/Fluid/Permeable Boundaries: As a continuation of flexibility, the virtual organization is characterized by vague boundaries as to the extent of its use and purpose. Since small tweaks can easily and largely affect the overall organization, it is quite possible to extend the boundaries of an organization so that they encompass new purpose, people, or control.

Virtual Schools

Glenn Russell
Monash University, Australia

INTRODUCTION: THE EMERGENCE OF THE VIRTUAL SCHOOL

Until recent times, schools have been characterised by the physical presence of teachers and students together. Usually, a building is used for instruction, and teaching materials such as books or blackboards are often in evidence. In the 20th century, alternatives to what may be called "bricks-and-mortar" schools emerged. These were forms of distance education, where children could learn without attending classes on a regular basis. The technologies used included mail, for correspondence schools, and the 20th century technologies of radio and television.

Virtual schools can be seen as a variant of distance education. Russell (2004) argued that they emerged in the closing years of the 20th century and can be understood as a form of schooling that uses online computers to provide some or all of a student's education. Typically, spatial and temporal distancing is employed, and this results in students being able to use their computers at convenient times in their homes or elsewhere, rather than being subject to meeting at an agreed upon time in a school building.

The concept of a virtual school is agreed upon only in broad terms, as there are a number of variants. Some virtual schools insist on an agreed upon minimum of face-to-face contact, while others are so organized that a student might never set foot in a classroom. It is possible for a virtual school to have no physical presence for students to visit, and an office building in one state or country can be used to deliver virtual school services to interstate or international students.

One way of categorizing virtual schools is by imagining where they might be placed on a scale of face-to-face contact between students and teachers. At the conservative end of this scale, there would be conventional schools, where students use online computers in classrooms or labs for some of their lessons. A trained teacher in the same subject area might be available to help students, or other teachers, volunteers, or parents could supervise them.

Toward the middle of such a scale would be mixed-mode examples, where some subjects are offered in virtual mode, but students are asked to visit the school on a regular basis to monitor their progress or to participate in other face-to-face subjects, such as sport, drama, or art. At the other end of the scale are virtual schools where the student and teacher never meet, and there is no requirement for the student to enter a school building for the duration of the course. One example of such a virtual school is Florida High School, where, as the Florida High School Evaluation (2002) noted, there is no Florida High School building, and students and teachers can be anywhere in the world.

FACTORS PROMOTING THE RISE OF VIRTUAL SCHOOLS

The principal factors that account for the growth of virtual schools include globalisation, technological change, availability of information technology (IT), economic rationalism, the model provided by higher education, perceptions about traditional schools, and the vested interests of those involved in them.

The first of these factors, globalisation, refers to a process in which traditional geographic boundaries are bypassed by international businesses that use IT for globally oriented companies. It is now possible for curriculum to be delivered remotely from across state and national borders. Educational administrators can purchase online units of work for their school, and parents in developed countries can sometimes choose between a traditional school and its virtual counterpart.

As IT continues to develop, there is a correspondingly increased capacity to deliver relevant curricula online. As broadband connections become more common, students will be less likely to encounter prolonged delays while Web pages load or other information is downloaded. Advances in computers and software design have led to developments such as full-motion video clips, animations, desktop videoconferencing, and online music. Collectively, what is referred to as the Internet is already very different from the simple slow-loading Web pages of the early 1990s.

Economic rationalism also drives the spread of virtual schools, because the application of economic rationalism is associated with productivity. For education, as Rutherford (1993) suggested, the collective or government provision of goods and services is a disincentive to private provision, and deregulation and commercialisation should be encouraged. Consistent with this understanding is the idea that schools, as we know them, are inefficient and should be radically changed. Perelman (1992) argued that schools are remnants of an earlier industrial age that ought to be replaced with technology.

The ways in which higher education has adopted online teaching provide an example of how online education can be accepted as an alternative. The online courses provided by universities in recent years have proliferated (Russell & Russell, 2001). As increasing numbers of parents complete an online tertiary course, there is a corresponding growth in the conceptual understanding that virtual schooling may also be a viable alternative.

Those convinced that existing schools are unsatisfactory can see virtual schools as one alternative. Criticism of schools for not adequately meeting student needs, for providing inadequate skills required for employment, or not preparing students for examinations and entrance tests, are continuing themes that can be identified in a number of educational systems. Discussions related to school reform can include funding, resourcing, teacher supply, curriculum change, and pedagogy, but they can also include more radical alternatives, such as virtual schooling.

PROBLEMS OF VIRTUAL SCHOOLS AND THEIR SOLUTIONS

Virtual schools face a number of challenges related to the way that teaching and learning are implemented in online environments. While similar problems can also be identified in conventional schools, the different natures of virtual schools serve to highlight these concerns. These problems include authenticity, interactivity, socialzsation, experiential learning, responsibility and accountability, teacher training, certification, class sizes, accreditation, student suitability, and equity.

The first of these problems, authenticity, relates to the verification of the student as the person who has completed the corresponding assignments and tests from a virtual school. Virtual schools may assign students a secure password to use over the Internet, but this procedure would not preclude students from giving their passwords to a parent or tutor who completed the work on their behalf. A possible solution that may have to be considered is to independently test students to confirm that they have the understanding, knowledge, and skills suggested by their submitted work.

Interactivity describes the relationship between the learner and the educational environment. For virtual school students, there is an interactive relationship involving the multimedia, the online materials used, and the teacher. Students would typically access materials on the World Wide Web, respond to them, and send completed work electronically to their teachers. The preferred way for students to become involved in online learning is to have an active engagement involving a response. If a student is directed to a static Web page containing a teacher's lecture notes, learning may be less effective, unless other teaching methods are used to supplement it. The solution to this problem will be found in both the increased capability of students' online computers to operate in a rich multimedia environment, and the recognition by course designers that virtual schools should take advantage of advances in learning theory and technological capability.

Socialization continues to be a problem with virtual schools, because there is an expectation in conventional schooling that students will learn how to work cooperatively with others and will internalize the norms and values necessary for living in a civilized community. Moll (1998) is concerned with disruption to the tradition of public education as the primary vehicle for the transference of national narratives and humanistic and democratic values. Clearly, socialization will still occur if students use online learning supplemented by some contact with teachers and opportunities for organized sports. However, students' ability to relate to others in society is likely to change. Despite this concern, a type of virtual school that routinely insists on organized face-to-face learning and social situations, with peers, teachers, and other adults, will reduce the problems that otherwise are likely to arise

A related concern to that of socialization is the belief that Web culture is inherently isolating, and that by encouraging students to pursue their education with a virtual school, an existing trend toward loss of community may be exacerbated. Kraut et al. (1998) originally suggested that Internet use could be associated with declines in participants' communication with family members in the household, declines in the size of their social circles, and increases in depression and loneliness. However, more recent research (Kraut, Kiesler, Boneva, Cummings, Helgeson, & Crawford, 2002) found that negative effects had largely dissipated.

There are some teaching activities in conventional schools referred to as experiential. These usually involve some form of hands-on activity or physical interaction with others. Typically, a teacher will provide a demonstration, explanation, or modeling of what is to be learned, and activities that follow provide opportunity to correct errors. While virtual schools commonly offer subjects such as mathematics and social studies, the study of physical education, drama, art, and the laboratory component of science is more problematic. Sometimes the problem does not arise, because students will enroll only for subjects that they missed or that they need for credit toward a qualification.

A common solution to these problems is for the virtual school to provide online or print-based teaching materials, as with other subjects in the range to be offered. Students complete the activities and send evidence of the completed work to the school. The Open School (2002) in British Columbia, Canada, offers art in both elementary and secondary school levels. At the Fraser Valley Distance Education Centre (2002), students are invited to participate in a science fair by sending in digital pictures and a digital video clip of their project to the supervising teacher.

Changing notions of responsibility, accountability, and student discipline are also likely to arise in virtual school environments (Russell, 2002). In a traditional school, teachers accept responsibility for the students in their charge, including the prevention of physical injury, and accountability for using appropriate teaching techniques. When there is a spatial and temporal distance between teacher and student, teachers are unable to exercise some of their accustomed responsibilities. While there is still a requirement to act ethically, and to ensure that appropriate teaching materials and methods are used, much of the responsibility shifts to parents, students, and to the suppliers of the online materials.

Teacher training is also emerging as an area of concern. Virtual teachers will find that some new skills are required, while others are less important. Class management skills in a face-to-face environment will differ from their online equivalents, as will many of the teaching practices. Salmon (2002) identified a number of skills that will be required by online teachers in the future. It is clear that there will be an ongoing need to use technological skills and to apply these skills to an appropriate educational context. However, it is unlikely that many teachers' colleges and other providers of trained teachers have modified their courses to reflect these changes, as mainstream teacher education is still focused on conventional school education. There are, nevertheless, some hopeful signs. The California Virtual School Report (2002) provided evidence of the use of online modules for teachers at Durham Virtual High School, in Canada, and a 15-week teacher-training program in Fairfax County School District.

Parents would normally expect that the virtual teacher working with their child would be a competent online teacher and be certified or registered with the corresponding school system. Where a student is working from home, and the principal contact with the teacher is by e-mail, the anonymity of the communication mode could conceivably cover the use of unqualified teachers. The necessity for demonstrating that a high-quality educational experience is being supplied is, however, likely to reduce this possibility. Florida Virtual High School uses only certified classroom teachers (Schnitz & Young, 2002, p. 4). As the online environment becomes more competitive, it is likely that virtual schools will provide evidence of their teachers' certifications.

With conventional schools, the issue of class sizes is a perennial problem. The diversity of virtual schools means that it is not easy to determine corresponding workloads. The evaluation of Virtual High School (VHS; Kozma et al., 2000) revealed that some of the teachers involved in the case study had to complete their VHS work at home in addition to their normal teaching load during the day. When teachers are asked to take responsibility for large groups of students, the time available for individual attention is likely to be reduced, and the quality of the educational service provided may be less satisfactory. There are indications that some virtual schools have recognised this problem. Louisiana Virtual School (2002), for example, is limited to 20 students per course.

Accreditation of courses across geographic regions will also become an increasing problem. Palloff and Pratt (2001) noted concerns with the quality of online high school programs as early as 2001. Varying standards can mean that a course in one area is not recognized in another. Students will increasingly be able to choose programs across state and even national borders and complete their schoolwork by sitting at home with their computers.

An important item relating to the quality of a student's educational experience in a virtual school is the recognition that not all students are suited to online learning. Already, some virtual schools try to determine whether the prospective student is suited to online learning by using questionnaires. Typically, these questionnaires ask students about their independent learning skills, motivation, time management abilities, and comfort with technology.

If virtual schools are perceived to be advantageous for those enrolled in them, there are also concerns as to when the access to them is seen as inequitable. Bikson and Paris (1999) found that there were "highly significant differences in household computer access based on income" (p. 9), in the United States. It is reasonable to assume that households with children will have less access to computers to use in a virtual school if they are part of a disadvantaged group. Unless there is careful planning, the use of technology-mediated education is likely, in the short term, to further entrench those inequalities that exist in society.

FUTURE TRENDS IN VIRTUAL SCHOOLS

Two broad trends can be identified in the growth of virtual schools. These are the continued expansion in the number of virtual schools, and the trend from virtual high schools to virtual K–12 schools. Research by Clark (2001, p. 3) indicated that more virtual schools began their operations in the United States during the period 2000–2001 (43%) than in the previous 4 years combined. Fifty-one percent of virtual schools surveyed offered junior high and middle school courses as well as high school courses, and about one in four schools offered courses across the whole K–12 spectrum (Clark, 2001, p. 4). In Canada, there is also evidence of growing demand for virtual schools. The 2-year cumulative growth rate for Alberta virtual schools was 125% (SAEE, 2002).

Collectively, the implication of these trends is that there will be increased attention devoted to those problems that arise from virtual schooling across the K–12 range. When virtual schools made their first appearance, it would have been possible for some educators to dismiss them because they were experimental, or ignore their existence because they catered only to a niche market of high school students. In some cases, this suggestion may still be valid, but support for virtual schooling is increasing, rather decreasing, and the nature of what is offered is becoming more comprehensive.

CONCLUSION

Virtual schools continue the tradition whereby students learn at a distance from their teachers. The availability of online courses through the Internet has simultaneously reduced the emphasis given to older forms of distance education, while it increased the opportunities for students to explore alternatives to traditional school education. It is likely that there will be an increase in the number of virtual schools, and that they will continue to attract students. The expected increase in the number and type of virtual schools is likely to provide both exciting possibilities and daunting challenges.

KEY TERMS

Bricks-and-Mortar Schools: These are traditional schools, where students attend at a physical school building.

Distance Education: A generic term referring to education where teachers and students are geographically separate. Modes employed include print and nonprint technologies.

Experiential Learning: Learning based on direct and unmediated instruction or on physical interaction with people and materials.

Globalization: The bypassing of traditional geographic borders using information technology to enable global orientation of business and remote curriculum delivery.

Interactivity: The relationship between the learner and the educational environment.

Socialization: The process by which students internalize the norms and values necessary for living in a civilized community.

Virtual School: A form of schooling that uses online computers for part or all of a student's education.

V

Virtual Teams as Sociotechnical Systems

Haydee M. Cuevas

Stephen M. Fiore
University of Central Florida, USA

Eduardo Salas
University of Central Florida, USA

Clint A. Bowers
University of Central Florida, USA

INTRODUCTION

A virtual team can be described as an organizational unit unconstrained by geographical, temporal, organizational, and/or national boundaries (Townsend, DeMarie & Hendrickson, 1998). Despite their rising popularity, numerous issues exist surrounding how virtual teams can productively coordinate their resources, activities, and information, often in dynamic and uncertain task environments (Fiore, Salas, Cuevas & Bowers, 2003; Townsend et al., 1998). With organizational structure increasing in complexity to include both co-located and virtual team members, explicit linkages between theory and practice are critically needed to mitigate the negative effects that technology-mediated interaction may have on virtual team productivity. Our goal here is to demonstrate how classic and current theories and principles from organizational psychology can be effectively integrated within a sociotechnical systems framework to address the unique challenges faced by this subset of teams. Specifically, we analyze the effects that collaborative information technology and lack of co-location may have on virtual team members. We conclude with suggested interventions for organizational practice.

BACKGROUND

Open Sociotechnical Systems

Radical changes in organizational structure brought about through advances in technology represent a critical challenge for the appropriate application of theoretically-based principles in system design. Researchers and practitioners need to focus on system design issues not only at the individual or task level, but also at the team and organizational level. This involves a system-level analysis (Hendrick, 1997) of the following sociotechnical factors that interact to shape organizational outcomes and may hinder attainment of organizational goals:

(1) *Personnel subsystem:* comprised of the organizational unit's members
(2) *Technological subsystem:* representing the technology available to the organizational unit
(3) *External environmental variables:* which act upon the organizational unit

Taken as a whole, these subsystems collectively represent the organizational unit as a *sociotechnical system*. Because the organizational unit both acts on and is acted upon by external forces, it would be considered an *open* sociotechnical system (Emery & Trist, 1960). Thus, the organizational unit can be viewed as a complex set of dynamically intertwined and interconnected elements, including inputs, processes (throughputs), outputs, feedback loops, and the environment in which it operates and interacts (Katz & Kahn, 1966).

Team Opacity in Distributed Environments

The technological component, in particular, plays a key mediating role by setting limits upon the system's actions as well as by creating new demands that must be reflected in the internal structure and goals of the organizational unit (Emery & Trist, 1960). In distributed environments, the technological subsystem may have a potentially greater effect on team member interactions than would be expected in traditional co-located task environments. Virtual teams rely primarily on electronic communication processes to work together both synchronously (e.g., video conferencing, Internet chat rooms) and asynchronously (e.g., electronic mail, bulletin boards) to accom-

Table 1. Factors influencing virtual team productivity

Factor	Definition/Description	Impact on Virtual Team Productivity
INPUT FACTORS		

Resources	Personnel subsystem:
	• Individual member knowledge, skills, attitudes
	• Team size, composition
		• May be differentially affected by technological subsystem limitations (e.g., media richness, information synchrony)
		• With low media richness, team opacity may:
		  • filter out critical paralinguistic cues
		  • hinder development of mutual trust (Avolio et al., 2001; Fiore, Salas & Cannon-Bowers, 2001)
		• Conversely, lack of visual cues may lead to:
		  • greater focus on task-relevant member attributes (e.g., skills)
		  • less focus on task-irrelevant stereotypical attributes (e.g., race)
		  • selection of leaders that more closely embody team values, ideals, and goals (McKenna & Green, 2002)

Task Demands	Nature of task (e.g., task complexity) and other work structure factors (e.g., communication channels) that form technological subsystem and external environment	• Team opacity may lead to:
		  • limited ability to monitor task-relevant cues provided by geographically dispersed teammates
		  • over-reliance on explicit communication strategies, resulting in poor task performance under conditions of high workload and task complexity (Entin & Serfaty, 1999)
		  • additional cognitive workload upon memory processes, inducing greater occurrence of memory failures (Fiore, Cuevas, Schooler & Salas, in press)

THROUGHPUT FACTORS		

Combination Processes	Various *implicit* (i.e., tacit) and *explicit* (i.e., overt) team processes and/or behaviors (e.g., communication, coordination, decision making) necessary to accomplish team's goals and/or task objectives	• With low media richness (e.g., electronic mail), team opacity may limit or altogether eliminate use of:
		  • nonverbal, paralinguistic cues (e.g., hand gestures) when conveying information crucial to completion of complex tasks (Tang, 1991)
		  • beneficial information yielded in *process* artifacts emerging from collaborative work (Tang, 1991)
		  • implicit communication and/or coordination strategies (Fiore et al., 2003)

Process Losses	Loss in team productivity resulting from poor coordination among members (i.e., lack of simultaneity of effort) and/or decreased social motivation (Steiner, 1972)	• Due to lack of nonverbal cues, ambiguous nature of distributed interaction, and subsequent over-reliance on explicit strategies (Fiore et al., 2003), team opacity may:
		  • negatively impact execution of combination processes needed to attain desired outcomes
		  • impede evolution of mutual trust, collective efficacy, and group cohesion, leading to poorly developed team attitudes and decreased social motivation

Motivation	Intrinsic and extrinsic factors that lead an individual to engage in a particular behavior or choose one course of action over another (Locke & Latham, 2002); motivation theories (e.g., goal-setting, self-regulation) focus on the underlying behaviors necessary to accomplish set goals (Bandura, 1986; Locke & Latham, 2002)	• Team opacity may negatively impact:
		  • *goal commitment* due to impoverished nature of interaction and lack of motivating influence of paralinguistic cues inherent in face-to-face interactions (Teasley, Covi, Krishnan & Olson, 2000)
		  • development of common, engaging *direction* for virtual team, depending upon information flow (i.e., synchronous or asynchronous), resulting in poor motivation to meet training and/or performance objectives (Fussell et al., 1998)
		  • *collective efficacy* (i.e., members' belief in their team's ability or competence to attain desired outcomes; Bandura, 1986) due to limited opportunities for monitoring and evaluating other members' performance (Fiore et al., 2003)

Shared Mental Models (SMMs)	Shared understanding among team members of each member's roles and responsibilities, task demands, and team-level interactions required to meet these demands (Cannon-Bowers, Salas & Converse, 1993); SMMs improve team's ability to coordinate efforts, adapt to changing demands, anticipate needs of task and other members, and foster development of mutual trust (Avolio et al., 2001; Entin & Serfaty, 1999)	• Team opacity hinders SMM development due to decreased awareness of team member actions and expectations, resulting in:
		  • increased communication and coordination overhead due to over-reliance on explicit strategies (Entin & Serfaty, 1999)
		  • uncoordinated efforts, low team productivity, and unsuccessful attainment of organizational goals (Espinosa, Lerch & Kraut, 2004)
		  • diminished identification of role knowledge and poor source monitoring (Durso, Hackworth, Barile, Dougherty & Ohrt, 1998)
		  • poorly developed team attitudes (Fiore et al., 2001)

plish their tasks (Avolio, Kahai, Dumdum & Sivasubramanium, 2001). However, such technology-mediated interactions may increase the level of abstraction forced upon teams—a phenomenon referred to as *team opacity* (Fiore et al., 2003). Team opacity describes the experience of increased ambiguity and artificiality (i.e., unnatural quality) associated with distributed interaction. This decreased awareness of team member actions, resulting from a distributed organizational structure, creates an environment lacking in the rich visual, auditory, and social array of cues normally experienced in co-located team interaction, thereby limiting the use of implicit (i.e., tacit) coordination and communication strategies, and impeding the development of positive team attitudes and successful team evolution (Fiore et al., 2003).

FACTORS INFLUENCING VIRTUAL TEAM PRODUCTIVITY

Following a sociotechnical systems approach, we next discuss how the structure of information flow (i.e., synchronous or asynchronous) and format (e.g., text, audio, video) associated with distributed environments may contribute to team opacity and negatively impact productivity (for a full discussion, see Fiore et al., 2003). As with traditional co-located teams, virtual team productivity is critically dependent upon the *resources* available to the team, the *task demands*, and the *combination processes* enacted by the team which dictate how these resources are used to meet task demands (Steiner, 1972). Whereas the personnel subsystem comprises the virtual team's principle resources, the technological subsystem and environmental constraints drive the task demands. The degree to which combination processes (e.g., coordination, communication, decision making) are effectively executed is especially susceptible to the impact of team opacity on the occurrence of *process losses*, the team's *motivation* to achieve task objectives, and the development of a *shared mental model*. Table 1 summarizes these important input and throughput factors, highlighting the potential effect of team opacity.

FUTURE TRENDS

In distributed environments, the technological subsystem sets significant limits upon the personnel subsystem's actions and creates new demands for optimal team productivity that must be addressed through training interventions and system design. Moreover, a virtual team is a *dynamic* organizational unit, developing as activities strengthen the quality of team member interactions (Morgan, Salas & Glickman, 1993). Fiore et al. (2003) described how these issues can be conceptualized within a distributed coordination space where virtual teams interact, evolve, and mature over *time* and *space*. Specifically, these activities, so critical to team development, occur not only during *in-process* interaction, but also during *pre-* and *post-process* interaction. Whereas in-process interaction occurs during actual task execution, pre-process interactions involve preparatory pre-task behaviors (e.g., planning session) where initial shared expectations are created in anticipation of team interaction (Fiore et al., 2001). Similarly, post-process interactions (e.g., after-action review) include post-task reflection on performance (Smith-Jentsch, Zeisig, Acton & McPherson, 1998). Such antecedent and/or consequent behaviors are critical to the team evolution and maturation cycle. Table 2 summarizes several organizational practices that can be employed at each of these stages to foster team development and the successful execution of team processes. Future research is clearly warranted to empirically evaluate the effectiveness of these interventions on virtual team productivity. Our goal in this article was to demonstrate how organizational psychology theories could be effectively integrated within a sociotechnical systems framework to address the unique challenges faced by virtual teams. Though much work still remains to be done and many questions still remain unanswered, we hope the issues set forth here will inspire others to explore further ways to achieve this goal.

CONCLUSION

As the prevalence of virtual teams increases, researchers must continue to address issues surrounding their design, implementation, and management. We must identify the sociotechnical factors that both help and hinder effective virtual team productivity so as to maximize their potential while mitigating the occurrence of process losses. Adopting a sociotechnical systems approach to investigate how team opacity interacts with these unique task demands and situational constraints to alter team processes and products will enable organizations to effectively utilize the technological subsystem's capabilities to support virtual team productivity. Similarly, a better understanding of the distinct forms of group dynamics that may emerge in virtual teams will advance the design of appropriate training interventions. Unquestionably, the future success of virtual teams within organizations will depend upon the joint optimization of the personnel and technological subsystems comprising this unique sociotechnical system.

Table 2. Pre-, in-, and post-process interventions to promote virtual team productivity

Intervention	**Rationale and Relevant Theoretical/Empirical Work**
PRE-PROCESS	

Pre-Task Briefing	• Specifying clear, challenging yet attainable goals may lead to:
	  • increased effort on task, better use of strategies, and commitment to team (Locke & Latham, 2002)
	  • better SMM of task demands and team-level interactions required to meet these demands (Cannon-Bowers et al., 1993)

Pre-Task Interaction	• Initial face-to-face or technology-mediated (e.g., video conferencing) pre-task interactions may facilitate development of:
	  • trust and cooperation among team members (Rocco, 1998; Zheng, Bos, Olson & Olson, 2001)
	  • team's social identity and positive team attitudes (Bos, Olson, Gergle, Olson & Wright, 2002; Zheng et al., 2001)

Team Building Exercises	• Distinct training interventions aimed at improving the effectiveness of team processes and operations by prompting members to evaluate their behaviors and relationships (Tannenbaum, Beard & Salas, 1992) • Valuable as both pre-process and in-process interventions

Role Identification (RI) & Interpersonal Relations (IR)	• Most beneficial for fostering positive team attitudes and commitment to team
	  • RI: identifies each member's roles and responsibilities to minimize any difficulties arising from role conflict or role ambiguity
	  • IR: improves relations among team members

Goal-Setting (GS) & Problem-Solving (PS)	• Well suited to enhance processes by which virtual teams use their resources to meet task demands
	  • GS: assists teams in setting individual and group goals, and determining strategies to meet these objectives
	  • PS: guides team members in developing requisite skills for identifying relevant elements in a problem (e.g., givens, goals, obstacles/constraints) and employing effective problem-solving strategies

IN-PROCESS	

Technological Support Tools	• Designed to increase awareness of member actions and provide feedback on performance to enhance combination processes (e.g., coordination) and foster development of positive collective efficacy (Steinfeld, Jang & Pfaff, 1999)
	  • *Team-level*: inform distributed workgroups of member actions and important changes in within-team and external information, without diverting their attention away from central tasks (Cadiz, Fussell, Kraut, Lerch & Scherlis, 1998)
	  • *Individual-level*: provide powerful and flexible tools with which to interact with shared workspace and its artifacts (Gutwin & Greenberg, 1998)

Cross-Training	• Particularly effective in fostering SMM development (Cannon-Bowers et al., 1993) • Helps members better understand each other's roles and responsibilities • Enables members to more accurately predict and anticipate each other's behavior and make greater use of implicit team processes (Entin & Serfaty, 1999)
Team Adaptation and Coordination Training (Entin & Serfaty, 1999)	• Focuses on building team's SMM • Enhances teamwork behaviors and coordination strategies by increasing quality and quantity of cues utilized by teams, leading to improved decision-making performance • Adaptive to varying levels of stress and workload
Cue-Recognition Training	• Increases saliency of critical aspects of task environment (Salas, Cannon-Bowers, Fiore & Stout, 2001) • Decreases occurrence of memory failures and increases probability that team members recognize when critical cues have been missed
POST-PROCESS	

Debriefing Sessions & After-Action Reviews	• Involves careful, well-structured dissemination of feedback information (Cannon-Bowers et al., 1993)
	• Promotes positive collective efficacy by prompting guided team self-correction and involving team members in self-regulation of their performance (Smith-Jenstch et al., 1998)
	• Strengthens team's SMM by:
	  • fostering shared knowledge regarding expectations and specific preferences of team members and effective teamwork processes (Smith-Jenstch et al., 1998)
	  • increasing source knowledge of member expertise (Libby, Trotman & Zimmer, 1987)

KEY TERMS

Explicit Team Processes: Openly articulated, overt communication and coordination behaviors. *Example*: Member A directly requests task-relevant information from Member B.

External Environment: Relevant work structure variables (e.g., task complexity) and other external forces (e.g., organizational climate) within the sociotechnical system that both act on and are acted upon by the organizational unit.

Implicit Team Processes: Largely unverbalized, tacit communication and coordination behaviors, founded on shared understanding of members' roles/abilities and task/situational demands. *Example*: Member A provides Member B with backup assistance without being asked.

Open Sociotechnical System: A complex set of dynamically intertwined and interconnected elements, including inputs, processes (throughputs), outputs, feedback loops, and the environment in which it operates and interacts.

Personnel Subsystem: Sociotechnical system component comprised of the organizational unit's members, including individual knowledge, skills, and attitudes, and team size and composition.

Team Opacity: Increased level of abstraction forced upon virtual teams due to the over-reliance on technology-mediated interactions; involves an experience of increased ambiguity and artificiality (i.e., unnatural quality) associated with distributed interaction, which inherently lacks the rich visual, auditory, and social array of cues traditionally available to co-located teams.

Team Productivity: Degree to which a group of two or more individuals can successfully coordinate their efforts to perform a task.

Technological Subsystem: Sociotechnical system component representing the technology (e.g., collaborative information technology) available to the organizational unit, influencing the nature of information flow (synchronous or asynchronous) and format (e.g., text, audio, video).

Virtual Team: An organizational unit that is unconstrained by geographical, temporal, organizational, and/or national boundaries, and whose members rely upon electronic communication processes to work together both synchronously (e.g., video conferencing) and asynchronously (e.g., electronic mail) to accomplish their tasks.

Virtual Work Research Agenda

France Bélanger
Virginia Polytechnic Institute and State University, USA

INTRODUCTION

The paper by Bélanger, Watson-Manheim, and Jordan (2002) addresses the gap between research conducted and practitioner concerns in virtual work. One of the key difficulties in conducting research in this area is the overlap between terms used (McCloskey & Igbaria, 1998; Pinsonneault & Boisvert, 2001). While there are other distributed work arrangements such as hotelling, neighborhood work centers and flextime, most of the previous literature has focused on telecommuting (telework) and virtual teams/organizations. In this article, the term virtual work represents work environments where individuals spend some time working in a non-face-to-face (FTF) mode, using information and communication technologies to perform work activities.

Virtual work environments are increasingly employed by organizations. While there is increased complexity and potential for problems, virtual work strategies allow organizations a great deal of flexibility to compete in a rapidly changing business environment. While existing research provides insights into such environments, it does not clearly deal with major concerns faced by managers (referred to as the "gap" between research and practice). One of the potential reasons for this gap is that practicing managers are concerned with current challenges in their own work setting while academics are concerned with developing more generalizable rules and understanding.

This article addresses these issues, with three particular objectives:

1. examine the gap between research and practice in virtual work;
2. investigate factors leading to the gap; and,
3. identify a research agenda that addresses emerging issues and concerns relevant to practice in virtual work.

BACKGROUND

To explore the gap between virtual work research and practice, the authors first review previous literature, which they then compare to concerns raised by practitioners in two organizations. To identify relevant academic research, the authors searched for articles in mainstream IS journals. They then used the "snowball" technique, mining citations in articles for further references. They did not include the large number of conference papers and studies of home-workers, entrepreneurs, or supplemental work at home. They focused on empirical and/or theoretically grounded studies.

Literature Review

Their review of recent literature (1998 to 2001) revealed six literature reviews and 35 empirical studies. In the original paper, a table including methodology details and key concepts was provided but is not included here for brevity, although sample references are provided. Overall, literature addresses the following questions:

- Who are the virtual workers? There are two types of studies that discuss who virtual workers are. The first type is descriptive, usually presenting demographics and other characteristics of virtual workers based on general surveys or public records (e.g., Johnson, 2001). The second type investigates characteristics of telecommuters (e.g., Bélanger, 1999b).
- How is communication influenced by virtual work? This area has been the most researched in recent years. The published work comprises studies of communication patterns (e.g., Bélanger, 1999a) and studies of choices of communication modes (e.g., Wiesenfeld, Raghuram, & Garud, 1999).
- What technologies are used and how do they influence virtual work outcomes? There were few studies prior to 1998 focusing on technologies in virtual work. Recent studies look at computer-mediated communication systems, the Web, the role of technologies in affecting productivity of teleworkers (e.g., Bélanger, Collins, & Cheney, 2001), and usage patterns of technology in virtual teams (e.g., Majchrzak, Rice, Malhotra, King, & Ba, 2000).
- What is the nature of the work-family conflict in virtual work? There are some recent studies looking at stress but most studies were published prior to 1998 (e.g., Duxbury, Higgins, & Mills, 1998), or in non-IS mainstream journals.

- What are the outcomes of virtual work environments? Most hypothesis-driven studies used outcomes of virtual work, such as productivity, satisfaction, or level of communication, as dependent measures (e.g., McCloskey, 2001). Potential outcomes were also discussed extensively in pre-1998 literature.
- What happens in virtual group work? Studies investigate trust, development processes, and performance in virtual teams, and perceptions in virtual groups (e.g., Maznevski & Chudoba, 2000).
- What are the key issues in managing remote group workers? Studies typically look at issues with managing teleworkers (e.g., Staples, 2001).

Overall, the review showed that a number of barriers, enablers, and outcomes of virtual work have been studied. The samples have often been limited, for example, one organization, which can limit the generalizability of the findings. However, sample size has increased in recent years. In general, given the complexity of organizations, the current research still seems to be narrowly focused.

Case Narratives

To investigate the gap, interviews were conducted in two organizations with distributed workers but with quite different levels of worker distribution. The first organization is Booz Allen Hamilton. It is a global management and technology consulting firm. For their IT practice of the Worldwide Technology Business (WTB), they rely on distributed teams comprised of geographically dispersed employees. The teams are classified as functional, delivery, development, and external teams. Their flexible matrix allows members to participate on multiple teams.

The organization has had success using technology support for team communication. The technologies available include project management, collaboration, and knowledge management tools. Management challenges, however, do occur with practical issues such as the needs for breadth of multi-disciplinary domains, collaboration tools, and training. In managing the breadth of multi-disciplinary domain, identifying the right "mix" of team members with requisite skill sets is a challenge. While electronic collaboration tools are available, managers are not sure whether and how using particular tools makes positive outcomes more likely. Computer and collaboration technology training is left up to each consultant. Management wonders whether project managers are effective because of interpersonal qualities or because of automated tools usage.

The second case is a Fortune 100 telecommunications company headquartered in Southeast USA. It services residential and business telephone customers in nine states. The narrative focused on the management of 700 network service technicians responsible for installation and repair of telephone services within one district. Technicians complete four to five work orders per day assigned by a centralized provisioning center. They are evaluated based on efficiency in completing orders and quality of the work performed. Some teams are staffed in shifts 24 hours/day, seven days/week, while others have eight-hour days with frequent overtime.

Technicians and supervisors use information and communication technologies extensively, including cell phones, pagers, and wireless laptops. The first work order is loaded on the technician's laptop before the work day begins. Technicians update the work order, and completed orders are updated in the system as soon as a worker establishes a connection. A new work order is then assigned. Such a system allows dynamic assignment of work orders based on changing priorities throughout the day.

Managers are responsible for overseeing eight to 15 technicians, including visiting and inspecting the site where work was completed. Supervisory duties also include providing training for technicians (formal and informal). They must respond to individual questions which arise due to unique field conditions or changes in technology. In addition, they must conduct performance evaluations, counsel technicians on career development, and mentor technicians new to the job.

Such responsibilities pose challenges for managers. Management challenges include work activity coordination, measurement tools, training, and information sharing for team building. Coordinating activities of distributed field workers who face process changes, often due to field conditions, is challenging. Supervisors are not able to observe the work performed, which causes difficulty in providing feedback to technicians on the quality of their work. Training in a timely and consistent manner is difficult with staggered schedules of field workers. In addition, it is difficult for distributed workers to develop relationships with team members. Thus, inability to share information with team members, especially for newer people, poses a challenge for managers.

MAIN TRUST OF THE ARTICLE

A number of managerial themes emerged from the interviews. The themes are summarized in Table 1, and only a few sample questions are provided in the following text for each theme. Please refer to Table 1 for further research questions.

Team building is an issue due to the complexity of lateral communication among team members in virtual work environments. The lack of physical interaction causes

Table 1. Gaps and overlap in virtual work research and practice

Practitioner Issues	Examples of questions of interest	Overlap*	Examples of questions/areas researched	Research in Virtual Work
Team building	What factors are critical for building and maintaining a solid team culture and effective communications process in distributed environments?		What is the effect of virtual work on communication patterns and structures in teams and work groups?	How is communication influenced by virtual work?
	What communication structures and mechanisms can be used to distribute information and coordinate tasks among team members in timely manner?		What effects does telework have on group communication structures?	How is communication influenced by virtual work?
Organizational/ management structure	Does management role change in distributed environments?		What factors lead to more successful management of remote workers?	What are key issues in managing remote workers?
	What role does distance play in determining organizational structure and job design?			
	How are resources best allocated in distributed environments?			
Information sharing & distribution	How can information sharing be facilitated in distributed environments?		How is communication and coordination performed in virtual work?	How is communication influenced by virtual work?
	How is time-sensitive information best distributed?			
	What are effective interpersonal networking techniques used by successful distributed workers?		How is communication in teams affected by virtual work?	How is communication influenced by virtual work?
Employee assessment & development	What are the best methods and metrics for employee assessment in virtual work?		Are demographics of teleworkers linked to success or other outcomes?	Who are the virtual workers?
	What is the role and appropriateness of employee monitoring in this environment?			
	How is the critical management function of employee development best performed in distributed work?			
	In distributed work teams that do not meet daily, are there differences between the factors considered in team members' evaluations and those of co-located teams?		How can trust be developed between distributed team members?	What happens in virtual group work?
	Should some performance evaluation factors be weighted more heavily than others in virtual work? Which?			
Work process training	What skills need to be developed for different types of virtual work environments?		What are the characteristics of individuals performing virtual work, including skills?	Who are the virtual workers?
	How can we train distributed workers for optimum job knowledge sharing and work in virtual teams?			
IT training and readiness	What IT training is needed and how is it most effectively employed in distributed work?			
	At what stage are employees (and org.) in their acceptance of and readiness to use information and communication tools?			
Communication tools & technology choice	How does management assess the appropriateness of available communication technologies and applications?		Which communication tools lead to greater success in telework?	What technologies are used and how do they influence virtual work outcomes?
	What tools are available, and which are best to support collaborative distributed work?		Which communications tools are available and used in virtual work?	What technologies are used and how do they influence outcomes?
	How does management assess the effectiveness of collaborative tools, where they are successful, and under what conditions?			
				What is the nature of work-family conflicts in virtual work?
				What are outcomes of virtual work?

* Filled cells indicate overlap. White cells indicate limited or no overlap.

difficulty in creating relationships. An example of a question practitioners need answered is: What factors are critical for building and maintaining a solid team culture and effective communication process in distributed work?

Hierarchical communication between employees and managers also becomes more complex in virtual work. Coordination of unpredictable tasks is difficult for supervisors. In relation to organizational management structure, practitioners need answers to issues like: How are resources best allocated in the distributed environment?

Communicating organizational information in a timely manner is a challenge. Information sharing among team members may be difficult since work teams are physically distributed. Timely updates are difficult without methods for sharing information such as posting system messages and alerts for fellow workers. A sample question of interest to practitioners could be: What are effective interpersonal networking techniques used by the most successful teleworkers?

Measuring and monitoring employees' work is complex in distributed work. Better measurement criteria on work patterns or processes would enable management to more fairly assess and provide effective feedback to employees. This leads to questions like: What are the best methods and metrics for employee assessment in virtual work?

Development and training of employees for future assignments can be difficult, particularly for new employees in distributed settings. A sample question that needs further investigation is: How are the critical management functions of employee development best performed in the distributed environment?

Ensuring that employees are performing work activities most effectively is difficult in distributed work. Tension occurs between organizational consistency and employee independence. This area has just started to be researched by academics (Cooper & Kurland, 2002; Kurland & Cooper, 2002). A sample question needing further investigation in this area is: How can we train distributed workers for optimum job knowledge sharing and work in virtual teams?

The use of information and communication technologies is critical to effective performance in distributed settings. However, the complexity and rapid change of technologies adds to the challenge of providing training at a distance. An example of a question of interest is: How is necessary IT training most effectively conducted in distributed settings?

Choosing the best communication technology is critical. Management in both organizations interviewed, however, had little guidance in how to make the choice. A typical question of interest could be: What tools are available, and which are best to support collaborative work in distributed settings?

FUTURE TRENDS

A summary of the issues raised in the case narratives as compared to the literature is presented in Table 1. It provides a high level view of potential gaps between virtual work research and practice. In general, the literature does not always adequately capture the complexity of virtual work environments, which creates a gap between managerial concerns and academic research. In addition, topics addressed by research are not always addressed in as much depth as what is needed by practitioners. For example, researchers look at coordination and communication in general while practitioners are interested in how communication within virtual work can be better used for information sharing, information distribution, performance feedback and/or relationship development. Some gaps, however, may be justifiable. For example, work-family conflict issues should be studied by researchers, but do not seem to be major concerns of practitioners. The need to address longer-term issues about societal effects of virtual work may justify research in this area. One overlap is team building where issues of trust and communication in virtual teams are researched and are seen as practical concerns by managers. Another overlap is evaluation of tools and technologies for virtual work. Research has focused on e-mail and the Web, also important to managers. In addition, managers are interested in groupware and knowledge management tools.

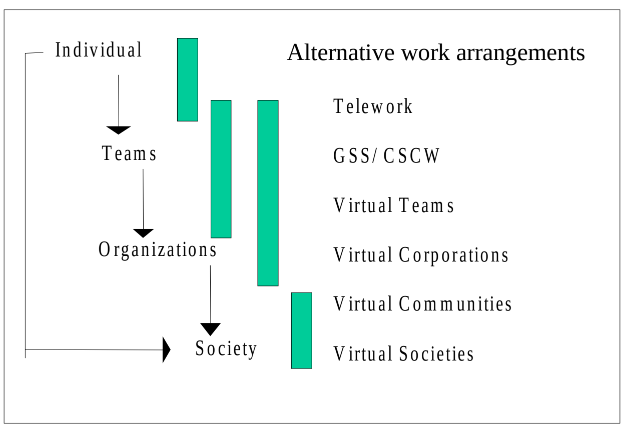
While exploring the gap, several factors that might cause a disparity between research on virtual work and concerns of practitioners became apparent. Possible reasons for the gap include multidisciplinary nature of managerial concerns, time-intensive requirements for research methodologies, and lack of proper definition of the unit of analysis.

Virtual work research is fragmented by areas while problems faced by managers are multi-disciplinary in nature. Business organizations require a more systemic and holistic approach to studying virtual work. For example, issues of technology and organizational communication cannot be separated in virtual work. Understanding interpersonal relations is critical to understand how relationships are formed and maintained in an environment where cooperating individuals are working in different contexts with different technologies.

Longitudinal case studies or multiple case studies are the most appropriate research methodologies to study virtual work. The type of research needed requires substantial time investments from the researchers' perspective. It is, therefore, more difficult to accomplish this research and get the appropriate rewards of timely publications.

The unit of analysis needs to be appropriate to the research question, and the research question should be relevant to the "unit" being studied. A proposed view of the appropriate unit of analysis in virtual work research adapted from Agres, Edberg, and Igbaria (1998) is shown in Figure 1. For example, the organizational level unit of analysis could include studies of telecommuting, GSS/CSCW, virtual teams or virtual corporations.

Figure 1. Proposed virtual work units of analysis



CONCLUSION

Through an in-depth review of virtual work literature and insights from two organizations, a gap between research and practice was identified since practitioners are faced with issues and challenges in virtual work environments for which research does not always capture the complexity. Although possible reasons provided for a gap between research and practice is not exhaustive, it is apparent that a need exists to have better communication between practitioners and researchers on issues of importance and on how each can benefit from one another's work. As academics, we should consider these as opportunities to perform research of importance to both the academe and practitioners.

KEY TERMS

Computer Supported Collaborative Work (CSCW): Research area that focuses on investigations and development of technologies that can be used for collaborative work in distributed settings.

Group Support Systems (GSS): A set of technologies used to help groups in their decision making processes.

Hotelling (Neighborhood Work Center): Organizational facility for employees to work at but where they do not have a permanently assigned desk. They must "check-in" every time they come to work there.

Longitudinal Case Studies: Research method that involves looking at particular cases over a longer period of time, with repeated measures to observe a phenomenon as it evolves.

Telecommuting (Telework): Work arrangement that allows employees to work at home during regular work hours.

Virtual Teams/Organizations: Teams and/or organizations where some or all of the members work from different physical locations.

Virtual Work: Work environments where individuals spend some time working in a non-face-to-face (FTF) mode, using information and communication technologies to perform work activities.

Virtual Work, Trust and Rationality

Peter Murphy
Monash University, Australia

INTRODUCTION

Since the development of the Internet—and the emergence of computer networking as a mass medium in the mid-1990s—many organizations and institutions have experimented with Internet protocol (IP)-based communications to coordinate work and activities across geographical distance. This has been in response to growing needs to coordinate business and projects between different offices, firms, regions, and states. Rather than organizations flying people to meet face-to-face, network technology presents opportunities for persons located apart to work together. It offers the potential for cheap and efficient collaborations across distance. Yet, while economic pragmatics drive organizations to adopt virtual work methods, virtual working is difficult to implement. This is because it strains many conventional assumptions about work behaviour and the cognitive and emotional foundations of collaboration.

BACKGROUND

Since the 1970s, there has been a general trend worldwide for organizations to move from being closed systems to open systems. This has involved growing pressures on organizations to interact with their environment rather than trying to internalize their environment. The most visible consequences of this have been the escalating tendency of organizations to contract out functions, to relocate parts of their operations across the world, and to grow the number of strategic collaborations with other organizations. The result is more and more organizational actors working with persons—often persons they do not know—in other locations. Working with people at a distance means working virtually (Duarte & Snyder, 1999; Franke, 2002; Igbaria & Tan, 1998; Jackson, 1999; Kisielnicki, 2002; Lipnack & Stamps, 2000; Mowshowitz, 2002; O'Hara-Devereaux & Eccles, 1994). Virtual collaborators (teams and partners) have no shared physical presence. Collaborators may see one another only rarely if at all.

The technologies of virtual collaboration are relatively straightforward: e-mail, ftp, collaborative groupware, and audio-video conferencing. Groupware and IP-based conferencing is still relatively under-utilized. Third-party hosted groupware offers solutions to high-level collaboration across firewalls. IP-based conferencing provides opportunities to enrich interactions with sound and visuals. Groupware to date, however, does little more than make conventional file storage and threaded discussion available to persons working in multiple locations across organizational boundaries. Conferencing software is only beginning to be able to deliver quality audio across low bandwidth connections. Typically, high-quality video and the sharing of complex software applications still require high network bandwidth, and are often unavailable from roaming and non-institutional locations.

While technology shapes the possibilities of virtual interactions, psychology is a more powerful factor in determining the viability of such interactions. A basic condition of virtual collaboration is the ability to work with others without seeing them, knowing them, or meeting them in person. While technology can enable such work, to effectively leverage these technological possibilities, organizations have to adapt themselves to different ways of working, and in some cases they have to re-invent themselves. Working virtually at the micro-level of teams, groups, and pairs is only effective where the larger organizational environment lends itself to virtual interaction.

There are three basic types of organization: social, procedural, and the virtual or self-organizing (Miller, 2002). Social organizations are the most common type. These are based on face-to-face interactions and on character norms such as loyalty, dedicated service, and "keeping your word". Procedural organizations are built on impersonal roles and rules. Virtual organizations are structured around more abstract patterns and forms. The family firm and the relationship-driven Japanese corporation are examples of the social organization (Fukuyama, 1995). The Fordist-type American corporation typifies the procedural kind (Chandler, 1977). In contrast, production and distribution reliant on intangible or intellectual capital, such as licensing, patents, or correspondence, encourages forms of virtual collaboration based on high degrees on self-organization (Barley, Freeman & Hybels, 1992).

In order to be effective, any organized human activity must be rational. Rationality is another word for continuity, identity, and stability of expectation. Organizational behaviours deteriorate or collapse if the members of an organization cannot see that these behaviours are for the most part rational. The emotional correlate of rationality is trust. What is felt to be reliable, and worthy of trust, is also that which is recognized to be rational. Any organization where people trust one other is more effective than an organization where persons are suspicious of each other (Kramer & Tyler, 1996).

In social organizations, people "with character" are generally recognized as rational actors. These might be persons who are dependable, loyal, and unwavering in their treatment of each other. Through demonstrating that they are good at following social norms, such agents generate trust (Fukuyama, 1995; Handy, 1995). With the development of equity corporations and modern management in the late nineteenth century, social organizations in many places were replaced at least in part by procedural or bureaucratic organizations (Chandler, 1977; Yates, 1989). These developed around rules, roles defined by rules, procedures, work demarcations, impersonal written communication, and file management. Knowledge of rules rather than of people provided organizational continuity, identity, and stability. Thus persons who were consistent at following and applying rules acquired reputations for trustworthiness. Predictability in decision-making and task execution became the primary source of trust in bureaucratic organizations—complementing and often superseding the loyalty and patronage work cultures of social organizations.

Virtual work does not follow the logics of either social or procedural organizations. Without face-to-face interaction, character norms cannot be the basis of organized action. At the same time, procedural rules are difficult to agree on, to follow, or to enforce because virtual collaborators do not share the same office, organization, or manager. Virtual actors have to deal with multiple rule sets across diverse institutions, geographies, and cultures. Under these conditions, rules become ambiguous, conflicted, and uncertain. One party's rationality becomes another's irrationality. Such conflicting expectations breed distrust. Thus, under virtual conditions, rationality and trust have to be generated by other means (Murphy, 2003).

CRITICAL ISSUES

Because there is not the same history of working virtually as there is of working socially or working procedurally, identification of the means by which virtual partners and teams generate rationality and trust is less developed. If virtual collaborators cannot rely on personal moral character or on impersonal "rules and roles" to facilitate their interaction, then what can they rely on? The simplest answer is that, in the absence of social cues or clear-cut procedural direction, persons working have to be self-organizing. The key to successful self-organization is the sense of pattern or designing intelligence. Where self-directed activity (Ray & Bronstein, 1995) dominates cooperative and peer interaction, design intelligence and pattern rationality function as the coordinating medium of organized activity and group behaviour. If not, collective cohesion readily collapses.

Human beings have a strong design sense. They pick up exceptionally quickly on design characteristics such as rhythm, harmony, and proportion. Pattern recognition is central to brain processing (Davies, 1992). For instance, we use our pattern sense to make judgments about regular sentences, trustworthy buildings, and reliable machines (Alexander, 1977; Fodor & Pylyshyn, 1988; Gelernter, 1998). Such pattern rationality is also conducive to building trust. Patterns generate feelings of surety, satisfaction, and reliability. This applies as much to work environments as to cities, machines, or sentences. To create patterns, organizations employ tacit forms of aesthetic cognition (Calas & Smircich, 1996). Aesthetic cognition uses beauty, elegance and economy rather than rules or roles to achieve its ends.

Successful virtual work is conducted like a design process (Murphy, 2003). It relies less on the passing around of overt messages, and more on the ability of collaborators to understand through the exercise of imagination where their part "fits" into the overall design of the workflow. "Fit" is achieved by thinking in aesthetic terms of proportionality, rhythm, and harmony rather than in terms of rules or roles. The rationality of a virtual organization is not the rationality of character or procedure but of design. Much of this "acting by design" is intuitive or unspoken. It rests on imaginative cognition. Persons who work virtually by necessity cannot talk a lot or interact a lot with each other—so they need to imagine a lot. They need to be good at projective or anticipatory thinking. This projective thinking is not the same as the anticipatory thinking involved in either relationship empathy or in Gantt chart style project management. Rather, it is much more figurative in nature. The virtual collaborator who uses imagination is good at "seeing the shape of things" in lieu of dense social relationships or strong procedural guidance.

Virtual team or partnership work relies heavily on imaginative visualization and intuition. This is a kind of tacit knowledge. It is tacit in the sense that it involves picture thinking and pattern cognition rather than verbalization. It requires the cognitive-psychological capacity to "figure" things out (Mintzberg & Westley, 2001). Such cognitive figurative methods are closer in kind to processes of creative design than they are to processes of social recognition. In this context tacit does not mean the implicit understanding we derive from the warm handshake or the disapproving stare of another person. The tacit nature of figurative work methods thus are different in nature from the tacit knowledge that we draw from the bodily presence of collocated work partners. In the case of the imagination, tacit refers to high levels of picture-like abstraction. At the same time, however, because many aspects of this design intelligence operate non-discursively, the imaginative abstraction that is required in virtual working is quite unlike the explicit rules of procedural organizations or the rule-driven inferential reasoning typical of procedural rationality.

Virtual work elides socio-emotive contents and makes conventional discursive (mile-stone) office planning difficult to implement. For virtual work to be successful, even on a micro-scale, it must draw heavily on the faculty of imaginative and figurative thinking. To be proficient at cooperation and interaction, virtual workers must be able to picture what is absent and organize that picture "aesthetically".

In virtual collaborations, designing intelligence generates shared integrative schemas—such as asynchronous rhythms of interaction or proportionate distributions of task load. Where virtual teams and collaborators "find their rhythm," they will—more likely than not—produce good work. Correspondingly, it is the act of producing good work that builds trust amongst virtual collaborators. Trust arises where collaborators know that each will "do their part". "Doing their part" does not mean sending lots of social messages, nor does it mean showing procedural fluency. Virtual trust is generated not through relationships or procedures but rather through the aura of reliability that arises from the visible effects of the "invisible" qualities of beauty, elegance and economy that virtual actors employ when they cooperate at a distance to produce things in imaginative ways. This means producing well-designed objects—be they physical goods, processes, systems, or learning objects—in a "choreographed" manner. The choreography of the virtual team rests not on social gestures or on rules but on a good sense of rhythmic or harmonic "fit". The sense of satisfaction and surety derived from such "fit" provides the emotional trust that is the counterpart of aesthetic rationality.

FUTURE TRENDS/CONCLUSION

As business and government are pressed to operate over increasingly large scales and long distances, and as inter-organizational, inter-agency, and inter-state activity becomes more common, the need for distance communications and virtual teams is growing and a class of virtual workers is gradually emerging.

All the while, established paradigms of work remain entrenched, meaning that there is a latent propensity to try and build virtual teams and partnerships around social communication and procedural norms. This creates conflict between the intrinsic nature of virtual cooperation and the extrinsic goal extending the reach of traditional organizational structures. As organizations at the micro-level of team and peer relations continue to expand their geographical scope, and as the boundaries of organizations become increasingly fluid as a result, a major challenge for the future will be increasing the understanding of the role of aesthetic rationality and designing trust in the formation of productive relations between actors who are separated by distance and time.

KEY TERMS

Design: The structured composition of an object, process or activity.

Distance Communication: Communication under conditions of geographic separation that minimize the possibility of face-to-face and synchronous interactions.

IP-Based: Network technologies based on Internet protocols.

Open System: Any system without strong boundaries, where information and other goods flow to and from the system's environment.

Organization: The deliberate integration of persons in order to achieve a goal or outcome.

Procedure: A rule that governs a formal organizational process.

Rationality: The ability to infer with relative certainty from existing or past behaviour and statements future behaviour and statements.

Trust: Confidence that an object, process, institution, or another person's actions can be relied upon to produce some good.

Virtual Interaction: Computer-mediated interaction between persons who do not occupy the same physical space.

Virtualization and Its Role in Business

Jerzy Kisielnicki
Warsaw University, Poland

INTRODUCTION

A new management trend of the global information technology (IT) application—virtualization—has appeared in contemporary management. Virtualization is a process of enterprise transformation (using IT) that allows breaking through various limitations of organizational constrains. Virtualization changes dramatically the image of business, especially of small and medium enterprises (SMEs); by adopting the concept of virtualization, they can become fully competitive and may effectively operate in the global market. Barriers of scale between SMEs and large organizations disappear. This new type of organization is often called in the literature a *modern organization* or *virtual organization*. Organizations of this type have an effective decision-making process and function based on economic criteria. Consequently, their opportunities to grow and compete in the global market are greater than for traditional SMEs. Hence, the thesis: virtualization allows individual organizations to enter strategic cooperative alliances with other similar businesses. Such virtual organizations have a competitive position in the global market.

In the literature, there are many terms used to define the virtual organization: "network organizations" (Drucker, 1988, p. 9); "organizations after re-engineering" (Hammmer &. Champy, 1993, pp. 77-79; Peters, 1994, pp. 5, 7); "intelligent enterprise" (Quinn, 1992, p. 3).

BACKGROUND

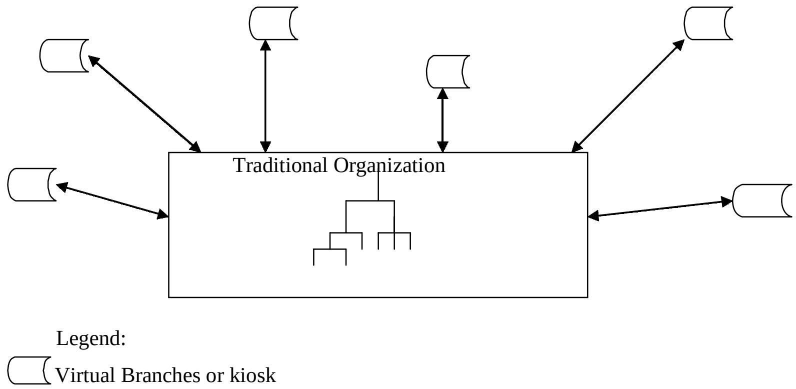
Virtualization, defined as a process of continuous transformation, is a herald of a new direction in the science of organization management. In the context of this analysis, this process may assume such form that will allow them to become competitive in the global market. The process of transformation consists of quick adjustments of the enterprise to new requirements (Hendberg, Dahlgren, Hansson, & Olive, 2000). This is done through changes in the organizational structure as well as in the portfolio of products and services. These changes are possible due to development in the IT sector, particularly Internet applications (Keeny & Marshall, 2000).

From the theoretical perspective, we can separate the following forms of virtualization:

1. Functional extension (i.e., a vertical development). This occurs when the enterprise either wishes to be closer to the customer and it does not have adequate resources, or when the establishment of a traditional branch is not profitable. The enterprise creates for this purpose virtual branches or *kiosks*. Sometimes it enables its customers to use its services via computer or mobile phone. Examples are Internet banks, bookshops (best-known is amazon.com), department stores, and travel agencies. Large companies also commonly extend their scope through such vertical development. It ensures increased competitiveness with a simultaneous control over the whole organization. SMEs apply such a strategy to a limited extent, most often for the purpose of marketing their presence in the Internet.
2. Creation of the virtual organization, or horizontal development. Such a development occurs through a virtual incorporation of other organizations. The literature lacks a unanimous definition of this concept (Hendberg, 2000; Kisielnicki, 1998; Quinn, 1992; Scholzch, 1996). For the purpose of this analysis, we assume that:

   • A virtual organization is created when its members voluntarily enter in relations of various types to achieve their common goal. Every member who creates this organization defines the duration of the relation. The member who first admits that the existence of that relation is unfavorable makes the decision on its liquidation and withdraws. The virtual organization operates in *cyberspace* and requires the existence of the Internet and global IT infrastructure.
   • Large-scale enterprises (LSEs) use IT to strengthen their competitive position in relation to other enterprises. As Hammer and Stanton (1999) rightfully notice, IT becomes—for a certain class of organizations—a "wall" that divides them from other enterprises. Large enterprises are described as "castles" (Hammer & Stanton). LSEs build these "castles" to protect themselves from competition. SMEs do not have such a sheath. They are more flexible than LSEs at a price: They are more prone to infiltration. In general however, the more experienced and knowl-

Figure 1. Virtual organization based off traditional structure



edgeable the SMEs are, the more attractive they are to other enterprises seeking their share in the virtual enterprise.

MAIN THRUST OF THE ARTICLE

Virtualization in Traditional Organizations

Virtualization allows for organizational development at a much lower cost than through the traditional process. Figure 1 presents a virtual organization based off a traditional structure and connected with its virtual elements. These elements are flexible, allowing for quick adjustment to the changing environment by the organization.

The virtualization may be developed as follows:

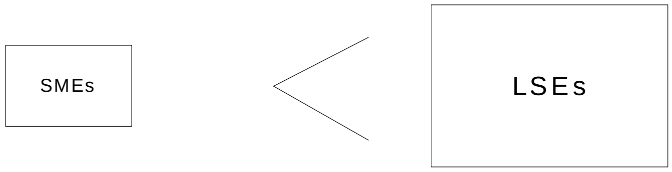
- The organization creates virtual kiosks or shops. For example, an organization that sells furniture using the Internet may present its products on a computer screen. It may also receive orders from customers located outside its traditional market. Other organizations (tourist, real estate, bookshops, stock exchange, etc.) may operate in the same manner.
- The organization places information about its activity on the Internet (Porter, 2001). It is available to its clients 24/7 rather than being limited to office hours. Internet banking services are a good example. In addition, the expenses connected with the services of an organization are shifted to the client (the client pays for the terminal, access to the Internet, etc.). The organization covers the cost of the development and maintenance of an application.
- The organization creates a possibility of working from home (called telework). It is a good way of increasing professional activity in those regions where it is difficult to find "traditional" employment. Also, through telework, a local organization may become a global one.

Virtualization allows traditional organizations to have a wider range of influence. Society is better informed of the organization's activities both by the organization itself and by its clients. The restrictions on this development are varied. The most common include: available financial resources for IT infrastructure, language, and a necessity to have global, reliable computer networks. It should also be stressed that, unfortunately, virtualization enables organizations that are socially unacceptable (pornography, terrorism) to operate freely.

Based on the analysis of organizations that use virtualization, it is estimated that their operations require five times lower investment outlays. Generally, minimum savings obtained as a result of virtualization exceeded 60%. Only in a few cases was this proportion less favorable.

In the organizations using telework, the proportions are difficult to calculate. The analysis of organizations using telework for outsourcing their services to developing countries confirms the effectiveness of virtualization. A good example is software development. The companies from highly developed countries (USA, Great Britain, etc.) employ programmers from India, China, or Pakistan. This situation is beneficial for both the company and the countries providing resources.

Figure 2. Comparison of individual SMEs and LSEs (LSEs have a competitive advantage over individual SMEs)



A different situation occurs when telework is connected with professional activation of the disabled or unemployed. Direct costs are higher, as we deal with the poorer part of the society. Thus additional costs have to be incurred for training, hardware, and software. Unfortunately, there is no data available to make a precise estimate. In many countries, the cost of training and equipment is covered by special social programs. It is also difficult to estimate advantages. It may be said that social effect (i.e., decreased unemployment) and - in case of the disabled - the ability to live a normal life are the most important ones. This is possible only through virtualization.

Generally, telework reduces operating costs (parking space, office space) and provides timesaving (i.e., no travelling to work) to employees.

Virtual Organization as a Chance for SMEs

Virtualization allows more and more SMEs to leave local markets and become global enterprises. Thus, the global market, for many years available only for LSEs, opens up to a wide range of enterprises. As G. Yip (2004, p. 27) states, "the skill of defining and implementation a global strategy is a true test of leadership and management skills." The contemporary global market most often exists as an e-market as well as an e-business (Turban, King, Lee, Warkentin, & Chung, 2002). The enterprise, irrespective of its size, that wants to make its existence in the global market should meet a number of conditions, such as:

1. Possessing a well-known and reputable brand
2. Built-up distribution and service network
3. Product or services that are unique and in demand
4. Management team able to support the global enterprise

To meet the conditions specified above, the enterprise must have at its disposal adequate funds as well as material and human resources. Comparing SMEs with LSEs, the former are in a very difficult situation. The enterprise, to make its appearance in the global market, must incur a definite outlay (a break-even point) to enter the global market. This break-even point is determined by:

1. Advertising and promotional campaign
2. Volume of production or services, allowing for selling price below the current market price
3. Quality of product or service meeting international standards, such as ISO
4. Access to the distribution channels
5. Formal barriers (legal, duties, taxation, etc.)

Operating in the global market is much more difficult than in local markets as it demands application of advanced IT solutions, access to the international data warehouses, etc. Only with the use of IT and access to information can a global company reduce the risk of failure.

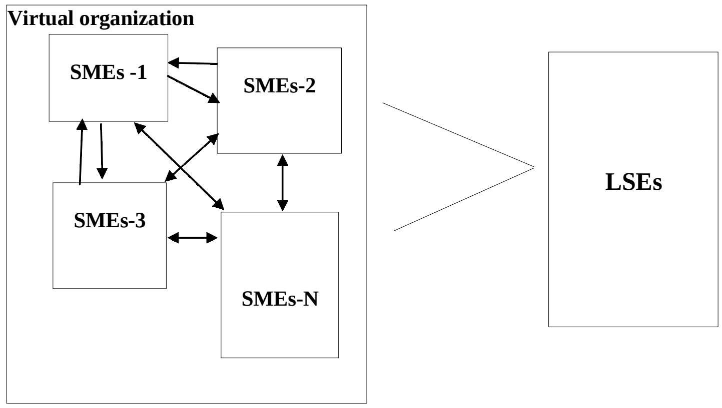
Operational costs of the enterprise are still larger if it operates in the global e-market (Elstrom, 2001). The surveys (Reichheld & Schefter, 2000; Reichheld, 2001) have shown that the cost of gaining a customer in this market is significantly higher than in the traditional market.

For example, in the fashion industry, the cost of gaining a customer in the e-market is up to 40% higher. The profits in the following years, however, grow much faster. In the near future, organizations that cannot succeed in this market will not be able to succeed at all.

Identification of the break-even point requires empirical surveys. It depends on the industry and the degree of globalization of the enterprise (there are not many enterprises that have been operating on all continents). To identify the break-even point, we may apply the methods of strategic analysis and especially the analysis of Porter's five forces. For example, the break-even point may be identified by the investment required to realize 2% of revenue from the global market. Sometimes, we can consider as an organization of such a type the one that has more than 50% of revenue from the global market. Because single SMEs do not have such resources to surpass the break-even point, they create strategic alliances in the form of the virtual enterprise.

Theoretically, development of the virtual organization may be significant. Practically, a degree of its development is connected with technical barriers and with the

Figure 3. Comparison of a virtual organization and LSEs (virtual organization as a set of SMEs is more competitive than LSEs)



necessity to achieve the goals set up for the virtual SMEs. Modification of the goal causes a fast modification of the enterprise.

FUTURE TRENDS

My research suggests that a significant number of students feels the need to learn business administration (Kisielnicki, 2001). At the same time, learning should be as close to the reality as possible. Virtualization is the discipline of studies which may cause the distance between theory and practice to diminish. One may even risk a statement that it is the exact direction of virtualization which, in the nearest future, shall have the most significant impact on society. Virtualization increases the effectiveness of the teaching process in the widest possible sense by supporting traditional teaching methods. Virtualization may be applied in such areas as lowering cost and decreasing time of training jet pilots and also in improvement of military command, operating on the stock exchange, or cognitive analysis of genetic processes. In science, there are many examples of big discoveries which were first tried on computer-simulated models. It is virtualization which allows for business simulation of both the decision-making process and the analysis of complex technical or sociological processes. In virtualization of teaching, there are two basic directions.

The first one is the direction of common education where everybody can, using IT, gain a given knowledge. A classic example is a virtual stock exchange. In many countries, a lot of people want to learn how to operate on the stock exchange before they actually start using it to make money. They can get the necessary experience using appropriate software. They can acquire the necessary skills in the virtual world. There are also numerous games available through the Internet. These games not only provide a pleasant time spent on playing but also teach foreign languages or how to drive a car.

Another direction is dedicated teaching. There are the following activities where virtualization can help:

- Self-evaluation, using special software to assess the level of language knowledge.
- Learning assistance, includes, amongst others, enterprise laboratories, business games, and special simulators that teach how to use specific technical equipment, e.g., flying simulators.
- Distant learning; a student who has a proper terminal and software may participate in classes from a distance. This direction of virtualization is similar to the previously presented distance work.

CONCLUSION

The virtual organization operates as a *transparent organization* in the sense that all of its initiatives are known to the competition. This enforces responsibility. The image of a virtual organization is influenced by the activities of its individual participants. Virtual organizations do not have common administration, offices, and real estate. In addition, virtual organizations do not have a joint executive team, middle management, or coordinators. Since the influence of each individual virtual organization is limited, the key success factor is mutual trust.

Virtual organizations give new insight into business management. They may trigger increased entrepreneurship and competitiveness. They also introduce new management methods different than traditional ones. Virtual organizations are an interesting alternative for current organizations. They are especially attractive for developing countries that want to operate in the international environment. It is fascinating how virtual organizations—without a formal reporting structure and control—can achieve high operational performance and thus have a competitive advantage over their traditional counterparts.

Regardless of speculation on future solutions, we can now safely define the areas where virtual organizations can easily outperform traditional organizations. They are: trade, tourism, and services. In these areas, the benefits of virtual organizations are as follows:

1. Operational flexibility is much higher, especially when a quick reaction to the emerging market niche is required
2. A transaction life cycle is much shorter (especially the closure)
3. Use of cyberspace to close some transactions (despite legal and organizational barriers)
4. Lower operational costs
5. Lower start-up costs
6. Ability to cooperate with organizations which LSEs cannot accept (for political, geographical, racial, religious reasons)

Depending on each individual opportunity, virtual organizations can be successful in other industries as well. Very rarely, traditional organizations can outperform the virtual organizations.

The economic metrics supporting the benefits of virtual organizations are generally available for individual cases. However, for illustration purposes, I include the results of research recently carried out in Poland:

1. Virtual travel agencies achieved 20% higher profit per transaction that traditional organizations.
2. Transaction life cycle was 100% faster in the Internet bank than in a brick-and-mortar bank.
3. The average transaction cost on the Internet bank was $0.10-0.15 compared to $1.10 in the brick-and-mortar bank.

We can put forward a hypothesis that progress in IT will create a snowball of virtual organizations. Don Tapscott (1998), introducing the 12 rules of the new economic deal, writes that they lead towards "virtual reality."

KEY TERMS

Cyberspace: An "online world of computer networks." This definition can be augmented by the following characteristics: The network consists of various globally distributed computers that can send and receive information using common protocols. In addition, this network does not have physically defined measured boundaries. Examples of the network types are: electronic mail (e-mail), World Wide Web (WWW), electronic data interchange (EDI), business-to-business (B2B) applications, business-to-customer (B2C) applications, peer-to-peer (P2P) applications (Defined by the Merriam-Webster Online Dictionary).

Virtual Organization (defined by Kisielnicki, 2002. p. 12)**:** A virtual organization is created voluntarily; its members create this organization to accomplish a certain goal. A virtual organization is created anytime a manager realizes that he or she needs the cooperation of other organizations to accomplish a goal. The duration of a virtual organization is defined by each of its members; a virtual organization operates in cyberspace, which means that its duration can be very short; so short, in fact, that it would be impossible to cooperate with other organizations using traditional methods. The decision to restructure or fold the organization can be made anytime by any of its members. A virtual organization does not have one president or general manager. The virtualization process is a process of transformation from traditional organization into virtual using informational technology. This process can result in two forms of virtual organization: traditional organization with virtual divisions or an association of many organizations, as depicted in Figure 3 (Kisielnicki, 2002, p. 102).

Virtual Organization (defined by Schozch)**:** An artificial organizational structure where individual organizations provide base competencies. The integration and coordinations of these base competencies allow for effective execution of chain process to deliver a product and satisfy a customer. This integration and coordination does not incur additional costs and maintains the customer focus (Scholzch, 1996).

Virtual Organization: A temporary network of independent enterprises—suppliers, customers, ever former competitors—linked through IT and working together to share their knowledge and costs to enter a new market (Byrne & Brandt, 1993).

VRML-Based System for a 3D Virtual Museum

José-Fernando Díez-Higuera
University of Valladolid, Spain

Francisco-Javier Díaz-Pernas
University of Valladolid, Spain

INTRODUCTION

In the last few years, because of the increasing growth of the Internet, general-purpose clients have achieved a high level of popularity for static consultation of text and pictures. This is the case of the World Wide Web (i.e., the Web browsers). Using a hypertext system, Web users can select and read in their computers information from all around the world, with no other requirement than an Internet connection and a navigation program. For a long time, the information available on the Internet has been series of written texts and 2D pictures (i.e., static information). This sort of information suited many publications, but it was highly unsatisfactory for others, like those related to objects of art, where real volume, and interactivity with the user, are of great importance. Here, the possibility of including 3D information in Web pages makes real sense.

As we become an increasingly visual society, a way to maintain heritage is to adapt museums to new times. The possibility of not only visiting and knowing the museums nearby but also enabling anybody to visit the building from their homes could be enabled. This would imply the incorporation of the virtual reality (Isdale, 1998), although today few museums allow this kind of visit via Internet. In virtual reality, human actions and experiences that interact with the real world are emulated although, obviously, with some limitations. With virtual reality the user could walk, examine and interact with the environment, in contrast to traditional media like television that present excellent graphics but lack interactivity. Although this is not a new idea, it is achieving a wider expression due to the availability of the Virtual Reality Modeling Language (VRML) (Carey, Bell, & Marrin, 1997), a widespread language for the description of 3D scenes and WWW hyperlinks (an analogy of the HTML for virtual reality).

VRML is, perhaps, most interesting for Internet users eager to discover new interesting sites in Internet, and for the people that use it like hobby, but VRML could also allow us to see a 3D artifact from any angle and perspective, to turn it in any way, and so on. In sum, we can manipulate it — something totally forbidden in a real museum.

This work deals with the design of a system which allows this interactive Web access to works of art in 3D, as a step in a research project dealing with the design and implementation of a virtual and interactive museum in 3D on the Web. Also, all the associated information like history, architectural data, archaeological data, and culture will be available at the click of a mouse.

BACKGROUND

Several museums around the world are already committed to a strong Web presence and many others will adopt one very soon. Dynamic museum leaders understood that the increasing number of internauts requires special attention from museums: Internet — and CD-ROM's — represent new media that will challenge museum communication strategies.

According to Proença, Brito, Ramalho, and Regalo (1998):

Two distinct Web approaches are being adopted by the museums. Some regard their presence on the Web as another way to publicize the museum and to promote their activities; others use the Web as a powerful resource to achieve their purposes: to conserve, to study and to display.

The most common attitude is to consider the Web as a simple sum of the different kinds of information already in use by museums — specially printed information — but gathered in a global structured way. These data include a museum description and a list of activities and collections, where a typical Web page structure contains: collections and exhibitions, visit planning and conditions, new acquisitions, projects and activities, museum organizational scheme and educational programs. Several museums on the Web follow this approach. Among them it may be worth a visit to Museo Arqueológico Nacional of Madrid (http://www.man.es/), On-line Picasso Project (www.tamu.edu/mocl/picasso/), Museo de Cera de Madrid (www.museoceramadrid.com), Asian Art Museum of San Francisco (www.asianart.org), The Museum of Modern

Art (www.moma.org) and Library of Congress Vatican Exhibit (www.ibiblio.org/expo/ vatican.exhibit/exhibit/ Main_Hall.html); this site has a good image quality, but with a traditional structure to present the exhibition themes.

Some museums demonstrate greater innovation in their Web presences: They have temporary exhibitions online, promote virtual visits and access to their databases, present technical information for museums professionals and researchers, keep available information about previous activities and exhibitions, and organize links to related sites. For these museums, the Web is also an exhibition and a presentation medium that must be integrated in the communication policy of the museum. Among them, it may be worth a visit to Musée des Beaux Arts de Montréal (www.mbam.qc.ca/ index.html), The Museum of Anthropology at University of British Columbia (www.moa.ubc.ca/Collect/moaview.html), and Museo del Prado (museoprado.mcu.es/prado/html/home.html).

Latest advances are becoming popular 3D (plus color) scanners, which allow the measurement of 3D artifacts such as art works (Gómez, Díaz & López, 1997; Rocchini, Cignoni, Montani, Pingi & Scopigno, 2001). After measuring, a 3D plus color model from the real object can be obtained. 3D scanning technology has been adopted in a number of recent projects in the framework of cultural heritage. Just to give some examples, we may cite the Digital Michelangelo Project of the Stanford University (Levoy et al., 2000) , the acquisition of a Michelangelo's Pietá by a team of the IBM T.J. Watson Research Center (Rushmeier, Bernardini, Mittleman & Taubin, 1998) , or the acquisition of a section of the Coliseum in Rome (Gaiani et al., 2000) . Unfortunately, a detailed 3D (plus color) model of a free form object usually requires a great amount of data. This data can hardly pass through the Web, even when using compression. Therefore, additional reduction of transmission requirements is desirable.

Recently developed image-based modeling and rendering techniques (Chen, 1995; Chen & Williams, 1993) have made it possible to simulate photo-realistic environments. Two of the most popular image-based modeling and rendering techniques are Apple's QuickTime VR and the Virtual Reality Modeling Language (VRML). QuickTime VR (Chen, 1995) has its roots in branching movies, for example, the movie-map (Lippman, 1980), the Digital Video Interactive (DVI) (Riply, 1989), and the "Virtual Museum" (Miller et al., 1992). QuickTime VR uses cylindrical panoramic images to compose a virtual environment, therefore provides users an immersive experience. However, it only allows panoramic views at separate positions. Recently, the Virtual Reality Modeling Language (VRML) (Carey et al., 1997) became a standard file format for the delivery of 3D models over the Internet. Subsequently, many efforts have been made to effectively compress and progressively transmit the VRML files over the Internet (Deering, 1995; Li & Kuo, 1998; Matsuba & Roehl, 1999; Taubin, Horn, Lazarus, & Rossignac, 1998).

Using these techniques, some systems allow to see art works in 3D (Cignoni, Montani, Rocchini, & Scopigno, 2001), while others allow a virtual walk through the rooms of some real building as The Virtual Living Kinka Kuji Tempers (Refsland, Ojika, & Berry, 2000), some reconstructed scenario as the Historic Villages of Shirakawa-go (Hirayu, Ojika, & Kijima, 2000) or some imaginary buildings as Virtual Museum of Helsinki (www.virtualhelsinki.net/museum) and Virtual Museum of Art (www.elpais.com.uy/muva).

The main feature of our system is that users may walk through a three-dimensional (3D) representation of the whole Fabio Neri's Palace, the building where Museum of Valladolid is located, viewing its collections, and seeing pictures in 2D and archaeological objects in 3D, together with information about them. To allow all of this, an architecture of interactive dynamic Web pages has been designed (Díez-Higuera & Díaz-Pernas, 2002). In order to capture 3D information, we have used the Laser Acquisition System developed by the Industrial Telematic Group of Telecommunications Engineering School of Valladolid (Gómez et al., 1997). These data, together with 2D images and information files, are compressed and stored in a remote server, and can be retrieved over the Internet. Rather than transmitting a high-resolution object, our system at the client end allows users to selectively retrieve images at specific resolutions. This selective retrieval is achieved by implementing a client-server communication protocol. Information is accessed through intuitive exploration of the site, and therefore, each session varies depending on both the participant and the path chosen. In this manner, the visitor becomes familiar with the virtual museum, in much the same way as they would become familiar with the physical museum. User may identify particular areas of interest, which may be revisited using familiar routes or accessed via browsing.

DESCRIPTION OF THE SYSTEM

Figure 1 shows the general architecture of the system. It has two main parts: the Dynamic Web pages system, based on the *Microsoft Internet Information Server*, which embraces the virtual visit to the 3D Museum and the access to data and its visualization in 3D; and the platform of telematic services, which implements the server-client architecture, allowing the transmission of three-dimensional and colorimetric data of the objects in several resolutions.

Client-Server Architecture

The server is used to store the huge amount of scene data that is being requested by the user, while the client is designed to interact with the user and retrieve the necessary scene data from the server. Java programming language has been chosen for the implementation of the server-client architecture. The reason is that Java allows the introduction of executable codes in Web pages, and, therefore, giving the desired portability, security and interactivity to the system.

Dynamic Web Pages System

A dynamic Web pages system has been implemented to give access to the database so the information required by the user about any object can be shown. This system has also been used for a 3D virtual walk through the museum.

Each section, or room, implemented in the museum becomes a specific VRML file (sometimes, even a single room is divided in several VRML files). Using smart nodes from VRML language, which activate any element in a 3D universe when the user clicks on it, the file stored in the URL of the VRML filecode shall be loaded, interconnect these files. Once the user is in a VRML file (containing any of the rooms where both 2D objects — pictures — and 3D ones are displayed) (s)he can walk around the room at will: Approach any object to have a first impression and, if wanted, click on it to acquire information about it (author, period, technique, etc.) as well as to visualize it in 3D (or with a higher resolution still image if the object is a picture). When the user clicks on any object, the dynamic Web pages system starts to work, giving access to the database and bringing the required information.

Format of the Data Used by the System

Virtual Reality Modeling Language (VRML) is the working format for the 3D display of the objects, as it is standard and commonly used in the Web. First of all, 3D plus color data must be acquired from art works. The corresponding object model, obtained from the acquired data, could then be directly expressed in VRML format. However, the raw format of the data in our database is not VRML. Instead, it is the specific one given by the Laser Acquisition System developed by the Industrial Telematic Group of the Telecommunications Engineering School of Valladolid (Gómez et al., 1997). This system, starting from a real object, gives a *.pie* file with the three-dimensional data, plus another three files (*.r, .g, and .b*) with its colorimetric information. Those files are converted into ASCII files, using software developed by the Industrial Telematic Group; these new files are *.pts*, with the Cartesian coordinates of all the points as read from the object, plus its colors, and *.tri*, with the triangular distribution of points for a certain resolution (which allows the construction of faces for the display of the object).

The server stores the last couple of files: one *.pts* file for each object, and several *.tri* (one for each different resolution). From them, and given a certain resolution, the server obtains the files needed by the client to reconstruct the VRML file. It is important to notice that there is no duplication of information in the server, as points and colors appear only once in the *.pts* file and the set required by the client at each moment is obtained from it. There are only several files of triangles, as the distribution of points on the faces is different for each resolution. Moreover, three-dimensional and colorimetric information is sent only once to the client. The result is that this design, as a whole, improves the efficiency of the system.

Also, we have developed an alternate solution which allows lower transmission requirements. In short, we allow art works to be requested in different levels of detail (LOD). User begins with the lowest LOD model, and requests a set of progressively increasing LOD models as his interest on the object increases. We benefit from this by building the different LOD models in particular way: Each LOD model is obtained from the immediately higher LOD model, by just picking some of its points. In this way, when the users ask for a higher LOD model, the whole model transmission is no more required. Instead, the new model can be reconstructed by adequately merging new points into the previously existing model. Unfortunately this strategy is not implemented in actual VRML; so we have implemented it by using a dedicated Java client. Basically, when the user asks for a superior LOD model, only additional 3D points, and a new faces description, are sent. This faces description must then be translated by the client. This is done by means of a *Look-Up Table* (LUT), which indicates actual position of the new points in a local VRML file.

User Interface

The user interface module is based on Web page template in which the virtual world is represented on a part of the screen, while on the rest, the name of the content plus the options that the user can select are left. We have a basic system in which the user can move along the building and rooms and, already inside these rooms, the user can select a picture or a 3D artifact in order to get information about it.

Different perspectives of the museum are shown in Figures 2, 3, and 4.

Figure 1. Global architecture of the proposed system

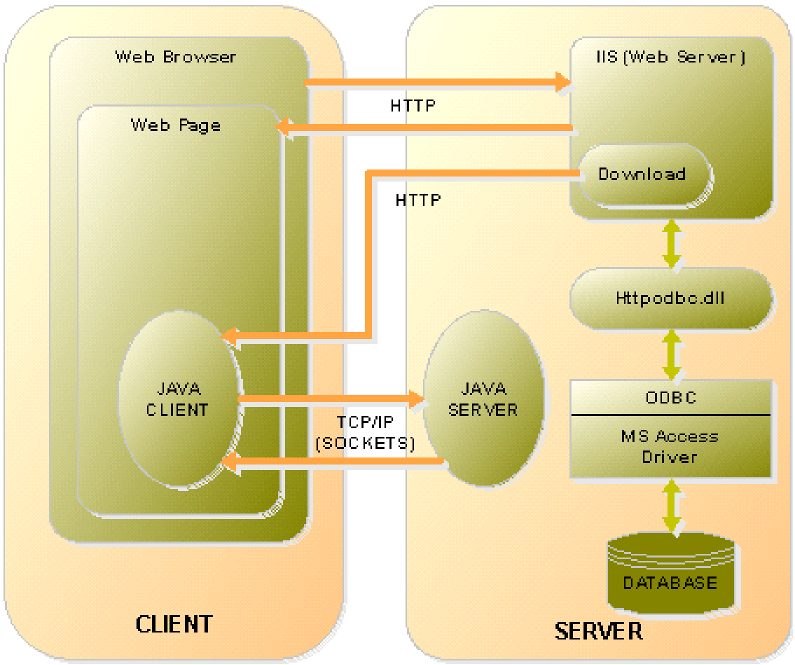

Figure 2. Initial Web page of the virtual museum: View of Fabio Neri's palace

Figure 3. General view from the patio

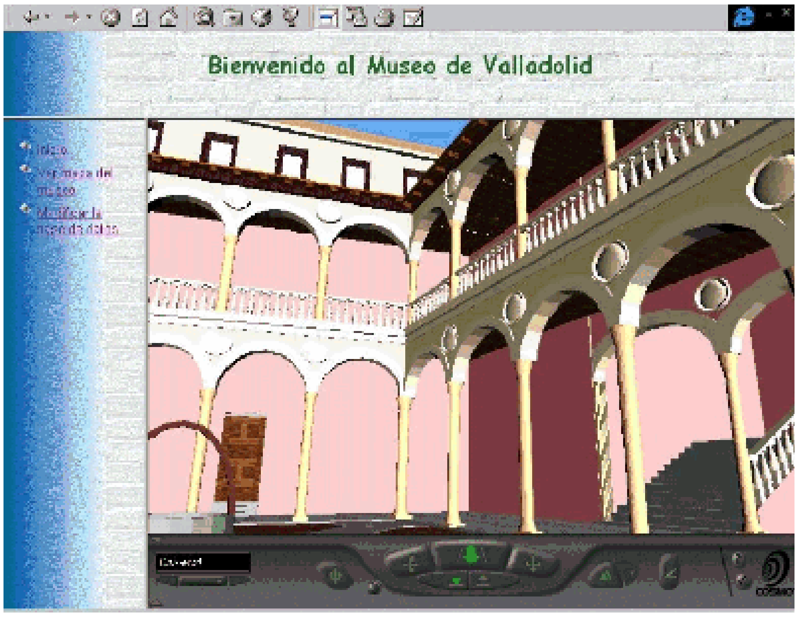

Figure 4. Initial view of the virtual room

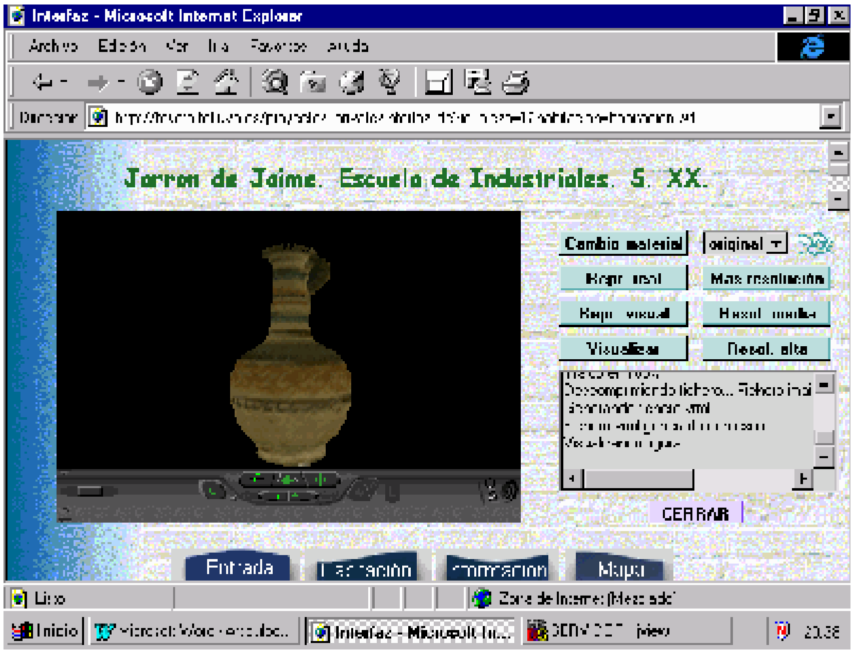
Figure 5. An example of 3D artifact



One of the features of the proposed system is that it allows the 3D display of an artifact in VRML format in different levels of resolution (see Figure 5), which implies that the user can manipulate it as he pleases.

FUTURE TRENDS

Our system marks the advent of a new and interactive form of documenting, referencing, and archiving heritage structures. Future work involves advanced development of this system as follows:

- Include dynamic elements like 3D surround sound, voice-overs for history, culture, and other information along with traditional audio pieces to make a complete user-friendly interactive interface.
- Increase the number of works of art and information in texts in order to give a more detailed presentation of archaeology in Spain.
- Achieve better frame rates by using clever culling techniques and modeling techniques for a smooth walk-through.
- Incorporate accurate details by using the latest photogrammetric techniques.
- Depict “as was”, “as is”, and “as it could be” transitions for studies specific to architecture, conservation, games for children and light simulations.

CONCLUSION

Our project resulted in the following observations:

- We achieved a fairly accurate 3D model of a complex heritage structure using archaeological orthographic projections as reference material.
- Construction of a virtual museum is possible, allowing users to examine, conduct research, or navigate any part of the building at their own convenience where they not only can see photos, and 3D objects, and even have the opportunity to play with them.
- The viability of the system has been demonstrated, as well as its correct operation in the net in the particular case of the Museum of Valladolid.

KEY TERMS

Client-Server Architecture: A network architecture in which each computer or process on the network is either a client or a server. Servers are powerful computers or processes dedicated to managing disk drives (file servers), printers (print servers), or network traffic (network servers). Clients are PCs or workstations on which users run applications. Clients rely on servers for resources, such as files, devices, and even processing power.

Dynamic HTML: A collective term for a combination of new HTML tags and options, style sheets and programming, which enable you to create web pages that are more interactive and faster to download.

Java: A platform-independent programming language, produced by Sun Microsystems. Java is built as a method to provide services over the WWW. With Java, a Web site provides a Java application (called an applet) which is downloaded by the client and executed on the client machine. Java is specifically built so that an application can be run on any kind of system, so a separate Mac, Windows, Sun, and so forth, version is not needed. Java also has some security features built in, to make it more difficult for destructive applets to be written.

QuickTime VR: An enhanced version of the standard developed by for displaying content (animation, audio, and) on computers. This enhanced version adds the ability to display and rotate objects in three dimensions.

URL: The address of a computer or a document on the Internet that consists of a communications protocol followed by a colon and two slashes (as http://), the identifier of a computer (as www.m-w.com) and usually a path through a directory to a file " called also *uniform resource locator, universal resource locator*.

Virtual Museum: A collection of digitally recorded images, sound files, text documents, and other data of historical, scientific, or cultural interest that are accessed through electronic media. A virtual museum does not house actual objects and therefore lacks the permanence and unique qualities of a museum in the institutional definition of the term.

Virtual Reality (VR): The use of computer modeling and simulation to enable a person to interact with an artificial three-dimensional visual or other sensory environment. VR applications immerse the user in a computer-generated environment that simulates reality through the use of interactive devices, which send and receive information and are worn as goggles, headsets, gloves, and so forth.

Virtual Reality Modeling Language (VRML): A programming language for the creation of virtual worlds. Using a VRML viewer, you can take a virtual tour of a 3D model building, or manipulate animations of 3D objects. Hyperlinks to other sites and files can be embedded in the world you visit.

Web Access by Older Adult Users

Shirley Ann Becker
Florida Institute of Technology, USA

INTRODUCTION

The older adult population in the U.S. continues to increase at a rapid pace due to aging baby boomers and increased life expectancy. Older Americans, 60 years and older, will comprise about 20% of the total population by 2030, which is more than twice the number of aging adults than in 2000 (Administration on Aging, 2002).

The Web offers an unprecedented opportunity for older adults to access a wealth of online resources. Increasingly, older adults are using the Web for information on self-diagnosis, treatment, and prevention of health problems (Preidt, 2003). They are taking advantage of electronic government resources to vote, file taxes, obtain social services, voice their opinions to officials, and search historical records. Older adults are also using the Web to stay socially active in terms of communicating with other users via lists and chat rooms (Czaja, Guerrier, Nair & Landauer, 1993; Kerschner & Hart, 1984).

Older adults are getting online by an estimated growth rate of 15% per year (Coulson, 2000). They log over eight hours of online time per week and visit more Web sites than persons in younger age groups when they are online (Morrell, Dailey, Feldman, Holt, Mayhorn & Echt, 2002). Their use of the Internet is predicted to increase as much as 358%, from 3.7 million users in 2001 to 17.3 million in 2005 (Scanlon, 2001).

Unfortunately, older adults may have trouble accessing a Web site because of design issues that impede its use. Barriers may be encountered due to a site's color scheme, font size and type, navigation, vertical screen length, image mouseovers, and sentence complexity, among others. In this information-rich society, many older adults will remain "information have-nots" unless these barriers are removed.

BACKGROUND

In the U.S., the Internet has emerged as a major communications medium with the potential to disseminate information to all citizens including older adults. Yet, there is an ongoing concern that the opportunities associated with Internet access may not be readily available to all citizens. This concern has been expressed in a recent Pew Foundation study (Lenhart, Horrigan, Rainie, Allen, Boyce, Madden & O'Grady, 2003, p. 6):

"Internet non-users will have less power as consumers and fewer economic opportunities, less access to high-quality health information, fewer options for dealing with government agencies, no chance to learn about their world from the millions of organizations and learning centers that have posted their material on the Web, and less opportunity to interact with others through email and instant messaging."

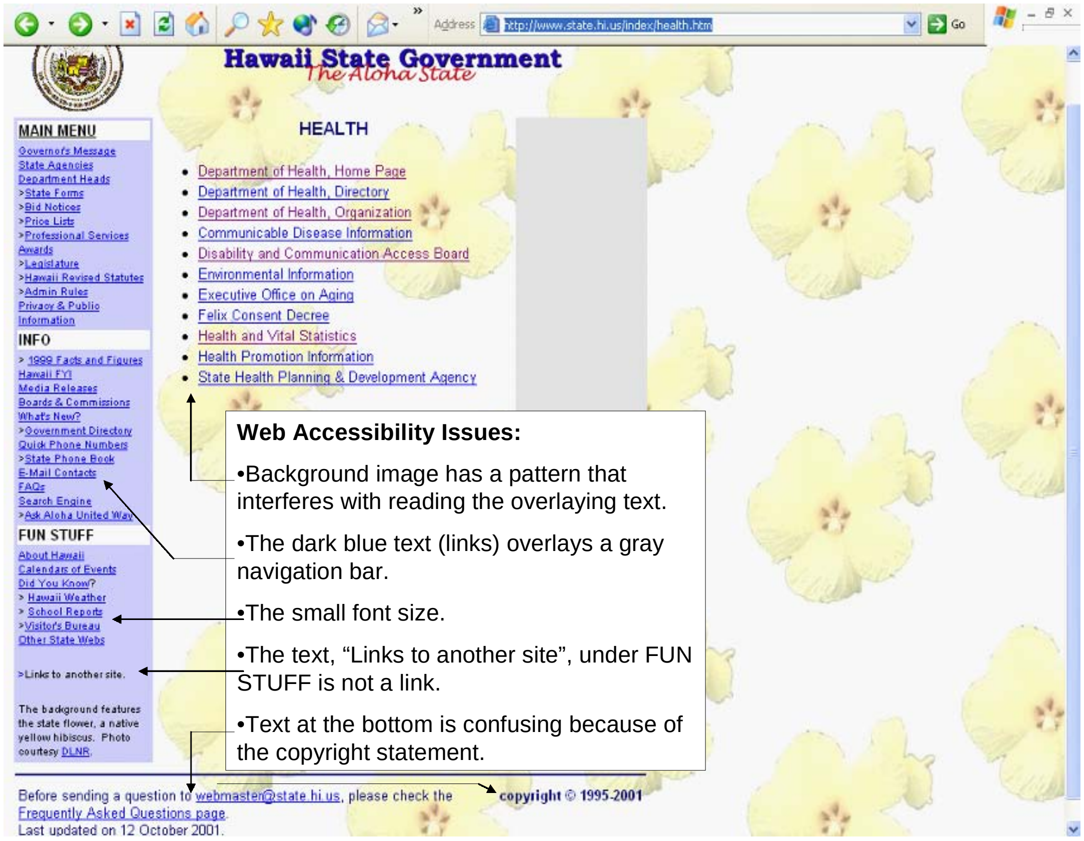
Older adults in particular may encounter Web accessibility barriers due to vision, cognition, and physical changes that are associated with the normal aging process. Reading complexity may also become a barrier when literacy skills of older adults are not taken into account in the design of Web content.

Vision

The aging eye has a reduced ability to focus on close objects due to a reduction in the elasticity in the lens. Other vision changes due to the normal aging process include: a decline in visual acuity, impacting the ability to see objects clearly, yellowing and thickening of the lens, impacting color perception, decreased light sensitivity, impacting adaptation to changes in light levels, increased sensitivity to glare from light reflecting or shining into the eye, and reduced depth perception, making it more difficult to judge the distance of an object (American Foundation for the Blind, 1999). These vision changes impact the use of the Web in terms of the legibility of written content on the page. They also impact searches, navigation, and reading speed and comprehension (Echt, 2002).

Figure 1 illustrates readability issues associated with a state government Web page when taking into account aging vision. The patterned background image may negatively impact readability, especially given the small size of the foreground text[1]. The format of the text at the bottom of the page also impacts readability given that the sentence "Before sending a question to <webmaster>, please check the Frequently Asked Questions page" breaks to

Figure 1. Illustration of Web barriers and aging vision (http://www.state.hi.us/index/health.htm)



accommodate the copyright statement appearing on the right.

The use of color can also impact the readability of information content on a Web page due to aging vision (refer to Becker, 2004a for a discussion on color and Web accessibility for older adults). For many older adults, foreground and background color combinations may render a Web page visually inaccessible. In Figure 1, the contrast between the text and background colors in the navigation bar may be insufficient for older adult readers. Figure 2 shows the New Mexico state government homepage with saturated colors for both the foreground and background. The edges of the text tend to blur when bright or neon colors are used in combination with saturated colors (e.g., bright yellow text displayed on a red background), thus reducing legibility of the text for many older adult users.

Cognition

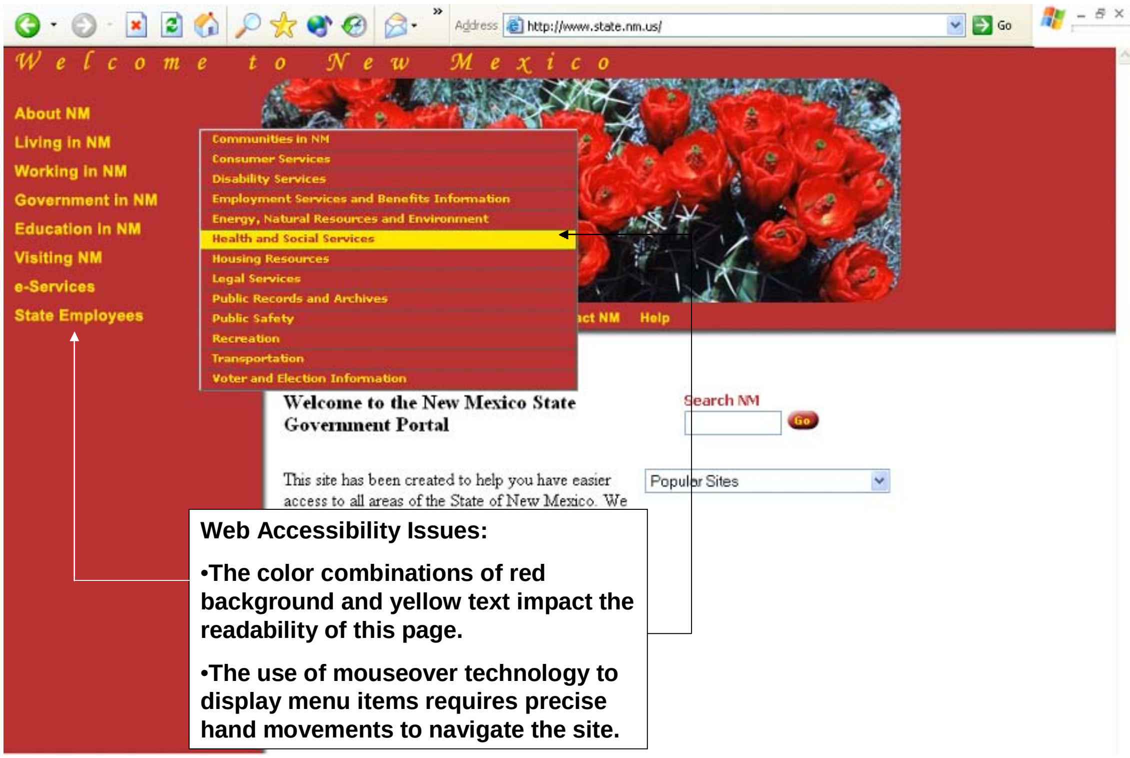
Studies show that an older adult's working and spatial memory task performance declines with age (Holt & Morrell, 2002). As a result, an older adult may not be able to discern details in the presence of distracting information. In addition, complex navigational schemes, nonintuitive searches and cluttered pages may impede use of a Web site because of declines in working and spatial memory.

Of 40 U.S. state government sites assessed, over 60% required traversing three or more screen pages to navigate directly to resources for older adults (Becker, 2004b). Less than 8% of these sites had a descriptive link on the homepage linking to senior resources. Those Web sites having nondescript links required trial and error searches for senior resources. This type of navigational complexity impedes the use of electronic government by many older adult users.

Physical Impairments

Older adults experience a decrease in motor coordination, and as such, may have difficulty with cursor positioning, precise mouse movement, and clicking on links (Chaparro, Bohan, Fernandez, Choi & Kattel, 1999; Ellis & Kurniawan, 2000; Hawthorne, 2000). Figure 2 shows a Web page that requires the precise use of mouseover technology in order

Figure 2. Illustration of Web barriers due to color and mouseovers (http://www.state.nm.us)



to navigate the Web site. This site becomes virtually inaccessible to those users who cannot precisely click on a link and move the mouse to the pop-up menu.

Literacy

The Joint Committee on National Health Education Standards (1995) defines health literacy as the capacity of an individual to obtain, interpret, and understand basic health information and services and the competence to use such information and services in ways that are health-enhancing. This includes the ability to understand instructions on prescription drug bottles, appointment slips, medical education brochures, doctor's directions and consent forms, and the ability to negotiate complex health care systems. In today's wired world, health literacy is expanded to include the comprehension of online health information.

The Web is transforming health care by providing online health information to patients, clinicians, caregivers, and family members. There are hundreds of health-related Web sites offering access to unprecedented amounts of health information. Because of their heavy use of health services, older adults could be among the major beneficiaries of Web-accessible health information. But, when the literacy requirements of these pages are misaligned with the literacy skills of older adults, the results could be devastating.

The Web offers an extraordinary opportunity to disseminate timely and much needed health care information to older adults. This opportunity is expanding further with technological advances in wireless communication and increasing availability of community computing resources through institutions such as nursing homes, schools, and libraries.

Older adults in general have a lower education level than younger adults according to the U.S. Census (www.census.gov). The National Adult Literacy Survey found that 71% of older adults performed in the lowest two levels of literacy defined in the survey (Kirsch, Yamamato, Norris, Rock, Jungeblut & O'Reilly, 2001). Approximately 67% of older adults appeared to have difficulty with finding and processing quantitative information when compared to younger adults (Brown, Prisuta, Jacobs & Campbell, 1996).

The reading complexity of content targeting older adults is illustrated by the following sentence appearing on the Alabama state Web site (http://www.adss.state.al.us/seniorrx.htm):

Table 1. NIA/NLM guidelines for making senior-friendly Web sites

Guideline	**Description**
Sans serif typeface	Sans serif font types should be used to display information content because they are not condensed.
12 point or greater font size	The use of a large font size improves legibility of information content such that text body, buttons, links, images, and other textual objects are readily seen by an older adult.
Mixed case letters in text body	The text body should be in mixed case text to improve readability. Upper case text should be reserved for headlines on a page.
Left justification	Text should be left justified because spacing between letters is consistently the same.
Plain background images	Patterned background images should be removed from a Web page because they reduce the legibility of text overlaying them.
Text effects only in headlines	Text effects including underlining, italics, bold, or strikethrough should not be used in the body of the text.

"In case you're not familiar with the program, SenioRx is a partnership of state agencies and community organizations designed to assist senior citizens (ages 60 and older) with chronic medical conditions who have no prescription insurance coverage and limited financial means (living below 200% of the poverty level) with applying for drug assistance programs provided by pharmaceutical manufacturers."

The reading grade level associated with this sentence is far beyond a 12th grade level because it is composed of 58 words. In addition, about 33% of the sentence is composed of three or more syllable words, adding to its complexity. Though there is only one sentence in this sample, it illustrates the reading comprehension barriers that older adults may encounter while surfing the Web.

WEB ACCESSIBILITY INITIATIVES

The National Institute on Aging in conjunction with the National Library of Medicine has developed Web accessibility guidelines for making sites senior-friendly (NIA & NLM, 2001). These guidelines are based on scientific findings from research in aging and cognition and human factors (Morrell et al., 2002). They provide information on how to improve the design, navigation, and information content of Web sites to remove accessibility barriers for older adult users. Table 1 lists several of these guidelines for promoting the development of accessible Web sites. Note that several of these guidelines, font size, and patterned background images were not followed in the design of the government Web page previously shown in Figure 1.

Another initiative is the National Cancer Society's usability.gov Web site, which provides information about making Web content more usable, accessible, and useful (*www.usability.gov*). It provides research and practitioner-based guidelines on design layout, navigation, information content, and other usability aspects of Web design targeting the general population of computer users. Though it does not specifically target the usability needs of older adults, many of these resources will improve Web site usability for this user group.

Nonprofit groups, including the SPRY foundation (*www.spry.org*), Seniornet (*www.seniornet.org*), and AARP (*www.aarp.org*), provide online resources and support research in Web accessibility for older adults, health literacy, and related areas. Much of the research conducted by these groups provides feedback on the digital divide, health literacy issues, community resources, and the status of older adults getting and staying online.

From a broader user perspective, there have been initiatives in promoting Web accessibility for those with disabilities. Microsoft, IBM, Apple, Watchfire and other corporations have provided resources, tools, and techniques for improved accessibility of Web designs. The Trace Research and Development Center at the University of Wisconsin (*www.tracecenter.org*) is one of several centers that focus on universal usability in order to make technology accessible to anyone, anytime, and anyplace. The ACM SIGCAPH (Special Interest Group on Computers and the Physically Handicapped) Web site provides a full listing of Web accessibility resources (*http://www.hcibib.org/accessibility/#ORGANIZATIONS*).

Section 508, an amendment to the 1973 Rehabilitation Act, was enacted by the U.S. government in order to eliminate information barriers for those persons with disabilities. It requires that individuals with or without disabilities have equal access to information provided by federal agencies (www.Section508.gov). Web content guidelines have been put forth by the World Wide Web Consortium (www.w3c.org/WAI/) in order to eliminate accessibility barriers. Though Section 508 does not specifically address the barriers to Web use due to the normal aging process, many guidelines on design layout, information content, navigation, and design consistency improve usability from an older adult perspective.

CONCLUSION

Though significant strides have been made to promote Web accessibility for older adults, there are still barriers to overcome. Web accessibility and online literacy research requires further study in determining an optimal presentation of content to meet the literacy needs of older adult users. The NIA/NLM guidelines recommend active versus passive voice sentence structures, short sentences, and appropriate reading grade levels. Because these guidelines are rather vague, it may be difficult to enforce them during the design of Web content. For example, what is a sufficiently "short" sentence in terms of word count and syllable complexity? Cultural diversity and English proficiency of the older adult population also require further study in terms of potential barriers to Web use.

KEY TERMS

Digital Divide: The digital divide is a term used to describe the disparity between persons who have access to information and computing technology and those who do not. Often, it is used to describe the lack of Internet accessibility to those living in rural or remote areas or who lack computing knowledge and skills.

Electronic Government: Electronic government (e-government) refers to the use of information and computing technologies by government agencies to deliver services, information, and resources to citizens, businesses, and other organizations.

Health Literacy: Health literacy is the capacity of an individual to obtain, interpret, and understand basic health information and services and the competence to use such information and services in ways that are health-enhancing (refer to text box 1).

Older Adults: An older adult is defined as a person who is 60 years or older in the National Institute on Aging's guidelines on making senior-friendly sites.

Visual Aging: Visual aging takes into account age-related changes in vision that have consequences on daily activities. In this article, the consequences are related to using the Web.

Web Accessibility: Web accessibility means that any person, regardless of disabilities, is able to use Web technology without encountering any barriers.

Web Usability: Web usability refers to the user satisfaction associated with a Web site. It typically includes the effectiveness of the site in meeting the needs of the user. It also includes the site's performance, reliability, and overall efficiency in supporting specified user goals.

ENDNOTES

Web Accessibility and the Law

Holly Yu
California State University, Los Angeles, USA

INTRODUCTION

In the past three decades, the method of receiving and conveying information has shifted from paper-based, typewriter-generated, hand-edited, and printing-press-produced publications to more technology-mediated, intelligent, WYSIWYG software-generated forms. Consequently, the concept of access to information has changed to reflect this phenomenon. The new forms of access to information that have made it easier for non-disabled people have often created barriers for people with disabilities.

The notion of access to information involving the civil rights of people with or without disabilities arises from the fact that access to information through technology has increasingly become a necessary tool for success and the source of opportunity in education and employment. With the advent of information technology and the unprecedented opportunities they created for people with and without disabilities, it has become apparent that information technologies have a tremendous potential for allowing people with disabilities to participate in mainstream activities and to support their ability to live independently.

The disability rights movement in the United States originated during the post-World War II era when large numbers of veterans who were disabled in the war joined the efforts of parents seeking education and independent living options for their children with disabilities (Slatin & Rush, 2003). Recently, we have seen a growing body of significant laws, regulations, and standards concerning Web accessibility that impact people with disabilities and their ability to fully overcome digital barriers and participate in the Web environment. In defining Web accessibility, Section 508 of the Rehabilitation Act of 1973 as amended in 1998 documents that "Web sites are accessible when individuals with disabilities can access and use them as effectively as people who don't have disabilities" (Section 508, 1998). A person with a disability is defined in the Americans with Disabilities Act (ADA) as "someone who has a physical or mental impairment that substantially limits one or more major life activities, a person who has a record of such impairment, or a person who is regarded as having such impairment" (ADA, 1990). The legal foundation for protecting the civil rights of persons with disabilities has been established through a series of federal and state laws, and court decisions. These laws provide a legal ground on Web accessibility implementation.

LAWS, REGUALTIONS, STANDARDS, AND GUIDELINES

Under the provisions of laws, some of the legal milestones that have direct impact on Web accessibility are Section 504 of the Rehabilitation Act of 1973, Americans with Disabilities Act (ADA) of 1990, and Section 508 of the Rehabilitation Act of 1973, as amended in 1998.

Section 504, Rehabilitation Act, 1973

Signed on October 1, 1973, Section 504 of the Rehabilitation Act is regarded as landmark legislation and the first civil rights law prohibiting recipients of federal funds from discriminatory practices on the basis of disability.

Core areas of the legislation consist of the prohibition of such activities as discriminatory employment practices, and discrimination in the delivery of educational offerings; health, welfare, and social services; or any other type of programs benefit or service supported in whole or in part by federal funds.

Section 504 is currently applied to all entities that receive federal government funds, including states, counties, cities, towns, villages, and their political subdivisions, public and private institutions, public and private agencies, and other entities that receive federal money. Each federal agency has its own set of Section 504 regulations that guide its own programs. Over the years, the Rehabilitation Act has been amended several times to address the constant changes in technology and its impact on society. The amendments most relevant to the access to information technology are those made to Section 508. The significance of the Section 504 lies not only in that it was the first statute applying civil rights protections to people with disabilities, but that it also "furnished the model for major subsequent enactments, including the ADA" (NCD, 2001). Section 504 was legislated too early to specifically addresses the issue of access to services and programs provided over the Web.

Americans with Disabilities Act (ADA), 1990

Passed on July 26, 1990, the ADA establishes a clear and comprehensive prohibition of discrimination on the basis of disability. While Section 504 applies to federal government agencies and those that receive federal funds, the ADA extends the rights of equal treatment for people with disabilities to the private area, to all places of public accommodation, employers, and entities that deliver government services. The core sections of the law are found in the first three titles: employment, state and local government activities, and public accommodation. Title II of the ADA requires that state and local governments give people with disabilities an equal opportunity to benefit from all of their programs, services, and activities, such as: public education, employment, transportation, recreation, health care, social services, courts, voting, and town meetings. Section 202, Title II indicates that:

"…no qualified individual with a disability shall, by reason of such disability, be excluded from participation in or be denied the benefits of the services, programs, or activities of a public entity, or be subjected to discrimination by such entity." (ADA, 1990)

Title II recognizes the special importance of communication, which includes access to information in its implementing regulation at 28 CFR Section 35.160(a). The regulation requires that a public entity must take appropriate steps to ensure that communications with persons with disabilities are as effective as communications with persons without disabilities. The ADA mandates for "effective communication, reasonable accommodations, and auxiliary aides and services" (ADA, 1990).

However, Web accessibility did not become prominent until 1996 when the Department of Justice (DOJ) responded to Senator Tom Harkin (D-Iowa), the author of the ADA, when he inquired on behalf of one of his constituents on Web page compatibility for the blind and other people with disabilities. In response, DOJ stated that ADA Title II and III do indeed require covered entities to provide "effective communication" regardless of the media used, and that information offered through digital media must be offered through "accessible means" as well. The Internet is an excellent source of information and, of course, people with disabilities should have access to it as effective as people without disabilities (DOJ, 1996). This response involves understanding to what extent the ADA requires Web pages to be accessible to people with disabilities. The DOJ's ruling explains how the mandate for "effective communication" in ADA should apply to Web pages and Web design.

Section 508 Rehabilitation Act, 1998

Signed into law on August 7, 1998, as part of the Workforce Investment Act, Congress revised Section 508, an amendment to the Rehabilitation Act of 1973. The core area of this amendment is to ensure that all Americans have access to information technology. The law applied specifically to all U.S. government agencies, but it also affects anyone who works with the U.S. government. The law requires that when developing, procuring, maintaining, or using electronic and information technology (EIT), federal departments or agencies should ensure that the EIT allows federal employees with disabilities to have access to and use of information and data that is comparable to the access to and use of information and data by other federal employees (Section 508, 1998).

Section 508 charges the Architectural and Transportation Barriers Compliance Board (Access Board) with the task of producing accessibility standards for all electronic and information technologies used, produced, purchased, or maintained by the federal government. On December 21, 2000, the Access Board finalized and issued the standards. With its publication, the federal government for the first time set specific access standards for information presented over the Web. According to the law, federal agencies were permitted a six-month period after the standards were issued to demonstrate that their information technology systems met the standards. Federal agencies became subject to civil rights litigation for noncompliance under Section 508 after June 21, 2001. These standards have been folded into the federal government's procurement regulations, namely the Federal Acquisition Regulations (FAR) to which most agencies are subject. Agencies not covered by the FAR should incorporate the Access Board's Section 508 Standards into their own procurement regulations. The standards define means of disseminating information, including computers, software, and electronic office equipment. They provide criteria that make these products accessible to people with disabilities, including those with vision, hearing, and mobility impairments. The scope of Section 508 and the Access Board's standards are limited to the federal sector. It does not explicitly apply to the private sector or to state and local governments.

The statements issued by the U.S. Department of Education and the Access Board support a concept of state government obligations wherein they abide by Section 508 by virtue of their linkage with funding supplied to state governments through the Assistive Technology Act (29 USC 3001). There is a statement in the U.S. Department of Education's enforcing regulations to the Assistive Technology Act at 34 CFR Part 345, requiring "compliance with Section 508 of the Rehabilitation Act of 1973" (34 CFR 345.31).

Web Content Accessibility Guidelines (WCAG)

Founded in 1994, the World Wide Web Consortium (W3C) was originally organized by the European Center for Nuclear Research (CERN) and by the Massachusetts Institute of Technology (MIT). The W3C launched the Web Accessibility Initiative (WAI) in April 1997 specifically to address the question of how to expand access to the Web for people with disabilities. In February 2000, the WAI published the Web Content Accessibility Guidelines 1.0 (WCAG) and Authoring Tool Accessibility Guidelines 1.0 (ATAG), and the User Agent Accessibility Guideline 1.0 (UAAG).

The WCAG establishes three priority checkpoints for Web content developers to meet. The guidelines include 64 checkpoints arranged under 14 separate guidelines within the three priorities.

- *Priority I.* Developers MUST satisfy Priority I checkpoints in order to attain a minimum degree of accessibility. Otherwise, one or more groups will find it impossible to access some part of the information.
- *Priority II.* Developers SHOULD satisfy Priority II checkpoints for a higher degree of accessibility.
- *Priority III.* Developers MAY address Priority III checkpoints for maximum accessibility and usability (WAI, 2000).

Topics of the guidelines include images, programming scripts, navigation, multimedia, forms, frames, and tables. The guidelines are detailed and prioritized with an associated checklist *(*www.w3.org/TR/WAI-WEBCONTENT/full-checklist.html*)*. WCAG 1.0 has become the basis for accessibility standards adopted by the international community.

Laws, Regulations, and Policies in Other Countries

The World Wide Web has no boundaries, therefore, "nations everywhere are developing policies and standards to enhance the accessibility of electronics and information technology" (Paciello, 2000). These nations include European countries (Belgium, France, Greece, Norway, Portugal, Sweden, and United Kingdom), Canada, Australia, and Japan. As a founding contributor, the European Community provides financial support to the WAI. Among these countries, Australia and Canada are two counties that have enacted legislation. Prominent Australian legal standards include the Disability Discrimination Act (DDA) of 1992 and the Anti-Discrimination Act of New South Wales of 1977. Australia's Human Rights and Equal Opportunity Commission, a government agency, is responsible for creating and establishing legal decrees mandating equality of access for the disabled. In Canada, the Equity and Diversity Directorate of the Public Service Commission of Canada (PSC) "was the first government institution in any country to create a series of Web accessibility guidelines used to evaluate Web pages" (Paciello, 2000). The Common Look and Feel Working Group, created in 1998 by the Treasury Board Secretariat's Internet Advisory Committee, is charged to establish standards and guidelines as a base for official government policy.

ISSUES RELATED TO WEB ACCESSIBILITY

The current problems encountered in the implementation of accessible Web design do not only stem from design issues, nor are they because of a lack of laws, regulations, and government-related standards, although there are unanswered questions in that laws create difficulty in the implementation process. The current problems we are facing are the absence of an obligation to fulfill legal requirements and by not being aware that ensuring resource accessibility is a legal mandate. Many Web developers have not focused on the extent to which their Web pages are accessible to people with disabilities. This situation reveals that institutions are only just beginning to apply accessible Web design techniques and are not aware of the urgency behind designing accessible Web pages.

A primary issue that constitutes a barrier for implementation is that the current legal framework for electronic and information technology accessibility is actually a patchwork of laws covering certain categories of technology in some settings, other categories in other settings, but nowhere reflecting an overview or comprehensive assessment of either the issues or the solutions (NCD, 2001). The absence of obligations in fulfilling legal requirements has further complicated the implementation process. In many cases, the absence of obligations is due to unfamiliarity with the legal responsibility for creating accessible Web sites. Compounding these problems have been the conflicting views between minimum compliance and maximum accessibility. There is a tendency that most Web designers are either unaware of the laws and regulations, or ignore the accessibility requirements, or only pay attention to them as part of legal requirements.

Part of problem created by today's networked environment is that stand-alone workstations utilizing assistive technology software solutions are no longer sufficient because in the Web environment, the linkage between an individual and the Internet community as a whole is addressed, and access to the Web cannot be handled on a case-by-case basis using workstations with assistive technology. When approaching the issue of accessibility, John Mueller, the author of *Accessibility for Everyone: Understanding the Section 508 Accessibility Requirements*, points out that the issue should be approached from the viewpoint of universal design: "The application you create should work equally well with any hardware the user might have attached to the machine" (2003). Assistive technology alone cannot overcome the barriers that are created at a more basic level, the format in which content is presented (Schmetzke, 2001). For example, when electronic forms are used, the form shall allow people with disabilities to fill out the required information and to complete the online transaction. If the instruction for where to enter the appropriate information is not given, even the smartest screen reader would not know what to do with the input box, therefore the user with visual impairment or blindness would not know what to do either. Access barriers created by inaccessible design cannot be overcome even with the most sophisticated assistive technology. Further, assistive technology may also give rise to issues of incompatibility. Therefore, the Web environment mandates that potential barriers in Web design going beyond the computer workstation be examined.

IMPLEMENTATION

The benefits resulting from the implementation of universal Web design principles, which allow pages to be accessible to the largest number of the population, have been emerging. Functionalities found in assistive technology can streamline our digital architecture, and the very functionality required in Web design by people with disabilities can meet dynamic requirements for Web-based transactions. A universal Web design will greatly reduce the cost for assistive technology geared specifically to individual computer workstations, and allow universal access for users from anywhere at anytime. In a broad sense, a universal Web design allows the disability community to benefit as a whole rather than achieving accessibility through a segregated, compartmentalized, and ad hoc approach.

The overwhelming benefits of creating universally accessible Web pages can hardly be disputed. However, accessibility barriers are usually systematic. There are practical and legal reasons for addressing accessibility issues in our education, policy, and design. As the rapid development of new Web applications continues, it is necessary to ensure that barriers themselves will not continue to expand. We have seen tremendous efforts underway in the implementation process.

Education to raise awareness of Web accessibility issues, understanding the laws related to accessibility, and the consequences of major disparities in our society are a first step toward solutions. It is crucial that people with disabilities be involved in the procurement and/or development of accessibility solutions. Thus, issues of compatibility and accessibility can be anticipated and addressed during the strategic planning stage. Identifying problems and implementing repairs are two integral elements of Web site accessibility assessment. One way to ensure the assessment can be carried out is to recommend its inclusion into the institution's Web planning and design process. Another is for the institution to develop its own checklists or follow the most up-to-date guidelines published by the W3C. The assessment should indicate the areas of violations and content that are inaccessible. Based on the assessment, a plan should be made to integrate the findings and recommendations for change. Developing tools to facilitate accessible Web design is a key to the ultimate success of an accessible Web site.

Principles of universal design should be achieved, and the view of depending heavily on the tool of the assistive devices to mediate and decode should be utilized as a last result. Conducting usability studies with the understanding that the accessibility is an integral part of usability will assist in promoting inclusion.

FUTURE TRENDS

The ultimate goal for Web sites is universal design, or pervasive accessibility-interfaces that adapt to the user, regardless of ability. It is so often that with each release of new technology, there will be fixes to accessibility problems. "Subsequently, that technology that increases access to people with disabilities is termed assistive and adaptive as opposed to being a technology that is in inherently accessible" (Paciello, 2000). As we observed, while much of today's technology is designed lacking accessibility, recent awareness of laws and guidelines, and advances in promoting accessibility give rise to hope for achieving the ultimate goal for accessibility. The benefits resulting from the implementation of universal Web design principles, which allow pages to be accessible to the largest number of segments of the population, have been emerging.

Discussions about the "digital divide" problem, needs for accessible Web design, and practical tips for designing barrier-free Web sites found in literature in recent years have demonstrated awareness-raising efforts (Casey, 1999; Rouse, 1999; Jobe, 2000; Valenza, 2000).

Awareness of the laws has recently increased the development of computers utilizing voice recognition and speech output systems. With technology advancement, personal computers with neural interfaces using brain and sensory technology that enable an individual to interact with a computer will allow people who have otherwise no use of their hands to interact with computers by sensing head and brain signals and translating those to computer input actions. The combination of Web and television services provides a promising future for the disabled community, particularly potential solutions for educaion.

CONCLUSION

The concept of accessible design or universal design is increasingly becoming an important component of Web design. Today, public and private entities are subject to the requirements of the ADA, Section 504, and Section 508, whether or not they receive federal funds. According to the definition of the law, denial of access resulting from the inaccessibility of mainstream information technology is considered to be discrimination. Barriers mostly resulting from the absence of obligations to fulfill legal requirements should be eliminated as the awareness of the importance of accessibility increases. Functionalities found in assistive technology can streamline our digital architecture, and the very functionality required in Web design by people with disabilities can meet dynamic requirements for Web-based transactions. A universal Web design will greatly reduce the cost for assistive technology geared specifically to individual computer workstations, and allow universal access for users from anywhere at anytime. The benefits and value for overcoming these barriers for the community of people with disabilities cannot be disputed, and maximum accessibility is a goal for us to achieve.

KEY TERMS

ALT-Text: Stands for Alternative Text, primarily used to render graphics when the image is not being displayed.

Americans with Disabilities Act (ADA): U.S. public law enacted in 1990 ensuring rights for people with disabilities. This legislation mandates reasonable accommodation and effective communication.

Bobby: A Web page accessibility validation service provided by the Center for Applied Special Technologies (CAST); uses the W3C's Web Content Accessibility Guidelines, and evaluates Web pages for possible errors and ranks them in order of priority.

JAWS: A Windows screen reader from Henter-Joyce; stands for Job Access for Windows. JAWS works with PCs to provide access to software applications and the Internet. With its internal software speech synthesizer and the computer's sound card, information from the screen is read aloud for visually impaired and blind people.

Section 508: Section 508 of the Rehabilitation Act is U.S. legislation that establishes requirements for electronic and information technology developed, maintained, procured, or used by the federal government.

W3C: The World Wide Web Consortium (W3C) develops interoperable technologies such as: specifications, guidelines, software, and tools to lead the Web to its full potential. W3C is a forum for information, commerce, communication, and collective understanding.

Web Accessibility Initiative (WAI): Established by W3C and the Yuri Rubinsky Insight Foundation in 1997, the WAI works with organizations around the world to promote Web accessibility in five key areas: technology, guidelines, tools, education and outreach, and research and development.

Web Content Accessibility Guidelines (WCAG 1.0): The official set of guidelines published by the W3C to assist Web content developers in the creation of accessible Web sites. The guidelines established three priority levels with 64 checkpoints for Web developers to meet.

Web Caching

Antonios Danalis
University of Delaware, USA

INTRODUCTION

The popularity of the World Wide Web has led to an exponential increase of the traffic generated by its users for over a decade. Such a growth, over such a long period of time, would have saturated both the content providers and the network links had Web caching not been efficiently deployed. Web caching can improve the overall performance of the World Wide Web in several ways, depending on the decisions made regarding the deployment of the corresponding caches. By placing caches in strategic positions, the core network traffic can be reduced, the load of a content provider can be scaled down, and the quality of service, as the users perceive it, can be improved. In this article we present an overview of the major design and implementation challenges in Web caching, as well as their solutions.

BACKGROUND

A Web cache can be placed at different positions on the Web and yield different benefits. Namely, it can be placed next to a content provider, in strategic positions inside the network, at the boundaries of local area networks, or inside the host that runs the requesting browser.

Most users tend to access particular pages quite often. An example could be the "home page" that has been set on their browser, or Web sites that contain documentation they are interested in. Furthermore, during browsing, many users visit the same pages multiple times in short periods of time, by using the history of their browsers. To exploit these access patterns, most browsers keep local copies of the frequently or recently accessed pages. This way, the user is served in near zero time, and the network traffic is reduced. Although this technique can have a positive effect on the browsing experience of a single user, it has a minimal effect on the network traffic. This is mostly due to the small disk space used by this type of caching and the lack of sharing between different user caches.

To yield significant results, dedicated computer systems, called proxies, are installed at the edges of local or wide area networks. These systems can achieve significant reduction in the network traffic and improvement in the user perceived quality of service, by filtering and serving the Web requests generated inside the entire network they serve. If a user has defined in the browser's settings a particular proxy to be used, every time he or she requests a Web page the browser will send this request to the proxy. If the proxy happens to have the page, the user will be served promptly without the original content provider being contacted. If the proxy cannot serve the request, it will fetch the appropriate Web objects (such as the text documents, images, applets) from the original server, and possibly keep a copy for later use. Transparent proxies are a special kind of proxy that end users do not explicitly specify in their browser's settings. Rather, the gateway of the network identifies Web requests and forwards them to the proxy. This model is more efficient, and easier to administrate, since all the users of the local network will be using the proxy, and they need not know about possible changes concerning the proxy.

To improve the performance of a content provider, a cache can be deployed on the server side. These caches, also called server accelerators, or reverse proxies, are usually deployed in front of clusters of Web servers (Challenger, Iyengar & Dantzig, 1999) and cache the most popular documents in their main memory. Since a few highly popular documents are in most cases responsible for a large percentage of requests, by using a server-side cache, a Web server can decrease its disk I/O load (Abrams et al., 1995; Markatos, 1996; Tatarinov, Rousskov & Soloviev, 1997) and significantly improve the request serving quality of service. Nevertheless, a reverse proxy benefits only a particular content provider and does not reduce the network traffic.

In addition to client and server-side caching, there exists the approach of adaptive caching (Michel et al., 1998). In this scheme caches can exist at different points inside the network, and be configured to cooperate with one another, in order to improve the overall performance and balance the load. In this model, different caches, potentially belonging to different organizations, are organized into dynamic groups, which each one can join or leave depending on content demand. The communication needed for a group to form and for documents to be located is done through the Cache Group Management Protocol (CGMP) and the Content Routing Protocol (CRP), respectively. Adaptive caching can deal very well with request surges, occurring when some documents become highly popular in a short period of time (usually articles in online newspapers), but assumes that cooperation across administrative boundaries is not an issue.

CRITICAL ISSUES OF WEB CACHING

To improve their effectiveness, caches can be combined in groups to serve requests cooperatively. Such groups may be organized in meshes, as in the case of adaptive caching, or in hierarchical formations, as in the case of the Harvest Cache project (Chankhunthod et al., 1996). In hierarchical designs, caches are usually organized in tree-like structures, and are configured such that child nodes can query their parents and their siblings, but never their children. Although grouping several caches can improve the scalability of the caching system, control messages between a large number of nodes could saturate the parent nodes and the network links (Baentsch, 1997). To make the communication between the caches efficient, several special purpose protocols have been introduced.

The most popular inter-cache communication protocols are ICP, CRP, CARP, cache digest, and WCCP (Melve, 1999). The Internet Cache Protocol (ICP) was developed for the communication of the caches in the Harvest project and was refined within Squid (SQUID). It is a lightweight message format, used by the caches for issuing queries and replies, to exchange information among one another regarding the optimal location from where a certain object can be retrieved. The large number of messages exchanged in ICP, when the number of caches is high, has been shown to impede scalability (Baentsch, 1997; Fan et al., 2000). To avoid similar effects, the Content Routing Protocol (CRP) uses multicast to query cache meshes. CRP exploits the overlapping that exists in cache group formations to propagate queries or popular objects between the groups. To further improve on the performance of the inter-cache communication protocol, cache digests can be used (Fan et al., 2000; Rousskov & Wessels, 1998). Cache digests compact (using a lossy algorithm) the information about the contents of a cache, and make it available to its neighbors. By checking the digests of its neighbors, a cache can identify, with some uncertainty, which neighbors are likely to have a given document. In addition to these protocols, there exist two proprietary ones, CARP and WCCP, designed by Microsoft and Cisco respectively. Unlike the protocols mentioned before, the Cache Array Routing Protocol (CARP) implements routing in a deterministic way. In particular, it uses hashing to identify which member of the proxy array has the requested document. This way it avoids the scalability problems that appear in ICP due to the large number of control messages. The Web Cache Communication Protocol (WCCP) is designed to support transparent caching. The idea is that a router (such as Cisco Cache Engine) that can recognize Web traffic will intercept user requests and redirect them to a cache.

The protocol used for the communication between the Web clients, proxies, and servers is the Hyper-Text Transfer Protocol (HTTP). HTTP runs on top of TCP/IP, which is the most common protocol used in the Internet for reliable transfers, flow control and congestion avoidance. To initialize a connection, TCP sends a special packet (SYN) from the client to the server, and the server responds with an acknowledgment. After initializing the connection, in order to request a page, the client has to send an additional message to the server, and wait for the reply. In the first version of HTTP, this four-step procedure had to take place for all individual objects of a page, such as images, or applets, separately. To reduce the number of round-trips needed, persistent connections, that is, connections that remain open after the retrieval of a file, were proposed (Caceres et al., 1998; Heidemann, Obraczka & Touch, 1997; Mogul, 1995). Persistent connections allow a client to fetch all the components of a Web page by facing the connection startup latency only once. In addition to the multiple steps handshake, slow-start is another feature of TCP that has negative effects in the context of Web transfers. As the name implies, slow starts demand that newly created TCP connections transmit data very slowly and they increase the throughput as they transmit more and more. In the general case, where flow control and congestion avoidance is necessary, this technique is very efficient. In the case of Web transfers though, where the majority is short-lived since most documents are a few kilobytes long (Arlitt & Williamson, 1996; Cunha, Bestavros & Crovella, 1995; Shriver et al., 2001), slow start translates to slow transfer. In order to deal with these issues, HTTP/1.1 (Fielding et al., 1997) was introduced. This new version, among other improvements, supports persistent connections and has been shown to dramatically outperform its predecessor (Nielsen et al., 1997).

In heavily loaded Web caching systems, disk I/O can become a significant bottleneck (Markatos et al., 1999; Mogul, 1999; Rousskov & Soloviev, 1998), because disks are significantly slower than the main memory, and traditional file systems are not optimized to handle Web traffic. To reduce this overhead, Gabber and Shriver (2000) proposed the use of a special purpose file system and Markatos et al. (1999) and Maltzahn, Richardson and Grunwald (1999) proposed the use of special purpose storing policies that reduce the overhead of file creation, deletion, and access. Such policies take into account Web access patterns when they make decisions regarding file placement. For example, in most cases, the HTML text of a Web page and the embedded objects (such as images) of the page will be requested one after the other. By placing these objects in files located close to each other on the disk (Maltzahn, Richardson & Grunwald, 1999), or in neighboring locations within the same file (Markatos et al., 1999), both reading and writing will access almost sequential disk blocks, yielding a significant performance improvement. Additionally, a specialized file system (Gabber & Shriver, 2000) could avoid keeping metadata to improve performance, or could use in-memory data structures to quickly identify cached objects without performing any disk I/O (Tomlinson, Major & Lee, 1999).

Regardless of the method used to access the disk, and no matter how large the storage space is, it is not possible to store the whole Internet. Therefore, there must exist some techniques to decide which documents to keep in the cache and which to replace when the cache fills up. Several algorithms have been proposed, each trying to keep the most valuable documents in the cache. To assign a value to a document, most algorithms take into account one or more parameters such as recency of access, frequency of access, document size, and fetching latency, and try to evict the documents with the lowest value. The effectiveness of a replacement policy is measured by Hit Rate (HR) and Byte Hit Rate (BHR). HR is the percentage of requests that are served from the proxy, and BHR is the percentage of bytes served from the cache. The Least Recently Used (*LRU*) algorithm is a replacement policy already known and used in virtual memory paging systems. Based on the fact that the possibility of a file to be requested again drops dramatically as the time since the previous request increases (Cao & Irano, 1997; Rizzo & Vicisano, 2000), it tries to replace the least recently used document, when space is needed for a new one. The *SIZE* algorithm (Rizzo & Vicisano, 2000) considers the large files to be the least valuable, and thus removes the largest document to make room for several smaller. Due to the high popularity of small files (Shriver et al., 2001), *SIZE* is among the best replacement algorithms. Capitalizing on frequency of use, the Least Frequently Used (LFU) algorithm evicts the documents that have been used the least amount of times. Although this algorithm can perform similarly to LRU for many access patterns, its main disadvantage is that it does not evict documents that were popular once, but not any more (such as old newspaper articles). To deal with this issue, Arlitt et al. (1999) presented LFU-DA, which is LFU with Dynamic Aging. Their variation takes into account the age of a document and thus manages to perform better than most existing algorithms in terms of both HR and BHR. To achieve even higher efficiency, researchers have introduced algorithms that combine the different dimensions. Lowest Relative Value (LRV) (Rizzo & Vicisano, 2000), for example, assigns a value to each document, calculated based on its age, popularity and size, and replaces the one with the lowest value. Hybrid (Wooster & Abrams, 1997) takes into account even more parameters, such as bandwidth to the content provider, and time to connect, for calculating the value of a document, and has been shown to outperform most traditional algorithms in terms of both HR and latency reduction. Finally, Cao and Irani (1997) proposed GreedyDual-Size, which consists of a family of replacement policies, all working under the same basic idea, but optimized for different goals. Therefore, depending on the goals a cache wants to achieve, GreedyDual-Size can be configured to maximize the HR, or minimize the average download latency, or reduce the network traffic.

Besides evicting documents when space needs to be made for new ones, a proxy needs to delete documents that are not valid any more, to preserve the consistency of its cache. The most common cache consistency mechanisms are time-to-live (TTL) fields, client polling, and invalidation protocols (Gwertzman & Seltzer, 1996). TTL is actually an estimation of how long the current copy of a document will be valid for. Although this approach can be very useful in cases where this information is known, as in the case of periodically changing news articles, it can lead to waste of bandwidth if the estimation is too conservative, or cache inconsistency if the value of TTL is too large. Adaptive TTL tries to find a better estimation by taking into account the document's age (Gwertzman & Seltzer, 1996). In client polling, every time a document is requested, the cache sends an if-modified-since (IMS) request to the original server. According to the result, the file is either proven valid and served by the cache, or the new version is fetched. This approach generates a large number of control messages, since an IMS is sent to the server for every document requested. To gain the benefits of both techniques, squid (SQUID) uses an adaptive TTL policy to decide when to send an IMS validation request to the server. Invalidation callbacks are an approach where the original server keeps track of the proxies that have a copy of its documents, and contacts them when the documents change. Callbacks provide strong consistency without saturating the network with control messages (Cao & Liu, 1998), but raise privacy and security concerns.

Dynamic pages, either created according to the preferences of each individual user, or updated dynamically to meet real-time changing data, such as the stock market or sports scores, raise important issues in regard to cache consistency. If a dynamic document is cached and served by a traditional proxy, it is very likely to be invalid even before the very next request. On the other hand, if a proxy decides not to cache dynamic objects, it will lose an important percentage of Web traffic (Caceres et al., 1998; Wolman et al., 1999). Markatos (2001) suggests caching of search engine results for hours or days, based on the fact that query results are already several days old.

Several approaches deal with dynamic pages by caching static, sub-document objects (Douglis, Haro & Rabinovich, 1997; Meira et al., 1999; Shi et al., 2003). Furthermore, Mohapatra and Chen (2002) and Challenger et al. (1999) construct a graph of the objects that constitute a Web page and upon a change, graph traversal reveals the objects that need to be updated for the page to be reconstructed. The transfer of "deltas", that is, the differences between the cached and the original document, is another technique shown to work well (Mogul et al., 1997; Savant & Suel, 2003). Finally Cao, Zhang and Beach (1998) suggested an approach where proxies can fetch from the server a special purpose program (a CacheApplet) attached to the data, to deal with reconstructing or refetching the page the way the original content provider wishes.

CONCLUSION AND FUTURE TRENDS

Web caching has been extensively deployed during the last years to support the needs of the exponentially growing World Wide Web. Depending on their placement, Web caches can accelerate the performance of a content provider, improve content availability, reduce network traffic and download latency, and improve the overall user experience of the Web. In this article we have presented the most important design and implementation issues concerning Web caches, as well as their solutions. Some issues, such as dynamic document handling, remain open and new ideas are still being proposed. In particular, the issues of caching dynamic documents (Rhea, Liang & Brewer, 2003; Yuan, Chen & Zhang, 2003; Yuan, Hua & Zhang, 2003) and ensuring cache consistency (Mikhailov & Wills, 2003; Pandey, Ramamritham & Chakrabarti, 2003) in the presence of changing, non-static Web pages, are expected to attract considerable scientific interest in the near future. Regardless of the final decisions to prevail though, it is most likely that in the following years, caching will keep being a key solution for the performance of the World Wide Web.

Yuan, C., Hua, Z., & Zhang, Z. (2003, September). Proxy+: Simple proxy augmentation for dynamic content processing. *8th International Web Caching Workshop and Content Delivery Workshop (WCW'03).*

KEY TERMS

Byte Hit Rate: The ratio of bytes served by the cache over the total number of bytes requested by the clients. BHR can be significantly different from HR in a case where only few, but large files are being served by the cache.

Hit Rate: The ratio of requests served by the cache (hits) over the total number of requests made by the clients.

HTTP: Hyper-Text Transfer Protocol. The protocol used for most of the communication on the Web, between the clients, the proxies, and the servers.

Layer 4 Switch: A switch that can retrieve from the network packets information about the port number they are using, and thus the application that generated them.

Proxy Cache: A machine dedicated to serving client requests for Web documents. Usually it is installed at the edge of local or wide area networks to provide fast responses to the users and reduce the traffic exiting the network.

Server Accelerator: A machine dedicated to improving the performance of a Web server by caching popular Web objects. Usually it is installed in front of a single or a farm of Web servers in order to improve their performance and load the balance among them.

Transparent Proxy: A proxy that closely cooperates with either a router or a Layer 4 switch, to intercept Web requests while invisible to the users. Other than being invisible it works as a regular proxy cache.

Web Initiatives and E-Commerce Strategy

Ron Craig
Wilfrid Laurier University, Canada

INTRODUCTION

Business use of modern computers started in the 1950s. Since then, IT has progressed through a series of hardware, software and applications improvements, delivering more value to individuals, firms, and organizations for lower cost. Productivity improvement (efficiency), at both the individual and organizational levels, has been a major focus. As well, firms have learned how to gain competitive advantage from IT.

While historical roots of the Web go back several decades, it was only in the last two that business really started to embrace the Internet, and in the last one that commercial opportunities on the Web grew rapidly. Business use has gone from simple operational efficiencies (e-mail on the Internet, replacement of private EDI networks, etc.) to effectiveness, enhanced services, and virtual products. Information and information products available in digital form, and the ability to quickly transfer these from one party to another, have led to a paradigm shift in the way many organizations operate. While the transition has followed the automate, infomate, transformate progression of historical IT, the pace has been unprecedented. There have been successes and failures, with fortunes made and lost.

Paralleling the improvement in IT and the Internet has been a series of economic shifts including globalization, flattening of hierarchical organizations, increasing emphasis on knowledge work (contrasted with manual labour), plus growth in the service sector and information economy. IT has both hastened these economic shifts, and provided a welcome means of addressing the accompanying pressures. E-commerce, which now inevitably includes Web initiatives, has most recently been at the forefront among these economic shifts.

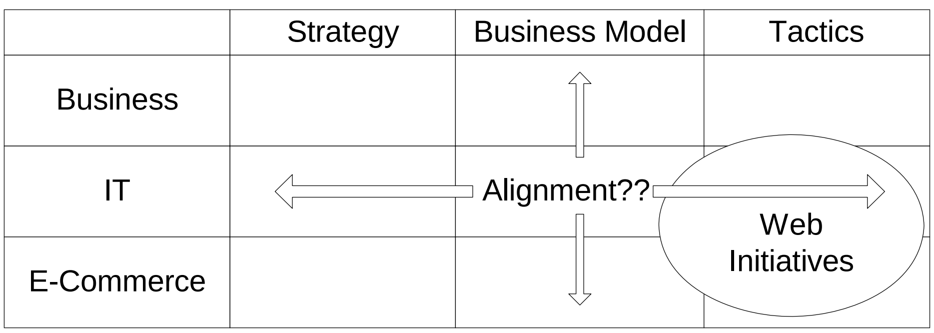
To consider Web initiatives and e-commerce (EC) strategy, one needs to first understand strategy, and then extend this to the organization's business model and tactics. A firm's general business strategy includes, but is not limited to, its IT strategy (Figure 1). Similarly, EC strategy is a subset of IT strategy. Strategy should drive actions (tactics) through an appropriate business model. When strategy (business, IT, and EC) and tactics are closely aligned, and tactics are successfully executed, desirable results are obtained.

In addition to commercial use of the Web, there are many non-commercial uses and non-commercial users (governments, educational institutions, medical organizations, etc.). The term e-business is often used to include both commercial and non-commercial activity on the Internet. In this article, the focus is on commercial activities.

BACKGROUND: BUSINESS STRATEGY, IT STRATEGY, AND WEB INITIATIVES

Business strategy and IT strategy have been extensively studied. The strategic alignment model of Henderson and Venkatraman (1993) identifies four domains of strategic

Figure 1. Strategic alignment



choice: business strategy, IT strategy, organizational infrastructure and processes, and IT infrastructure and processes. This model recognizes that a firm's IT operates within, and supports, a larger environment. As well, a firm's IT strategy can lead, lag, be independent of, or be aligned with a firm's business strategy. When alignment exists, there are significant payoffs (Tallon & Kraemer, 2003).

On the business strategy side, Porter provides several frameworks to guide firms in selecting their strategy and business model. His five-forces model, value chain network, and generic strategies (Porter, 1996) are useful frameworks when considering both business and IT strategies. In response to the question of whether or not the Internet renders established rules of strategy obsolete (as some have proposed), Porter answers that it makes strategy more vital than ever (Porter, 2001). He shows how the Internet has both positive and negative effects on industry structure, and identifies six principles of strategic positioning: (1) start with the right goal – superior long-term return on investment; (2) a firm's strategy enables it to deliver a value proposition, or set of benefits, that differentiates itself from competitors; (3) a firm's strategy is reflected in a distinctive value chain; (4) effective strategies require trade-offs; (5) strategy defines how all the elements of what a company does fit together; and (6) strategy involves continuity of direction. Porter concludes, "In our quest to see how the Internet is different, we have failed to see how the Internet is the same."

An extension to Porter's value chain is the virtual value chain (Rayport & Sviokla, 1995). Just as the physical value chain identifies the value-adding stages through which physical goods flow, the virtual value chain identifies the value-adding steps for information (gathering, organizing, selecting, synthesizing, and distributing). For virtual products and services, EC strategy and Web initiatives are especially important.

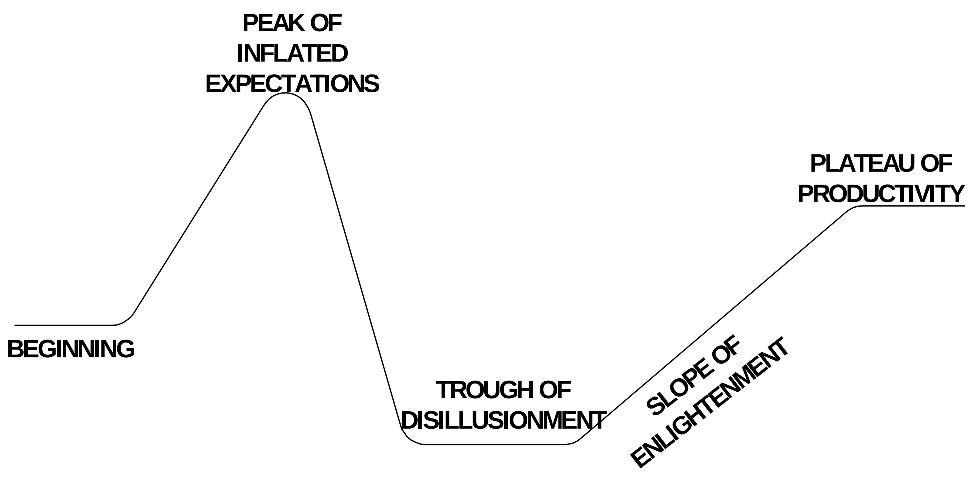
Hence, firms need to consider their IT and EC strategies as part of their business strategy. None of these should be developed or implemented independently. Decisions within any firm are made in the context of a particular business strategy, a particular set of experience and skills, a particular culture and organizational structure, and a particular set of technology and data capabilities (Hammer, 2001). Web initiatives, as a subset of EC and IT strategy, lie at the execution end (as shown in Figure 1).

E-COMMERCE STRATEGY

During the rampant optimism of the mid to late '90s, there seemed to be much more hype than reality concerning e-business. Statements were made that business was different now, that the Internet and Web changes everything, and that new e-business models were needed. The feeding frenzy among venture capitalists, eager to fund almost any start-up, allowed incomplete and ill-conceived concepts to be financed. It did not take long before reality took hold again, as the dot.com boom became the dot.com bust. The pendulum has now shifted from an overemphasis on "e" to a more balanced perspective on both "e" and "c". The Gartner Group Hype Cycle (Figure 2) provides a somewhat light-hearted, yet still realistic, view of this technology lifecycle. EC has gone through the first half of this cycle, and is now maturing.

Understanding an organization's strategic grid position (Figure 3) is critical for developing an appropriate IT

Figure 2. Gartner Group Technology Hype Cycle



and EC strategy and determining the requisite level of resources to commit. EC is not strategic to all firms, nor is all EC strategic. As Carr (2003) argues, much of IT today is a commodity-like service for many organizations, and can be managed as such. Yet, EC and Web initiatives can be strategic. There are usually significant resource implications for firms transitioning from one quadrant to another within this grid (i.e., changing their EC strategy).

An important component of EC strategy is the business model used by a firm. As shown in the previous section, strategy is about making decisions and choices. For some firms, there will be much greater emphasis on the virtual side of their business; for others it will be the opposite. However, all firms need to consider the needs of their customers and the strategies (both business and IT) of their competitors, and be able to deliver required goods/services in a sustainable manner. Hence, the firm's business model must align with the strategy selected (be it EC strategy, IT strategy, or business strategy). Magretta (2002) identifies two tests for a powerful business model – the narrative test, and the numbers test. The first test requires a logical, defendable explanation of who one's customers are, what they value, and how the firm will be profitable by providing that value. The second test requires evidence of ongoing financial viability, based on realistic assumptions and a financial analysis. Online auction giant eBay passed both these tests, as did Amazon. In contrast, most online grocery models failed because of false assumptions about what customers valued, and overly optimistic estimates of marketing, technology and delivery cost. Another retailer, Lands End, utilized Web initiatives and other IT to successfully pioneer mass customization for apparel (Ives & Piccoli, 2003).

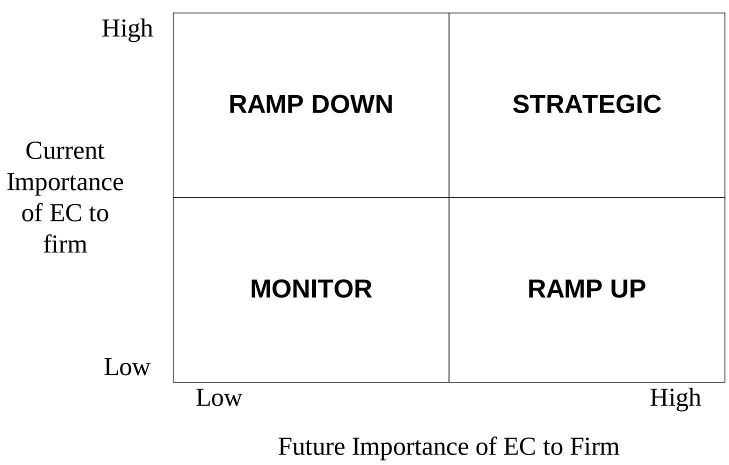
A business model is about much more than simply technology. In the earlier days of the dot.com boom, there was an overemphasis on executing Web initiatives while ignoring the rest of the business model. Now, as the EC field matures, firms have a better understanding of the opportunities, the costs/benefits, risks, and the technology and applications to use. While technology is an important component, so are organizational characteristics (culture, interorganizational relationships, leadership, reward and control systems, staffing, structure), resources (capabilities, financial, fixed assets, human, marketing, relationships, reputation and brand awareness, technology), and managerial preferences (beliefs and values, personality and needs, job experience and context, leadership style, political elements) (Crossan et al., 2002).

One question facing firms is when to use Web initiatives. Andal-Ancion et al. (2003) identify 10 drivers of new information technology (NIT), which also apply to Web initiatives. These different drivers determine the competitive advantages of deploying NIT, and fit under three general classifications: (1) Inherent characteristics of the product or service (electronic delivery, information intensity, customizability, and aggregation effects), (2) Interactions between a company and its customers (search costs, real-time interface, and contracting risk), and (3) Interactions between a company and its partners and competitors (network effects, standardization benefits, and missing competencies).

In their paper, they apply these drivers to various industries and firms, explaining the basis for disintermediation, remediation, or network-based mediation within an industry. These drivers should also be considered when a firm develops its EC strategy and considers Web initiatives.

A particular Internet benefit comes from its ability to integrate business processes across organizations, facili-

Figure 3. EC importance strategic grid



tated by the sharing of information between the various partners. This is seen in B2B exchanges (whether private or public) and portals. After a rocky start with involvement in public exchanges (which tended to overemphasize price), many firms are now participating in, or hosting, private by-invitation-only exchanges (Hoffman et al., 2002). Once again, it was lack of understanding of a sustainable B-model that resulted in so many failures. The original plan was to use the Internet's power and reach to form a more efficient marketplace. Most exchanges failed once their venture capital financing dried up. The strongest surviving exchanges are those that added value for all participants (appropriate alignment, per Figure 1). Examples of successful industry exchanges include Covisint LLC (automotive), Trade-Ranger Inc (energy/chemical), and Global Healthcare Exchange LLC (health care).

In the area of supply chain management (SCM), the sharing of information allows efficiency improvements all along the chain – firms can reduce inventory levels, increase the accuracy of their forecasting, and supply parts in a timely and cost-efficient manner. With the move from EDI to the Internet, even small firms can easily participate.

Michael Hammer (2001) identifies nine things that firms must do to thrive in the customer economy of today. Four of these items (make yourself easy to do business with; sell through, not to, your distribution channels; push past your boundaries in pursuit of efficiency; and lose your identify in an extended enterprise) are directly facilitated by the Internet and Web initiatives.

When developing an EC or Web initiative there are many things to consider. A partial list includes: the source and target (business, consumer, government), the focus (internal or external or both), whether the objective is efficiency or effectiveness, go it alone versus partnership, proactive versus reactive approach, targeting one-time versus ongoing customers, physical versus virtual goods, and single good/service versus package.

From an ROI perspective, any investment in Web and e-commerce should provide a reasonable return. Yet, traditional investment analysis techniques may not be appropriate. Kohli et al. (2003) discuss the unique challenges that e-business environments pose to the measurement of IT payoff. These include the productivity paradox, level of measurement, choice of metrics, and the measurement process. The authors identify four general areas for future research (appropriate metrics, the e-business environment, technology, and business process change).

FUTURE TRENDS

There is considerable uncertainty about predicting the future, particularly with IT and EC. Yet, there are current observable trends.

On the technology side, there is the gradual convergence of technical standards/protocols (although some areas, such as Web service standards, are currently described as a battle ground – Koch, 2003). A benefit of collaborative consortiums is that a single protocol can be agreed upon by all participants. Certainly, the number of technologies and software capabilities will increase, and the move towards commoditization will continue, with the vendor community battling the Open Source community. For most firms, the problem will continue to be which technology to implement for what purpose. Overall, firms will continue to have more difficulty implementing technical initiatives because of non-technical issues. Usability of Web sites will continue to improve, as firms apply human factors analysis and other design procedures to implement better Web sites (see the Nielsen Norman group at www.useit.com). Research opportunities in this area will include empirical studies of how different types of organizations are using new technology, along with the study of implementation methods and challenges, and normative studies of how organizations should decide on which technologies to implement, when and how.

Customer trends are also noticeable. Today's customers have heightened expectations. One approach to meeting these is through self-service applications (a "win/win" for both customers and the firm) for which Web initiatives are ideal. The development and use of intra-organizational applications will continue to grow. Growing use of analytics will assist firms in segmenting their customers, quickly becoming aware of demand shifts, and providing increased value at lower cost. Retail customers will have fewer Web site security concerns and continue to become more comfortable with Web purchasing of goods and services. Research opportunities include developing better analytics, and studying the behaviour of early adopters, mainstreamers, and laggards.

At the firm level, several things are noticeable. As firms have gained experience with EC, many problems (such as channel conflict) have been identified and dealt with. SCM has led in consolidating firms into value chain networks. An increased understanding of the business levers for effective e-commerce strategies is leading to better decisions and standardization on best practices (which results in operational efficiency, but not necessarily in competitive advantage). In addition, there will be continued digitization of business processes; current estimates are that only 20%-25% are currently digitized (Kalakotra & Robinson, 2003). Smaller firms, facing resource scarcity, are likely to continue to lag in EC initiatives (Craig, 2002).

Shaw (1999) identified seven issues for EC research: (1) scope, components and potential impacts, (2) B2C EC, (3) strategy for developing online business and digital services, (4) B2B EC, (5) security, privacy and legal concerns, (6) technology and infrastructure for EC, (7) strategy for coordinating channel partners and streamlining their processes. While much has been learned about these areas, as many new questions have appeared; so these seven issues remain as attractive EC research areas.

CONCLUSION

Business success comes from making difficult decisions about business, IT and EC strategy, then implementing these successfully, using appropriate resources. While spending on IT and EC will continue, it is possible to under-spend, as well as overspend. Firms need to set priorities for investments, and ensure their business strategy aligns with their IT strategy (Farrell et al., 2003) and EC strategy. Sometimes this will result in being an IT and EC leader within an industry segment, and sometimes it will mean staying within the mainstream group or even lagging (Carr, 2003). This is an importance choice for firms and should be made consciously, rather than by default.

Web initiatives, when undertaken as part of a firm's EC strategy, will only be successfully implemented when adequate resources are provided for each project, and appropriate project management processes followed. For leading edge (bleeding edge?) projects, significant contingency allowances are important, and firms must be prepared for occasional failures (one could call these "learning experiences").

Finally, firms should not overly focus on technology (Barua et al., 2001; Davenport et al., 2001) when it comes to EC and Web initiatives. Good, appropriate technology (not necessarily the best), successfully implemented, will bring significant benefits at a reasonable cost.

KEY TERMS

Business Model: A specific arrangement of organizational strategies, goals, processes, resources (technologies, finances, people, etc.), structures, products and services that enable a firm to successfully compete in the marketplace. Many EC researchers have taken a narrower view, based on organizations involved (i.e., B2B, B2C, B2G, etc.), or specific framework used (i.e., hierarchy, hub, or intermediary for e-markets). While there is not yet a consensus about what makes up a business model, the trend is away from a narrower view.

E-Business Model: That subset of the general business model that supports e-business.

E-Commerce: Commercial activities taking place over electronic networks (primarily the Internet); e-commerce is a subset of general commerce.

E-Commerce Strategy: A subset of general business and information technology strategy, focusing on Web-based commercial opportunities. It may dominate general strategy in some firms.

M-Commerce: Mobile commerce, with wireless access to the Web.

Protocol: A set of rules and procedures that govern transmission between the components of an electronic network.

Strategy: The determination of the basic long-term goals and objectives of an organization, and the adoption of courses of action and allocation of resources necessary for achieving these goals; major components of strategy include: goals, product/market focus, business system focus, and competitive premise.

Web Initiative: Any use of the World Wide Web for a specific purpose.

Web Personalization: Customizing Web content, in real time, to a specific user.

Web Search via Learning from Relevance Feedback

Xiannong Meng
Bucknell University, USA

Zhixiang Chen
University of Texas-Pan Americana, USA

INTRODUCTION

Recently, three general approaches have been taken to increase Web search accuracy and performance. One is the development of meta-search engines (e.g., MetaCrawler, *www.metacrawler.com*) that forward user queries to multiple search engines at the same time in order to increase the coverage and hope to include what the user wants in a short list of top-ranked results. Another approach is the development of topic-specific search engines that are specialized in particular topics. These topics range from vacation guides (*www.vocations.com*) to kids' health (*www.kidshealth.com*). The third approach is to use some group or personal profiles to personalize the Web search. Examples of such efforts include *GroupLens* (Konstan et al., 1997).

Those meta-search engines suffer to a certain extent the inherited problem of information overflow that it is difficult for users to pin down specific information for which they are searching. Specialized search engines typically contain much more accurate and narrowly focused information. However, it is not easy for a novice user to know where and which specialized engine to use. Most personalized Web search projects reported so far involve collecting users' behavior at a centralized server or a proxy server. While it is effective for the purpose of e-commerce, where vendors can collectively learn consumer behaviors, this approach does present the privacy problem.

The clustering, user profiling and other advanced techniques used by those search engines and other projects such as Bollacker et al. (1998) are *static* in the sense that they are built before the search begins. They cannot be changed dynamically during the real-time search process. Thus they do not reflect the changing interests of the user at different time, at different location or on different subjects. Intelligent Web search systems that dynamically learn the users' information needs in real-time must be built to advance the state of the art in Web search. Machine learning techniques can be used to improve Web search, because machine learning algorithms are able to adjust the search process dynamically so as to satisfy users' information needs.

BACKGROUND

There have been great research efforts on applications of machine learning to automatic extraction, clustering and classification of information from the Web. Some earlier research includes *WebWatcher* (Armstrong et al., 1995), which interactively helps users locate desired information by employing learned knowledge about which hyperlinks are likely to lead to the target information; *Syskill and Webert* (Pazzani et al., 1996), a system that uses a Bayesian classifier to learn about interesting Web pages for the user; and *NewsWeeder* (Lang, 1995), a news-filtering system that allows the users to rate each news article being read and learns a user profile based on those ratings. Some research is aimed at providing adaptive Web service through learning. For example, *Ahoy! The Homepage Finder* (Shakes et al., 1997) performs dynamic reference shifting; and *Adaptive Web Sites* (Perkowitz & Etzioni, 2000) automatically improves their organization and presentation based on user access data.

A series of work in Chen et al. (1999, 2000, 2001, 2002) and Meng and Chen (2004) study intelligent Web search as an adaptive learning process, where the search engine acts as a learner and the user as a teacher. The user sends a query to the engine, and the engine uses the query to search the index database and returns a list of URLs that are ranked according to a ranking function. Then the user provides the engine relevance feedback, and the engine uses the feedback to improve its next search and returns a refined list of URLs. The learning (or search) process ends when the engine finds the desired documents for the user. Conceptually, a query entered by the user can be understood as the logical expression of the collection of the documents wanted by the user. A list of URLs returned by the engine can be interpreted as an approximation to the collection of the desired documents.

ADAPTIVE LEARNING FOR WEB SEARCH

Let ***X*** denote the set of all index keywords for the whole Web (or, practically, a portion of the whole Web). Given any Web document *d*, let *I(d)* denote the set of all index keywords in ***X*** that are used to index *d* with non-zero values. Then, the following two properties hold. (1) The size of *I(d)* is substantially smaller than the size of ***X***. Practically, *I(d)* can be bounded by a constant. The rationale behind this is that in the simplest case only a few of the keywords in *d* are needed to index it. (2) For any search process related to the search query *q*, let *D(q)* denote the collection of all the documents that match *q*; then the set of index keywords relevant to *q*, denoted by *F(q)*, is $F(q) = \cup_{d \in D(q)} I(d)$. Although the size of *F(q)* varies from different queries, it is still substantially smaller than the size of *X*, and might be bounded by a few hundred or a few thousand in practice.

Definition 1 - *Given any search query q, F(q), which is given in the previous paragraph, is defined as the set of dynamic features relevant to the search query q.*

Definition 2 - *Given any search query q, the dynamic vector space V(q) relevant to q is defined as the vector space that is constructed with all the documents in D(q) such that each of those documents is indexed by the dynamic features in F(q).*

Adaptive learning for intelligent Web search as studied in Chen et al. (1999, 2000, 2001, 2002) and Meng and Chen (2004) is formulated as follows. Let *S* be a Web search system. For any query *q*, *S* first finds the set of documents *D(q)* that match the query *q*. It finds *D(q)* with the help of a general-purpose search strategy through searching its internal database, or through external search engine such as AltaVista (*www.altavista.com*) when no matches are found within its internal database. It then finds the set of dynamic features *F(q)*, and later constructs the dynamic vector space *V(q)*. Once *D(q)*, *F(q)* and *V(q)* have been found, *S* starts its adaptive learning process with the help of the learning algorithm that is to be presented in the following subsections. More precisely, let $F(q) = \{K_1, \ldots, K_n\}$ such that each K_i denotes a dynamic feature (i.e., an index keyword). *S* maintains a common weight vector $w = (w_1, \ldots, w_n)$ for dynamic features in *F(q)*. The components of *w* have non-negative real values. The learning algorithm uses *w* to extract and learn the most relevant features and to classify documents in *D(q)* as relevant or irrelevant.

Practically efficient adaptive learning algorithms such as TW2 have been developed in (Chen et al. (1999, 2000,

Figure 1. Algorithm TW2

Step 0: Set $w_0 = (w_{01}, \ldots, w_{0n}) = (0, \ldots, 0)$.

Step $i > 0$: Classify documents in $D(q)$ with $\sum_{j=1}^{n} w_{ij} x_j > \theta$.

While (user judged a document $x = (x_1, \ldots, x_n)$) do
    If (x is relevant) do //promotion
        For $(j = 1;\ j \le n;\ j{+}{+})$
            If $(x_j = 0)$ set $w_{i+1,j} = w_{ij}$
            If $(x_j \ne 0\ \&\ w_{ij} = 0)$ set $w_{i+1,j} = \alpha$
            If $(x_j \ne 0\ \&\ w_{ij} \ne 0)$ set $w_{i+1,j} = \alpha w_{ij}$
    If (x is irrelevant) do //demotion
        For $(j = 1;\ j \le n;\ j{+}{+})$
            Set $w_{i+1,j} = w_{ij} / \alpha$
If (user has not judged any document) stop
Else set $i = i + 1$ and go to step $i + 1$.

2001, 2002) and Meng and Chen (2004). For example, for each query *q* entered by the user, algorithm *TW2* uses a common weight vector *w* and a real-valued threshold *q* to classify documents in *D(q)*. Let *a > 1* be the promotion and demotion factor. *TW2* classifies documents whose vectors $x = (x_1, \ldots, x_n)$ satisfy $\sum_{i=1}^{n} w_i x_i > \theta$ as relevant, and all others as irrelevant. When the user responds with a document that may or may not contradict to the current classification, TW2 updates the weights through promotion or demotion. The detailed description of TW2 is given in Figure 1.

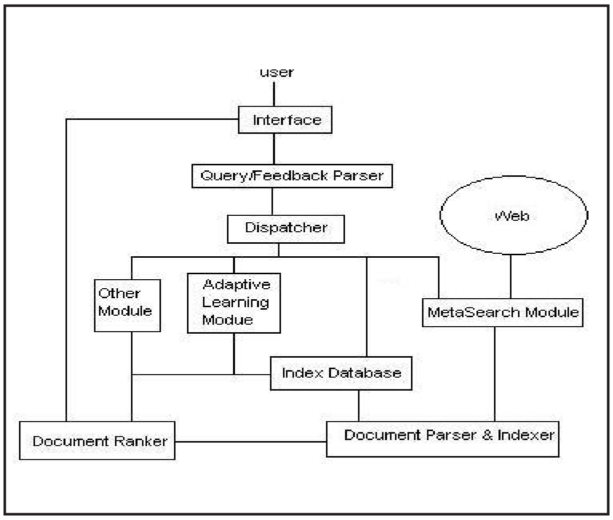
In contrast to the linear lower bounds proved for Rocchio's similarity-based relevance feedback algorithm (Chen & Zhu, 2002), *TW2* has a very small mistake bounds for learning any collection of documents represented by a disjunction of a small number of relevant features. As pointed out in Chen et al. (2002) that to learn a collection of documents represented by a disjunction of at most *k* relevant features (or index keywords) over the *n*-dimensional Boolean vector space, *TW2* makes at most $\frac{\alpha^2 A}{(\alpha-1)\theta} + (\alpha+1)k \ln_\alpha \theta - \alpha$ mistakes, where A is the number of dynamic features occurring in the learning process.

Other multiplicative adaptive algorithms for user preference retrieval were designed in Chen (2001) and Meng and Chen (2004). It was shown that those two algorithms have substantially better performances than Rocchio's similarity-based relevance feedback and the gradient descent procedure (Wong et al., 1988).

SYSTEM IMPLEMENTATION

Several experimental intelligent Web search systems have been implemented and analyzed in Chen et al. (1999, 2000, 2001, 2002) Meng and Chen (2004). An exemplary architecture of those systems is shown in Figure 2. In general, such a system has a graphic user interface to allow the user to enter his/her query and to specify the number of the top matched document URLs to be returned. It may or may not maintain an internal index database of documents. It has a meta-search module to query a set of general-purpose search engines such as AltaVista whenever needed. When the user enters a query and starts a search process, it first searches its internal index database. If no relevant documents can be found within its index database then it receives a list of top matched documents externally with the help of its meta-search module.

Figure 2. System architecture



At each iteration, the system provides the user a short list of documents so that the user can judge whether a document is relevant or not. After the user finishes judging documents as relevance feedback to the system, the query/feedback parser parses out the feedback and sends it to the adaptive learning module for the underlying learning algorithms to learn the user's preference. At the end of the current iteration of learning, the system re-ranks the documents with its document ranker and displays a short list of documents to the user. At each iteration, the dispatcher parses query or relevance feedback information from the interface and decides which of the following components should be invoked to continue the search process: adaptive learning module, or index database, meta search module, or other module if there is one. The document parser and indexer can parse and index documents returned by the meta search module, and send those documents to the index database or document ranker. The other module can have additional functions for clustering, profiling, personalizing or feature extracting, to enhance the capability of the adaptive learning module.

The experimental systems in Chen et al. (1999, 2000, 2001, 2002) and Meng and Chen (2004) are evaluated with performance metrics of relative recall, precision, response time, and/or ranking accuracy. For example, relative recall and precision are defined as follows. For any query *q*, the relative recall and precision are

$$Rrecall = \frac{|Rm|}{|R|}, \quad Rprecision = \frac{|Rm|}{m},$$

where *R* is the total number of relevant documents among the set of the retrieved documents, and Rm is the number of relevant documents ranked among the top *m* positions in the final search result of the search engine. Empirical analytical results in Chen et al. (1999, 2000, 2001, 2002) and Meng and Chen (2004) all show that adaptive learning algorithms significantly increase Web search performance and accuracy in comparison to general-purpose search engines such as AltaVista.

FUTURE TRENDS

With an overwhelming amount of information available on the Web, using an adaptive learning approach to refine Web search results will become the natural next step of Web search. Users can interact with search engines to refine their queries to narrow down the collection of search results. In this refinement process, the search engine is *learning* the user's information needs to provide more accurate search results. During this interactive process, the search engines can also pick up other information automatically or manually regarding this particular search from the user. Such information may include past search history, and user preferences, among others. With the capability of interacting with users, the search engines will become more intelligent and a true assistant in serving users' information needs.

CONCLUSION

This article presents an overview of research on intelligent Web search through adaptive learning from relevance feedback (Chen et al., 1999, 2000, 2001, 2002; Meng & Chen, 2004).

The authors believe that other techniques such as Web mining and clustering shall be used to further enhance the performance of the adaptive learning algorithms. Adaptive learning approach to intelligence Web search requires the user to interact with the search engine. Through such interaction the user provides relevance feedback to the adaptive learning algorithm used by the search engine to improve search results. Adaptive learning algorithms cannot work well without users' interaction of relevance feedback. On other hand, Web mining and clustering can uncover hidden patterns of user access behaviors and associations of these patterns with groups of users from large Web access logs and user profiles. These patterns and associations can be used to predict user interests or information needs in order to help the search engine to filter out undesired Web pages and to recommend desired ones. Web mining and clustering are essentially retrospective techniques, and cannot adaptively interact with the user. Once incorporated with an adaptive learning algorithm, these techniques can help the learning algorithm to build the initial search result for the user before the interaction starts. They can also help the adaptive learning algorithm to include, or exclude, some of the Web pages, when a new search result is computed with respect to the user's recent relevance feedback.

KEY TERMS

Adaptive Learning: An algorithm that can learn a hidden concept from interactive feedback provided by a user or the underlying environment.

Document Ranking: A function that scores documents in a collection according to their relevance to a given query so that the more relevant a function is, the higher score it has.

Intelligent Web Search: A Web search system that learns a user's information preference.

Precision: Precision is the percentage of relevant document in a given query in the set of documents that are returned by an information retrieval system.

Recall: Recall is the percentage of relevant documents in a given query in a collection that are returned by an information retrieval system.

Relevance Feedback: The information that is judged by a user and provided to an information system.

Vector Space: A model that represents every document in a collection with an n-dimensional vector for some constant n.

Web Technologies and Data Warehousing Synergies

John M. Artz
The George Washington University, USA

INTRODUCTION

Data warehousing is an emerging technology that greatly extends the capabilities of relational databases specifically in the analysis of very large sets of time-oriented data. The emergence of data warehousing has been somewhat eclipsed over the past decade by the simultaneous emergence of Web technologies. However, Web technologies and data warehousing have some natural synergies that are not immediately obvious. First, Web technologies make data warehouse data more easily available to a much wider variety of users. Second, data warehouse technologies can be used to analyze traffic to a Web site in order to gain a much better understanding of the visitors to the Web site. It is this second synergy that is the focus of this article.

DATA WAREHOUSE

A data warehouse is a repository of nonvolatile temporal data used in the analysis and tracking of key business processes. Temporal or time varying is the most important characteristic that distinguishes a data warehouse from a traditional relational database, which represents the state of an organization at a point in time. A relational database is a snapshot of the organization, whereas the data warehouse is a collection of longitudinal data.

One could argue that it should be possible to store longitudinal data in a relational database, and this claim is true. However, relational databases, which model data as entities, create sever limitations in data exploitation. First, although standard SQL does provide a DateTime data type, it is very limited in its handling of dates and times. If an analyst wanted to compare summary data on weekends versus weekdays or holidays versus non-holidays, it would be difficult if not impossible using standard SQL. Second, analysis involving drill down or roll up operations becomes extremely awkward using standard SQL against entities as represented in relational tables.

Data warehousing technology overcomes these deficiencies in the relational model by representing data in a dimensional model. A dimensional model consists of a fact table (see Figure 1) and the associated dimensions. The fact table contains measures of the business process being tracked and the dimensional tables contain information on factors that may influence those measures. More specifically, the fact table contains dependent variables while the dimension tables contain independent variables. Online analytical processing (OLAP) tools provide a means of summarizing the measures in the fact table according to the dimensions provided in the dimension table toward the end of determining what factors influence the business process being modeled. Typically OLAP tools provide a means of easily producing higher levels of summary (roll-up) or greater levels of detail (drill-down).

WEB LOG

A visitor to a Web site requests a page by typing in the address of the page in a Web browser, or by clicking on a link that automatically requests that page. A message is

Figure 1. A dimensional model

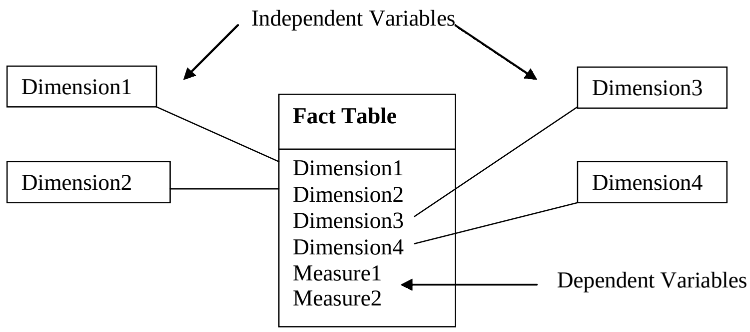

Figure 2. A typical Web log record

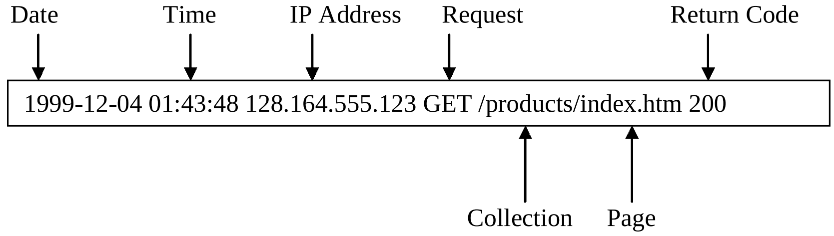


sent to the Web server, at that address, and the Web server responds by returning the page. Each request that is processed by the Web server is recorded in a file called the Web log, which contains a record of all activity on the Web site. The record typically contains the date and time, the IP address of the requestor, the page requested and the result. A typical record in standard format is shown in Figure 2.

From this simple log record we can determine quite a bit about the traffic coming to the Web site. For example, we can determine peak times for visitors by date or time and we can determine if Web site usage is cyclical or has other temporal patterns. Further, we can determine which pages or collections are most heavily visited and if their usage also reflects a temporal pattern. Answers to these questions are useful for site management and maintenance and for determining the effectiveness of design decisions or the behavior of the visitors to the site.

SYNERGY

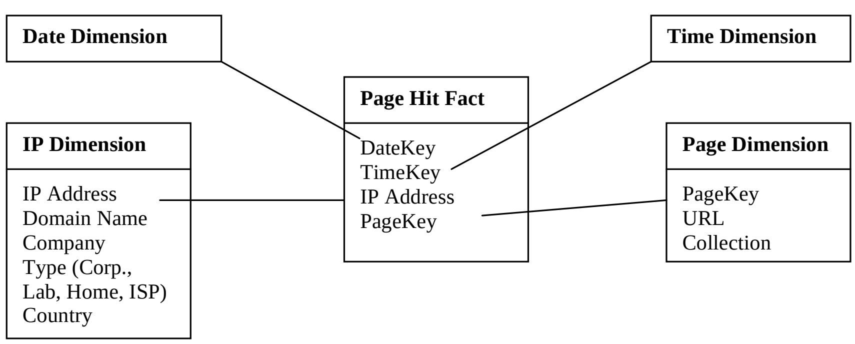
A lot of valuable information can be derived from the Web log. But that is only the beginning. By viewing the Web log as a data source for a data warehouse, it becomes an even richer source of information about the Web site and its visitors. Consider the dimensional model in Figure 3. From this we can derive relationships between visitors and the pages they visit. Web log records can be summarized to produce dwell time (the time a visitor spends viewing a page) and visit length (the time a visitor spends at the site). Further, if the site is used for sales, the IP dimension can be converted to a customer dimension and the page dimension can be converted into a product dimension allowing analysis of customer purchasing behavior. For a more in depth examination of the process of evolving a Web log into a customer data warehouse, see *From Web Log to Data Warehouse: An Evolving Example*, listed in the references.

FUTURE TRENDS

According to information navigators, there are approximately 72 million hosts on the Web. Many of these hosts do not support Web sites, but many others (such as those owned by ISPs) have multiple Web sites. If only 10 million of these Web sites attract as few as 100 visitors a minute, then 1 billion records are generated every minute. This becomes 60 billion records per hour, or 1.4 trillion records per day. This is an enormous amount of information providing great insight into the behavior of consumers and information seekers, among others. This huge volume of temporal data cannot be exploited effectively without data warehouse technology. Hence, the growth of the Web may well push the growth of data warehousing.

At the same time, data warehousing concepts continue to evolve and the technology continues to improve.

Figure 3. A dimensional model based on the Web log



OLAP tools are making it easier to analyze dimensional data through visual interfaces and data mining tools are making it easier to find useful patterns in large volumes of data. In today's tools there are gaps between SQL and OLAP, and again between OLAP and data mining. These disparate approaches will eventually become integrated in seamless tool sets that provide a variety of analytical techniques along with some guidance on which approaches to use.

The collection and analysis of all these data is, in many ways, a double-edged sword. From a productivity perspective, making white-collar workers more productive is clearly a good thing. However, measuring and monitoring have a very dark downside. There has been much concern since the industrial revolution that the mechanization of manufacturing could lead to undesirable working conditions for factory workers. Similarly, the mechanization of white-collar work could have similar impacts.

Further, the amassing of huge amounts of personal information is a sword that swings both ways also. On the positive side, understanding our needs allows product producers to meet those needs more fully. When you go to a shopping Web site you are often prompted with teasers that say "If you liked product X you should try product Y". If product Y is something that you think you might want, this is good. However, many people feel that the collection of such large amounts of personal data could have serious implications for personal privacy. Indeed, it may. It all depends on how the data are used and on how that use is perceived.

CONCLUSION

Data warehousing technologies and Web technologies are highly synergistic. Web technologies make data warehouse data more accessible to a much wider variety of users on both the Internet and the Intranet. Since the value of data is determined by their usefulness in supporting decision-making, Web technologies help increase the value of the data in the warehouse. Perhaps, more importantly, as shown in this article, data warehouse technologies can be used to analyze the enormous volumes of data generated by a Web site. As Web sites generate large volumes of data for data warehouses and in turn provide easy access to those data, it is conceivable that these two highly synergistic technologies may become indistinguishable in the future.

KEY TERMS

Data Mining: The use of computer algorithms to discover relationships between data items than are hidden in the complexity of the data.

Data Warehouse: A repository of nonvolatile temporal data used in the analysis and tracking of key business processes.

Dimensional Model: A data model that represents measures of a key business process in the form of facts and the independent variables that affect those measurements.

Key Business Process: A collection of intentional business activities that is both measurable and worthy of improvement or optimization.

OLAP: On Line Analytical Process usually distinguished from On Line Transaction Processing, which is the model associated with transaction-oriented databases.

Temporal Data: Time oriented data.

Web Log: A file in which a Web server records requests for pages.

INTRODUCTION

Bioinformatics means solving problems arising from biology using methods from computer science. The National Center for Biotechnology Information (*www.ncbi.nih.gov*) defines bioinformatics as:

"…the field of science in which biology, computer science, and information technology merge into a single discipline...There are three important sub-disciplines within bioinformatics: the development of new algorithms and statistics with which to access relationships among members of large data sets; the analysis and interpretation of various types of data including nucleotide and amino acid sequences, protein domains, and protein structures; and the development and implementation of tools that enable efficient access and management of different types of information."

There are many sub-areas in bioinformatics: data comparison, data analysis, DNA assembly, protein structure prediction, data visualization, protein alignment, phylogenetic analysis, drug design, and others.

The biological data (sequences and structures) are naturally very large. In addition, the number of records in the biological databases is increasing every year because of intensive research in the field of molecular biology. Analysis of this overwhelming amount of data requires intelligent bioinformatics tools in order to manage these data efficiently.

During the past two decades, the world has witnessed a technological evolution that has provided an unprecedented new medium of communications to mankind. By means of the World Wide Web, information in all forms has been disseminated throughout the world. Since the beginning, research in bioinformatics primarily used the Internet due to the fast information dissemination it allows, at essentially no cost.

This article aims to discuss some bioinformatics Web tools, but given the accelerated growth of the Web and the instability of the URLs (Uniform Resource Locators), an Internet search engine should be used to identify the current URL.

BACKGROUND

Living organisms possess entities called *genes* that are the basic inherited units of biological function and structure. An organism inherits its genes from its parents, and relays its own genes to its offspring.

Molecular biologists, in the later half of the 20th century, determined that the gene is made of DNA (deoxyribonucleic acid)—that is, DNA is the heredity material of all species. More than 50 years ago, Crick and Watson (1953) discovered the *double helix* structure of DNA and concluded that this specific form is fundamental to DNA's function.

Each strand of the DNA double helix is a polymer (a compound made up of small simple molecules) consisting of four elements called *nucleotides*: *A*, *T*, *C*, and *G* (for adenine, thymine, cytosine, and guanine). The two strands of DNA are complementary: when a *T* resides on one strand, an *A* occupies the corresponding position on the other strand; when there is a *G* on one strand, a *C* occupies the corresponding position on the other. The sequence of nucleotides encodes the "instructions" for forming all other cellular components and provides a template for the production of an identical second strand in a process called replication.

From a computer scientist's point of view, the DNA is information storage and a transmission system. Like the binary alphabet {0,1} used in computers, the alphabet of DNA {*A*, *T*, *C*, *G*} can encode messages of arbitrary complexity when encoded into long sequences.

The decoding of the genetic information is carried out through intermediary RNA (ribonucleic acid) molecules that are transcribed from specific regions of the DNA. RNA molecules use the base uracile (U) instead of a thymine. RNA is then translated into a protein—a chain assembled from the 20 different simple amino acids. Each consecutive triplet of DNA elements specifies one amino acid in a protein chain. Once synthesized, the protein chain folds—according to the laws of chemistry/physics—into a specific shape, based on the properties and order of its amino acids. The structures of a protein can be viewed hierarchically (Lehninger, Nelson & Cox, 2000): primary (linear amino acid sequence), secondary (local sequence elements with well-determined regular shape like á-helices and â-strands), tertiary (formed by packing secondary structures into one or several compact globular units), and quaternary (combination of tertiary structures).

BIOINFORMATICS WEB TOOLS

Sequence Analysis

There is a known relationship between sequence and structure of proteins, since proteins with similar sequences tend to have similar three-dimensional structures and functions. Sequence alignment methods are useful when it is necessary to predict the structure (or function) of a new protein whose sequence has just been determined. Therefore, alignment provides a powerful tool to compare two (or more) sequences and could reflect a common evolutionary origin.

ClustalW is a general purpose multiple sequence alignment program for DNA or proteins (Higgins et al., 1994). ClustalW currently supports seven multiple sequence formats that are detailed (including examples) in the *ClustalW Services Help Menu*: NBRF/PIR, EMBL/SwissProt, FASTA, GDE, ALN/ClustalW, GCG/MSF, and RSF. It produces biologically meaningful multiple sequence alignments of divergent sequences and calculates the best match for the selected sequences, considering individual weights, amino acid substitution matrices—like PAM (Altschul, Gish, Miller, Myers & Lipman, 1991) or Blosum (Henikoff & Henikoff, 1992)—and gap penalties (Apostolico & Giancarlo, 1998). After the identities, similarities and differences can be seen. ClustalW is freely available on the Internet, either as a Web-based tool or for downloading.

Another tool, T-Coffee (Notredame, Higgins & Heringa, 2000) is more accurate than ClustalW for sequences with less than 30% identity, but much slower. The T-Coffee input must have from 3 to 30 sequences (or 10,000 characters) in the FASTA format. The submission form is simple, but it does not allow user-selected options.

Cinema—Colour INteractive Editor for Multiple Alignments—is a program for sequence alignment that allows visualization and manipulation of both protein and DNA sequences (Parry-Smith, Payne, Michie & Attwood, 1997). It is a complete package in Java, locally installed, that runs on most platforms. This tool allows upload of an alignment from a local computer to the Cinema server. The input file must be in a PIR format and may then be imported into Cinema via the *Load Alignment File* option.

Structural Analysis

The Dali—Distance mAtrix aLIgnment—server (Holm & Sander, 1994) is a network service for comparing three-dimensional (3D) protein structures. Once the coordinates of a query protein structure is submitted, Dali compares them against those in the Protein Data Bank (PDB). The input file must be in the PDB format (Berman et al., 2000) and can be submitted by e-mail or interactively from the Web. The input options are *disabled*. The results are mailed back to the user. In favorable cases, comparing 3D structures may reveal biologically interesting similarities that are not detectable in primary sequences. There is a Dali database built based on exhaustive all-against-all 3D structure comparison of protein structures currently in the Protein Data Bank (PDB). The classification and alignments are continuously updated using the Dali search engine.

The Macromolecular Structure Database tool (MSD) (Golovin et al., 2004) allows one to search the active site database based on ligand or active site information. The PDB contains a significant number of protein structures that have ligands bound which are often more highly conserved across a functional family than the overall structure and fold of the macromolecule. The target of the search can be based on an uploaded file. It is possible to limit the scope of a search using restrictions based on author, keywords, experiment, resolution, and release date. Results of the search are presented in a list of PDB ID codes that can be analyzed further or viewed within a structure viewer like Rasmol (Sayle & Milner-White, 1995)—a program that intends the visualization of proteins, nucleic acids, and small molecules.

Swiss-Model (Schwede, Kopp, Guex & Peitsch, 2003) is a server for automated comparative modeling of 3D protein structures, and provides several levels of user interaction using a Web-based interface: in the first approach mode, only an amino acid sequence is submitted to build a 3D model. It could also be accessible from the program DeepView—an integrated sequence-to-structure workbench. All models are mailed back with a detailed modeling report. Template selection, alignment, and model building are automatically done by the server. The Swiss-Model alignment interface allows the submission of multiple sequence alignments in the following formats: FASTA, MSF, ClustalW, PFAM, and SELEX. The alignment must contain at least the target sequence and one template from the ExPDB template library, because the modeling process is based on this user-defined template.

Homology and Similarity Tools

The extent of similarity between two sequences can be based on percent sequence identity and/or conservation. In BLAST—**B**asic **L**ocal **A**lignment **S**earch **T**ool (Altschul et al., 1990)—similarity refers to a positive matrix score. A homology class is a class whose members have been inferred to have evolved from a common ancestor.

The BLAST input file could be a sequence in FASTA format, lines of sequence data, or NCBI sequence identifiers, as explained at the *Blast Search Format* form. BLAST emphasizes regions of local alignment to detect relationships among sequences which share only isolated regions of similarity. Results (many formats available) can be seen by using the browser or e-mailed to the user. Since the BLAST algorithm can detect both local and global alignments, regions of similarity in unrelated proteins can be detected, such that the discovery of similarities may provide important clues to the function of uncharacterized proteins.

FASTA (Pearson, 2000) provides sequence similarity and homology searching among a protein sequence to another protein sequence or to a protein database, or a DNA sequence to another DNA sequence or a DNA library. It can be very specific when identifying long regions of low similarity, especially for highly diverged sequences. Release 3.x of the FASTA package provides a modular set of sequence comparison programs that can run on conventional single processor computers or in parallel on multiprocessor computers.

BLAST and FASTA are used for database searching because they are fast. They use slightly different approaches to discover similar sequences, but both make refinements during searching process to increase the searching speed.

Protein Function Analysis

InterProScan (Zdobnov & Apweiler, 2001) is a tool that combines different protein signature recognition methods into a single resource. The number of signature databases and their associated scanning tools, as well as the further refinement procedures, increase the complexity of the problem. InterProScan performs considerable data look-ups from databases and program outputs. This Web tool allows the input of protein sequences, either in single or multiple files. The input file format for protein sequence(s) are free text, FASTA, or UniProt; for nucleotide sequence, the GenBank format is also accepted.

GeneQuiz (Scharf et al., 1994) is an integrated system for large-scale biological sequence analysis that goes from a protein sequence to a biochemical function, using a variety of search and analysis methods and up-to-date protein and DNA databases. The input file must be in the FASTA format; the maximum number of sequences that can be uploaded per day is 12, and the maximum number of amino acids is 18,000. GeneQuiz automatically runs a series of sequence analysis tools, including BLAST and FASTA. The results are displayed as structured text. The server is freely provided to the biological research community.

STING Millennium Suite—SMS (Neshich et al., 2003)—is a Web-based suite of programs and databases providing visualization and analysis of molecular sequence and structure for the PDB data. SMS operates with a huge collection of data (PDB, HSSP, Prosite). STING Millennium is both a didactic and a research tool. The interface is user friendly, and there are many options available for macromolecular studies.

ExPASy—Expert Protein Analysis System (Gasteiger et al., 2003)—provides access to a variety of databases and analytical tools dedicated to proteins and proteomics, including Swiss-Prot and TrEMBL, Swiss-2Dpage, PROSITE, ENZYME, and the Swiss-Model repository. There is also the UniPRot (Universal Protein Resource) (Apweiler et al., 2004), a catalog of protein information, a central repository of protein sequence and function created by joining Swiss-Prot, TrEMBL, and PIR analysis tools. Others tools are also available at ExPaSy: pattern and profile searches; topology prediction; primary, secondary, and tertiary structure analysis; sequence alignment; and others.

PSORT (Gardy et al., 2003) is a set of computational methods that make predictions for the protein sites in a cell, examining a given protein sequence for amino acid composition, similarity to proteins of known localization, presence of a signal peptide, transmembrane alpha-helices, and motifs corresponding to specific localizations. A version of PSORT-B for Linux platforms has been recently released. PSORT is recommended for bacterial/plant sequences, but the PSORT-B currently accepts only protein sequences from Gram-negative bacteria. The input file format is FASTA, and the output format can be selected by the user from among formats described in the PSORT documentation.

RNA Analysis

The RNAsoft suite of programs (Andronescu, Aguirre-Hernandez, Condon & Hoos, 2003) provides tools for predicting the secondary structure of a pair of DNA or RNA molecules, testing that combinatorial tag sets of DNA and RNA molecules have no unwanted secondary structure and designing RNA strands that fold to a given input secondary structure. The tools are based on standard thermodynamic models of RNA secondary structure formation and can be used for prediction as well as design of molecular structures. RNAsoft online access is freely available; however, some restrictions have been imposed on the size of the input data, in order to not overload the server limits.

The Vienna RNA package consists of a portable ISO C code library and several programs for the prediction and comparison of RNA secondary structures. This tool has a Web interface to the RNAfold program (Hofacker, 2003) and can predict secondary structures of single-stranded RNA or DNA sequences. The input file is a string of letters, consisting of A, U, G, and C. The result page shows the optimal structure, the energy of the optimal structure, and the ensemble free energy, if requested by user.

Others

A set of tools for clustering, analysis, and visualization of gene expression and other genomic data can be found in Expression Profiler—EP (Vilo, Kapushesky, Kemmeren, Sarkans & Brazma, 2003). Besides, EP allows searching gene ontology categories, generating sequence logos, extracting regulatory sequences, and studying protein interactions. It also links analysis results to external tools and databases.

ESTAnnotator (Hotz-Wagenblatt et al., 2003) is a tool for the throughput annotation of expressed sequence tags (ESTs) by automatically running a collection of bioinformatics methods. There are mainly four steps: a repeated quality check is performed, low-quality sequences are masked, successive steps of database searching and EST clustering are performed, already known transcripts that are present within mRNA and genomic DNA reference databases are identified, and finally, tools for the clustering of anonymous ESTs and for further database searches at the protein level are applied. The outputs are presented in a descriptive summary. ESTAnnotator was already successfully applied to the systematic identification and characterization of novel human genes involved in cartilage/bone formation, growth, differentiation, and homeostasis.

FUTURE TRENDS AND CONCLUSION

The WWW has a vast collection of bioinformatics tools that offer imminent possibilities for sharing, researching, and disseminating biological information. As presented, the bioinformatics research community has used Web-based application platforms intensively as the main suite for biological data analysis. Unfortunately, some application platforms use tools such as ClustalW, BLAST, or FASTA to analyze and search data from different databanks. This requires extra programs or software components for data format conversion of programs' output data. This not only complicates the software development process, but also sometimes distracts from the main research intention. For example, programs such as ClustalW output their results in a particular format, and this format cannot be easily parsed. A small change of the ClustalW source, such as an extra or missing field in the output, could break the program. The same problem happens with biological databases such as Swiss-Prot, PDB, and others.

In order to organize this area, *Nucleic Acids Research*, one of the most important magazines of this field, has devoted its first issue each year, over the last several years, to documenting the availability and features of the specialized databases.

There is also a XML (eXtensible Markup Language) framework (Shui, Wong, Graham, Lee & Church, 2003) proposal to integrate different biological databanks into a unified XML framework. The proposed framework has been implemented with the emphasis of reusing the existing bioinformatics data and tools.

As the Web continues to expand, newer tools will arise, and new challenges will be proposed to researchers. In fact, a safely prediction can be made: Web-based tools are invaluable ones for daily use of those working in this exciting area of bioinformatics, and this availability and use will continue to grow.

KEY TERMS

Alignment: Explicit mapping of characters of a sequence to characters of one or more other sequence(s).

Alpha-Helix: A helical conformation of a polypeptide chain, once of the most common secondary structure in proteins.

Base Pair: Two nucleotides in nucleic acid chains are paired by hydrogen bonding of their bases; for example A with T or U, and G with C.

DNA (deoxyribonucleic acid): A specific sequence of deoxyribonucleotide units covalently joined through phosphodiester bonds.

Domain: Combines several secondary structure elements and motifs; has a specific function.

Genome: The genetic information of an organism.

Homology: Relationship by evolutionary descent from a common ancestral precursor.

Motif: Combines a few secondary structure elements with a specific geometric arrangement.

Protein: A macromolecule composed of one or more polypeptide chains, each with a characteristic sequence of amino acids linked by peptide bonds.

RNA (ribonucleic acid): A specific sequence linked by successive phosphodiester bonds.

Similarity: Maximum degree of match between two aligned sequences as indicated by some (arbitrarily chosen) scoring function, for example, percent identity.

Web Usability

Shirley Ann Becker
Florida Institute of Technology, USA

INTRODUCTION

The study of computing technology and user interfaces was initiated during the 1970s when industrial research laboratories began to focus on human-computer interaction (HCI) (Badre, 2002). In the 1980s, the personal computer was introduced, thus expanding the need for designing effective user interfaces. HCI became a discipline during this time, and the Association for Computing Machinery (ACM) established the Special Interest Group in Computer Human Interaction. One of the first textbooks on HCI, *Designing the User Interface: Strategies for Effective Human-Computer Interaction* (Schneiderman, 19891), was published. Shortly thereafter, HCI became part of the ACM curriculum promoting the development of effective user interfaces. Software tools were developed in order to assist in designing usable interfaces while employing usability engineering methods. Many of these methods focused on usability from the perspective of ease of use, ease of learning, user satisfaction, and zero defects (Nielsen, 1993).

The World Wide Web (Web) became an integral part of HCI research in the 1990s, as organizations rushed to deploy a corporate Web site. Many of these Web sites took advantage of cutting-edge technology, including graphics and animation, with little regard for the impact on the user. As a result, users became disgruntled by lengthy download times, complex navigation schemes, nonintuitive search mechanisms, and disorganized content.

While others were predicting a "Y2K meltdown," Jakob Nielsen (1999a) correctly predicted a "Web meltdown" due to the number of poorly designed Web sites that cluttered the Internet. Numerous studies showed that users were frustrated with glitzy Web sites that had too many usability barriers. A Forrester report estimated a 50% loss of potential online sales due to users not finding a product or service on the Web site (Manning, McCarthy & Souza, 1998). As importantly, 40% of users did not return to a site when their initial visit was a negative one.

Shortly after 2000, electronic commerce sites (dot coms) began to fail at an increasing rate. A Deloitte and Touche report found that many retailers had developed online sites to "test the waters" for consumer demand with no clearly articulated strategy for success (Speigel, 2000). The demise of many dot coms has been attributed to unfriendly user interfaces that negatively impacted the online experience.

BACKGROUND

Many researchers and practitioners alike have studied usability in order to develop Web sites that are navigable, consistent, appealing, clear, simple, and forgiving of user mistakes (Murray & Costanza, 1999). Existing user interface design recommendations were extended to include user interfaces for the Web (Lynch & Horton, 1999; Schneiderman, 1998). Those experienced in designing user interfaces provided heuristics and guidelines for designing Web pages, often by identifying design layout, navigation, and performance issues associated with particular Web sites (Flanders & Willis, 1998; Hurst, 1999; Spool, Scanlon, Schroeder, Snyder & DeAngelo, 1999). Jakob Nielsen, a well-known usability expert, provided much needed guidance on Web usability through featured online articles (www.useit.com/alertbox) and published guidelines (Nielsen, 1999b; Nielsen & Tahir, 2002).

Web usability has been defined as the measure of the quality of the user's online experience. There are several factors that are commonly used as a means of measuring this experience. These factors include (www.usability.gov):

- Learnability – A measure of the user's learning time for accomplishing basic tasks given that the user interface has not previously been used (or used infrequently).
- Efficiency – A measure of the user's time and error rate for task completion.
- Effectiveness – A measure of user productivity in performing a task.
- Satisfaction – A measure of the attitude, perceptions, and feelings about the site.
- Memorability – A measure of user recall such that a previously visited site can be used effectively with no new learning curve.

It is commonly accepted that the usability of a Web site is impacted by the user's online goal, the user's profile, and his or her computing environment. A user, for example, would have some tolerance for lengthy download times when searching for medical information with graphic illustrations. This tolerance level is greatly reduced when searching for information on the cost of an airline ticket. The user profile, including age, gender, income, education, computer skills, and other factors, influences the online experience. Web content written at a high reading grade level, for example, may be difficult to comprehend for users with low English proficiency. The use of color to convey meaning on a Web site may impede its use by those who have color-deficient sight. Small font size, patterned background images, and pastel colors may become Web barriers to older adults experiencing vision degradation due to aging (Morrell, 2002). The user's computing environment also has an impact on Web usability. Environmental factors, such as hardware, software, browsers, connectivity, and bandwidth, impede the use of a Web site when it is cluttered with graphics, animation, and other objects adding little value to the online experience.

Since 1998, much has been accomplished in promoting Web usability for persons with disabilities. Section 508 of the 1973 Rehabilitation Act was enacted to eliminate information technology barriers in order to provide those with disabilities equal access. The law applies to all federal agencies when they develop, procure, maintain, or use electronic and information technology (http://www.Section508.gov). As a result of this initiative, significant strides have been made to electronic government access by enforcing the Web content guidelines put forth by the World Wide Web Consortium. Though not mandated by law, many commercial and nonprofit Web sites have implemented Section 508 in order to provide access to a broad user base.

WEB USABILITY ASSESSMENT METHODS

There are several popular methods that have been employed to effectively study Web usability. The inquiry approach makes use of field observation, interviews, self-reporting logs and online sessions. The inspection approach utilizes heuristic evaluations, walkthroughs, and checklists. Usability testing may also be used in conjunction with the other approaches to gather feedback during and after Web site design (Hom, 1998).

- Field Observation – The user is observed while surfing a Web site in order to gather usability data in a real-world setting.
- Interviews, Surveys, and Questionnaires – The objective of these methods is typically to gather feedback about the user's perspective of usability. In terms of data gathering, the interview is a formal, structured process, whereas the survey is an informal, interactive process. Interviews and surveys may involve one or more users in a focus group setting. The questionnaire provides the means to obtain written responses regarding a user's online experience.
- Session and Self-Reporting Logs – The user records his or her actions and makes observations during an online session. Software is often used during a session to automatically record data about the user's online experience. The self-reporting log requires

Table 1. Web usability online resources

Resource	Description

the user to manually record data while surfing the Web.

- Heuristic Evaluation – A usability expert (or group of experts) assesses a user interface to determine whether the Web design follows established usability practices (heuristics).
- Walkthrough – A usability expert (or group of experts) evaluates online experiences by constructing scenarios of Web use and then role-playing the targeted user.
- Usability Inspection – A usability expert (or group of experts) conducts usability inspections of a user interface in order to uncover usability problems in the design.
- Checklists – A usability expert (or group of experts) uses a checklist often in conjunction with an inspection to ensure that established usability practices are evaluated.
- Usability Testing – Experiments are conducted regarding usability aspects of a Web design. The objective is to gather data about an online experience in order to draw conclusions about the usability of the site. Though usability testing can involve sophisticated technology including usability labs, videotaping, and eye-tracking, this does not have to be the case (Murray & Costanzo, 1999). Often, usability test cases can be generated from an existing Web design without the use of sophisticated technology.

WEB RESOURCES

There are valuable online resources promoting usable Web designs. Many of these sites offer links for usability design and testing, good practices and lessons learned in the field. Some of the more popular sources for Web usability guidance are listed in Table 1. Though too numerous to list, there are many educational sites that offer resources on research activities and course materials. The Trace Research and Development Center at the University of Wisconsin-Madision, in particular, offers usability resources and links promoting universal usability (*http://trace.wisc.edu/world/web/*).

FUTURE TRENDS

Murray and Costanzo (1999) point out that from a HCI perspective, Web development is significantly different from software development. As such, there are challenges facing developers who are pursuing usable Web designs. These challenges include the following:

- The demographic diversity of online customers makes it difficult to develop user-friendly interfaces to meet all needs. For example, older adult users (60 years and older) may have trouble seeing Web content based on the use of color, font size, font type, and patterned background images (Becker, 2004; Morrell, Dailey, Feldman, Mayhorn & Echt, 2002). These design elements may have no usability impact on a younger adult for whom aging vision changes have not yet occurred. Web site images or textual references to religious holidays (e.g., Valentine's Day), as another example, may be offensive in certain global regions due to local religious or cultural beliefs (Becker, 2002).
- There is significant diversity among hardware, software, and network components being used to surf the Web. The usability of mobile technology, for example, must take into account the tiny screen in which Web content is displayed (Russell & Chaparro, 2002).
- Slower network access speeds impact usability due to performance degradation for a Web page with graphics and animation. Usability is also impacted by the browser version being used to surf the Web. Web content may display differently in older browser versions of Netscape© and Internet Explorer© than newer versions.
- The internationalization of many Web sites must account for culture, religion, and language in designing localized, user-friendly interfaces. Too often, organizations develop localized versions that do not meet the needs of regional customers (Marcus & Gould, 2000). The localized site may still have design aspects of the country of origin such as: English content, clichés, acronyms, and abbreviations (Becker & Mottay, 2001). Graphics may become a usability issue when cultural and religious beliefs are not taken into account during Web design (e.g., scantily clad figure on a homepage).
- Unlike software, users do not have a vested interest in a particular site. Often times, a user has purchased software and therefore is willing to accept usability barriers associated with it. Since there is no personal investment in a Web site, a user is more likely to leave and not return to a Web site that is perceived as unusable.

CONCLUSION

Web usability remains an important consideration in the design of effective user interfaces. There has been significant research on Web usability in terms of design layout, performance, navigation, and searches, among other areas. This initial work has been broadened to include usable Web designs for all users regardless of age, skills, education, culture, language, or religion. The Web accessibility initiative has promoted Web designs that take into account users with vision, physical, and cognitive disabilities. The internationalization of Web sites has promoted Web designs that meet the needs of a particular locale taking into account the customs, culture, religion, education, and other factors. Though much has been accomplished in developing usable Web sites, there is still work to be done. New technologies and expanded marketplaces pose unique challenges for universally usable Web designs.

KEY TERMS

Dot Com: A Web site that is intended for business use, though the term is commonly used to represent any kind of Web site. The term evolved from the "com" part of a Web site's address, which represents commercial sites. It came to be associated with Internet companies that failed during the mid 2000s (*www.searchWebservices.com*).

Internationalization: It is the process of making a Web site interoperable in a specific market or locale. In general, interoperability means that the functionality of the site is not dependent on a specific language or culture and is readily adaptable to others.

Localization: It is the process of adapting an internationalized Web site to meet language, culture, religion, and other requirements of a specific market or locale.

Universal Usability: Universal usability can be defined as having more than 90% of all households as successful users of information and communications services at least once a week (Schneiderman, 2000, p. 85).

Usability: The ISO 9241-11 standard states that usability is the "effectiveness, efficiency and satisfaction with which a specified set of users can achieve a specified set of tasks in a particular environment".

Usability Engineering: It is a systematic approach to making software (Web designs) easy to use, thus meet the needs of the targeted users.

Web Accessibility: Web accessibility means that any person, regardless of disabilities, is able to use Web technology without encountering any barriers.

ENDNOTES

[1] The textbook is now in its 4th edition taking into account human factors associated with interactive systems (Schneiderman & Plaisant, 2004).

Web-Based Distance Learning and the Second Digital Divide

Sheryl Burgstahler
University of Washington, USA

INTRODUCTION

In no field have we witnessed a greater impact of emerging technologies than in that of distance learning. Correspondence courses using printed material and postal mail have been replaced by Web-based courses with the potential to make learning available to anyone, anywhere at anytime. This potential cannot be realized, however, unless two digital divides are eliminated. Some people are on the wrong side of the first "digital divide" between the technology "haves" and the technology "have-nots". The benefits of technology are less available to those who are poor, who live in rural areas, who are members of minority racial or ethnic groups, and/or who have disabilities (Kaye, 2000; U.S. Department of Commerce, 1999). Lack of access to new technologies limits their options for taking and teaching technology-based courses. This is true for individuals with disabilities, even though the rapid development of assistive technology makes it possible for an individual with almost any type of disability to operate a computer (2003 Closing the Gap Resource Directory, 2003). Unfortunately, many people with disabilities still do not have access to these empowering tools, putting them on the "have not" side of the first digital divide.

Within the group of "haves" with respect to the first digital divide, however, many people with disabilities face a "second digital divide." This line separates people who can make full use of the technological tools, services, and information to which they have access, from those who cannot. Too often people with disabilities lucky enough to be on the right side of the first digital divide, find themselves on the wrong side of this second digital divide (Waddell, 1999). For example, a person who is blind may use a text-to-speech system that reads aloud text that appears on the screen. Because it cannot interpret graphics, it will simply say "image map" at a place where an image map would be displayed to someone using the full features of a multimedia Web browser. It cannot read aloud information within this and other graphic images. This person cannot access the content presented unless this content is provided in a text-based form.

BACKGROUND

Section 504 of the Rehabilitation Act of 1973 mandated that qualified people with disabilities be provided with access to programs and services that receive federal funds. The Americans with Disabilities Act (ADA) of 1990 reinforced and extended Section 504, requiring that people with disabilities have access to public programs and services, regardless of whether or not they are federally funded. According to these laws, no otherwise qualified individuals with disabilities shall, solely by reason of their disabilities, be excluded from the participation in, be denied the benefits of, or be subjected to discrimination in these programs and services, unless it would pose an undue burden to do so. A United States Department of Justice ruling (ADA Accessibility, 1996) clarified that ADA accessibility requirements apply to programs offered on the Internet by stating, "Covered entities that use the Internet for communications regarding their programs, goods, or services must be prepared to offer those communications through accessible means as well." Clearly, if qualified individuals with disabilities enroll in distance learning courses or are qualified to teach them, these opportunities should be made accessible to them. However, the inaccessible design of most Web-based distance learning courses imposes barriers to people with some types of disabilities (Schmetzke, 2001).

UNIVERSAL DESIGN

If an applicant who is blind is the best candidate to teach a Web-based course which has been developed without text alternatives for critical content displayed using graphics, the course will need to be modified in order for him to teach it. If planning for access was done as the course was being developed, this costly redesign would not be necessary. Simple design decisions could have been made to assure accessibility to potential students and instructors with a wide range of abilities and disabilities. This proactive process is called "universal design". Universal design is defined as "the design of products and environments to be usable by all people, to the greatest extent possible, without the need for adaptation or specialized design" (National Center for Universal Design, 2003, p.1). Applying universal design principles makes products and environments usable by people with a wide variety of characteristics, including gender, height, age, ethnicity, primary language, and level of ability to see, hear, speak, and move.

The concept of universal design was first applied to architecture. It has since been applied to the design of household appliances, instructional learning environments, Web sites and other products and environments (Bar & Galluzzo, 1999; Bowe, 2000; Burgstahler, 2001). When the wide range of characteristics of potential students and instructors is considered, distance learning course designers can create learning environments that are accessible to all participants, just as sidewalks with curbcuts are used by everyone, including those who push delivery carts, baby strollers, and wheelchairs.

For many years, examples of isolated distance learning courses designed to be accessible to individuals with disabilities could be found, including a course co-taught by the author of this article and a professor who is blind (Burgstahler, 2000). However, few distance learning programs have policies and guidelines that specifically address the accessibility of distance learning tools and resources (Burgstahler, 2000; Kessler & Keefe, 1999; Schmetzke, 2001). Comprehensive policies, such as the mandate that distance learning options offered by California Community Colleges must afford students with disabilities maximum access (Distance education: Access guidelines for students with disabilities, 1999), are rare.

EXAMPLES OF ACCESSIBLE DESIGN FEATURES

To create Web pages that are accessible to everyone, developers must either avoid certain types of inaccessible features or formats or create alternative methods for navigating or accessing content provided through inaccessible features or formats (Thompson, Burgstahler, & Comden, 2003). For example, including <alt> attributes with descriptive text makes graphic image content accessible to individuals who are blind. Developers should also assure that all functions at a Web site can be accessed using a keyboard alone, so that those who cannot manipulate a mouse can navigate the pages using the keyboard or a keyboard alternative. Another useful feature is to add a "Skip Navigation" link to the top of each page; otherwise, most speech-to-text systems for individuals who are blind will read through all of the navigation links on a page before reading the content in the body of the page.

Students and instructors who have limited vision may use software that enlarges screen images, but allows them to view only a small portion of the content of a standard screen image at one time. Page layouts that are uncluttered and consistent from page to page can facilitate locating and understanding Web content for people with low vision, as well as for those with some types of learning disabilities. Assuring that content and navigation do not require that a viewer distinguish one color from another makes Web-based distance learning accessible to those who are colorblind.

Internet resources that do not require the ability to hear are accessible to people who are deaf or hard of hearing. However, when Web sites include audio output without providing text captioning or transcription, they cannot access the content. Similarly, distance learning programs should provide audio-descriptions (i.e., aural descriptions) of visual content or text-based descriptions for those who are blind.

Some distance learning programs employ real-time "chat" communication in their courses. In this case, students communicate synchronously (at the same time). Synchronous communication is difficult or impossible to use by someone whose input method is slow. For example, a person with limited hand use who can only type characters slowly or someone with a learning disability who takes a long time to compose his thoughts may not be fully included in the discussion. In contrast, with a synchronous tool such as electronic mail, all students and instructors can fully participate. In addition, since flickers at certain rates (often between 2 to 55 hertz) can induce seizures for people who are susceptible to them, they should be avoided.

Tools, Guidelines, and Standards for Accessibility

The most current version of HTML (Hypertext Markup Language) makes it relatively easy to develop accessible Web sites. Commonly used development tools such as WebCT™(n.d.) and Blackboard™ (n.d.) include accessibility tools as well. Electronic tools that can test Web resources for some accessibility features and training courses and reference materials to help distance learning designers develop skills for making distance learning programs accessible are also widely available (Disabilities, Opportunities, Internetworking, and Technology, n.d.).

Technical guidelines and standards have been developed to provide guidance to organizations that wish to make Web content accessible to students with disabilities. The most widely used are those created by the World Wide Web Consortium and the U.S. federal government.

Table 1. Quick tips to make accessible Web sites

For Complete Guidelines & Checklist: www.w3.org/WAI

- **Images & animations**: Use the alt attribute to describe the function of each visual.
- **Image maps.** Use the client-side map and text for hotspots.
- Multimedia. Provide captioning and transcripts of audio, and descriptions of video.
- **Hypertext links.** Use text that makes sense when read out of context. For example, avoid "click here".
- **Page organization.** Use headings, lists, and consistent structure. Use CSS for layout and style where possible.
- **Graphs & charts.** Summarize or use the longdesc attribute.
- **Scripts, applets, & plug-ins.** Provide alternative content in case active features are inaccessible or unsupported.
- **Frames.** Use the noframes element and meaningful titles.
- **Tables.** Make line-by-line reading sensible. Summarize.
- Check your work. Validate. Use tools, checklist, and guidelines at *http://www.w3.org/TR/WCAG*

Table 2. Steps to creating accessible distance learning programs

- Make sure that all stakeholders, including potential students and instructors with disabilities, are represented as accessibility policies, procedures, and guidelines are being developed.
- Review policies and guidelines that have been created by other organizations, such as the California Community Colleges.
- Develop a policy statement that commits the organization to making programs, services, and resources accessible to people with disabilities.
- Articulate access challenges that may face potential participants with disabilities in the context of the programs, services, and/or resources offered and the tools used for their delivery.
- Consult with legal experts to fully understand the requirements for program, information, and service accessibility mandated by the ADA and other legislation relevant to your organization.
- Develop guidelines for all media, tools and strategies used in the distance learning courses; consider Section 508 standards as a model as appropriate.
- Assign a person or a department within the organization to be responsible for updating disability-related program access policies and guidelines and assuring compliance throughout the organization.
- Disseminate accessibility policy, guidelines, and procedures throughout the organization.
- Provide regular training and support regarding accessibility issues.
- Consider developing a plan to phase in compliance with program accessibility guidelines for previously developed courses, with a date at which all programs will be compliant.
- Regularly evaluate progress toward accessibility.
- Besides taking proactive steps to assure accessibility, develop procedures for responding quickly to requests for disability-related accommodations.

The Web Accessibility Initiative (WAI) of the World Wide Web Consortium developed Web Content Accessibility Guidelines (1999) for designing Web pages that are accessible to people with disabilities. Besides providing comprehensive guidelines, the WAI provides the quick tips for making accessible Web pages listed in Table 1 (World Wide Web Consortium Web Accessibility Initiative, 2001).

Section 508, which was added in 1986 to the Rehabilitation Act of 1973 (Architectural and Transportation Barriers Compliance Board, 2000), requires that electronic and information technologies that federal agencies procure, develop, maintain, and use are accessible to people with disabilities, both employees and members of the public, unless it would pose an undue burden to do so. As mandated in Section 508, the U.S. Architectural and Transportation Barriers Compliance Board (Access Board) developed accessibility standards to which federal agencies must comply (Electronic and Information Technology Accessibility Standards, 2000). Although most distance learning programs are not covered entities under this legislation, they can use the Section 508 standards as guidelines for designing accessible courses. These programs can also benefit from following the leadership of the federal government in being pro-active with respect to the accessibility of information technology (IT). "Use of an 'ad hoc' or 'as needed' approach to IT accessibility will result in barriers for persons with disabilities. A much better approach is to integrate accessibility reviews into the earliest stages of design, development, and procurement of IT." (U.S. Department of Justice, 2002)

FUTURE TRENDS AND STEPS TO AN ACCESSIBLE DISTANCE LEARNING PROGRAM

It is unlikely that distance learning courses in the future will be universally designed unless relevant policies, guidelines, and procedures are in place within distance learning programs. Organizations can begin the process of developing accessibility policies, procedures, and guidelines by addressing issues listed in Table 2, as published in *Educational Technology Review* (Burgstahler, 2002).

CONCLUSION

Well-designed distance learning courses create learning opportunities for everyone and thus do not erect barriers for potential students and instructors with disabilities. Employing universal design principles as distance learning courses are created can make learning opportunities accessible to everyone, everywhere, at any time and thereby eliminate the second digital divide.

KEY TERMS

Accessible: A product, information, or environment that is fully usable by a person, with or without assistive technology.

Assistive Technology: "Any item, piece of equipment, or system, whether acquired commercially, modified, or customized, that is commonly used to increase, maintain, or improve functional capabilities of individuals with disabilities." (Technology-Related Assistance, 1988). Examples of assistive technology include wheelchairs, hand controls for automobiles, prostheses, communication aids, hand splints, hearing aids, and alternatives to computer keyboards (Technology-Related Assistance).

Electronic Technology: Encompasses information technology, but also includes any equipment or interconnected system or subsystem of equipment, that is used in the creation, conversion, or duplication of data or information. Electronic technology includes telecommunications products such as telephones and office equipment such as fax machines.

Hypertext Markup Language (HTML): A language used to organize and present content on Web pages. HTML uses tags such as <h1> and </h1> to structure text into headings, paragraphs, lists, hypertext links, and so forth.

Information Technology: "Any equipment or interconnected system or subsystem of equipment, that is used in the automatic acquisition, storage, manipulation, management, movement, control, display, switching, interchange, transmission, or reception of data or information." Information technology includes "computers, ancillary equipment, software, firmware and similar procedures" (Electronic and Information Technology Accessibility Standards, 2000, p.80499).

Person with a Disability: Any "person who (a) has a physical or mental impairment that substantially limits one or more major life activities, (b) has record of such an impairment, or (c) is regarded as having such an impairment. Major life activities include walking, seeing, hearing, speaking, breathing, learning, working, caring for oneself, and performing manual tasks" (Americans with Disabilities Act of 1990).

Universal Design: "The design of products and environments to be usable by all people, to the greatest extent possible, without the need for adaptation or specialized design" (National Center for Universal Design).

Web-Based Supply Chain Strategy

Hanns-Christian L. Hanebeck
GlobeRanger Corporation and University of Dallas, USA

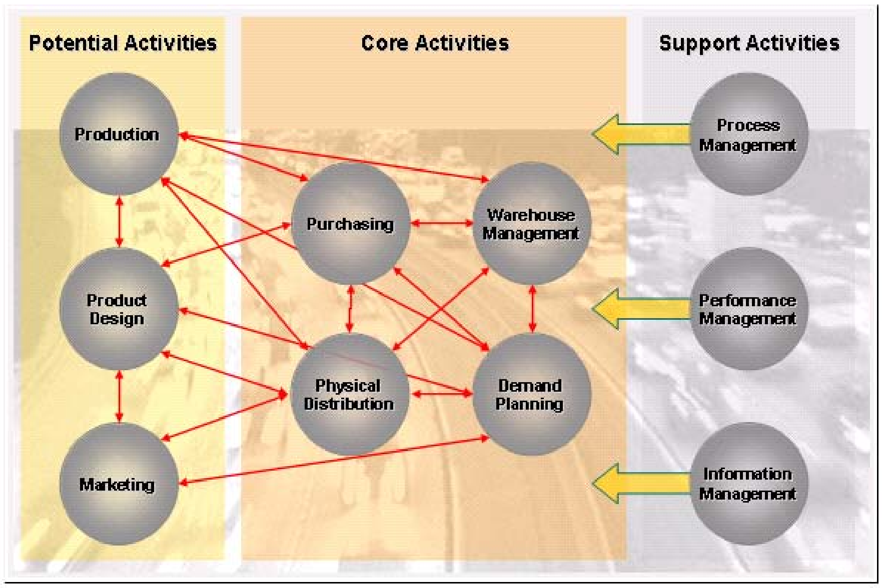
INTRODUCTION: SUPPLY CHAIN MANAGEMENT

Supply chain management is a fairly new creature and one that has evolved out of a variety of different enterprise functions over the past two decades. Traditionally, the majority of activities within supply chain management were related to the physical transport of goods from one point to another. Today, we understand supply chain management to include a broader range of activities such as demand planning, purchasing, warehousing, and transportation at the very least. Many authors will also throw production, product, and package design as well as marketing into the definition (Dornier et al., 1998; Schary & Skjøtt-Larsen, 2001; Taylor, 1997; Gourdin, 2001). For the context of this article, we refer to supply chain management as activities that are related to the planning and fulfillment of market demand. All of the activities within supply chain management can be performed by one or more than one legal entity. We further understand supply chain management as a business process rather than a function or department within a given company. Figure 1 below illustrates the set of core and potential activities as well as supporting ones such as process, performance, and information management.

BACKGROUND: CORPORATE STRATEGY

Strategy refers to the competitive positioning of a company or product in a given market. According to Michael E. Porter, the essence of strategy lies in the activities a company performs – either choosing to perform the same activities differently from rivals or choosing to perform different activities than its rivals (Porter, 1996). These activities can be viewed as distinct activities in some cases or as business processes in others. Ultimately, the execution of activities leads to the occupation of a unique and defensible position from which the firm can outperform its competitors. The degree of defensibility depends on what Porter calls trade-offs: well-defined synergies that tie the activities of a company to one another and create a network for value creation that is harder to imitate than single activities would be. This view of strategy closely ties into the approach of strategic capabilities

Figure 1. Strategic supply chain activities



(Stalk et al., 1992; Hamel & Prahalad, 1990) and also into the more recent approach of the resource-based view (Collis & Montgomery, 1995; Kaplan et al., 2001).

FUTURE TRENDS: SUPPLY CHAIN STRATEGY

Before we venture into the definition of supply chain strategy, it is important to clarify the relationship between strategy and activities a bit further. In its simplest form, strategy is the definition of a desired future state of the firm or business unit or product. Activities are either stand-alone tasks or they are chains of tasks, which are *de facto* business processes. In this sense, strategy drives the definition of processes and processes in turn rely on technologies as much as on other resources in their execution. The explicit dependencies between strategy, process, and technology are illustrated by the framework as shown in Figure 2.

Returning to supply chain management, we can now define supply chain strategy. If corporate strategy is the selection and execution of specific activities in a given firm, then supply chain strategy necessarily is the choice and performance of unique activities within supply and demand management to ultimately achieve higher corporate goals. Further, it is important to differentiate between firms that are primarily driven by supply chain management activities (strategic role) and those where the supply chain is just an enabling function (support role).

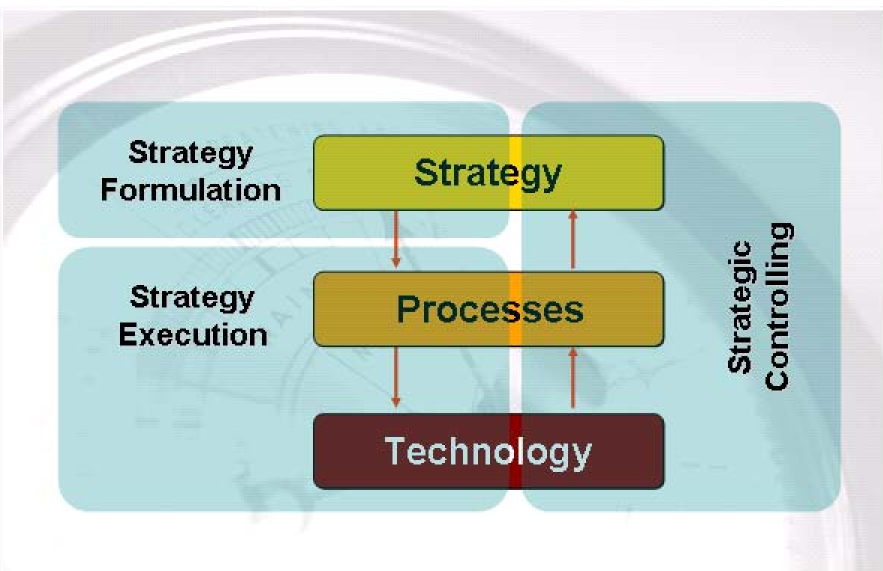
In its support role, supply chain management translates corporate strategy into strategic supply chain objectives. These strategic objectives then drive the definition of processes through the choice of activities. Processes, in turn, are supported by supply chain technologies. As a result, supply chain processes and technologies subsequently become a directly dependent function of corporate strategy. Supply chain managers in this situation have to perform three strategy-relevant tasks:

(1) Definition of supply chain activities in close reliance on the essence and intent of corporate strategy.
(2) Creation (as opposed to depletion) of synergy between all supply chain activities as well as towards all other activities of the firm.
(3) Continuous monitoring of strategy achievement throughout the execution of supply chain activities.

Seen in this light, supply chain management actively contributes to corporate strategy achievement and is as important a corporate function as marketing, finance, or human resources. This view of supply chain as a support function has gained in importance over the past few years and will continue to do so.

In the strategic role, supply chain management drives the definition of corporate strategy and thus will translate its own strategic requirements into business processes and technologies. Supply chain management in the strategic role takes on a life of its own in that the dominant

Figure 2. Strategy framework (Hanebeck 2001)



ingredients of corporate strategy are all ultimately tasks of supply chain management. The core competency of a company often times is based on supply chain management. The relation between supply chain strategy, processes, and technologies is much more immediate, yet the general relationships remain the same as in the support function.

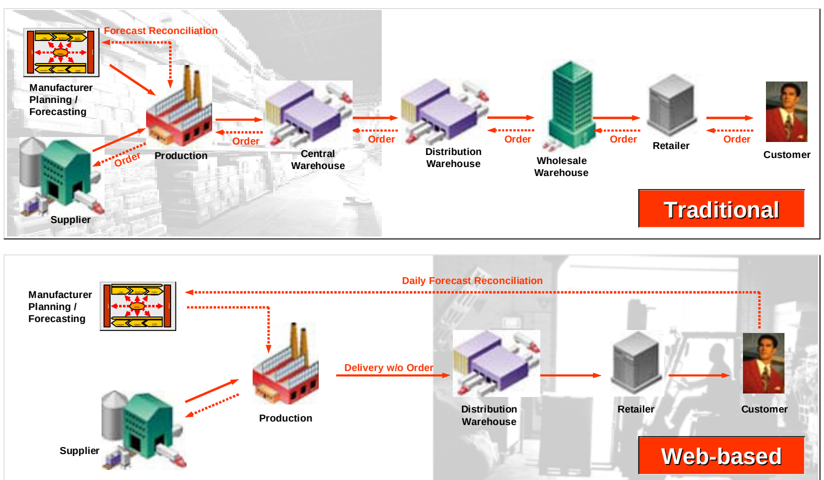
CONCLUSION: WEB-BASED SUPPLY CHAIN STRATEGY

As we had initially stated, supply chain management can be performed by one or more than one legal entity. The latter circumstance is characterized by several firms all executing activities within a single, logically coherent supply chain. This situation poses very specific additional challenges that a single firm would not encounter. On one hand, the coordination of supply chain activities now resides with several firms and thus in the hands of several potentially independent actors. On the other hand, supply chain information has to transcend the traditional boundaries of enterprise systems such as enterprise resource planning (ERP), supply chain planning (SCP), or supply chain execution (SCE) systems. These systems were developed in the 70s to early 90s. As a consequence, they were never intended to enable the close sharing of information across enterprise boundaries and beyond the communities of immediate users. Traditional enterprise systems are thus too inflexible and cumbersome to use when it comes to information sharing between various partners. Yet, this sharing of information is exactly what new theoretical concepts such as supply chain collaboration, event management, or visibility require. In fact, these concepts necessitate a shared platform that allows the exchange and filtering of supply chain relevant data and information in order for it to be used by many diverse and highly involved firms. To make things worse, turning enterprise-level systems inside-out to cater to data and information sharing does not seem very feasible due to their high degree of internal complexity.

A possible way around the re-design of enterprise-level systems is the sharing of supply chain data on a common platform such as a Web-accessible database that allows data and reporting structures to be reconfigured as new needs arise. Such a database can be resident in any of the partners' locations or elsewhere and can provide instrumental support in the coordination of partners as they thrive to accomplish a common goal. Based on our definition of supply chain strategy as the choice and performance of supply chain activities, the partially Web-based execution of supply chain processes constitutes an integral part of the technology layer within the strategy framework illustrated above.

How does this work in a concrete example? Figure 3 illustrates the differences between traditional and Web-based supply chains. What becomes readily apparent is that traditional supply chains rely on slow, error-prone, node-to-node communication that gradually ripples through the system before new information from the point of sale (POS) affects supplier and manufacturing nodes at the opposite end. The occurrence of the bullwhip effect is a good example of the inherent inefficiencies in traditional supply chains (Whang, 1997). Web-based supply chains on the other hand are characterized by a much higher degree of information sharing and also by much faster communication. Naturally, the availability of Web-based technological capabilities as described above allows for a much higher degree of operational effectiveness and strategic efficiency.

Figure 3. Traditional versus Web-based supply chains (Hanebeck, 2001)



The transformation from a traditional to a Web-based supply chain usually takes time and is not easy to accomplish. A key issue for Web-based supply chains lies in the establishment of trust between parties that oftentimes have conflicting goals and need to negotiate their fair share of revenues from a shared financial stream. This latter problem is virtually always a critical factor in supply chain efficiency in that manufacturers, distributors, and wholesalers usually try to reverse-engineer retail revenues and profits based on quantities sold in specific locations. This naturally leads to a lack of trust that can only be overcome by gradual and iterative negotiation. The emergence and proliferation of Web-based supply chain technologies will ultimately contribute to the building of trust as these technologies provide a factual basis for information and pose a strong competitive impetus to grow more efficient over time.

It is interesting to see that the concept of Web-based supply chains resembles the organizational structure of virtual corporations in many ways. Virtual corporations are temporary networks of independent companies - suppliers, customers, even erstwhile rivals - linked by information technology to share skills, costs, and access to one another's markets (Byrne et al., 1993). Virtual corporations are increasingly becoming an acceptable organizational alternative for supply chain managers as they already display many of the same characteristics that their logistical operations have. In virtual organizations, every member focuses on their own core competency (Hamel & Prahalad, 1990) and strives to be the best available provider of that competency. This is true for Web-based supply chains as well. As the above definition illustrates, all members are linked by information technologies in order to communicate and transact. Virtual corporations certainly cannot live up to their often lofty expectations without the same high flexibility and speed that Web-based supply chains offer.

In summary, Web-based supply chains are a very elegant and promising concept in theory that has a lot of potential in practice as we venture into the 21st Century. However, as this article has outlined, every successful endeavor independent of its nature begins with a sound strategy that translates into innovative supply chain processes, which in turn utilize technologies such as Web- and Internet-based systems. Technology in and by itself is of little to no value. The same is true for Web-based supply chains: they too need synergistic and integrated strategies as a foundation on which to drive projects towards implementations that are successful in realizing tangible business benefits. These benefits will drive the company's competitiveness and comparative advantage that ultimately compels others to follow suit until potentially every supply chain, someday, could be a Web-based supply chain.

KEY TERMS

Activities: Single tasks or chains of tasks that form business processes and that allow a firm to differentiate itself in the market place.

Bullwhip Effect: A situation in which ineffective network effects occur because each successive node in the supply chain orders more supplies than the previous one based on wrong assumptions, a lack of communication, and flawed planning processes.

Strategic (Supply Chain) Role: A situation in which supply chain management is the most important corporate function and thus dominates the definition of corporate strategy.

Strategy: The competitive positioning of a company or product in a given market. In its essence strategy means choosing to perform the same activities differently or different activities from rival firms.

Strategy Framework: Strategy drives the definition of processes, which in turn rely on technologies for their flawless execution.

Supporting (Supply Chain) Role: A situation in which supply chain management is driven by other, more important corporate functions and subsequently translates corporate strategy into specific requirements for supply chain management.

Supply Chain Management: All activities that are related to the planning and fulfillment of demand.

Supply Chain Strategy: The choice and performance of unique activities within supply and demand management to ultimately achieve corporate strategy.

Virtual Corporation: A temporary network of independent companies - suppliers, customers, even erstwhile rivals - linked by information technology to share skills, costs, and access to one another's markets (Byrne et al., 1993).

Wireless Ad Hoc Networking

Fazli Erbas
University of Hanover, Germany

INTRODUCTION

Mobile ad hoc networks represent a new form of communication consisting of mobile wireless terminals (e.g., handset, PDAs, notebooks). These type of networks are wireless multi-hop packet networks without any fixed infrastructure and centralized administration, in contrast to today's wireless communications, which is based on a fixed, pre-established infrastructure. The design of wireless ad hoc networks faces many unique challenges. In this article, mobile ad hoc networks and their characteristics are described, and the design issues, applications and future trends of such networks will be discussed.

BACKGROUND

In recent years, widespread availability of wireless communication and handheld devices stimulated the research and development on self-organizing networks that do not require a pre-established infrastructure and any centralized architecture. Those spontaneous networks provide mobile users with ubiquitous communication capability and information access regardless of their location. This type of networking is called mobile ad hoc networks.

The idea of mobile ad hoc networks has been under development from the 1970s and 1980s in the framework of Mobile Packet Radio Technology (PRNET-1973) (Jubin & Tornow, 1987) and Survivable Adaptive Networks (SURAN-1983) (Schacham & Westcott, 1987). These projects supported research on the development of automatic call set up and maintenance in packet radio networks with moderate mobility. However, interest in this area grew rapidly due to the popularity of a large number of portable digital devices, such as laptop and palmtop computers, and the common availability of wireless communication devices.

In the middle of the 1990s, with the definition of standards, commercial radio technologies have begun to appear and the wireless research community identified in ad hoc networks a challenging evolution of wireless networks. The success of a network technology is associated with the development of networking products that can provide wireless network access at a competitive price. A major factor in achieving this goal is the availability of appropriate networking standards. Today's emerging standards and technologies for constructing a mobile ad hoc network are IEEE 802.11, Bluetooth and ETSI Hiperlan/2. The deployment of mobile ad hoc networks opens a wide-range of potential utilisation from military to miscellaneous commercial, private and industrial scenarios (Perkins, 2001).

MOBILE AD HOC NETWORKS AND THEIR CHARACTERISTICS

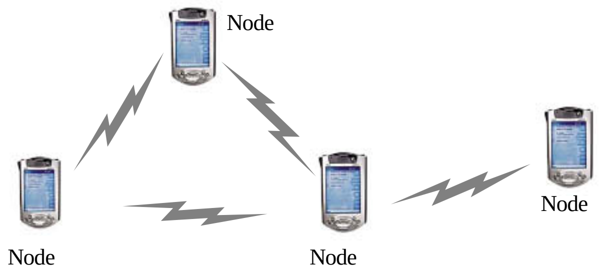
A mobile ad hoc network (MANET) consists of a collection of mobile wireless and autonomous hosts –in this sense simply referred to as "*nodes*"– which spontaneously form a temporary network. The devices may be of various types (e.g., notebook computers, PDAs, cell phones, etc.) and various capacities (e.g., computing power, memory, disk, etc.).

The most important characteristic of such a network is its independence of any fixed infrastructure (e.g., base station or access point) or centralized administration. All networking functions, such as determining the network topology, multiple access, and routing of data over the most appropriate paths, must be performed in a distributed way. These tasks are particularly challenging due to the limited communication bandwidth available in the wireless channel.

Actually, the idea of ad hoc networking is sometimes also called infrastructureless networking (Frodigh, Johansson & Larsson, 2000). An ad hoc network is able to operate autonomously and is completely self-organized and self-configured. Therefore, it can be easily and rapidly installed. In an ad hoc environment people and vehicles can be interworked in areas without a pre-existing communication infrastructure, or when the use of such infrastructure requires wireless extension.

Autonomous nodes may move arbitrarily so that the topology changes frequently without any prior notice. The wireless transmission range of the nodes is also limited; therefore the connection (e.g., wireless link) between the neighboring nodes may break as soon as they move out of range. Consequently, topology of the network and the interconnection patterns among nodes may change dynamically so that links between nodes become

Figure 1. A mobile ad hoc network



unusable. Because of the dynamic nature of ad hoc networks, new routes must be considered and maintained using routing protocols.

Another important property of ad hoc networks is the multi-hop capability. It is given that cellular networks — also called single-hop networks — rely on a fixed wired infrastructure to achieve the task of routing and maintain the connection end-to-end. On the contrary, a mobile node in an ad hoc network that cannot reach the destination directly, because it does not lie within its radio transmission range, will need to relay its information flow through other nodes. This implies the mobile hosts to incorporate routing functionality so that they can act both as routers and hosts.

Other important characteristics of MANET include (Perkins, 2001):

- **Dynamic topologies:** Nodes are free to move arbitrarily; thus, the network topology may change randomly and rapidly at unpredictable times.
- **Bandwith-constrained links:** Caused by the limits of the air interface. Furthermore, multiple access, multipath fading, noise and signal interference decrease the limited capacity available at the allocated frequency rate.
- **Energy-constrained operation:** MANETs inherently imply an underlying reliance on portable, finite power sources.
- **Limited security:** Mobile networks are in general more vulnerable to eavesdropping, spoofing and denial-of-service attacks than fixed-cable networks.

DESIGNING ISSUES

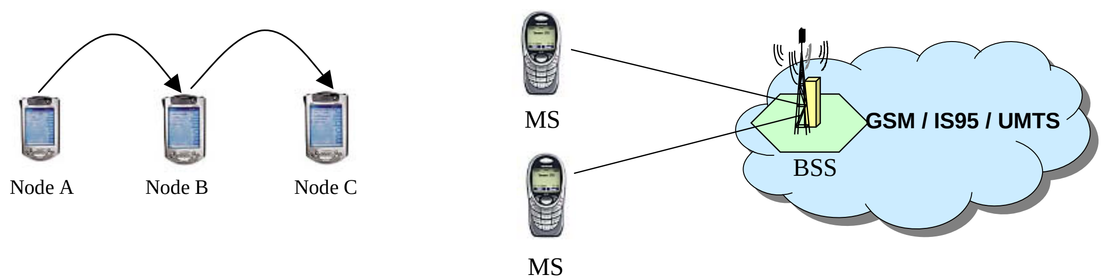
Physical Layer and MAC Layer

A well-designed architecture for mobile ad hoc networks involves all networking layers, ranging from the physical layer to the application layer. Information as node distribution, network density, link failures, and etcetera, must be shared among layers, and the MAC (medium access control) layer and the network layer need to collaborate in order to have a better view of the network topology and to optimise the number of messages in the network (Bruno, Conti, & Gregori, 2001; Kurose, Schwartz, & Yemini, 2000).

The main aspects of designing the physical transmission system are dependent on several characteristics of the radio propagation channel such as path loss, interference and fading. In addition, since mobile terminals usually have limited power resources, the transceiver must be power efficient. These aspects are taken into account while designing the modulation, coding, and power control features in the radio equipment. In principle, the radio equipment in the nodes forming a mobile ad hoc network can use any technology as long as it provides reliable links between neighboring mobile terminals on a common channel. Candidate physical layers that have gained prominence are infrared and spread spectrum radio techniques.

The MAC (medium access control) layer plays the key role in determining the channel usage efficiency by resolving contention amongst a number of unsupervised terminals sharing the common channel. An efficient MAC protocol allows coordinated access to the limited resources. The main goal of a MAC protocol is therefore maximizing the probability of successful transmissions and maintaining fairness amongst all users.

Figure 2. Mobile ad hoc networks (multi-hop networks) in comparison to today's cellular (single-hop) networks



(Node C is reached from node A via node B in multihop way)

Though research on medium access schemes for wired local area networks (LANs) have been done for many years, the same concepts cannot be directly applied to wireless LANs. In a wired medium, the transmitted signals are almost received with the same signal strength at all terminals connected to the same shared medium. Hence a terminal in a LAN can avoid contention by sensing the presence of a carrier to determine if any other terminal is using the channel before it starts a transmission.

However, designing MAC protocols for wireless networks faces a different set of challenges. Propagation path losses in the wireless channel cause the signal power to decline with distance.

Since the strength of the received signal depends on the distance from the transmitter, the same signal is not heard equally well by all terminals. Hence carrier sensing is not very effective in wireless. Typical problems of using carrier sensing to determine the availability of the wireless channel are *hidden node problem* and *exposed node problem* (Nasipuri, 2002). Both the hidden node and the exposed node problems arise due to the fact that carrier sensing is only performed at the transmitter, whereas its effect is determined by the interference power at the receiver, which are usually different due to propagation path loss characteristics.

In order to address the hidden terminal problem, IEEE 802.11 has the option of adding the mechanism of an exchange of *REQUEST TO SEND (RTS)* and *CLEAR TO SEND (CTS)* control packets between a transmitting and receiving nodes before initiating the transmission of a data packet.

Several concerns with the IEEE 802.11 MAC has motivated researchers to explore newer techniques to improve the channel utilization and throughput in mobile ad hoc networks. The basic access method of the IEEE 802.11 MAC protocol is susceptible to inefficiencies due to the hidden and exposed terminal problems. The RTS/CTS option reduces the hidden terminal problem but not the inefficiency caused by the exposed terminal problem.

A wireless transceiver cannot transmit and receive at the same time as the transmitted signal will always be far stronger than any received signal. Hence, a wireless terminal cannot detect if its transmission has been successful. To inform the transmitting node about the successful packet transmission, the receiver sends an ACK (acknowledgement) packet back to the transmitter after it receives a data packet. If the transmitter does not receive an ACK within a fixed period of time, it assumes that the transmitted packet has been lost. Many different schemes have been designed for reducing these problems in wireless channel access.

ROUTING

Movements of nodes in a mobile ad hoc network cause the nodes to move in and out of range from one another. Consequently, topology of the network and the link and connection patterns between nodes may change dynamically so that links between nodes become unusable. As depicted, in contrast to conventional wireless networks, mobile ad hoc networks have no fixed network infrastructure or centralized administrative support for their operations. Because of the dynamic nature of ad hoc networks, new routes must be considered and maintained using routing protocols. Since the network relies on multi-hop transmissions for communication, this imposes major challenges for the network layer to determine the multi-hop route over which data packets can be transmitted between a given pair of source and destination nodes.

Because of this time-varying nature of the topology of mobile ad hoc networks, traditional routing techniques, such as the shortest-path and link-state protocols that are used in fixed networks, cannot be directly applied to ad hoc networks. A fundamental quality of routing protocols for ad hoc networks is that they must dynamically adapt to variations of the network topology. This is implemented by devising techniques for efficiently tracking changes in the network topology and rediscovering new routes when older ones are broken. Since an ad hoc network is infrastructureless, these operations are to be performed in a distributed fashion with the collective cooperation of all nodes in the network (Royer & Toh, 1999; Perkins, 2001). Some of the desirable qualities of dynamic routing protocols for ad hoc networks are:

- **Routing overhead:** Tracking changes of the network topology requires exchange of control packets amongst the mobile nodes. These control packets must carry various types of information, such as node identities, neighbor lists, distance metrics, and etcetera, which consume additional bandwidth for transmission. Since wireless channel bandwidth is at a premium, it is desirable that the routing protocol minimizes the number and size of control packets for tracking the variations of the network.
- **Path optimality:** With constraints on the routing overhead, routing protocols for mobile ad hoc networks are more concerned with avoiding interruptions of communication between source and destination nodes rather than the optimality of the routes. Hence, in order to avoid excess transmission of control packets, the network may be al-

lowed to operate with suboptimal (which are not necessarily the shortest) routes until they break. However, a good routing protocol should minimize overhead as well as the path lengths. Otherwise, it will lead to excessive transmission delays and wastage of power.

- **Loop freedom:** Since the routes are maintained in a distributed fashion, the possibility of loops within a route is a serious concern. The routing protocol must incorporate special features so that the routes remain free of loops.
- **Complexity:** Another problem of distributed routing architectures is the amount of storage space utilized for routing. Ad hoc networks may be applied to small portable devices, such as PDA and handhelds, which are memory and hardware scarce. Hence, it is desirable that the routing protocol be designed to require low storage complexity.
- **Scalability:** Routing protocols should be able to function efficiently even if the size of the network becomes large. This is not very easy to achieve, as determining an unknown route between a pair of mobile nodes becomes more costly in terms of the required time, number of operations, and expended bandwidth when the number of nodes increases.

Because of its many challenges, routing has been a primary focus of researchers in mobile ad hoc networks. The MANET working group within the IETF (IETF, 2004) studies solutions for routing framework and develops IP-based routing protocols for mobile ad hoc networks. (Macker & Corson, 1998; Corson & Macker, 1999). Consequently, a large number of dynamic routing protocols applicable to mobile ad hoc networks have been developed.

APPLICATIONS

The term ad hoc means "as needed for a specific case," "done or set up solely in response to a particular situation or problem without considering wider issues." Both definitions stress out the urgent, specific and short-term need character. Indeed, an ad hoc network will be deployed in an area where a support for mobile communication is not available due to low expected usage and high costs. The network can disappear after its function has been served.

One of the original motivations for the development of this technology lay in satisfying military needs like battlefield survivability. Soldiers must be able to move about freely without any restrictions imposed by wired communication devices. Moreover, the military cannot rely on access to a fixed preplaced communication infrastructure especially during manoeuvres in enemy territories (Perkins, 2001).

Other potential practical utilities of mobile ad hoc networks could include:

- Commercial and industrial scenarios: Associates sharing information during a meeting, participants in a conference exchanging documents or presentations
- Educational scenarios: Students using laptop computers to participate in an interactive lecture
- Emergency coordination in disaster areas, where a hurricane or earthquake have destroyed the communication infrastructure
- Extension of the coverage area of cellular networks
- Communication between smart household appliances in the home environment
- Communication between "wearable" computing devices
- Inter-vehicle communication like within a convoy or in highway
- Sensor Networks: represent a special kind of ad hoc networks. They typically consist of nodes equipped with sensing, processing and communication abilities. Sensor networks are used to monitor remote or inhospitable physical environments

FUTURE TRENDS

Need for wireless ad hoc networking will arises in the context of shared desktop meetings (e.g., cooperate learning, workshops, conferences), disaster recovery, wireless inter-vehicle communication, proprietary local networks for private, commercial, business and governmental, use (universities, hospitals, home environments, office environments) or in various military applications.

New technological standards, regulations (e.g., IEEE 802.11, IEEE 802.15), emerging products (e.g., PDAs, notebooks) and new business models will enable fast deployment of such networking concepts.

CONCLUSION

Wireless ad hoc networking is a new form of communication offering new emerging technologies and applications. Several issues have to be considered which are arising due to characteristics of this type of networks. The critical issues discussed in this article offer many implications and challenges to technology, business and the user community as well.

The successful deployment and a broad acceptance of such networks will depend on the availability of appropriate standards and regulations. Further, the development of new products and business models at a competitive price will play key role.

KEY TERMS

Carrier Sensing: Determination that the medium is not being used by a neighboring transmitter before accessing the channel.

Cellular Networks: A network consisting of several cells served by fixed, pre-established infrastructure to cover a geographic area, for example, GSM, IS-95, UMTS.

Dynamic Topology: Due to the node mobility the network topology of mobile multi-hop ad hoc networks are changing continuously in time.

Exposed Node: This is the reverse problem, where a transmitting or "exposed" node is within range of a sender, but is out of range of the intended destination.

Hidden Node: A node may be hidden or out of range from a sender but within range of its intended receiver.

MANET (Mobile Ad Hoc Networks): A network of wireless mobile nodes formed dynamically, self-organizing and without any central administration.

Multi-Hop: The mobile nodes are cooperating to forward data on behalf of one another node to reach distant stations that would otherwise have been out of range of sending node.

Node: Mobile terminal.

RTS/CTS (Request To Send/Clear To Send): Control packets between the transmitting and receiving nodes before initiating the transmission of a data packet.

Single-Hop: Direct communication between two nodes or entities without any intermediate station or network entity.

W

Wireless Middleware

Kenneth J. MacGregor
University of Cape Town, South Africa

INTRODUCTION

Middleware is not a new concept in distributed computing. It was first accepted as a term used to describe distributed software architecture during the 1990s and has evolved significantly since then with the increase in computer networking and the resulting use of distributed systems. The following is aA definition of middleware that was proposed by Emmerich (2000) and embodies the concepts of middleware: “Middleware is a layer between network operating systems and application components which facilitates communication and coordination of distributed components” (p.120).

Middleware has become widely adopted in industry to simplify the problem of constructing distributed systems as it resolves the heterogeneity between systems and provides higher-level primitives for application engineers to focus on application requirements and not their connectivity.

Wireless middleware, as a specialized subset of middleware, has come into increased significance in the current decade due to the proliferation of wireless networks. Additionally, in the last few years, there has been an upsurge in the development of the mobile devices sector. Personal Digital Assistants (PDAs) and a new generation of cellular phones have the ability to access different types of network services and run many applications. To cope with these innovations, the role of wireless middleware has become increasingly important in providing a reliable channel for data access between mobile devices and servers on a wired network. This provides applications running on the mobile client to synchronize with and participate in the application dialogues that are hosted on the enterprise servers.

Wireless middleware is an intermediate software component that is generally located on a wired network between the wireless device and the application or data residing on a wired network. The purpose of the middleware is to increase performance of applications running across the wireless network by serving as a communication facilitator between components that run on wireless and wired devices (Wireless Nets). Wireless middleware serves as a communication facilitator by addressing the numerous ways in which communication can fail among components in a distributed application. Sources of communication failure, among many others, include a component going off line voluntarily but unexpectedly, a component unexpectedly terminating, a component failing to respond to a request in a reasonable amount of time, and communication being severed in the midst of a request (Sunsted, 1999).

TYPES OF WIRELESS NETWORKS

Currently there are two distinct types of wireless networks that can be categorized by their transmission range and that differ significantly in the latency and bandwidth characteristics of the transmission.

Fixed Wireless Networks

Fixed Wireless Networks use wireless transmitters with a relatively short transmission distance and normally correspond to one of the IEEE 802.11 standards. Networks of this type have many of the characteristics of fixed wire networks, such as low latency, high bandwidth, and relatively good reliability. These networks tend to be used in a specific area such as a Starbucks coffee shop, an airline lounge, or a corporate office. For wireless networks of this type, the standard middleware that is normally employed in wired networks and can be used as such are the de facto standard interprocess communication mechanisms such as XML and SOAP, which are becoming increasingly common.

Highly Mobile Wireless Networks

These wireless networks are used predominately to serve highly mobile clients such as mobile cellular phones or satellite communications. Networks of this type have extremely high latency, relatively low bandwidth, and greater unreliability, as any number of interruptions can occur to disrupt the communication with the client. As this type of network is increasingly becoming used for M-commerce, specialized middleware is required to cater to the additional challenges.

It is this type of wireless network (i.e., high latency, low bandwidth, unreliable, and insecure networks) to which the remainder of this entry refers.

CHALLENGES FOR WIRELESS MIDDLEWARE

Wireless middleware is presented with many challenges by the very nature of the wireless environment. These challenges are not adequately addressed by standard data communication methods that were designed for wired environments. One of the main advantages of middleware is to allow applications to run on multiple platforms without the need to rewrite them. As such, wireless middleware should support heterogeneous devices, permit applications to be ported from one device to another, and, in addition, handle the limitations of mobile devices, among which are the small amount of memory and the lack of processing power. Wireless middleware on mobile devices has some distinct issues not present in traditional fixed line systems.

Disconnected Operation

Wireless communication devices tend to lose and regain network connectivity much more often than non-mobile applications. The middleware must be able to cope with intermittent communication links and implement software layers that ensure the delivery of important data between the server and the wireless device.

Resource Constraints

Mobile applications must be optimized aggressively for small ROM and RAM footprints, as well as for low usage of CPU cycles and battery power.

Multiple Bearers

Internet applications only need to support HTTP or TCP/IP. Wireless applications are written to perform on many different networks. A bearer in a wireless network is a transport mechanism of which wireless bearers could be SMS, GPRS, Infrared, Bluetooth, or HTTP. An application written for one bearer typically needs to undergo substantial modifications in order to run on another bearer.

Heterogeneous Software

There are a number of operating systems that are prevalent in the wireless device market. Because of the memory restrictions placed on these systems, they do not possess all the features of server operating systems. Thus, it is often difficult to ensure that the middleware can effectively run on all the required hardware devices. Often, features that are available on one device are not available on another device with a different operating system. For example, object serialization, which is a standard method of communication for components between clients and server systems, is not available in Windows CE.Net. Thus, programming communications between components where the device is a CE device require the applications developer to interface with a middleware product that cannot serialize objects.

Security

Security is a key concern in a mobile environment. Identification, authentication, and data encryption must be embedded into wireless middleware applications.

Scalability

As a result of the proliferation of wireless devices, scalability of applications can easily grow to hundreds of thousands of client systems. Ensuring the scalability of applications to this number of clients presents a major problem.

Deployment and Management

Deploying applications to many clients, managing them, supporting them, and ensuring their integrity and support when they are not online, present another major challenge to the middleware.

COMMERCIAL SIGNIFICANCE OF WIRELESS MIDDLEWARE

The development of application software such as M-Commerce applications and client/server applications should not be designed so they are independent of the network over which they are deployed. This ensures that applications do not require to be rewritten for new technologies, and the applications developer and business enterprise can concentrate on the business benefits of the application and not the technology on which they reside. For example, a stock ordering application running on a PDA for a manufacturing concern should integrate with the manufacturing schedule in the corporate head office. The speed of taking the orders, scheduling them, and getting them in the production schedule is what is important to the manufacturing company. Wireless middleware provides this network transparency and enables wired applications to be ported to wireless environments with the minimum of software modification.

Wireless Network Requirements

In order to meet the needs of the applications running on them, typical wireless middleware solutions have the following basic requirements:

- **Intelligent restarts**
  The middleware should neither raise communication errors nor lose data when a mobile device loses network coverage. It should incorporate a recovery mechanism that detects when a transmission has been cut, and when the connection is reestablished, the middleware resumes transmission from the break point instead of at the beginning of the transmission.
- **Store-and-forward messaging**
  Message queuing is implemented to ensure that users disconnected from the network will receive their messages once the station comes back online. This, however, can lead to a large number of messages being stored for stolen or broken clients.

Small Footprint

It is particularly important that the messaging client library, stored in the wireless device should have a small memory footprint (ROM and RAM).

Open bearer Models

The middleware should offer the same set of communication abstractions on top of various wireless bearers. Modern wireless communications use GSM, GPRS, and possibly 3G mobile communication protocols. This allows applications to be developed once and operate on top of various bearers. This, however, may lead to the least rich subset of the possible bearers being implemented.

Multi-Platform Language Availability

The API should be compatible with computer languages available on multiple platforms and operating systems. This allows applications to be adapted for various platforms more easily.

Security

Security is essential in a wireless system, particularly for applications such as M-Conmmerce, which are becoming increasingly widespread (Allnet, 2002). As wireless communications cannot be physically secured, the needs of wireless access present a new series of challenges. Wireless access to enterprise systems puts not only the client device, but also the data, well beyond the physical control of the organization. Sniffing of data traffic can be done without any risk of detection over a much wider range of locations. Furthermore, the client device, in the case of a cell phone or PDA, is even easier to steal than a laptop computer with the additional loss of security. Compromise of the wireless client thus poses a double threat to data: the remote access to data that the device enables, and immediate access to the downloaded data which is stored within it. The wireless middleware should incorporate a security mechanism. Thus, access control, identification, authentication, and end-to-end data encryption should be provided by the middleware. Providing these facilities in the middleware and not in the application dramatically simplifies the development of secure mobile solutions.

Scalability

The middleware must support scalability, as many thousands of clients could be connected. It must not become overloaded when repeatedly sending messages, and must handle increasing congestion resulting from disconnect clients. In addition, it must be able to identify and delete messages that can never be delivered perhaps due to a wireless device becoming broken or stolen.

Intelligent restarts are required in order to enhance the robustness of the distributed system that is built using the middleware. A robust distributed system must detect failures, reconfigure the system so that computations may continue, and recover when a link is repaired.

MESSAGING MIDDLEWARE

These basic requirements of wireless middleware can be met by messaging middleware.

Messaging middleware allows general-purpose messages to be exchanged in a client/server system using message queues. Applications communicate over networks by putting messages in queues and getting messages from queues. This messaging and queuing allows clients and servers to communicate across a network without being linked by a private, dedicated, logical connection. The clients and servers can run at different times. All communication is by putting messages on queues and by taking messages from queues. It is used when a distributed application can tolerate a certain level of time-independent responses. For example, nomadic client/server systems can accumulate outgoing transactions in queues and do a bulk upload when a connection can be established with an office server.

Since most of the commercial middleware products are based on the Java Messaging System (JMS) (JMS

Specification, 2002), we will look at how it can be used as a wireless middleware.

JMS, developed by Sun Microsystems, Inc., is part of the Java2 Enterprise Edition (J2EE) platform. JMS is an Application Programming Interface (API) for accessing Messaging applications in Java Programs. The JMS API is not specifically intended for the wireless domain. Traditional JMS was designed to allow Java applications to communicate with existing wireline messaging systems. As a result, a full JMS implementation is too "fat" for wireless devices because low power consumption and a smaller memory footprint are required (Spiritsoft, 2002). However, JMS has become the "de facto" standard as an API for wireless middleware, and most wireless middleware products are based on it.

THE JMS API

The JMS API allows applications to create, send, receive, and read messages which can arrive asynchronously, which means that the client does not have to specifically request messages in order to receive them. In addition, the programmer can specify different levels of reliability, depending on the type of message that is transmitted. Unlike traditional low level network remote procedure call mechanisms, JMS is *loosely coupled*, which means that the sending and receiving applications do not both have to be available at the same time in order to enable communication (Java, 2002).

The JMS API Architecture

The following components are present in a JMS implementation:

- *JMS Provider* – Provides administrative and control features. It is the system that implements JMS interfaces.
- *JMS Clients* – Components or programs, written in Java, that are the producers and consumers of messages, clients, and servers. In the wireless domain, clients may include cellular phones and PDAs.
- *Messages* – The objects that are transmitted between JMS clients.
- *Administered Objects* – These are configured by the administrator and include destinations and connection factories. Together, the administered objects form the Java Naming and Directory Interface (JNDI) API namespace. For one client to establish a logical connection with another through the JMS Provider, it needs to perform a lookup of administered objects, using a standard directory service.

Further details on the JMS communication API can be found on the Java tutorial.

JMS supports the two more common approaches to messaging; namely, *point-to-point* and *publish-subscribe*, which permit messages to be transmitted directly between a client and a server, or for a client to subscribe to specific messages (e.g., sports scores) and servers to broadcast these messages to the specific clients that request them.

NETWORK PROTOCOLS

Contemporary middleware products, whether message oriented or otherwise, have not been designed for mobile devices (Maffeis, 2002). This inappropriateness stems partly from the use of communication protocols that were designed for wired networks. The dominant wired network is the Internet, which has the Transmission Control Protocol (TCP) as its transport protocol. Regular TCP, which is TCP designed for wired networks, could be used in the JMS Connection object; however, this may lead to intolerable inefficiencies. Wireless links do not provide the degree of reliability that hosts expect. The lack of reliability stems from high error rates of wireless links when compared to wired links. Additionally, certain wireless links, such as cellular networks, are subject to intermittent connectivity problems due to handoffs that involve calls being transferred between base transceiver stations in adjacent cells. The root of the problem is that congestion avoidance in the wired TCP algorithms is based on the assumption that most packet losses are due to congestion. As a result, the TCP sender spends excessive amounts of time waiting for acknowledgements that do not arrive.

As a result, most wireless middleware products and JMS implementations use either different transport mechanisms, such as a reliable data protocol similar to that described in RFC 908 (Velten et al., 1984), or a significantly lightweight versions of the standard TCP protocol.

FUTURE TRENDS

As wireless devices become increasingly powerful and more accepted, wireless middleware will have to play an increasing role in ensuring that applications run efficiently in this environment. Currently, the versions of wireless middleware being used are, at best, second-generation versions; however, work is being undertaken in a number of areas.

Network Protocols

Alternative network protocols suitable for wireless communication are being analysed (Farooq & Tassiulas, 2003). This will lead to faster communications between the wired and wireless devices.

Application Communication Paradigms

As wireless technology becomes more available, developers of distributed applications are becoming more interested in how that technology affects the performance of their systems. Thus, the efficiency of different paradigms of communication, such as publish/subscribe, is being investigated (Caporuscio & Carzaniga, 2002); Farooq et al., 2004).

Efficiency of Wired Protocols

As most distributed applications on the Internet are using protocols such as SOAP and XML, work is being undertaken to optimize these protocols for wireless communications (Hanslo, 2004).

Alternative Middleware Products

Currently, Java (JMS, in particular) is effectively the only platform suitable for mobile communications. As the market for wireless applications becomes larger and more profitable, there will be more middleware products vying for a share. Thus, there will be greater competition and more choice for the applications developer. Some of these middleware products could permit applications for wireless ad hoc networks such as peer-to-peer computing, which could easily be developed (Kortuem, 2002).

As a result of this work, wireless applications will be developed, integrated into the enterprise, and executed with the efficiency and reliability that is expected from wired applications.

Conclusion

Wireless middleware has evolved from the traditional middleware background to a product field in its own right. The early attempts of stating that standard wired middleware products are "suitable for wireless" have passed and the wireless middleware products in commercial use today have different requirements, use different transport protocols, and have a different concept of robustness of connection from traditional products. In the future, more advanced products that are specifically catered to the wireless domain will be produced. These products will enable more advanced applications to be implemented and will further increase the usefulness of the mobile devices and PDAs. Finally, with the use of wireless middleware, ubiquitous computing will become a reality.

KEY TERMS

Application Synchronization: A specific type of wireless application whereby the data on the wireless device is synchronized with that on the main server.

Handover: In a cellular network, the radio and fixed voice connections are not permanently allocated for the duration of a call. Handover, or handoff as it is called in North America, means switching an ongoing call to a different channel or cell. This often results in loss of connection.

M-Commerce: A wireless application that involves the change of money. This could be through the use of a mobile device to pay for services.

Network Bandwidth: The data capacity through a network.

Network Latency: The time for a message to travel over the network from the sender to the receiver. In cellular networks, this includes the time from the device over the network to the base station, over a landline to the service provider, and out to the application. It could possibly include satellite transmission time from the earth station to the satellite and down to another earth station.

Point to Point: The communication from a single client to a single server.

Publish Subscribe: A method of communication by which clients register to be notified when some event occurs. When the event happens, the server checks though the list of subscribed clients and broadcasts to them the event data. This is often used in wireless applications for information on stock price changes, sports results, and so forth.

Wireless Application: An application running on a wireless device that transmits and receives data over a wireless network.

Wireless Technologies to Enable Electronic Business

Richi Nayak
Queensland University of Technology, Australia

INTRODUCTION

Research and practices in electronic business (e-business) have witnessed an exponential growth in the last few years (Liautand & Hammond, 2001). Wireless technology has also evolved from simple analog products designed for business use to emerging radioactive, signal-based wireless communications (Shafi, 2001). The tremendous potential of mobile computing and e-business has created a new concept of mobile e-business or e-business over wireless devices (m-business).

BACKGROUND

M-business can be defined as the use of mobile technology in exchange of goods, services, information, and knowledge. M-commerce is the execution of transactions done on mobile equipment via mobile networks, which may be wireless or switched public networks. M-business includes the range of online business activities, business-to-business and business-to-consumer, for products and services through wireless devices such as mobile phones with display screens, personal digital assistance (PDA), two-way pagers, and low-end or reduced-size laptops.

Example applications are mobile ticketing and receipting, banking, gaming, e-mail communication, weather forecast, sport scores access, movie database access, stock exchange information, ordering of books, and other daily needs such as food and groceries. With new emerging mobile applications, users only receive selective and real-time information personalized to their interests (Ratsimor, Korolev, Joshi & Finin, 2001). For example by using a positioning system, the advertising information of local services and entertainment can be sent whenever a user is passing by a shopping mall. Another application is "inventory management" that tracks the location of goods, services, and people to determine delivery times. Multiple trucks carry large amounts of inventory that companies could access for just-in-time delivery (Varshney & Vetter, 2002).

Significant benefits of m-business to consumers are convenience, portability, safety, integrating existing mobile phones with mobile computing technology, verifiable receipts, and transaction records that can be made available instantly and permanently on a smartcard. Significant advantages of m-business to service providers and content providers include driving additional revenue and decreasing consumer attrition by offering new m-business services to specific groups of customers.

WIRELESS TECHNOLOGIES TO ENABLE M-BUSINESS

Many wireless technologies exist to enables m-business services (Tsalgatidou, Veijalainen, Markkula, Katasonov & Hadjiefthymiades, 2003). All technologies try to achieve benefits such as being powerful, simple, economical, and secure. Some examples of these techniques follow.

Wireless Application Protocol technology links wireless devices to the Internet by optimizing Internet information so it can be displayed on the small screen of a portable device.[1] Web pages accessed by WAP-enabled mobile portals during m-business transactions must be written in WML.[2] It is not sure how well WAP will be able to proliferate (Tsalgatidou et al., 2000). Developments such as third-generation (3G) mobile communications and XYPOINT WebWirelessNow applications (Wen, 2001) already allow mobile phone consumers to experience the Web services without WAP.

Wireless Internet connecting technologies that offer textual interface such as WAP significantly suffer from the constraints of wireless communication such as having a small display screen. An alternative solution is providing voice access to users. Advances in speech recognition and text-to-speech technologies have made voice-based communication possible between computers and users over the phone.

VoxML[3] technology, based on the W3C XML standard, enables the application interface to be in the form of dialogues. However, there is an extra overhead for content providers to offer the same Web service through different channels, for example, providing a voice-enabled browser for their wireless customers along with the HTML/XML/WML browser. Another overhead is the processing power that speech recognition requires. Also this type of data transfer mode is not appropriate for applications with confidential data where one could be overheard. Overall, the success of this technology depends on public acceptance of mobile phones as data-delivering tools and the type of applications best suited to their use.

The *Bluetooth* technology further enhances the sphere of mobility by conducting m-business without a heavy network infrastructure unlike WAP and VoxML technologies.[4] The Bluetooth technology is designed to allow low-cost, short-range data (asynchronous) and voice (synchronous) radio link (2.4 GHz, 1 Mb/sec) to facilitate protected connections for stationary (homes, buildings, shopping centers, restaurants, cars, etc.) and mobile (phones, PDAs) computing environments. A simple example of a Bluetooth application is to automatically update mobile phone contents such as phone list, e-mails, and memos without any user involvement when the phone comes within the range of the home/office PC. Currently, the Bluetooth networks providing m-business services are limited to 10 meters only. Also, it has too many flaws in terms of security for the services to be trusted. A promising future of Bluetooth technology is its integration with WAP or VoxML.

Based on infrared technology, the *IrDA (Infrared Data Association)* easy-to-use technology provides low-cost, short-range, point-to-point connectivity between devices, interoperable/cross-platform at a wide range of speeds (115.2kb/s to 4Mb/s) with a physical range of 1 meter. IrDA technology is embedded into 40 million new devices each year such as personal computers, laptops, mobile phones, PDAs, digital cameras, pagers, and so forth.[5] The keyword of IrDA advantages is simplicity for ad-hoc, point-to-point exchange. However, the requirement of direct line of sight for devices to communicate is surely a disadvantage for conducting m-business.

IEEE802.11 (Wi-Fi) technology provides a high data rate over different ranges (54Mbps using the 2.4 and 5 GHz ISM band, 11Mbps using the 2.4 GHz ISM band).[6] The single Media Access Control protocol helps to keep the cost down, but interoperability is a problem. The data transmission rate has to be defined before the transmission between devices can start. In terms of the transmission itself, it is based on the well-known TCP/IP protocol. The availability of unlicensed spectrum is a significant enabler for broad acceptance of this technology. However, the technology has some security flaws. Because of the large physical range (100+ meters) and "always-on" connection model, this technology consumes a lot of power, limiting its use in PDAs, phones, and other lightweight mobile devices. The greatest advantage of this technology for conducting m-commerce is its speed.

HiperLAN, a specification substandard of IEEE802.11, is a short-range technology (from 10 to 100 meters) adapted to 3G networks with low power requirements.[7] HiperLAN provides flexible services such as mobility management and quality of service at low cost. The technology has a potential for conducting m-commerce in terms of supporting both ad hoc and client/server networks.

Ultra Wideband technology is a recent RF technology with advantages like large bandwidth, high data transfer rates, and immunity to interference.[8] Still, the technology is in its early stage of development, and there are not many products using this technology yet. However, in the future this network technology may be a very good alternative for conducting m-commerce.

Mobile Agent technology offers a new computing paradigm in which a program, in the form of software agents, is initiated at the host, can suspend its execution on a host computer, launch itself to another agent-enabled host on the network, resume execution on the new host, and return back to its host with the result (Hayzelden & Bigham, 1999). This type of paradigm advocates the client/server model where the client is a mobile portal and the server is a fixed network. The mobile agent performs various optimizations on the server in lieu of its mobile portal to reduce the problems such as C-autonomy, limited bandwidth, and limited computational power. The fixed network offers its services to the agent such as access to local resources and applications, the local exchange of information between agents via message passing, basic security services, creation of new agents, and so froth. Many research papers emphasize that one of the most promising approaches for developing e-business appli-

Figure 1. A typical platform enabling m-business services

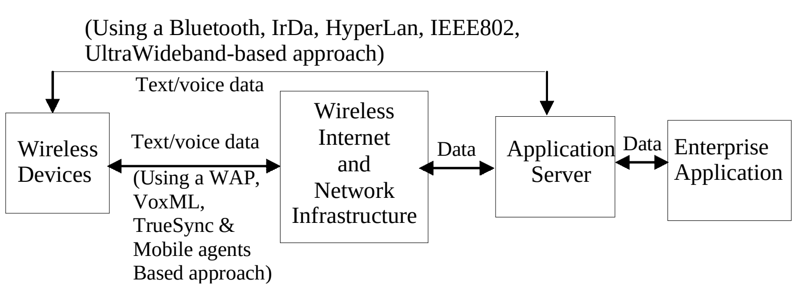

Figure 2. A mobile commerce cycle (Varshey & Vetter, 2002)

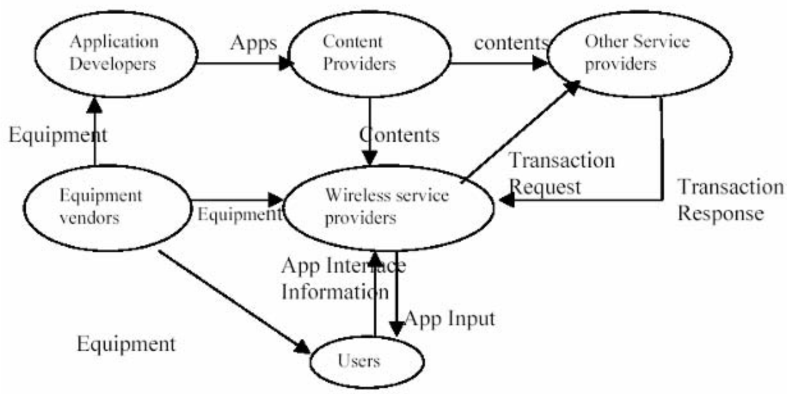

cations is mobile agent technology (Dikaiakos & Samaras, 2001; Tsalgatidou et al., 2000).

Figure 1 illustrates a typical platform to enable an m-commerce application. According to the wireless technology, a request from the wireless device is passed on to the application server, where the request is processed and output is returned.

Varshey and Vetter (2002) proposed a mobile commerce cycle that shows the possible interaction between various entities (see Figure 2).

CHALLENGES IN M-BUSINESS

As m-business bears its roots in e-business, many technical, legal, and business perspectives are extrapolated from e-business. But m-business embraces a number of technologies to enable its activities, such as wireless devices, software, and protocols, as well as eliciting a number of issues of its own.

Limited Environment of Mobile Devices

These devices usually have limited display size, input capabilities, data transfer rate, computation power, storage, power usage, and so forth; some may be overcome with the technological developments. For example, low bandwidth problem can be handled by the use of software compression techniques or by only sending the relevant information with the use of positioning systems to reduce the traffic. Such mobile applications should be developed so that a large footprint is not required (one innovation is NTT DoCoMo).[9] However, a low-power, inexpensive, and high-resolution color and larger size display will positively affect the m-business.

Security

Consumers should feel the same sense of security when they shop using a mobile phone as when they shop in the physical world. Connection to a wireless link does not require physical access to the network or devices in an "always-on" mode when connected, as in 3G devices. This makes wireless devices more susceptible to attack. In addition, mobile devices are prone to be lost or stolen. Various encryption and integrity mechanism are required to protect digitally encoded speech and control information in m-business services (Chari, Kermani, Smith & Tassiulas, 2001).

Transactional Issues

Usually transactional models with ACID (Atomicity, Consistency, Isolation, Durability) properties assist an application developer in providing powerful abstraction and semantics to concurrent executions and recovery in transaction management. M-business transactions require these properties to be redefined due to additional requirements such as: (1) the need to transfer money and goods along with data transfer, and (2) increased risk of incomplete transactions as mobile terminals can easily lose network connections.[10] Approaches such as the asymmetric cryptographic algorithms (also called Public Key algorithms) with certification authorities are utilized to fulfill ACID properties of m-business transactions (Veijalainen, 1999; Tsalgatidou et al., 2000).

Interoperability

The m-business market is still in its infancy with many standards, and many standards are competing with each other. This creates doubt for the success of global roaming and for the infrastructure. There is interference to one technology with the use of another technology in terms of broadband spectrum. There have been some improvements in convergence of functions between phones and PDAs. But still, each PDA device comes with its own operating system.

Slow Growth

M-business has not lived up to the promises of the past. Users are not keen to upgrade their mobile phones to take full benefit of m-business applications. Users feel that existing m-business applications do not drive the force to adopt new communications such as 3G. Accordingly, there is delay in implementing system infrastructure such as 3G mobile networks.

FUTURE TRENDS AND CONCLUSION

M-business applications improve the value of the service for the providers, and give an easy and natural interfacing and interacting to the users with mobile portals. Considering it is difficult to provide full convenience due to the limited nature of the wireless devices, the application seems to be able to offer ease of navigation and provide real-time information to users using mobile devices, anytime anywhere.

Many optimists see m-business as a technology that is just one step from everyday use. Many pessimists see many unsolved problems and predict that m-business will not break through in the next few years. As usual, the truth lies somewhere in the middle. Basic techniques are already available. Millions of people are already using mobile portals. Businesses are making profit by moving on to e-business solutions. The potential of m-business is enormous.

So why not integrate them all? Major mobile service providers are taking initiatives (such as MeT,[11] GMCF,[12] WDF,[13] NTT DoCoMo) to envision this technology to flourish. The remaining tasks are rigorous testing and refining of protocols especially suited for m-business applications, resolving related technical and business issues, thus winning the trust of consumers to use m-business services.

KEY TERMS

Electronic Business (E-Business): Any type of business transaction or interaction in which the participants operate or transact business or conduct their trade electronically.

Mobile Electronic Business (M-Business): A range of online business activities, business-to-business and business-to-consumer, for products and services through wireless devices such as mobile phones with display screens, personal digital assistance (PDA), two-way pagers, and low-end or reduced-size laptops.

Voice Markup Language (VoxML): Based on the W3C XML standard; designed to support interactive dialogues. VoxML masks the technology behind the voice-to-voice communications by using XML data-tagging structures to link the text-to-speech that generates audio with the speech-recognition software that interprets a user's command.

Wireless Application Protocol (WAP): An approach to link wireless devices to the Internet by optimizing Internet information so it can be displayed on the small screen of a portable device.

Amy Woszczynski
Kennesaw State University, USA

INTRODUCTION

Women have been involved with information technology (IT) since the 19th century, when Ada the Countess of Lovelace served as the first programmer of Charles Babbage's analytical engine. Grace Murray Hopper's contributions to COBOL and computing several decades ago are considered so significant that an annual conference is held in her honor (see *www.gracehopper.org*). In fact, the earliest computer programmers tended to be women more often than men (Panteli, Stack & Ramsay, 2001). As the IT field progressed, however, it evolved into what many still view as a male-dominated domain, some say due to its increasing association with power and money (Tapia, Kvasny & Trauth, 2003). Today, women are estimated to make up nearly half of World Wide Web users (Newburger, 2001), but this has apparently not translated into a proportionate participation in IT careers.

IT managers must recruit and retain a skilled and diverse workforce in order to meet the needs of increasingly global enterprises where cross-cultural, heterogeneous workgroups are the norm. However, numerous sources (Computing Research Association, 1999; ITAA, 2003) agree that the proportion of females to males selecting and completing degrees in IT-related fields is declining. Not only are women missing out on career opportunities, the IT profession is also missing potentially valuable alternative perspectives on system design (Woodfield, 2002).

Furthermore, the worldwide digital divide is more extreme for women than men (Hafkin & Taggart, 2001). In many developing countries, women's access to computers is even more limited than men's, and Internet usage statistics, where available, suggest that the majority of users are male. However, IT is an important driver for economic development and should provide women with new opportunities to better their circumstances, provided that a variety of challenges, such as technical education and social and political norms, can be addressed (Hafkin & Taggart, 2001).

Even in more developed countries, females face well-documented (Margolis & Fisher, 2002; Von Hellens & Nielsen, 2001) obstacles all along the pipeline, beginning as early as middle school and continuing through college, graduate school, and industry. Solutions to recruiting and retaining women in IT may serve other underrepresented groups as well, making IT classrooms and IT workplaces more congenial and ultimately more productive environments for everyone.

BACKGROUND

Part of the challenge of recruiting and retaining women in IT stems from the changing nature of IT work. IT is defined for the purpose of this article as an umbrella term that encompasses a variety of job categories that continue to evolve, as hardware, software, and methods continue to increase in sophistication. Traditional professional IT job categories included programmer, systems analyst, system administrator, and software designer. Earlier investigations into women and computing suggested that IT work by its nature was a poor fit for females, seen as solitary and boring, a stereotype that apparently still exists today (AAUW, 2000a). However, as the field has evolved, and as IT has become more integrated into most business organizations and into the work and home lives of many individuals, a wider variety of IT work has emerged. Today, in addition to earlier job titles, IT work also includes software engineer, business analyst, database designer, database administrator, network analyst, network administrator, Web developer, Web engineer, human interface designer, project manager, applications developer, security administrator, and help desk technician.

University curricula have also evolved and expanded to provide formal education, skills, and knowledge suited to these new job types. Entry into the IT field can come from numerous directions, including electrical engineering, computer engineering, computer science (CS), several flavors of information systems (IS), and a more narrowly defined type of IT that focuses on fourth-generation language application development and maintenance. A majority of the data and research studies that point to the precipitous decline in women in IT, however, focuses narrowly on computer science and engineering only (Wardle & Burton, 2002).

THE IT PIPELINE: CHALLENGES AND OPPORTUNITIES

Early Influences

A growing body of educational research documents a variety of factors that influence female attitudes, perceptions, and behaviors toward computers in K-12 (e.g., AAUW, 2000b; Taggart & O'Gara, 2000; Whitley, 1997; Young, 2000). In addition to general socio-cultural trends that appear to dampen girls' enthusiasm and self-efficacy regarding math and sciences around middle-school, girls seem to be influenced by:

- low interest in male-oriented computer games;
- teacher, parental, and peer attitudes that stereotype computing as male oriented;
- lack of access to and experience with computers, leading to lower self-efficacy;
- perceived usefulness, or lack thereof, of computers to themselves and to society;
- lack of IT role models and mentors.

These variables have been grouped into two main categories: environmental and individual. Environmental variables are those which make up the context within which career decisions are made, such as school or work, while individual variables are characteristics of individuals, such as aptitudes and preferences (Woszczynski, Myers & Beise, 2003). Both interact to influence the choices and behaviors of individual girls and women (Trauth, 2002).

College, Graduate School, and the IT Workplace

Some of these same factors apply as women move into college and graduate school. Often due to less previous experience with computers and less preparatory coursework, women continue to experience ambivalence about their interest and abilities in IT, in spite of equal performance regarding computer skills. They often encounter hostile academic environments (Margolis & Fisher, 2002; McGrath-Cohoon, 2001), and their career choices are often influenced by work-family balance concerns.

In the workplace, women are employed at lower levels, make less money, are more likely to leave their organization than men (Baroudi & Igbaria, 1994-1995; Igbaria, Parasuraman & Greenhaus, 1997), and may even be channeled into "softer" positions considered more suited to women, and coincidentally have lower status, are lower paid, and are less visible (Panteli et al., 2001). Some of this may be related to the assumption that women tend to be younger, less experienced, and spend less time in the workplace due to opting out of traditional career paths to raise families, preferring part-time or more flexible options when returning to work. The few studies that have controlled for differences in variables such as age, education, and work experience have shown mixed results (Baroudi & Igbaria, 1994-1995; Igbaria et al., 1997).

Academic institutions and business organizations alike are realizing that they need to supplement earlier efforts that focused on recruiting more women into the field with more attention to retaining them, once there, in school and in the workplace (Tapia et al., 2003). Again, it is expected that both environmental and individual variables will interact to determine outcomes for women.

Interventions and Solutions

A growing body of literature is providing a range of useful approaches to addressing these challenges (e.g., Wardle & Burton, 2002). One way of addressing the problem is to focus on individual factors, that is, change the individuals, by changing attitudes, dispelling stereotypes, improving preparation, and increasing experience with computers. Suggestions aimed at K-12 levels and beyond include:

- Providing more (and more equal) access to computing resources.
- Designing girl-friendly games and applications, to encourage more experience with computers which leads to higher self-efficacy.
- Creating videotapes and other positive media images that demonstrate women in professional IT roles, thus changing attitudes.
- Encouraging girls to take more courses that adequately prepare them for IT-related college majors.

Taken to an extreme, this approach implies that in order to succeed in this male-dominated field, women must become more like men. An alternative perspective, then, is to change the environment, by making it less hostile, less masculine, more family friendly, and more accepting of diversity. Interventions that have been suggested and implemented (e.g., AAUW, 2000b) to address environmental factors, at multiple academic levels, include:

- Train teachers to provide more equal access and to reduce stereotyping of computing as a male domain.
- Provide students with female mentors and role models (female faculty members and mentors from industry).
- Create communities, study groups, clubs, and other social supports for female students.
- Broaden the range of computing activities for younger students.
- Develop programs that do not depend on substantial mathematical and scientific background prior to beginning college. Provide bridge opportunities to increase experience, build competency, and improve self-efficacy.

Finally, many business organizations have implemented a variety of programs to address many of the individual and environmental factors listed above (Bentsen, 2000; McCracken, 2000; Taggart & O'Gara, 2000):

- IT training (intra-organizational and community outreach).
- Mentoring programs, support networks, and general diversity training.
- Visible top management support and an external advisory council to promote cultural change.
- Promotion of work/life balance values and programs for women *and* men.
- Provision of programs that support time management and work-family concerns, such as continuing education, flex-time, day- and elder-care, and concierge services (vs. on-site game tables and sports outings).
- Examination of explicit and implicit reward systems, which may evaluate men differently than women, which may not reward teamwork and communication as valuable leadership skills as much as more traditional definitions of achievement.

FUTURE TRENDS

When IT workers are compared to other categories of workers, two interesting findings emerge: first, persons with a formal education in IT are less likely to pursue work outside of IT than are persons with formal educations in other areas. Second, the IT workforce contains a large number of people without CS or IS credentials, or even necessarily traditional undergraduate educations (Wardle & Burton, 2002). This situation has likely arisen because IT is a relatively new field, because it has grown rapidly, and because there is a growing need to apply IT to other functional areas, from which these employees come.

A related issue is that a frequently cited source of enrollments in computer science programs (Computing Research Association, 1999) focuses solely on research institutions (defined as those that offer a PhD in Computer Science). PhD-granting programs clearly play an important role in the pipeline by providing female IT academics to serve as role models for women enrolled in college. However, a recent study in Georgia (Randall, Price & Reichgelt, 2003) suggests that: 1) more women (all majors) attend non-PhD-granting state universities and colleges than attend research institutions; 2) CS, IS, and IT degree programs at these state universities and colleges attract a higher percentage of women than do the research institutions; and 3) IS and IT programs attract more women than CS programs. The applied nature of IS/IT programs is likely to be part of the reason that these programs are more attractive than CS programs, given women's apparent preferences for work that involves social interaction and social benefit (AAUW, 2000a).

A wider range of data needs to be collected from both academia and industry to gain a better, more up-to-date understanding of the status of women in IT. In addition, students, parents, teachers, and the general public need more education about the range of IT programs and jobs available now and in the future, in the interest of dispelling stereotypes and raising awareness of the variety of career paths and choices in IT.

Past literature on the subject of women in IT has included disparate samples from limited populations. As a result, the picture of why women leave the IT field, or choose not to get into it in the first place, is incomplete and fragmented. One limitation in past research is that, like many academic studies, the subjects are most often students. This is due to convenience as well as the assumption that focusing on students will eventually result in changes to the workplace. However, there is a dearth of research in the IT workplace regarding gender and diversity, and more is needed to understand the problem and apply effective solutions.

Finally, although a number of interventions have been suggested and even implemented, little is known about their effectiveness over time. Researchers need to develop studies that analyze their effects over time. Combined quantitative and qualitative analyses of successful techniques that improve recruitment and retention of females in IS should be provided.

CONCLUSION

Numerous suggestions and guidelines for improving women's representation in the IT workforce with respect to recruitment and retention have been offered. Recurring themes include the lack of self-confidence regarding computing (which can be alleviated with more experience), lack of pre-college preparation, the need for mentors and role models, the importance of community and study groups, and the need to value both family and work priorities. More systemic solutions would transform the "masculinized" IT academic departments and workplaces to become friendlier, more supportive environments for all workers. A summary of recommendations for IT practitioners, IT educators, and IT researchers toward addressing both individual and environmental factors includes:

1. Apply initiatives that work to recruit and retain women in IT education as tools for managers seeking qualified women for IT positions. These include development of mentoring programs, support networks, and general training on respect for diversity and multiculturalism for all workers.
2. Enhance general business initiatives applied to all women to develop more conducive environments for IT women. Rather than on-site games and sports outings, many women find more appealing practical programs that support time management and work-family concerns, such as continuing education, flex-time, day- and elder-care, and concierge services (Bentsen, 2000). Such programs are likely to increasingly appeal to men as well, as youthful IT workers age, marry, and have children.
3. Get involved in post-secondary education to identify, attract, support, and develop well-qualified women for IT positions. Broaden the definition of IT to include not just CS, but also IS and related majors, and contribute to continued curriculum development that balances important theoretical foundations with applied, practical application. Such curricula are more likely to appeal to women, who tend to view computers more as useful tools rather than fun toys.
4. Share knowledge about the evolving nature of IT work, particularly with parents, counselors, teenagers, and other influential groups. Narrow stereotypes need to be replaced by the realities of an exciting and socially fulfilling IT career.

Finally, many organizations are beginning to appreciate the value of a newer, more facilitative leadership style that is often associated with women, that includes teamwork, participatory decision making, and interpersonal communication skills. If such behavior is recognized and rewarded, this could help attract and promote more women into the managerial ranks of IT, eventually transforming the IT workplace, and perhaps leading to broader perspectives in software and interface design.

KEY TERMS

Computer Science (CS): A traditional IT curriculum whose focus is technical and theoretical rather than applied, with emphasis on software creation.

Environmental Variables: The context within which career decisions are made, such as the school and work environments.

Fourth-Generation Language: Business application languages and tools such as database and decision supports tools such as SQL, ACCESS, and EXCEL; ERP and other reporting tools; and Web development environments such as Cold Fusion and Frontpage.

Individual Variables: Characteristics of individuals, such as attitudes and preferences.

Information Systems (IS): A curriculum that integrates technical skills and knowledge with applied business and organizational knowledge. Sometimes found in business schools, other times in schools of science, engineering, or in standalone IT academic units. Variations include Business Information Systems (BIS), Computer Information Systems (CIS), and Management Information Systems (MIS).

Information Technology (IT): (a) An umbrella term that encompasses a range of professional positions requiring at least a baccalaureate degree in Computer Science, Information Systems, or closely related majors. (b) A major that focuses mainly on fourth-generation language application development and maintenance.

World Wide Web Search Technologies

INTRODUCTION

The World Wide Web now holds more than six billion pages covering almost all daily issues. The Web's fast growing size and lack of structural style present a new challenge for information retrieval (Lawrence & Giles, 1999a). Traditional search techniques are based on users typing in search keywords which the search services can then use to locate the desired Web pages. However, this approach normally retrieves too many documents, of which only a small fraction are relevant to the users' needs. Furthermore, the most relevant documents do not necessarily appear at the top of the query output list. Numerous search technologies have been applied to Web search engines; however, the dominant search methods have yet to be identified. This article provides an overview of the existing technologies for Web search engines and classifies them into six categories: i) hyperlink exploration, ii) information retrieval, iii) metasearches, iv) SQL approaches, v) content-based multimedia searches, and vi) others. At the end of this article, a comparative study of major commercial and experimental search engines is presented, and some future research directions for Web search engines are suggested. Related Web search technology review can also be found in Arasu, Cho, Garcia-Molina, Paepcke, and Raghavan (2001) and Lawrence and Giles (1999b).

Requirements of Web Search Engines

It is first necessary to examine what kind of features a Web search engine is expected to have in order to conduct effective and efficient Web searches. The requirements for a Web search engine are listed below in order of importance:

1. Effective and efficient location and ranking of Web documents;
2. Thorough Web coverage;
3. Up-to-date Web information;
4. Unbiased access to Web pages;
5. An easy-to-use user interface which also allows users to compose any reasonable query;
6. Expressive and useful search results; and
7. A system that adapts well to user queries.

BACKGROUND

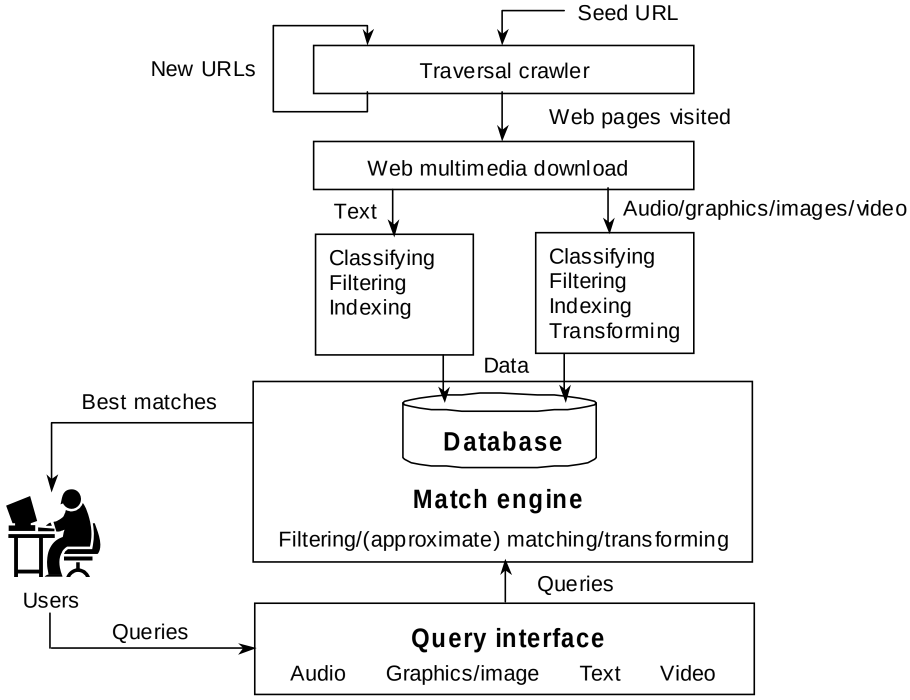
Two different approaches are applied to Web search services: genuine search engines and directories. The difference lies in how listings are compiled.

- Search engines, such as Google, create their listings automatically.
- A directory, such as Yahoo!, depends on humans for its listings.

Some search engines, known as hybrid search engines, maintain an associated directory. Figure 1 shows the system structure of a typical search engine. Search engines traditionally consist of three components: i) the crawler, ii) the indexing software, and iii) the search and ranking software:

- A crawler is a program that automatically scans various Web sites and collects Web documents from them. Two search algorithms, breadth-first searches and depth-first searches, are widely used by crawlers to traverse the Web.
- Automatic indexing is the process of algorithmically examining information items to build a data struc-

Figure 1. System structure of a Web search engine



ture that can be quickly searched. Traditional search engines utilize the following information, provided by HTML scripts, to locate the desired Web pages: i) content, ii) descriptions, iii) hyperlink, iv) hyperlink text, v) keywords, vi) page title, vii) text with a different font, and viii) the first sentence.

- Query processing is the activity of analyzing a query and comparing it to indexes to find relevant items. A user enters a keyword or keywords, along with Boolean modifiers such as "and", "or", or "not", into a search engine, which then scans indexed Web pages for the keywords. To determine in which order to display pages to the user, the engine uses an algorithm to rank pages that contain the keywords.

SEARCH ENGINE TECHNOLOGIES

This section examines the existing technologies for Web search engines and classifies them into six categories: i) hyperlink exploration, ii) information retrieval, iii) metasearches, iv) SQL approaches, v) content-based multimedia searches, and vi) others.

Hyperlink Exploration

Links can be tremendously important sources of information for indexers; the creation of a hyperlink by the author of a Web page represents an implicit endorsement of the page being pointed to. This approach is based on identifying two important types of Web pages for a given topic:

- Authorities, which provide the best source of information on the topic, and
- Hubs, which provide collections of links to authorities.

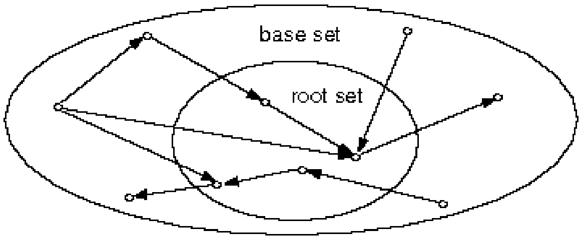
Authorities and hubs are either given top ranking in the search results or used to find related Web pages. A simple method to update a non-negative authority with a weight x_p and a non-negative hub with a weight y_p is given by Chakrabarti et al. (1999). If a page is pointed to by many good hubs, its authority weight is updated by using the following formula:

$$x_p = \sum_{q \text{ such that } q \to p} y_q ,$$

where the notation $q \to p$ indicates that q links to p. Similarly, if a page points to many good authorities, its hub weight is updated via

$$y_p = \sum_{q \text{ such that } p \to q} x_q .$$

Figure 2. Expanding the root set into a base set



Unfortunately, applying the above formulas to the entire Web to find authorities and hubs is impracticable. Ideally, the formulas are applied to a small collection S_σ of pages which contain plenty of relevant documents. The concepts of a root set and a base set have been proposed by (Kleinberg, 1999) to find S_σ. The root set is usually constructed by collecting the t highest-ranked pages for the query σ from a search engine such as Google or Yahoo!. However, the root set may not contain most of the strongest authorities. A base set is therefore built by including any page pointed to by a page in the root set and any page that points to a page in the root set. Figure 2 shows an example of a root set and a base set. The previously mentioned formulas can then be applied to a much smaller set, the base set, instead of the entire Web.

Information Retrieval (IR)

IR techniques are widely used in Web document searches. Among them, relevance feedback and data clustering are two of the most popular techniques used by search engines:

- An initial query is usually a wild guess. Retrieved query results are then used to help construct a more precise query or modify the database indexes (Chang & Hsu, 1999). Two relevance feedback methods, query modification and indexing modification, can be used to improve the search.
- Data clustering is used to improve the search results by dividing the whole data set into data clusters. Each data cluster contains objects of high similarity, and clusters are produced that group documents relevant to the user's query separately from irrelevant ones. For example, the formula below gives a similarity measure:

$$S_{D_i,D_j} = \frac{2\sum_{k=1}^{L}\left(weight_{ik} \cdot weight_{jk}\right)}{\sum_{k=1}^{L} weight_{ik}^2 + \sum_{k=1}^{L} weight_{jk}^2},$$

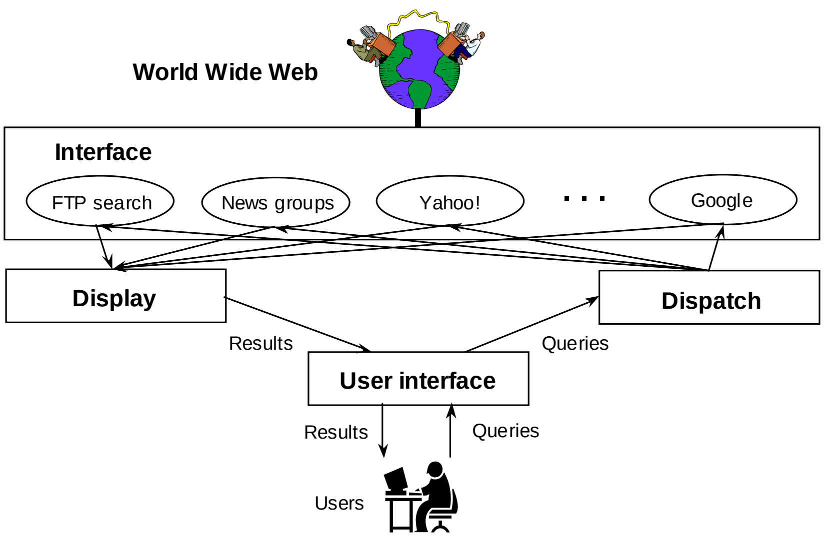
  where $weight_{ik}$ is the weight assigned to $term_k$ in a document D_i (Baeza-Yates, 1992).

Relevance feedback has not so far been applied to any commercial products because it requires some interaction with users, who normally prefer to use a keyword-only interface, whereas data clustering has achieved more success since it does not require any interaction with users to achieve acceptable results.

Metasearches

Metasearch engines (Dreilinger & Howe, 1997) conduct a search using several other search engines simultaneously and then present the results in some sort of integrated format. Figure 3 shows the system structure of a metasearch engine, which consists of three major components:

Figure 3. System structure of a metasearch engine



- Dispatch: Determines to which search engines a specific query is sent. The selection is usually based on network and local computational resources, as well as the long-term performance of search engines on specific query terms.
- Interface: Adapts the user's query format to match the format of a particular search engine, which varies from engine to engine.
- Display: Raw results from the selected search engines are integrated for display to the user. Each search engine also produces different raw results from other search engines and these must be combined to give a uniform format for ease-of-use.

SQL Approaches

Structured Query Language (SQL) approaches view the World Wide Web as a huge database where each record matches a Web page, and use SQL-like languages to support effective and flexible query processing. A typical SQL-like language syntax (Konopnicki & Shmueli, 1998) is

Query:=**select**Attribute_List
from Domain_Specifications
[**where** Search_Conditions];

A query example is given in the following to show the use of the language.

SQL Example. *Find pages in the World Wide Web Consortium (W3C) site where the pages have fewer than 2000 bytes.*
select url **from** http://www.w3c.org/ **where** bytes < 2000;

url is a page's URL and each page has attributes such as bytes, keywords, and text.

Various SQL-like languages have been proposed for Web search engines. The methods introduced previously treat the Web as a graph of discrete objects; another object-oriented approach (Arocena & Mendelzon, 1998) considers the Web as a graph of structured objects. However, neither approach has achieved much success because of its complicated syntax, especially for the latter method.

Content-Based Multimedia Searches

Only a few multimedia search engines are available currently, most of which use name or keyword matching where the keywords are entered by Web reviewers rather than using automatic indexing. The low number of content-based multimedia search engines is mainly due to the difficulty of automated multimedia indexing. Numerous multimedia indexing methods have been suggested in the literature (Yoshitaka & Ichikawa, 1999), yet most do not meet the efficiency requirements of Web multimedia searches, where users expect both a prompt response and the search of a huge volume of Web multimedia data. A few content-based image and video search engines are available online (Lew, 2000). However, a de facto Web image or video search engine is still out of reach because the system's key component—image or video collection and indexing—is either not yet fully automated or not practicable. Similarly, effective Web audio search engines have yet to be constructed since audio information retrieval (Foote, 1999) is considered to be one of the most difficult challenges for multimedia retrieval.

Others

Apart from the above major search techniques, some ad hoc methods worth mentioning include:

- Work aimed at making the components needed for Web searches more efficient and effective, such as better ranking algorithms and more efficient crawlers. Zhang and Dong (2000) propose a ranking algorithm based on a Markov model, which synthesizes the relevance, authority, integrativity, and novelty of each Web resource, and can be computed efficiently through solving a group of linear equations.
- Various enhanced crawlers can be found in the literature (Aggarwal, Al-Garawi, & Yu, 2001). Some crawlers are extensible, personally customized, relocatable, scalable, and Web-site-specific (Heydon & Najork, 1999).
- Artificial Intelligence (AI) can also be used to collect and recommend Web pages. The Webnaut system (Nick & Themis, 2001) learns the user's interests and can adapt as his or her interests change over time. The learning process is driven by user feedback to an intelligent agent's filtered selections.

MAJOR SEARCH ENGINES

Some of the currently available major commercial search engines are listed in Table 1, although many table entries are incomplete as some of the information is classified as confidential due to business considerations (Sullivan, 2003). Most search services are backed up by or are cooperating with several other services. This is because an independent or stand-alone service contains less information and thus tends to lose its users. In the table, the

Table 1. Major commercial Web search engines (SE: Search Engine and AS: Answering Service)

No.	Name	URL	Type	Backup	Method
1	AOL Search	http://search.aol.com/	Hybrid SE	Open Directory

14	Open Directory	http://dmoz.org/	Directory		volunteers
15	Yahoo!	http://www.yahoo.com/	Directory	Google	reviewers

column Backup gives the major backup information provider, and most unfilled methods use keyword matching to locate the desired documents. Most search engines on the list not only provide Web search services but also act as portals, which are Web home bases from which users can access a variety of services, including searches, e-commerce, chat rooms, news, and so forth. Table 2 lists some major experimental search engines, which use advanced search technologies not yet implemented by the commercial search engines. The list in Table 2 is a snapshot of the current situation; the list is highly volatile either because a successful experimental search engine is usually commercialized in a short time or because a prototype system is normally removed after its founders leave the organization. The two tables list major general-purpose search engines; special-purpose search engines including specialty searches, regional searches, kid searches, and so forth, are not considered in this article. They use much smaller databases and therefore give more precise and limited search results.

FUTURE TRENDS

Users of search engines often submit ambiguous queries. Ambiguous queries can be categorized into four types: i) disorderly, ii) incomplete, iii) incorrect, and iv) superfluous queries. Below are examples of perfect and ambiguous queries and the ranked search results from Infoseek, at http://www.infoseek.com/, for the book, *Intelligent multimedia information retrieval*, edited by Mark T. Maybury.

Table 2. Major experimental Web search engines

  1. Abstract Stein Mulleller Thiel 95
  2. Corpora Oct 1998 to -: Corpora: TWLT 14: lan guage technology in multimedia information
  3. 3 2.1 Introduction to the workplan

     ...

  6. Intelligent multimedia information retrieval

- Incorrect query: *Intelligent multi-media information retrieval*
  1. Artificial intelligence research laboratory at Iowa State University
  2. Vasant Honavar's home in cyberspace
  3. CIIR multi-media indexing

     ...

  31. Intelligent multimedia information retrieval

- Superfluous query: *Intelligent multimedia infor mation retrieval systems*
  1. Research in multimedia and multimodal parsing and generation
  2. Intelligent multimedia information retrieval

This example shows that even a slight variation in the query produces significant differences among the search results. Users tend to submit ambiguous queries to search engines, most of which use the technology of keyword matching to look for the desired pages. The ambiguity creates undesired search results if keyword matching is used.

CONCLUSION

In less than a decade, the World Wide Web has become one of the three major media, with the other two being print and television. Searching for Web pages is both one of the most common tasks performed on the Web and one of the most frustrating and problematic. This article gave an overview of the current technologies for Web search engines with an emphasis on non-traditional approaches and classified the technologies into six categories. However, apart from the traditional keyword matching techniques, no one method dominates Web search engine technologies. The major reason for this is that the amount of information posted on the World Wide Web is huge and the page formats vary widely.

Another problem with search engines is the skewed search results because of the corporate payments to search engines to boost their rankings. Most search engines list non-commercial pages for free, whereas they charge commercial pages for listing. Take the Google search engine as an example. Other than waiting for their pages being crawled and listed on the Google, the Web content providers may submit their pages via "Add your URL to Google" at http://www.google.com/addurl.html. On the other hand, they may advertise with the Google by using the following two methods:

- AdWords: With AdWords customers create their own ads, choose keywords to tell the Google where to show their ads and pay only when someone clicks on them.
- AdSense: It is for the Web content providers who want to make more revenue from advertising but do not want to serve untargeted ads to their users. AdSense solves this dilemma by delivering text-based AdWords ads that are relevant to what readers see on the pages.

Though the search results are distorted by corporate payments, it is necessary for the search engines to survive and improve their services. Also, the users can normally tell the differences between the paid contents and the ranked search results because they are usually at the different places on the result pages.

KEY TERMS

Authority: A Web site that provides the best source of information on a specific topic.

Automatic Indexing: A process that algorithmically examines information items to build a data structure that can be quickly searched.

Crawler/Spider: A program that automatically scans various Web sites and collects Web documents from them. It follows the links on a site to find other relevant pages and is usually used to feed pages to search engines.

Directory: Other than search engines, directories provide another approach of Web searches. A directory is a subject guide, typically organized by major topics and subtopics, which are created based on the submissions from either Webmasters or editors who have reviewed the pages.

Hub: A Web site that provides collections of links to authorities.

Hyperlinks: A hyperlink is a selectable connection from one word, phrase, picture, or information object to another. By clicking on a hyperlink, a Web user can move easily from one Web page to another page. The most common form of hyperlinks is the highlighted word, phrase, or picture.

Metasearch Engine: It conducts a search using several other search engines simultaneously and then presents the results in some sort of integrated format. This lets users see at a glance which particular search engine returned the best results for a query without having to search each one individually.

Search Engine: A software system such as Google and Alta Vista that searches documents on the World Wide Web and USENET newsgroups for specified keywords and returns a list of the documents which are relevant to the keywords.

Structured Query Language (SQL): It is a standard interactive and programming language for accessing and manipulating a database. Its commands include selection, insertion, update, deletion, finding out the location of data, and so forth.

Uniform Resource Locator (URL): It is the address of an object accessible on the Internet. The object could be an HTML document, a text file, an image file, a program such as a common gateway interface application, and so forth. They are mainly used in HTML documents to specify the target of a hyperlink.

XML Schema Integration and E-Commerce

INTRODUCTION

XML (eXtensible Markup Language) is used to describe semi-structured data, i.e., irregular or incomplete data whose structure may be subject to unpredictable changes. Unlike traditional semi-structured data, XML documents are self-describing, thus XML provides a platform-independent means to describe data and, therefore, can transport data from one platform to another (Bray, Paoli, & Sperberg-McQueen, 1998). XML documents can be both created and used by applications. The valid content, allowed structure, and metadata properties of XML documents are described by their related schema(s) (Thompson, Beech, Maloney, & Mendelsohn, 2001). An XML document is said to be *valid* if it conforms to its related schema. A schema also gives additional semantic meaning to the data it is used to tag. The schema is provided independently of the data it describes. Any given data set may rely on multiple schemas for validation. Any given schema may itself refer to multiple schemas.

In e-commerce, XML documents can be used to publish everything from product catalogs and airline schedules to stock reports and bank statements. XML forms can be used to place orders, make reservations, and schedule shipments. XML eliminates the need for custom interfaces with every customer and supplier, allowing buyers to compare products across many vendors and catalog formats, and sellers to publish their catalog information once to reach many potential buyers. XML can also enable online businesses to build on one another's published content and services to create innovative virtual companies, markets, and trading communities. With a global view of the Internet-wide shopping directories, a query system can locate all merchants carrying a specific product or service and then query each local schema in parallel to locate the best deals. The query system can sort the offers according to criteria set by the buyers–the cheapest flight, the roomiest aircraft, or some weighted combination. The traditional method used for business-to-business (B2B) information exchange is through Electronic Data Interchange (EDI), which is complex, expensive, and necessitates a custom integration solution between each pair of trading partners. A query-based system that uses XML as the common format to enterprise integration is simpler and more open than traditional EDI, as it eliminates the proprietary message formats used by each company. A complete business integration solution also requires metadata for each commerce community, a means to map each local schema into an integrated global view, and a server for processing XML documents and invoking appropriate applications and services.

RELATED WORK

The problem of schema and integration of heterogeneous and federated databases has been addressed widely. Several approaches to schema integration exist as described in Batini, Lanzerini, and Navathe (1986); Behrens, 2000; Christophides, Cluet, and Simon, (2000); Haas, Miller, Niswanger, Roth, Schwarz, and Wimmers (1999); Miller, Ioannidis, and Ramakrishnan (1993); Parent and Spaccapietra (1998); and Ram and Ramesh (1998). A global schema in the general sense can be viewed as a regular schema, the rules of which encompass the rules of a common data model. A global schema eliminates data model differences and is created by integrating local schemas. The creation of a global schema also helps to eliminate duplication, avoid problems of multiple updates, and thus minimize inconsistencies.

Most schema integration approaches decompose integration into a multi-layered architecture like the one followed in this paper constituting *pre-integration*, *comparison,* and *integration* (Batini et al., 1986; Miller, 1998).

There have been some recent systems (Adali, Candan, Papakonstantinou, & Subramanian, 1996; Papakonstantinou, Garcia-Molina, & Widom, 1995; Tomasic, Raschid, & Valduriez, 1996) that integrate data from multiple sources. Most of these systems provide a set of mediated/global schema(s). Some systems like *Garlic* (Roth & Schwarz, 1997) use wrappers to describe the data from different sources in its repositories and provide a mechanism for a middleware engine to retrieve the data. The *Garlic* system also builds global schema from the individual repositories. The *comparison* and *restructuring* phase of integration is handled in some systems through human interaction using a graphical user interface as in Clio (Hernandez, Miller, Haas, Yan, Ho, & Tian, 2001; Miller, Haas, & Hernandez, 2000; Miller et al., 2001; Yan, Miller, Haas, & Fagin, 2001) and in others semi-automatically through machine learning techniques such as in *Tukwila* data integration system at University of Washington. The *Tukwila* integration system reformulates the user query into a query over the data sources, which are mainly XML documents corresponding to DTD schemas and relational data.

INTEGRATION REQUIREMENTS, ARCHITECTURE AND METHODOLOGY

XML Schema (Thompson et al., 2001) has recently been recommended as the standard schema language to validate XML documents. It has a stronger expressive power than the DTD (Document Type Definition) schema for the purpose of data exchange and integration from various sources of data.

Since here we assume that the schemas to be integrated currently validate a set of existing XML documents, data integrity and continued document delivery are chief concerns of the integration process, thus closely linking XML Schema integration to the theoretical requirements and process of database integration.

Satisfying the condition that the global schema meets the requirements of all the initial schemas is the most difficult part of integration, and is worsened by data model heterogeneity.

We define an object-oriented data model that we call XSDM (XML Schema Data Model) for the purpose of XML Schema integration. We use the three-layered architecture of *pre-integration*, *comparison*, and *integration* to achieve XML Schema integration.

The XML Schema integration process developed in this paper uses a *one shot n-ary* (Batini et al., 1986) strategy. The *one shot n-ary* style integrates all the initial schemas at once. Schema integration should be both *extensible* and *scalable*. It should be easy to add or remove sources of data (i.e., schemas), to manage large numbers of schemas, and to adjust the resulting global schema. With the XML Schema integration approach, multiple schemas can be integrated at one time.

Any global integrated schema must meet the following three criteria: *completeness*, *minimality*, and *understandability*. In order to meet the first criteria of *completeness,* all the elements in the initial schemas should be in the merged schema. The merged schema can be used to validate any of the XML instance documents that were previously validated by one of the initial schema specifications. To satisfy the second criterion, *minimality*, each unique element is defined only once in the schema. Redundancy is eliminated wherever possible through the identification of equivalent elements and attributes, and the subsequent use of substitution groups. Datatypes for terminal elements are expanded through the use of constraint facet redefinition, or unions of incompatible datatypes, only to the point necessary to satisfy boundary conditions. Optionality of elements (i.e., minOccurs and maxOccurs values) is expanded to meet boundary restrictions only. Finally, to comply with the third criterion, *understandability*, in the case of XML Schema integration, the global schema is formulated in a referenced style, rather than an inline style (nested definitions), for ease of reading and assessment.

During *pre-integration*, an analysis of the schemas to be integrated occurs. Priority of integration is determined if the process is not to be *one shot*. Preferences may be given to retaining the entire or certain portions of schemas as whole parts of the global schema. Designer interaction occurs in view integration as assertions of relationships and constraints of elements are discovered.

During the *comparison* stage of integration, correspondences as well as conflicts between elements are identified. There are four *semantic relationships* defined by Batini et al. (1986). The schematic representations can be viewed as *identical*, *equivalent*, *compatible*, or *incompatible*. We identify six types of semantic relationships, which apply to XML Schema elements – *identical*, *equal*, *equivalent*, *subset*, *unique*, and *incompatible*.

The fundamental activity in the *comparison* phase of integration is *conflict resolution*. Conflict identification and resolution is central to successful integration. *Naming conflicts*, *datatype conflicts* & *scale differences*, and *structural conflicts* can occur during XML Schema Integration.

During the *conformance* phase, the *semantic relationships* and *conflicts* identified in the comparison phase are resolved. Initial schemas may be transformed in order to make them more suitable for integration. The XML

Schemas in question are, by definition, *correct*, *complete*, and *minimal* because XML documents exist that have been successfully validated by the schema(s) in question. A well-formed XML Schema, by definition, is *minimal* and *complete*. There is only one root element. All other elements present in the schema are related to the root element as either direct or indirect children. Each element has a unique name. Each element is defined only once. The schema should be viewed as a document that is fixed in nature. The schema is currently used to validate an existing non-empty set of XML documents. Therefore, it is important that these initial schemas are not altered in any fashion.

Transformations that occur to align the initial schemas are accomplished using *restructuring* (renaming, substitution groups, and subsetting) in the global schema only. The datatypes of terminal elements and attributes are expanded in the global schema to meet boundary restrictions through constraint facet redefinition and unions of incompatible datatypes. Optionality (minOccurs, maxOccurs) of child-elements is expanded to satisfy the largest minimum boundaries.

During schema *merging*, initial schemas are superimposed onto each other to result in the merged global schema. The merged schema is *complete* and *minimal*. The global schema is rearranged to ensure the highest level of minimality and understandability.

CONCLUSIONS AND FUTURE WORK

We have defined an object-oriented data model XSDM (XML Schema Data Model) and have defined the requirements, architecture, and a detailed methodology for integrating XML Schemas. In our opinion, this is the first detailed methodology for integrating XML Schema, although a number of papers have appeared on general integration framework as has been cited in the related work. We are developing a semi-automated Java-based XML Schema integration process, which can also be applied to DTD integration.

It may also prove possible to integrate XML Schemas with other schema language specifications using the work contained in this paper as a basis for comparison, conflict resolution, and merging. This possibility has not been explored in this paper; rather, it is presented as a suggestion for further research.

We are currently working on an XML Schema query system, based on the data model and integration strategies discussed in the paper.

KEY TERMS

Business-to-Business (B2B): Used to describe an e-business solution that caters to other businesses. It offers integrated business applications and services that allow small and mid-sized organizations and divisions of large enterprises to connect employees, customers, and suppliers for improved efficiency.

DTD (Document Type Definition): An XML DTD is a mechanism to define the structure of XML documents. An XML DTD lists the various elements and attributes in a document and the context in which they are to be used. It can also list any elements a document cannot contain.

e-Business (e-Mail, e-Commerce, e-Zine, e-Solution, e-Market, e-Service, etc.): Oftentimes used without the hyphen, the "e" originally stood for "electronic," as in "online." Today the term is used rather freely to describe any situation or solution that has made the migration from real world to the Internet.

Electronic Data Interchange (EDI): Exchange between businesses of computer-readable data in a standard format.

eXtensible Markup Language (XML): A simplified meta language, derived from Standard Generalized Markup Language (SGML), emerging as the standard for self-describing data exchange in Internet applications.

Global Schema: Schema obtained after integrating local schemas.

XML Schema: A database-inspired method for specifying constraints on XML documents using an XML-based language. Schemas address deficiencies in DTDs, such as the inability to put constraints on the kinds of data that can occur in a particular field (for example, all numeric). Since schemas are founded on XML, they are hierarchical, so it is easier to create an unambiguous specification, and possible to determine the scope over which a comment is meant to apply.
