Electronic Business (E-Business): The conduct of business through the Internet. It is a more generic term than e-commerce because it refers to not only buying and selling, but also servicing customers and collaborating with business partners with the scope of enhancing the efficiency and effectiveness of business processes. An example of activity falling in the area of e-business is the *front office* (client-oriented business processes such as sales, catalogues, CRM, etc.) *back office* (internal business processes such as administration and logistics) *integration*.

Electronic Commerce (E-Commerce): The sale of products and services over the Internet.

Electronic Markets (E-Markets): An online environment where buyers and sellers use the Internet as a communication platform in order to exchange information, goods, and services, independent from time and space.

Online Storefront: A Web site, available on a public network such as the Internet, which offers goods and services for sale. An online storefront is the virtual electronic version of a physical store/place of business that a customer would visit to purchase goods and services.

Small and Medium Enterprises (SMEs): A heterogeneous group, including a wide variety of enterprises, having very different levels of sophistication (in terms of products and services offered, and skills of the workers), and operating in various markets and institutional environments. The quantitative definition of SMEs varies by country and is usually based on the number of employees and the value of assets or turnover. An example of such a definition is given in the "Commission Recommendation of 3 April 1996 (96/280/EC) concerning the definition of small and medium-sized enterprises."

Self-Regulation: "Self-regulation means that businesses involved in electronic business voluntarily undertake to comply with certain rules of conduct when dealing electronically with others. Self-regulation can take different forms, e.g., adopting a code of conduct or participating in a national or international trustmark scheme" (Recommendation 32: E-Commerce Self-Regulatory Instruments; retrieved December 1, 2003, from *www.unece.org/cefact/rec/rec32/rec32_2001_%20final.pdf*).

ENDNOTES

[1] Telematica Instituut is a non-profit research institute managed and funded by top companies and the government. It is a partnership between the business community, research centers, and government, to translate fundamental knowledge into market-oriented research, in the field of telematics for the public and private sectors.

[2] Syntens is a national innovation network for SMEs founded by the Dutch Ministry of Economic Affairs. It delivers expertise, consultancy, and guidance in the area of technological innovation.

[3] MKB is the Dutch abbreviation for SME.

[4] The Royal Association MKB-Nederland is one of the largest employer organizations in The Netherlands. MKB-Nederland promotes the interests of small and medium Dutch enterprises as an influential negotiating partner for local, national, and European authorities.

Electronic Government Strategies and Research in the U.S.

Charles C. Hinnant
The University of Georgia, USA

Steve Sawyer
The Pennsylvania State University, USA

INTRODUCTION

Since the mid-1990s, adoption of wide-area computer networks, such as the Internet and the World Wide Web (WWW), by the public, educational institutions and private sector organizations has helped spur an interest in using these new Information and Communication Technologies (ICT) as a means to increase the efficiency and effectiveness of organizational processes. Private sector firms have focused on using Internet-based technologies, especially the browser-based technologies of the WWW, as a means to conduct business transactions. The use of such electronic transmission technologies in carrying out business activities has generally been dubbed electronic commerce, or e-commerce (Schneider, 2003). Attempts to reinvent public organizations in the United States during the 1990s were heavily grounded in the belief that the adoption of new forms of ICT will streamline both service generation and delivery (Osborne & Gaebler, 1993; Gore, 1993). Some government actors and observers, such as the National Science Foundation, have more recently referred to the overall use of ICT to carry out the activities of government institutions as digital government. The term *digital government* has in many respects grown to refer to the development, adoption or use of ICT as a key component of a public organization's internal information and control systems, as well as any use of ICT to facilitate interaction with external stakeholders. Some scholars have attempted to examine how governments have used ICT systems, such as the Internet and WWW, as a means to facilitate interactions with citizens and other stakeholders in an attempt to foster democratic processes via electronic media. These activities have been called electronic democracy, or *e-democracy*. This broad concept is then usually subdivided into two subsets of activities, electronic politics and electronic government. Electronic politics, or *e-politics*, centers on activities that facilitate civic awareness of political processes, as well as the ability of citizens to participate in those processes. Electronic government, or *e-government*, includes the use of ICT by government agencies to provide programmatic information and services to citizens and other stakeholders (Watson & Mundy, 2001).

CURRENT E-GOVERNMENT STRATEGIES AND APPLICATIONS

While the use of ICT in public organizations is far from a new phenomenon, using them to communicate directly with, and provide services directly to, government stakeholders is a relatively new occurrence. Since the Internet and the hypertext-based WWW provide a ready-made communication system that can be accessed and navigated with the use of graphical user interfaces (GUIs), such as the now ubiquitous browser, a great deal of attention has been focused on how such ICT can be employed strategically to alter traditional linkages with various government stakeholders, as well improve intra-organizational activities. In regards to external linkages, these strategies can be organized into one of many activities focused on altering government interaction with citizens, business, or other government entities.

Government-to-Citizen (G-to-C) Activities

Communicating with the citizens served by public organizations, may include developing an organizational website with information about government programs, as well providing additional methods of communicating with public employees. In addition, it is now quite common for citizens and other stakeholders to pay taxes, pay license fees, or conduct other transactions with public organizations via ICT. Such activities streamline traditional transactions between government and stakeholders, therefore, providing an opportunity for increased levels of government accountability, as well intra-organizational efficiency. More advanced G-to-C activities include providing another means for citizens to become involved in various political processes. For example, several federal regulatory agencies, such as the Environmental Protection Agency (EPA) and Federal Communications Commission (FCC), are developing new methods of allowing citizens to participate in regulatory activities, such as rulemaking, through the use of Internet-based systems.

Government-to-Business (G-to-B) Activities

While business firms also benefit from the ready accessibility of basic programmatic information, the potential to conduct electronic transactions via the Internet is perhaps of greatest interest to businesses that sell goods and services to public organizations. It is important to realize that various government purchases account for a sizeable percentage of all goods and services sold each year. Federal executive agencies alone purchase over $200 billion worth of goods and services each year. Agencies such as the General Services Administration (GSA), with its Federal Procurement Data Center, are making use of new forms of ICT in order to process and track governmental purchases. Moon (2002a) indicates that many state governments are also attempting to use ICT to improve procurement systems. For example, many states now post solicitations for bids online, make use of electronic ordering, are automating procurement systems, and are adopting purchasing cards. State governments, however, have been slower to adopt the use of digital signatures, Internet-based bidding, or reverse auctions.

Government-to-Government (G-to-G) Activities

The ability of new ICT to enhance communication and information sharing among public organizations with similar goals is often seen by public agencies as a major reason for adopting such technologies. This is especially true in certain functional areas, such as law enforcement and national security. For example, many law enforcement organizations maintain crime databases that are not readily shared outside of their jurisdiction. Some state-level initiatives, such as the Justice Net project in Pennsylvania, have attempted to overcome the social and technical barriers of sharing databases maintained by local, state, and federal government agencies. At the federal government level, the perceived need for increased coordination in response to national security concerns was a primary reason for the reorganization of several established agencies under the institutional umbrella of the Department of Homeland Security (Yen, 2004). As such institutional reorganizations take place, increased ICT compatability is sought as a means of enhancing social coordination both within and between government organizations.

Development of E-Government Applications

The traditional approach to developing and deploying ICT to support and enable government activities was to devise purpose-built specialty systems (Danziger, Dutton, Kling, & Kraemer, 1982). In recent years, governments have increasingly employed Commercial Off-The-Shelf (COTS) products as well. This latter trend in systems development has been spurred on as digital technologies have become more powerful, incorporated Internet capabilities, and become more reliable. This dual approach of ICT development – purpose-built systems to support the specialized functions of government (such as voting and public safety) and attention to COTS (to support human resources, payroll, and other standard operational processes) – is representative of current attempts to development e-government applications.

The use of COTS in e-government has often focused on the emphasis on implementing Enterprise Resource Packages (ERP) to support large scale transaction processing and operational activities. Such efforts with respect to ERP are emblematic of the move towards developing and adhering to concepts of enterprise-wide architecture and systems standards within large public organizations (NASCIO, 2002). The adoption of such technologies in an attempt to enhance government operations has also focused attention towards efforts to integrate commercial ICT into an organization's social structure. Purpose-built systems are often developed for a myriad of advanced Internet-based applications since their goals are usually unique to governmental functions. For instance, the delivery of complex government information to external stakeholders has been a focus of specialized application systems such as those used to allow for enhanced visualization of large federal data sets (MacEachren, Hardisty, Dai, & Pickle, in press). Likewise, increased interest in online voting has initiated development of ICT-based voting systems that are intended to support e-democracy and bring about greater civil engagement (Chadwick, 2004). Whether designed to enhance G-to-C, G-to-B, or G-to-G activities, increased interest in using ICT to support governmental activities made the development of e-government applications a vibrant and innovative sector of the broader IT industry.

Researchers believe that the adoption of e-government strategies and applications will evolve over time, noting that certain types of activities, such as posting basic program information, are relatively simple practices to adopt; while other activities, such as the processing of financial transactions (taxes, license payments, etc), require more technical capacity and sophisticated knowledge of information management. West (2004) highlights four stages of e-government evolution that correspond to real transformation in regards to how public organizations operate. These stages including the *billboard* stage in which public organizations focus primarily on providing programmatic information to stakeholders, the *partial-service delivery* stage in which public organizations offer some online services, the *portal* stage in which information and services are integrated, and *interactive democracy* which would offer online methods of public outreach, such as two-way communication. Other researchers, such as Moon (2002b), conceptualize e-government evolution into five stages. These include *information dissemination, two-way communication, service transactions, vertical and horizontal integration, and political participation*. Regardless of the conceptual framework, the core belief is that public organizations will adopt more advanced e-government strategies and applications over time as they are perceived to be beneficial and as core resources allow.

CURRENT STATUS OF E-GOVERNMENT RESEARCH

The growing accessibility of the Internet and WWW to citizens, stakeholder groups, and a variety of public and private sector organizations brought about a growing belief that such technology could be used to transform traditional bureaucratic arrangements. For example, some researchers have examined how website characteristics, such as levels of interactivity and organizational transparency, might serve as indications of how open or transparent a public organization is to various stakeholders. By examining the websites of national-level agencies, such research has served to document the rapid adoption of WWW-based technology by national governments and has sought to examine how the use of ICT may lead to greater levels of accountability in regards to governmental activities (La Porte, Demchak, & Friis, 2001). Other researchers have adopted a dual approach to examining the extent to which national governments have adopted e-government. For instance, a research study conducted by the consulting firm Accenture examined the level of e-government services offered by 22 countries and also conducted citizen surveys in 12 countries to assess how citizens viewed e-government. The results indicate that Canada, Singapore, and United States lead in the quality and availability of e-government services (Accenture, 2004).

Other scholars have attempted to explore how ICT may serve to transform broader institutional relationships. For example, some scholars have examined how administrative reform movements, such as the reinventing government movement that was initiated during the Clinton Administration, are based at least partially on the presumption that ICT can be used to alter bureaucratic arrangements and, therefore, increase the efficiency and effectiveness with which public services are produced (Gore, 1993). In her examination of federal agencies during the 1990s, Fountain (2001) suggests that WWW-based technologies, such as agency websites, internal ICT networks, and cross-agency systems, can at least potentially bring about increased levels of efficiency and effectiveness. By examining public organizations as they undergo broader administrative reforms, this research highlights the underlying assumption that successful institutional reforms are dependent on harnessing ICT.

While some researchers examine national governments, other researchers have focused primarily on studying the e-government activities of state or local governments. West (2004) has examined the extent to which state governments have adopted new forms of ICT and the extent to which such technologies have influenced the delivery of public services, democratic responsiveness, and public attitudes. While acknowledging that most state governments have adopted the early stages of e-government, he believes that many of the purported benefits of e-government have yet to be realized. For example, most state government now have program information available via the WWW and many states allow for online transactions, and yet most state governments still have not been able to adopt more advanced e-government strategies which would allow for heightened levels of political participation.

Examining the adoption and use of e-government activities by local governments leads to similar findings. Moon (2002b) employed survey data collected by the International City Management Association (ICMA) in order to assess the level of adoption of many e-government practices. His evaluation of over 1400 survey responses also indicates that many local governments have adopted at least rudimentary attempts to post information and provide basic online services. However, few local governments have adopted more advanced forms of ICT that foster high levels of interactivity, communication and actual political participation. This study indicates that the amount of resources available to public organizations may be a primary factor in the adoption of more advanced technologies. Other studies of local governments have also indicated a reluctance to adopt more advanced online technologies. Hinnant and O'Looney's (2003) investigation of one online innovation, the personalization of online services, also hints that the adoption of more advanced technologies may be slowed by resource limitations, such as a lack of technical expertise and budgetary considerations. Furthermore, many advanced e-government technologies may also pose public organizations with new social challenges. For example, some ICT practices, such as personalization, require tracking the online activities and interests of individual citizens. Managing and using behavioral information may pose privacy issues that some public organizations have heretofore not been forced to address.

FUTURE CHALLENGES AND TRENDS

Overall, research indicates that the adoption of e-government strategies is still in its infancy. While some innovations, such as information dissemination and even service provision through integrated online WWW portals, has been widely accepted by federal, state, and local governments, more needs to be achieved in order to realize the purported benefits of e-government (Gant, Gant, & Johnson, 2002). Government faces many challenges in regards to realizing the potential of e-government activities. One challenge that is often discussed is one of ICT access. While many citizens have now adopted ICT such as the Internet and WWW, some demographics groups may still be without sufficient access to the very communication systems that e-government often relies upon (Thomas & Streib, 2003). Some research also indicates that even when citizens have sufficient access, some demographic groups may not possess the basic technical skills required to truly make use of e-government systems (Mossberger, Tolbert, & Stansbury, 2003). Private sector firms may not view such issues as overly important as long as their message and online commerce sites are available to their target market. However, government must necessarily be concerned with issues of access and use since it, as an institution, is accountable to the greater public. The access issue may eventually resolve itself as ICT is even more widely adopted within society but it does currently pose an important challenge to public organizations.

Other challenges to the adoption and use of ICT include resource limitations. For example, many governments face severe resource constraints that serve as obstacles to employing ICT. Since governments often face fluctuating budgets and sometimes inconsistent leadership, it is often difficult to support technical and administrative reforms that take years of nurturing and support in order to bring about lasting change. Governments should seek to develop funding, as well as professional resources, that will serve to maintain and advance e-government initiatives well past the initial adoption of such innovations. Similarly, many governments are being forced to deal with technical and administrative issues that arise from the employment of ICT itself. For example, employing ICT to deliver services to the public requires more attention to issues such as information assurance, ICT systems security and overall organizational accountability. If government wishes stakeholders, such as citizens and private sector firms, to be willing participants in e-government activities, it must provide assurances that such information-intensive activities are well planned out and relatively secure from potential abuse. In essence, governments must seek to promote trust on the part of its stakeholders (Welch & Hinnant, 2003).

CONCLUSION

The adoption of new forms of ICT leads to potential benefits for government organizations. As noted, e-government activities are potentially important technical, as well as administrative, reforms. They may eventually bring about greater levels of efficiency and effectiveness in regards to government operations and service production. Furthermore, they may even bring about heightened levels of government accountability and greater levels of participation in political processes. However, it is important to realize that while the Internet and WWW may serve as paths to better government, observers should not ignore prior research regarding the adoption of ICT by complex organizations. While ICT may be an important driver of change, its impact within the greater social structure of organizations or institutions is sometimes difficult to predict. For instance, previous research examining the adoption of new ICT within public organizations indicates that ICT reinforce preexisting social arrangements or shift power towards higher levels of management (Kraemer & King, 1986). Moreover, adoption of new ICT may shift power towards those in the organization who manage the technology itself (Bugler & Bretschneider, 1993; Kraemer & King, 1986; Kraemer, King, Dunkle, & Lane, 1989). Such findings should serve as caution to those who believe that the adoption of ICT as part of broader e-government initiatives yield only expected results. As government further adopts and even relies upon e-government strategies as a core part of its operations, it must develop institutional mechanisms that better anticipate and manage unexpected results.

KEY TERMS

Digital Government: The development, adoption, or use of ICT by government organizations and actors.

Electronic Commerce (E-Commerce): Conducting business and communication transactions over electronic computer networks. This may include the selling of goods and services as well as the transfer of funds from customers. This may also include inter-firm (business-to-business) transactions as well as intra-firm computer-based activities.

Electronic Democracy (E-Democracy): The use of ICT such as the Internet or WWW to foster democratic processes such as citizen participation.

Electronic Government (E-Government): The use of ICT such as the Internet and WWW by public organizations such as government agencies to provide information and public services to citizens and other government stakeholders.

Electronic Politics (E-Politics): The use of ICT such as the Internet and WWW by political actors to inform and facilitate public participation in the political process.

Electronic Procurement (E-Procurement): The use of ICT such as the Internet and WWW by government agencies to facilitate the purchasing of goods and services.

Internet: A large system of interconnected computer networks composed of backbone networks, mid-level networks, and local networks. This includes networks owned and managed by public, private, and nonprofit sector organizations.

World Wide Web (WWW or Web): A hypertext-based client-server system that is one component of the larger Internet. The hypertext-based format of the WWW allows users to navigate through the system by using graphical user interface software know as browsers.

Electronic/Digital Government Innovation, and Publishing Trends with IT

Yukiko Inoue

Suzanne T. Bell
University of Guam, Guam

INTRODUCTION

With scientific achievement and technological advancement, "American society is poised for a radical shift in the manner in which individuals learn and work, conduct their business, and are entertained and informed, arising from the innovation of new information technologies" (Schorr & Stolfo, 1998, p. 15). One of the significant innovations in information technology in this digital age has been the creation and ongoing development of the Internet: The Internet increases communication flexibility while reducing cost by permitting the exchange of large amounts of data instantaneously regardless of geographic distance (McNeal, Tolbert, Mossberger, & Dotterweich, 2003). Internet technology has changed rules about how information is managed, collected, and disseminated in commercial, government, and private domains. The Federal Government is increasing the reliability and efficiency of information services and resources provided to the public since the development of Internet technology as follows (Aldrich, Bertot, & McClure, 2000):

From the initial steps to establish the Internet in the late 1960s (originally ARPANET) to the establishment of the National Information Infrastructure (NII) and National Performance Review (NPR) initiatives in 1993, the federal government has adapted progressive computer and telecommunication technologies both operationally and in policy to harness computing power to improve government performance and enhance citizen access to government and other information services and resources. (p. 349)

BACKGROUND

For over one hundred years, the U.S. government agencies have collected and provided data and information (such as statutes and regulations, court decisions, votes by Congress, and the records of hearings) for citizens. For making government more convenient and accessible, during the 1980s, federal information dissemination began a transition to significant use of electronic formats (Notess, 1998). "Information technology, already an essential part of government operations, will continue to be vitally important to administration, decision making, and direct service delivery" (Dawes, Bloniarz, Kelly, & Fletcher, 1999, p. 6). As Coglianese (2004) confirms, information technology holds the potential for improving the process by which government makes regulatory decisions effecting vital aspects of society and the economy.

Digital government, however, is not just about using Web-based technology to deliver services, or converting paper-based processes into electronic ones. Digital government is a fundamental shift in government culture, allowing those interested in public policy and government to respond much more quickly ("What is digital," Department of Information Service [DIS], 2003). The DIS defines digital government in five ways: 1) replacing old bureaucratic service lines with accessible information and service, available 24-hours a day, directly from the desktop, using powerful new technologies such as digital signatures and electronic forms; 2) offering a "one-stop-shop" to many government services through the state's Internet Portal Access Washington; 3) making the process of accessing government services immediate, simple, seamless and intuitive; 4) reducing paperwork and its costs within government in order to move funds into direct delivery of services; and 5) improving service delivery to all segments of the U.S. population by reducing traditional counter lines with those accessing government services through the Internet. Specifically, digital government transforms government activities in two ways: 1) by improving service delivery and associated costs; and 2) by enhancing communication between citizens and government (McNeal, et al., 2003).

DIGITAL GOVERNMENT INNOVATIONS AND CRITICAL ISSUES

Digital Government Initiatives

The government is a dynamic mixture of structures and functions; the government's following six digital initiatives are complex efforts intended to use new technologies to support a transformation in the effectiveness and efficiency of the government (Pardo, 2000):

1. **Citizen access to government:** includes establishing mechanisms that deliver information based on the customer's perspective rather than a functional perspective.
2. **Facilitating compliance with rule**s: provides electronic access to services that facilitate compliance with a set of rules or regulations (e.g., driver's license renewal, hunting and fishing licenses, and business permits).
3. **Citizen access to personal benefits:** electronic access to citizens' personal benefits, for example, online applications for public assistance and workers' compensation.
4. **Procurement including bidding, purchasing, and payment:** procurement applications allow government agencies to reap the benefits being realized in the private sector through electronic commerce applications.
5. **Government-to-government information and service integration:** integrating service delivery programs across government agencies and between levels of government require electronic information sharing and integration.
6. **Citizen participation:** online democracy includes access to elected officials, discussion forums, "town meeting," voter registration, and ultimately online voting (and this particular one must face issues of the digital divide and security). (pp. 3-4)

Three Aspects of Digital Government

Digital government enables constituents to access information and services from home, which reduces traffic flow, and improves the environment. There are at least three distinct aspects of digital government: 1) information dissemination, 2) interactive service delivery, and 3) online monetary transactions. Atkinson and Ulevich (2000) suggest what government policy makers should be doing in each of these areas (see Table 1). The authors further point out: 1) most applications still focus on information dissemination from the government to user but several agencies are beginning to combine resources to better carry out tasks, record transactions, and benefit the consumer; 2) many agencies allow individuals to obtain

Table 1. A summary of what the government should be doing with information dissemination

• Developing enterprise-wide information architecture. • Implement a standardized information tagging system. • Create an entryway/portal to government services. • Expand the amount of information accessible on searchable databases. • Use "information on request" to provide people with government information. • Develop "expert systems" to access information. • Make the Web the first place to put information, not the last. • Measure customer satisfaction. (pp. 17-19)
Interactive service delivery
• Expand and standardize the number of applications for online forms. • Whenever possible, use Web-based technology. • Online forms should use shared information about the submitter. • Integrate form (putting form online is one thing, streamlining and consolidating information is another). • Focus on intergovernmental solutions. (pp. 20-21)
Online monetary transactions
• Use EFT in all monetary transactions. • Implement the use of electronic checks. • Develop government-wide electronic procurement systems. • Make it easier for citizens and business to directly file their taxes online. • Attach digital signature functions. (pp. 22-23)

forms online, print them, and then mail the paper copies, where the information is then either entered by hand or scanned into a computer, while a few agencies are beginning to allow citizens and businesses to file forms online; and 3) monetary functions increasingly rely on electronic funds transactions (EFT), and virtually all of these activities could be done electronically, replacing paper.

Critical Issues of Internet Adoption

Through the Web revolution, more effective, convenient, and flexible digital government services are happening, yet *security* and *privacy* are the two critical issues in digital government applications. Building secure digital government systems requires a careful balancing between providing convenient access and appropriately monitoring permission, and technology-based solutions are still at their infancy and the existing alternatives consist essentially of enforcing privacy by law or self-regulation of operational practices ("Security and privacy," CISC, 2004).

Concerning barriers to Internet use (e.g., cost, systems incompatibility, legal issues such as intellectual property and security, human resistance, and privacy), Lan and Falcone (1997) identify four factors in terms of positive and negative impacts of policy decisions on Internet adoption: 1) the technical characteristics of information technologies; 2) user preferences for information resources; 3) the institutional arrangements that define, govern, and constrain provider/user relationships; and 4) psychological factors affecting information processing. Other legal issues include: electronic signatures and records must still meet formal legal requirements for paper documents; and agencies must ensure that the electronic signature or records and all relevant information will be available as needed (Champion, 2003).

Web Site-Specific Policy

Halchin (2002) recommends developing a government-wide disclosure policy that applies specifically to agency Web sites, chiefly because such guidelines could help agency officials determine what types of information are potentially compromising, and could include procedures for reviewing and reposting documents and information that were removed or altered. Based on the fact that currently 54 federal agencies have Chief Information Officers but the Federal Government as a whole does not, it is extremely important to establish the position of a Chief Information Officer (CIO) for the Federal Government so that a federal CIO would report directly to the President and direct the process of developing a concerted digital government conversion plan (Atkinson & Ulevich, 2000).

Online electronic government access contains a tremendous amount of information on a plethora of subjects. The material is available virtually in one place, a personal computer, yet U.S. federal agencies have altered their Web sites particularly since the events of terrorist attacks on American soil, September 11, 2001(Halchin, 2002); for example:

The Department of Energy (DOE) removed from its Web site detailed maps and descriptions of all ten nuclear facilities with weapons-grade plutonium and highly enriched uranium; The National Aeronautics and Space Administration's (NASA) John Glenn Research Center has limited public access to many of its Web sites; The Nuclear Regulatory Commission (NRC) removed its Web site, then reposted selected content; and The Agency for Toxic Substances and Disease Registry (ATSDR) removed a report on chemical site security from its Web site. (pp. 246-247)

As Internet information is selectively provided to citizens, the Internet's open nature remains an ideal arena for dissemination of misinformation. The issue is also how to deal with false information on the Web and how to decide whether a source is reliable. Ultimately each individual is responsible for his or her use of technology and for decisions taken based on information gathered from the Web (Thompson, 2004).

FUTURE TRENDS

The Government Printing Office

The U.S. Government Printing Office (GPO) keeps America informed. The GPO began operations accordance with Congressional Joint Resolution 25 of June 23, 1860 ("About the U.S.," GPO, 2003) with the mission to inform the Nation by producing, procuring and distributing publications from Congress, executive departments and establishments of the federal government. The GPO is part of the legislative branch of the federal government and operates under the authority of the public printing and documents chapters of Title 44 of the U.S. Code.

The Federal Depository Library Program

In order to organize, manage, and disseminate the federal government's information, the Depository Library Act of 1962 expanded the Federal Depository Library Program (FDLP), which is administered by GPO. For more than 100 years, FDLP has been an important channel through which the U.S. government has made information available to the public (Lopresti & Gorin, 2002). Withstanding this historic goal of information dissemination, a compelling letter dated August 25, 2000, was sent to all 1330 of the Nation's depository libraries from the Director of the FDLP and then Superintendent of Documents, Francis J. Buckley. ("SuDocs Letter," GPO, 2000). This document announced a most profound change in how the American public would access government information in the future via electronic format. Buckley's announcement stated that as a result of the proposed Congressional appropriation for the FDLP, the shift to a primarily electronic program would accelerate. Consequently, both diminished funding for federal publishing and developing technologies greatly accelerated the migration and rapid growth of online electronic content delivery ("Library programs," GPO, 2000). The Superintendent of Document's announcement rippled through the FDLP community, gathering reactions such as "the government's target of making all its services available electronically by 2005 is a milestone in the application of electronic communications" (Ryan, 2002, p. 48). As new materials are produced in electronic formats with no printed equivalents, apprehension regarding weaknesses in the current state of online government information has become evident; some researchers, libraries, and governments are concerned about the accessibility, authentication, cataloguing, and long-term preservation of electronic records (Carvin, 2004).

While printing will not disappear, the University of Arizona, based on their pilot project with GPO, has decided to become the first all-electronic selective depository library (James, 2003). James continues that it should be determined what services GPO can offer exclusively to depository libraries that will attract and keep libraries in the program when citizens can obtain *everything* free on the Internet. The trend toward government information online definitely continues to be a major one. However, the widespread utilization of electronic information dissemination, fewer staff and financial resources, and other barriers all present new and difficult challenges for the regional libraries (Barkley, 2002). To access the electronic information, the librarians must remain current with computer and Internet skills, in addition to knowledge of the legal system and the legislative process (Yang, 2002).

CONCLUSION

Predictions for the future include that citizens can log onto an Internet site, easily find the government services they are looking for and proceed to conduct an online transaction (Atkinson & Ulevich, 2000). In addition to Web portals to provide information and services, electronic/ digital government innovations offer management and policy-making tools. Government has been at the forefront of information technology research and, as Coglianese (2004) states, "efforts to help improve the ability of agencies to manage the rulemaking process as well as increase public participation in process deserve careful consideration" (p.85). Digital government and regulatory policy making capabilities are only beginning to emerge but in the future it can be expected to fall within the main four areas (information technology, agency management of rule making, public involvement in the rulemaking process, and regulatory compliance) and these areas of the research will be enhanced through coordinated research efforts that involve perspectives from both the social and information science (Coglianese, 2004).

Digital government will cut the cost and improve the quality of government, but real progress in a timely manner depends upon digital government rapidly becoming a priority of Congress and the Administration, both in terms of funding and leadership (Atkinson & Ulevich, 2000). The WWW technologies (specifically, intranets using Web browsers such as Netscape, or Microsoft Internet Explorer) are changing rapidly, creating enormous opportunities for central and local governments; however, there are diverse problems such as new methodologies of authentication, record keeping, security, and self-service access (Safai-Amini, 2000). Finally, in today's electronic information age, "libraries must act as expert service providers rather than warehousing physical collections" (James, 2003, p. 19).

KEY TERMS

ARPANET: Advanced research projects agency network that the Internet has roots in, developed by the Department of Defense.

Electronic Signature: The Electronic Signature Act that President Clinton signed into law on June 30, 2001 facilitates electronic contractual arrangements involving cryptography principles, resulting in a digital approval process, allowing for a handwritten signature or digital certification.

Federal Depository Library Program (FDLP): Federal program of disseminating government program information products in all media to participating libraries.

Internet: World's largest network, a worldwide collection of networks that link together millions of businesses, governments, educational institutions, and individuals using modems, telephone lines, and other communications devices and media. Also called the Net.

Intranet: A network based Internet belonging to an organization or groups where information is accessed with authorization.

National Information Infrastructure (NII): A futuristic network of high-speed data communications links that eventually will connect virtually every facet of our society.

National Performance Review (NPR): A management reform initiatives established by the national administration to identify ways to make the government work better and cost less.

Public Printer: The head of the Government Printing Office (GPO).

Web Portal (Portal): Provides Internet access to a broad array of Web pages and linked services.

World Wide Web (WWW): Worldwide collection of electronic documents on the Internet that have built-in hyperlinks to other related documents. Also called the Web.

E-Mail and Communication

Dianne Willis
Leeds Metropolitan University, UK

INTRODUCTION

Electronic mail is the most frequently used application of the Internet. IDC research in 2002 suggested that the daily output of e-mails will reach 35 billion by 2005.

Sands (2003) stated than in the past 5 years, e-mail has matured until almost everyone in the developed world is expected to be able to be contacted via e-mail. He also stated that it is now as taken for granted as the telephone within a few short years of its introduction. E-mail has become a vital aspect of the communication process.

E-mail is being increasingly adopted as a major communication tool in U.K. higher education establishments (colleges of higher and further education and universities).

As the use of e-mail grows, the effect on communication patterns needs to be established. This article looks at communication theories, identifying when e-mail is an appropriate medium, and current patterns of e-mail usage within a higher education institution in the United Kingdom (the author's own).

COMMUNICATION AND E-MAIL

Communication takes place on an ongoing basis between individuals and groups using a variety of media. However, not all communication is clear to all parties—misunderstandings arise. To prevent these problems, people develop communication strategies. Te'eni (2001) suggested that communication complexity is a major aspect of strategy selection, because it reflects difficulties in communication, while the selected strategy is the means by which complexity is reduced. Te'eni introduced the terms "cognitive," "dynamic," and "affective" as being the components of communication complexity. Cognitive complexity is defined as a function of the intensity of information exchanged and the multiplicity of views held. Dynamic complexity refers to how far the communication process depends on time constraints and unclear processes that may increase the likelihood of misunderstanding. Affective complexity refers to how sensitive communication is to attitudes or changes in disposition toward the communication partner or subject matter.

He suggested a model depicting the relationship between communication goals and strategies (Figure 1).

Te'eni (2001) also suggested that certain medium attributes are more effective for certain strategies and produce a model of the relationship (see Figure 2). Te'eni takes on board the variety of communication technologies available today, including e-mail, which leads to a greater choice in terms of communication medium.

E-mail, like a letter, has low channel capacity, but like face-to-face communication, it enables instant response,

Figure 1. Adapted from: The complexity of communication goals affects strategy selection, Te'eni (2001), p. 269.

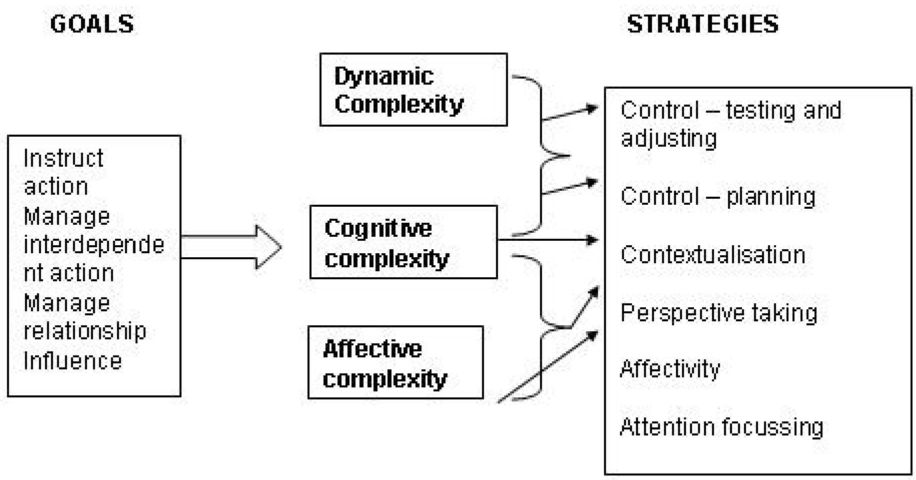

Figure 2. Adapted from: Strategies affect and are affected by medium and message, Te'eni (2001), p. 271.

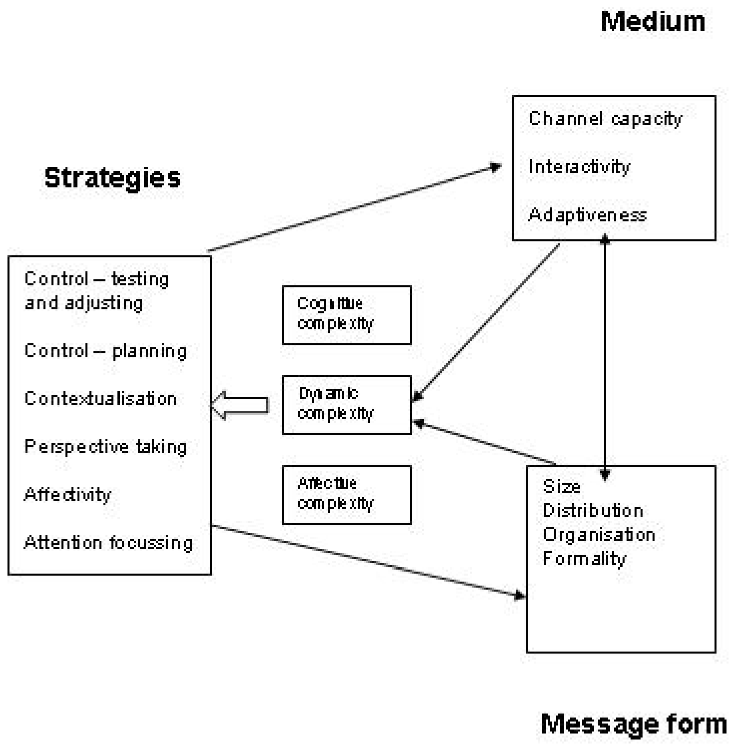


though without the nonverbal feedback used for control through testing and adjusting. Markus (1994) and Romm and Pliskin (1998) suggested that e-mail is uncontrolled and disturbs relationships, even when it does not reduce the level of social interaction. Sproull and Kiesler (1992) posited that e-mail increases the ability to distribute messages en masse, and at the same time, reduces the costs involved, making it a very attractive proposition for organisations, even if the desired richness of the communication is not met.

There is also a general belief that synchronous media are richer than asynchronous media, because the lack of delay can assist in the interpretation of the message. E-mail is ranked by some writers as somewhere between the telephone and nonelectronic written communications (Trevino et al., 1987). This would lead to the selection of other media in preference to e-mail. Consideration of the modern working environment would suggest that this is not the case, and some discussion of possible underlying reasons would be useful.

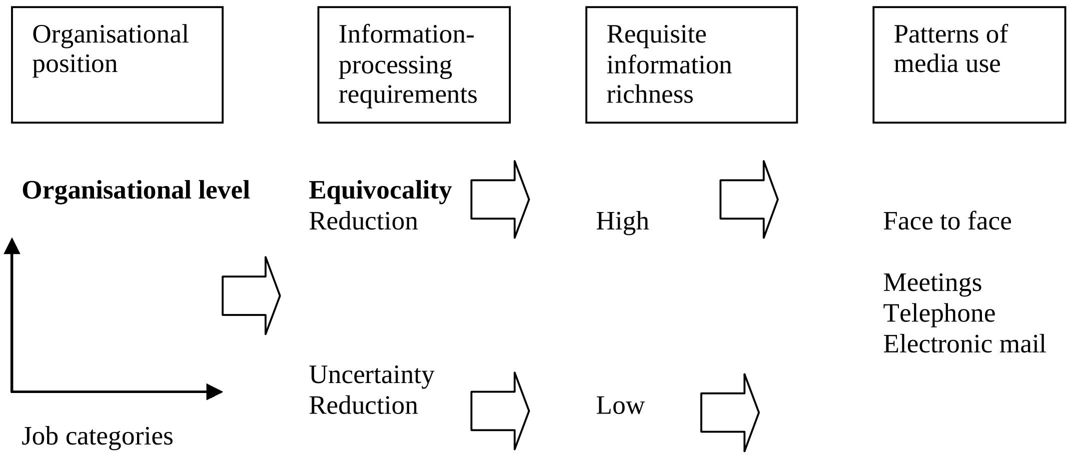
E-mail does have some specialist characteristics that might lead to it being chosen where theory would dictate the choice of another medium. Multiple addressability, the capacity to keep a permanent record, and the ability to field and search for information contained within e-mails adds much to the concept of richness. Markus (1994) and Panteli (2002) both suggested that this may be sufficient to make it a richer medium than the telephone. A communicator will generally have a choice in how to communicate. What may be more useful to study is the complexity of the communication to explain the choices of strategies, messages, and media. Communication complexity arises from trying to ensure the message is received when conditions are not ideal, i.e., when there is some form of interference in transmission of the message. Wood (1986) identified the intensity of communication as an important issue in the communication process, whereas Te'eni (2001) concentrated on interdependency.

Rice and Shook (1990) produced a model of the communication process, illustrated in Figure 3, that identifies appropriate media for communication in terms of media richness:

E-mail ranks toward the low end of the richness scale, supposedly limiting its communication possibilities.

E-mail can be viewed primarily as a sociotechnical system. A working definition of a sociotechnical system states that changes in one part of the system, be it technical or social, will affect the other parts and, thus, the system as a whole. A sociotechnical system is concerned with the interactions between the psychological and social factors and the needs and demands of the human part of the organization (its structural and technological requirements) (Mullins, 2002). E-mail satisfies the criteria for a sociotechnical system in that it consists of technology and the software needed to run the system as well as operate within the social norms adopted by the

Figure 3. Adapted from: Visual model of theoretical argument motivating the meta-analysis and individual level analyses (Rice and Shook, 1990, p. 196).



organisation choosing to use e-mail as a communication tool. These social norms will help to determine the way in which e-mail is used and the extent to which it will become a dominant communication form. The relative importance of each part of the system, the social and the technical, will vary between different institutions. When any new technology is introduced, it is important that the user population have a positive attitude toward the new technology. For it to be successful, any new technology needs to be understood and valued by the users.

Increasingly, e-mail has become a common mode of communication for many people, though exceptions must be made for those who do not have easy and regular access to the technology required. Anderson et al. (2000) considered in-depth universal access to e-mail and the personal and social benefits this can bestow. They argued that e-mail is a mechanism that provides global communication possibilities. However, the lack of access by certain sections of a society leads to the formation of an information elite, often referred to as the "information rich." Those without access are known as the "information poor." The extent to which e-mail can impact global communications must be considered in the light of equal access for all. Anderson et al. (2000) posited that there are no fundamental technical barriers to providing universal access to e-mail, so the responsibility for pushing forward equal access lies with society rather than with the technology. Cost implications are a major consideration here. Equal access to e-mail and, hence, to the communication space, would require a program of investment in access points in a variety of places, including schools, libraries, and even supermarkets. The maintenance of such access points would also need to be carefully considered. While these issues are under consideration in the United Kingdom, from the point of view of access to government offices, little is being considered from the viewpoint of universal access.

From the preceding discussion, it can be argued that e-mail is manifestly a less "rich" medium than is face-to-face communication, and careful consideration must be given to whether there are conditions in which it is totally inappropriate as a medium. Consideration must be given to what would happen to the social side of the system if e-mail is used inappropriately. Would this change patterns of usage or bring about new norms of social behaviour? There have been several examples recently cited in the UK press, where staff have been dismissed for inappropriate use of e-mail. Recent UK legislation, The Regulation of Investigatory Powers Act 2000, gives employers the power to intercept employee e-mail. This legislation is commonly known as the "Snooping Bill" and is hotly debated in terms of the underlying concepts of privacy and freedom of speech.

E-mail lends itself to informal communication, ensuring interaction and conveying important information quickly. Remembering that the main advantage of e-mail is speed, messages should be kept short and to the point to facilitate a quick response. Sherwood (2000) believed that e-mail is a fundamentally different form of communication than paper-based communication, with the speed of the process making it lean toward a more conversational tone. As recipients of e-mail can quickly respond, ask questions, or seek clarification, there is a tendency for e-mails to be not so rigorously or painstakingly constructed as letters or memos. E-mail also does not convey emotions nearly as well as face-to-face or telephone conversations, as it lacks the cues available in these forms of interaction. E-mail can be seen merely as a facilitating tool for the communication process.

Kraut and Attewell (1997) found that the use of e-mail correlated with the use of other media in that people classified as "heavy communicators" are likely to use all forms of media more often. One of the advantages of e-mail is in terms of its relatively low cost when compared with alternative communication forms, so it is often regarded as a cost-saving method. It may be the case that rather than substituting for other communication forms, e-mail may actually stimulate new relationships within the social system that will eventually lead to an increase in the total amount of communication taking place, which may then not constitute a cost savings. People generally have a preference in communication method. From an organisational standpoint, it is helpful when these preferences are for the most cost effective form of communication.

Problems with e-mail identified by Woolston and Lipschutz (1998) include the following:

- Nonverbal cues are limited, leading to possible misinterpretation of the feelings associated with e-mail
- Discussion of confidential information is not always secure
- E-mails are context deficient, there is no simple way of determining that the sender of an e-mail is who they claim to be
- Overload

There is increasing concern about overload in the new information world, given the numbers of e-mail messages in circulation on a daily basis. It is possible that the ease of use of the technology and the ready availability of multiple mailing lists adds to this feeling of overload.

One of the major advantages claimed for e-mail is that it provides a record of the communication, which was not always available in face-to-face or telephone conversations. This record seems to be of increasing importance in modern academic life. One respondent in an earlier study (Coakes & Willis, 2000) cited this record as a useful defence against possible litigation.

THE INSTITUTIONAL EXPERIENCE

The author has been studying the effect of e-mail in U.K. higher education institutions over the past 6 years. The present study of an individual department in the author's institution was prompted by comments such as "the institution is totally e-mail driven." This was backed up by staff saying that if their e-mail was down, they were unable to find out what was happening. There was also a concern that e-mail was used increasingly in instances where face-to-face communication was required.

Large quantities of information are passed around the institution using e-mail with little to no checking as to whether or not the message has been read. There is an implicit assumption that if something has been sent round in an e-mail, it has been communicated adequately. This work challenges that assumption and looks at the reality as seen from a staff viewpoint in a single department.

Short and long individual interviews were conducted over a 2 year period with 48 staff (Willis, 2003) to ascertain the following:

1. Whether they felt that e-mail was being used appropriately, i.e., if the right medium was being chosen for the message that needed to be communicated
2. Whether staff primarily instigated or responded to e-mail communication
3. How comfortable staff were with that mode of communication

Early results indicate that e-mail is often used when face-to-face communication is needed for a variety of reasons, including time and the need for a record of the communication. All 48 staff interviewed agreed that e-mail was the dominant form of communication within the department, though it was not the preferred method. In response to the question on preferred method of communication, 80% chose face-to-face, mainly because of the richness of the medium. Interestingly, although it was not the preferred method, 75% said they tended to use e-mail, as it was much faster, saving time, and was more efficient than trying to arrange a meeting.

Unsurprisingly, given the culture in the institution, e-mail overload is becoming an issue, as some staff are receiving in excess of 200 e-mails a day. In terms of this volume of messages, it must be questioned whether e-mail is actually a suitable medium to get any message through, despite the advantages claimed for e-mail.

A second issue of concern was that of the time taken to answer the large volume of e-mails. Some staff interviewed reported that they were much more desk bound since the advent of e-mail and actually had to spend so much time answering messages that they were unable to walk along the corridor and seek out colleagues for discussion.

A final issue identified was that of the increasing volume of SPAM. One interviewee receives an average of 75 SPAM e-mails per day. This has led in the past to the accidental erasure of legitimate messages by the setting up filters that do not work as effectively as was hoped.

Research by the law firm Masons (www.out-law.com) showed that in May 2003, over half of all e-mails sent were

Table 1. Research comments

"I regard e-mail as part of my job—I must answer it on a daily basis."	"E-mail enables me to work more efficiently."
"E-mail ties me to the office, and I am unable to find time for face-to-face communication."	"I get much more work done as I can deal with my e-mail as and when I like."
"E-mail is a way of passing on large amounts of work without consideration for the individual."	"I love e-mail, but I'm very nosy—I have to look to see what I've been sent even when I should be working on something else."
"SPAM is becoming a real problem, I get 75–100 messages a day."	"I can contact colleagues abroad much more easily for collaboration on projects."

classified as SPAM, and this figure is expected to continue rising. The reality of this is that it will become increasingly difficult to sort legitimate messages (HAM) from the rest. Obviously, this will have an effect on the time problem identified earlier.

Table 1 illustrates some comments taken from the research.

FUTURE TRENDS

It is likely that in the near future e-mail will take on a greater role in terms of a mechanism for student support. This would obviously increase the load on individual lecturers who are already reaching the limit of their ability to deal with ever-increasing volumes of e-mail. While e-mail can provide a useful method of communication between students and staff, the overload issue and the efficiency of the method of communication are called into question.

The use of a Virtual Learning Environment (VLE), WebCT, is being explored as an alternative to e-mail. Messages can be posted to whole groups and discussions can be held with the group of students attached to the module to address problems that previously would have been sorted on an individual basis.

Bulletin boards are another mechanism being examined to potentially reduce e-mail overload. Individuals will access information on an interest basis, which will prevent the common problems of sending information to the whole institution when it is only relevant to some members.

In terms of e-mail generally, it appears that the increase in volume is set to continue, for the near future at least, and it is to be hoped that this will not mean that the medium will become virtually unusable, though this issue is raised frequently in the U.K. press.

CONCLUSION

The theory states that e-mail is a relatively lean medium, though it has better interactive opportunities than letters and enables asynchronous working. The ability to communicate without resorting to "telephone tag" is very helpful to people who are busy. In the author's work environment, the inconvenience of e-mail tends to be overlooked, as the culture of the organisation drives its use.

Given that e-mail is a major communication method within the organisation, care must be taken that the volume of e-mail received by each member of staff does not reach the point where it becomes impossible for them to deal with it.

Guidelines for the effective use of e-mail include the following:

- Take care to avoid overload.
- Speed is the biggest advantage for e-mail; make sure the culture is such that this is adhered to in communication.
- Look for ways of using e-mail to facilitate student support.
- Use Web sites or the intranet to provide large quantities of information.
- Target the message carefully to increase efficiency.
- Think before replying.
- Use high priority sparingly.
- Delete unwanted material to facilitate effective use and save server space.

To sum up, it can be seen that e-mail has many of the advantages claimed by the theory. However, care must be taken to ensure that it does not become the sole communication medium. Appropriateness must be the watchword, or the quantity of material communicated will increase but the quality will not.

KEY TERMS

Affective Complexity: How much communication is sensitive to attitudes or changes in disposition toward the communication partner or subject matter.

Channel Capacity: The potential to transmit a high variety of cues and languages.

Cognitive Complexity: A function of the intensity of information exchanged and the multiplicity of views held.

Communication Strategies: The means by which communication goals can be fulfilled.

Computer-Mediated Communication: The dialogue that unfolds between users of electronic media.

Dynamic Complexity: How much the communication process depends on time constraints, unclear or deficient feedback, and changes during the process.

E-Mail: Messages sent and received electronically via telecommunication links.

HAM: Legitimate e-mail communications.

Sociotechnical System: The relationship between technical and social variables in a system. Changes in one part, technical or social, will affect the other parts and, thus, the whole system.

SPAM: Unsolicited marketing messages sent by e-mail or posted on newsgroups.

E-Mail as a Strategic Tool in Organizations

Denise Johnson McManus
Wake Forest University, USA

Houston Hume Carr
Auburn University, USA

INTRODUCTION

During the past decade, strategic information technology (IT) applications, such as electronic mail (e-mail), have been used to gain competitive advantage over rivals or prevent rivals from gaining a competitive advantage. The use of e-mail has been considered a component of overall business strategy, and its application depends more on understanding unique business opportunities than on competitive benefits from technological features that are easily duplicated. Since the first message was sent in 1971 by Ray Tomlinson, e-mail has emerged as an important technological requirement in business. E-mail is as common as the U.S. postal mail in the twentieth century. Businesses, schools, and universities are insisting that employees and students have an e-mail account to check updates or download information concerning business tasks or class activities. Given the widespread acceptance and use of this technology, the strategic value of e-mail within an organization should be apparent.

Companies have discovered that they must aggressively pursue new information technologies to exploit their own core competencies. Contemporary organizations have found ways to not only build more functionality onto their core mail systems, but also combine their core capabilities with strategic and creative ways of using e-mail. Clearly the definition and parameters around e-mail are changing, and the use of electronic communication is revolutionizing how firms do business.

BACKGROUND

E-mail, as a specific information technology, not only has proven to be one of the primary technologies by which an organization can begin to achieve radical and beneficial organizational change, but also has become an integral part of the corporate culture in many organizations (Carroll, 1993). This technology, which is considered the electronic transmission of messages, documents, data, and images, has enabled people to send electronic correspondence to others with e-mail addresses anywhere in the world, and is fast, inexpensive, and easy to use, making it a convenient and flexible way to improve corporate communications. As a competitive information technology, e-mail offers many advantages to the dynamic environment of today's businesses (Reark, 1998).

Literature suggested that e-mail may be used to improve relationships with customers, to link organizations with their strategic business partners, and to enhance communication between managers responsible for business redesign (Kirschner, 1995). This technology may be used to facilitate better coordination of a firm's communication between departments and divisions—*intraorganizational* uses of e-mail. Although internal communication was considered to be the core use of e-mail, firms are increasingly using it for outside communications—*interorganizational* uses of e-mail which include improving relationships with customers. Lastly, researchers have suggested that the primary benefit of e-mail have been its efficiency (Palme, 1995). For example, e-mail decreased the use of paper, eliminated time delays, and allowed the sender to transmit messages to a list of specific individuals; we refer to these as the organizational benefits of e-mail.

In 2000, more than seven trillion e-mail messages traveled the wires in the U.S. alone, up from a mere four trillion in 1999, and thus supporting the argument that e-mail correspondence is the fastest growing communication medium in the world. The most recent findings report that the average businessperson sends and receives approximately 90 e-mail messages daily (Casperson, 2002). As international competitiveness concerns have forced businesses to right-size, e-mail has surfaced as one of the facilitators that permit savings in middle-management expenditures. The increasing ubiquity of e-mail lessens telephone tag and makes direct communication more efficient, even when there are no other sophisticated systems supports (King & Teo, 1994).

Furthermore, the utilization of e-mail to communicate with customers and suppliers indicates the need for interorganizational linkages. Customers prefer to communicate with key people in a firm through the use of e-mail, because it produces a record of their communication as opposed to multiple phone calls. This perceived personalized service allows direct access to a person who could answer their questions and solve their problems. Providing this dependable link to the customer gave the company an edge over its biggest competitors.

STRATEGIC USES OF E-MAIL

Technology reaches its greatest potential when it supports the strategic operations of the organization. It is not necessary for a technology to be new for it to be used strategically. An established technology can provide a competitive advantage when it is viewed from a strategic perspective. For example, the often touted success of American Hospital Supply (AHD) was the result of using old technology in a new way. AHD simply placed tried-and-true terminals on the desks of purchasing agents, supplanting catalogs. Thus, even a simple, well-established IT has been used as a competitive tool when corporate management develops a strategic viewpoint about its computing and telecommunications resources.

E-mail was seen as a facilitator of business change as early as 1995 (Garai & Pravda, 1995) and has become as indispensable a business tool as the telephone, the postal service, or the fax machine (Harper, 2002). The increasing use of e-mail systems resulted from the desire of users to share information. For these and other reasons, e-mail has become a vital technology in today's organizations, thus improving a firm's competitive position by increasing productivity and enhancing communication inside (intraorganizational) and outside (interorganizational) the organization (McManus, Carr, Sankar & Ford, 2002).

E-mail is an example of an information technology that has potential as a strategic tool because of its capacity to increase efficiency, decrease costs, and improve productivity. Intraorganizational uses of e-mail include what has been termed productivity use and functional coupling use. Productivity use represents the use of e-mail to increase the speed, efficiency, and effectiveness of communication (e.g., scheduling meetings) (McManus et al., 2002). The utilization of e-mail for these tasks improved the productivity of individuals, giving them the ability to concentrate on more critical tasks.

As literature has indicated, many businesses have restructured themselves into high-performance teams to accomplish strategic and tactical goals. Such restructuring places a premium on reliable and timely communication between team members and functional departments. This coordination of efforts between functional areas avoids duplication and supports the timely completion of critical tasks. E-mail has been shown to support functional coupling to accomplish tasks or to achieve communications that typically involve multiple departments or divisions (e.g., polling opinions on a topic). Therefore, e-mail facilitated functional coupling by providing better coordination of a firm's internal processes (McManus et al., 2002).

Furthermore, it is not uncommon for organizations to read employees' e-mail that is believed to be inappropriate for the business environment. These findings have been supported in other studies, which refer to such applications as "inappropriate use" of e-mail technology (Rice, 1994). This stands to reason that if employees are utilizing time for social activities, the company is not achieving its business goals. Previous literature indicated that many office workers are tempted to do a little business of their own on company time, with e-mail and fast Web connections at their fingertips (Whitford, 1998). The misuse of e-mail for non-business activities has the potential to negatively impact the competitive performance of the company. Therefore, as e-mail is viewed as a strategic information technology resource, consideration of the misuse of the resource is important to avoid negating benefits.

E-mail supports the drive for competitive advantage by reducing cost and increasing productivity, providing linkages with suppliers and customers, and changing the way goods and services are provided and supported. It is these competitive uses of e-mail that make it a strategic resource. If e-mail were removed from many modern organizations, they would likely fail to remain competitive. "Building an e-mail database should be central and basic to business because this means of communications is both extremely effective and very economical" (American Gas, 2002, p.10). These strategic uses of e-mail ultimately provide a method of gaining a competitive advantage over rivals and should be a component of overall corporate strategy. Therefore, to consider e-mail other than a strategic resource places it back into a utilitarian category.

FUTURE TRENDS

During the height of the technology boom of the mid-1990s, information technology (IT) investments were in excess of 50% of capital budget expenditures in U.S. organizations (Rockart, Earl & Ross, 1996). Managers and researchers agree that IT must be appropriately utilized within these organizations in order to achieve increased worker productivity, better decision making, or other expected benefits. Thus, researchers continue to develop new theories in an effort to inform IS professionals who design and manage information technology, such as e-mail, which support managerial communication.

CONCLUSION

The strategic use of information technology capabilities within the broader corporate framework may well be the key to the future success of many businesses. The notion of strategic integration and communication of information systems with the production, marketing, financial, and other functional systems in the organization should influence technology selection and the strategic direction in some firms. Today's companies have discovered that they must aggressively pursue new information technologies, such as e-mail, to exploit their own core competencies. Successful organizations have found ways to combine their core capabilities with the available information technologies to remain competitive.

Although computer and telecommunications equipment have been used extensively in modern firms, these technologies are not new. Their widespread adoption and continued application in business have established computers as crucial vehicles for organizational effectiveness. The impact of IT has been pervasive, reaching into the decision-making processes in both small and large organizations. E-mail, as an IT capability, has been used to change a product or service, differentiate a product or service, open new markets electronically, and create barriers to entry by competitors (Stephens & Loughman, 1994).

Cooperative systems for exchanging information electronically across organizational boundaries allowed organizations to coordinate and share information when pursuing common objectives. It is vital that management realize the power of IT to build a sustainable competitive advantage, by leveraging unique corporate abilities with IT to achieve long-term performance gains (Kettinger, Grover, Guha & Segars, 1994). For example, properly implementing internal e-mail systems in multi-office organizations saves time and money over conventional courier services and fax (Vice, 1994). Therefore, organizations must realize that electronic communication is a necessity in the current dynamic global marketplace, and the effective use of any information technology can create a competitive advantage.

KEY TERMS

Competitive Advantage: The ability to gain a disproportionately larger share of a market because of cost leadership or product or service differentiation.

Electronic Communication: From a human perspective, it is the transfer of information—textual, graphic, oral, or visual—from one point/person to another via electric, electromagnetic, or photonic means. Machine-to-machine communications deals in bits and bytes only.

Electronic Mail: Allows users to communicate electronically with other users as if two typewriters were connected by a channel. E-mail adds a new dimension to the office environment, replacing paper copies and reducing time of transmittal. E-mail is the transmission of messages, textual or graphic, over various communications networks.

Information Technology: Computer systems and applications that include the organization's hardware, software, networking, and telecommunications.

Interorganizational Communications: Communications that include entities that are legally external from the organization where legal recourse may occur due to the content of the message.

Intraorganizational Communications: Communications internal to the legal boundaries of an organization, though it may cross departmental or divisional boundaries. There is no legal recourse for the content of a message.

Strategic: A tactical plan of action that is essential to the strategy of an organization, such as the use of communication to gain a competitive advantage.

Uncertainty: Not known or established; questionable. Uncertainty is generally caused by a lack of information.

Email Usage in South Pacific Distance Education

Jonathan Frank
Suffolk University, USA

Janet Toland

INTRODUCTION

The impact of cultural diversity on group interactions through technology is an active research area. Current research has found that a student's culture appears to influence online interactions with teachers and other students (Freedman & Liu, 1996). Students from Asian and Western cultures have different Web-based learning styles (Liang & McQueen, 1999), and Scandinavian students demonstrate a more restrained online presence compared to their more expressive American counterparts (Bannon, 1995). Differences were also found across cultures in online compared to face-to-face discussions (Warschauer, 1996). Student engagement, discourse, and interaction are valued highly in "western" universities. With growing internationalization of western campuses, increasing use of educational technology both on and off campus, and rising distance learning enrollments, intercultural frictions are bound to increase.

This research adds to the body of knowledge by evaluating e-mail effectiveness as a communication medium in facilitating meaningful class participation in two distance education institutions. This work investigates online student interaction in the South Pacific region. The scattered geography of the South Pacific has produced immense variations in culture among a relatively low population base. For example, in the tiny island group of Vanuatu with a population of less than 200,000, over 110 different languages are spoken (Myers & Tan, 2002). This makes the South Pacific an ideal laboratory in which to explore the impact of cultural differences on online learning, as the region contains a broad representation of the cultural characteristics found throughout the world.

Subjects were drawn from business information systems and computer information technology classes at the University of the South Pacific and Central Queensland University. Three research questions were addressed:

- Does cultural background affect the extent to which distance education students use e-mail to communicate with educators and other students for academic and social reasons?
- Does cultural background affect the academic content of e-mail messages from distance education students?
- Does cultural background influence distance education students' preference to ask questions or provide answers using e-mail instead of face-to-face communication?

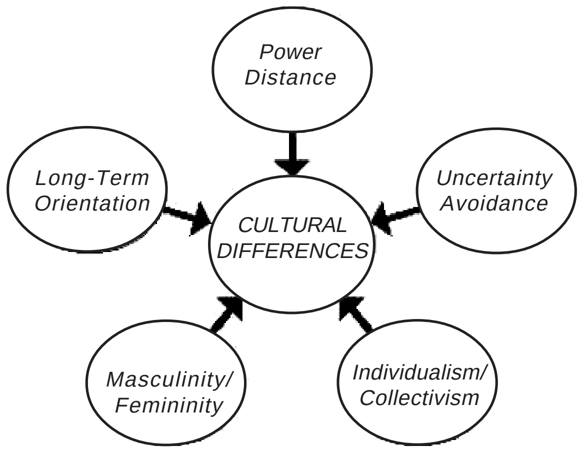
BACKGROUND

There have been a number of papers that have examined the impact of cultural diversity and group interaction in computer-mediated communication environments (Jarvenpaa & Leidner, 1998). Hofstede's (1991) well-known model categorizes different cultures according to five pairs of dimensions (Figure 1)

Although not exhaustive, Hofstede's model has been widely used, and it provides a useful starting point for exploring the influence of cultural backgrounds (Holden, 2002; Myers & Tan, 2002). For this research the focus was on the dimensions of individualism versus collectivism, and high power distance versus low power distance. These two dimensions were considered to have the most impact on learning style, the individualism/collectivism dimension will affect the way students interact with their peers, and the power distance dimension will influence the way they interact with their professor.

Hofstede's work indicated that there was a strong correlation between a country's national wealth and the degree of individualism in its culture. Richer countries tend to have an individualistic style, whereas poorer countries are more collectivist. As a poorer country becomes wealthier, it tends to move towards an individualistic pattern. Additionally, people from a rural background tend to be more collectivist than those from an urban background. Countries which fall into the low power distance, individualist category are Australia, New

Figure 1. Hofstede's model of cultural differences



Zealand, North America, England, and Scandinavia; countries in Asia, India, and South America would be considered high power distance and collectivist (Hofstede, 1991).

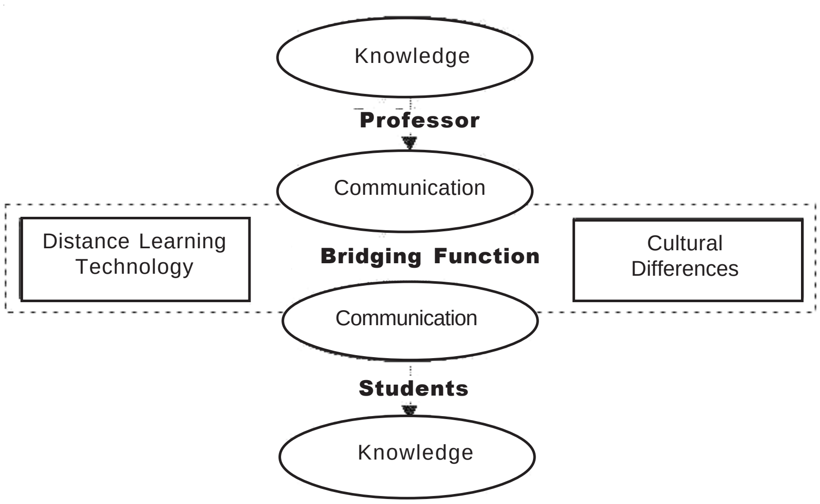
If a country is collectivist, it is also likely to exhibit characteristics of a high power distance country, where the views of senior people tend not to be questioned. Pacific Island people are in the high power distance category with their system of chiefs and their tradition of not questioning the chief's decision. South Pacific society is also collectivist with the custom of "Kere Kere" or not being able to refuse a favor that is asked of you by a member of your own in-group.

There have been a number of recent publications reviewing aspects of the development of IT in the South Pacific (Davis, McMaster & Nowak, 2002; Olutimayin, 2002; Purcell & Toland, 2004), however no research has yet been published that maps Hofstede's model on the many South Pacific cultures. Lynch, Szorengi, and Lodhia (2002) have explored Hofstede's framework with respect to Fiji, hypothesizing where the indigenous Fijian population and the Indo Fijian population would fit into the framework, however they are still in the process of collecting empirical evidence to validate their theories. This research forms a useful starting point to locate South Pacific cultures on the dimensions of individualism, collectivism, and power distance.

Most research on the effect of cultural differences has focused on traditional face-to-face teaching, rather than distance education. The literature has often cited difficulties in motivating students from collectivist (as opposed to individualistic) cultures to "speak up" in a face-to-face learning situation. Students from a collectivist culture prefer to listen, reflect, and discuss material with their peers, before preparing a written response. In common with many other collectivist cultures, it would be considered undesirable for students to speak up in class, as communication is mostly teacher centered. In Fiji, lecturers have widely commented on the "quietness" of their students (Handel, 1998). Additionally, in some pacific cultural norms, student silence is seen as a sign of respect for teachers (Matthewson et al., 1998).

More research is needed to understand fully the cultural contexts in which distance education programs are situated and how distance students process materials, especially in a second language (Guy, 1991). One study

Figure 2. Container model of knowledge transfer



concluded that students from collectivist cultures would be less receptive to distance education than students from individualistic cultures. Cultural differences also affect the way students interact with different types of messages (Anakwe, 1999). It has been shown that students from individualistic cultures are more willing to respond to ambiguous messages, which may result in a different approach to e-mail (Gudykunst, 1997).

THE SOUTH PACIFIC STUDY

The two distance education institutions studied have different approaches to education. In the University of the South Pacific (USP), knowledge transfer tends to occur in a one-directional mode from professor to student. This familiar model is often called the container or transfer model of knowledge transfer, or *migratory* knowledge (Badaracco, 1991). USP's distance education model reflects the traditional correspondence course model, in that learning materials are packaged for students, and little interaction is anticipated between student and teacher. Figure 2 proposes an adaptation of the container model, incorporating a bridging function (Jin et al., 1998) as well as components to reflect the effect of distance learning technology and cultural factors on knowledge transfer.

In contrast, Central Queensland University (CQU) distance education pedagogy is extraordinarily dependent on e-mail interaction between students and professors. Fifty percent of students' grades are based on group exercises. Groups consist of 5-10 students from 12 countries. Students are assigned to groups by the course coordinator to maximize in-group diversity. Students are required to post within group and between group evaluations to a threaded discussion forum each week. Students are encouraged to learn from each other, as well as their professor (Romm, 2001; Jones, 1999).

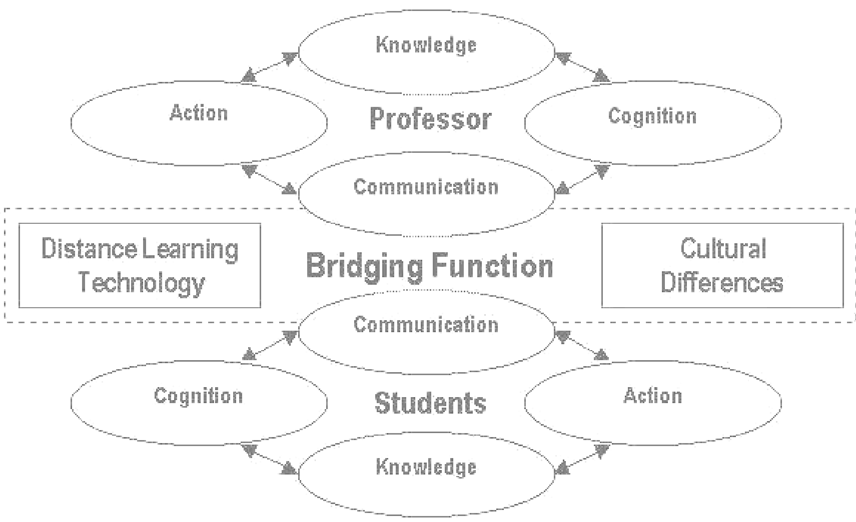
The *social construction* model of learning and knowledge transfer (Figure 3) fits well with the CQU approach to learning. This model represents knowledge as one part of a process. It considers knowledge, cognition, action, and communication as inseparable.

"The term enactment captures this interrelationship among the different aspects of knowing, acting, communicating, and perceiving. Knowledge takes on meaning as the entity interacts with its environment through communicating with other entities, acting (and thereby changing the environment) and interpreting cues arising from these interactions." Weick (1979)

FINDINGS

To assess the impact of these two approaches to distance education on students from different cultures, two studies were conducted in parallel. The University of South Pacific study examined how distance education students from different cultural backgrounds used e-mail to communicate with other students and teachers. Four hundred USP students located at different regional centers were surveyed about their e-mail usage. In the Central Queensland University study, postings to threaded dis-

Figure 3. Social construction model of knowledge transfer



cussion groups by 867 distance education students based in Fiji and Australia were analyzed. For a detailed discussion of research methodology and findings, see Frank, Toland, and Schenk (2004).

Study findings suggested differences in usage of e-mail by students from individualistic and collectivist cultures both in terms of the quantity of messages sent, and in the nature of those messages. Australian students (individualist—low power distance culture) send significantly more posts to their discussion board than do Fijian students (collectivist—high power distance culture). Australian students appear more ready to respond to questions than Fijian students do. Fijian students volunteer fewer answers to the threaded discussion group. One explanation might be associated with fear of "losing face" among their peer group. Another possibility might be Fijian students view participation on the list as not directly affecting their grade, and therefore see no reason to volunteer answers.

An analysis of Fijian messages confirmed that a large percentage of messages were social in nature; students seem to use the lists more for forming groups than Australian students. Further investigation of questions asked by Fijian students indicated a need for reduction in ambiguity about assignment specifications.

CONCLUSION

The South Pacific region, isolated, vast, and culturally diverse, was selected as an appropriate research environment in which to study the effect of cultural differences and educational technology on distance education. The research context was two competing distance education institutions in Fiji: the University of the South Pacific and Central Queensland University. E-mail was used for teaching and learning in different ways at these institutions. At Central Queensland University, interactive e-mail was incorporated into distance education pedagogy across all courses, whereas at the University of the South Pacific e-mail was used more informally.

Three research questions were addressed: Does cultural background affect the extent to which distance education students use e-mail to communicate with educators and other students for academic and social reasons? Does cultural background affect the academic content of e-mail messages? Does cultural background influence students' preference to ask questions or provide answers using e-mail?

Two studies were conducted in parallel. Subjects were drawn from business information systems and computer information technology taught by distance educators at the University of the South Pacific and Central Queensland University. Four hundred University of the South Pacific students located at different regional centers were surveyed about their e-mail usage. In the Central Queensland University study, postings to course discussion lists by 867 students based in Fiji and Australia were analyzed. The results of these studies suggest that there are significant differences in the use of e-mail by distance education students from different cultural backgrounds.

High power-distance/collectivist students are more likely to use e-mail to interact socially with their peers than they are to use it for contacting their professors. These distance education students tend to ask more questions than low power-distance/individualist students, and their questions are more likely to focus on group formation or reduction of assignment ambiguity. They also tend to volunteer fewer answers than low power-distance/individualistic students. Anxiety over "loss of face" may contribute to collectivist students' reluctance to volunteer answers.

FUTURE TRENDS

Notwithstanding the geographical limitations of these studies, the findings may have wider relevance as distance education classes worldwide become more culturally diverse. Future researchers might wish to pursue a more qualitative study in different geographic settings, interviewing students and academics to gain a more in-depth understanding of the reasons for some of the observed behaviors. Additional research in this area is important as we expand teaching across cultural boundaries through the use of distance education.

KEY TERMS

Container Model: Knowledge flows directly from the teacher to the learner, independently of the learner's environment.

Cultural Diversity: The way that people have different values and attitudes depending on where they were born and the society that brought them up.

Enactment: Knowledge only takes on meaning as it interacts with the learner's environment.

Individualism/Collectivism: An individualist society is one where each person is expected to be self-sufficient and look after themselves and their immediate family. A collectivist society is one where every person is a member of a group, and loyalty is to that group. Typically, in an individualist society, any money earned will be kept by the individual that earns it, whereas in a collectivist society, earnings will be shared among the group

Long-Term Orientation: This refers to a society's attitude towards time, do they tend to plan for a long- or a short-term time horizon.

Masculinity/Femininity: Societies that are masculine would favor values such as assertiveness, competitiveness, and toughness. Societies with a more feminine focus would be more nurturing, cooperative, and concerned with the quality of life.

Migratory Knowledge: Knowledge that can travel directly from teacher to learner without changing in form or substance.

Online Group Interaction: The use of computer-mediated communication such as e-mail, chat, or a threaded discussion by a group to communicate for the purposes of carrying out a task.

Power Distance: The way authority figures are perceived: in countries with a high power distance, a leader is an authoritarian figure or a benevolent dictator and their authority will not be questioned; in a low power distance country, individuals are prepared to argue with leaders, who must be able to justify their decisions.

Social Construction: In this model of learning, knowledge, cognition, action, and communication are seen as inseparable.

Uncertainty Avoidance: This is how a society reacts to change or something that is unknown; a society with a high uncertainty avoidance will resist anything that is different.

Empirical Study of E-Commerce Adoption in SMEs in Thailand

Chalermsak Lertwongsatien
Ministry of Finance, Thailand

Nitaya Wongpinunwatana
Thammasat University, Thailand

INTRODUCTION

It was predicted that in 2004, e-commerce would generate worldwide revenue as high as $6.9 trillion, and the number of Internet users would grow as high as 765 million users in 2005 (CommerceNet, 2003). Though about 40% of online spending originates in the United States, this proportion is predicted to fall to about 38% by 2006, due to increased online spending of residents in Asia and Western Europe (Virgoroso, 2002). In addition, it was expected that online buying in Asia will grow about 89% in 2002 (Virgoroso, 2002), and the Asia Pacific will be the second most profitable, with a value of $1.6 trillion (CommerceNet, 2003).

As one of the fast growing countries in Asia, Thailand has initiated and implemented a series of national plans and activities to promote diffusion of e-commerce in both public and private sectors. Despite optimism towards e-commerce, evidence from a recent survey by the EIU (Economic Intelligence Unit) suggested that Thailand's adoption rate is still slow. According to the 2002 EIU e-readiness survey, Thailand was ranked 46 from the 60 main economies of the world (EIU, 2002). It is therefore important to understand factors affecting a firm's decision on e-commerce adoption. A deeper and clearer understanding on such issues would help design appropriate e-commerce models to target consumers in these economies and also to formulate appropriate policies to accelerate e-commerce diffusion in other countries.

This article examines the factors influencing e-commerce adoption decisions in small and medium enterprises (SMEs) in Thailand. We classify firms into three main groups—*adopters*, *prospectors*, and *laggards*—based on their extent of e-commerce innovativeness (Roger, 1995), defined as the extent to which an organization is relatively earlier to adopt e-commerce than others.

To begin, adopters are firms that have already implemented and used e-commerce in their business activities. These firms are creative and innovative in applying leading-edge technologies, such as e-commerce, compared with their competitors. Second, prospectors are firms that have not yet implemented e-commerce, but they have a specific plan in the near future to adopt and implement e-commerce. Prospectors tend to avoid the immediate application of leading-edge technologies; however, after a certain period of time, they readily adopt innovations that have been proven effective. Finally, laggards are firms that have not implemented e-commerce and have no plan or intention to adopt e-commerce in the near future. Laggards typically are slow in adopting new innovation; however, they may decide to adopt the technologies when forced by business competition.

Most of the IT innovation studies have been conducted in the US. However, Asian firms are different from U.S. firms in many respects, such as geographic, political, and cultural aspects. The research findings from this study can help in determining whether the organizational innovation theory can be generalized across other settings, particularly in Asian settings.

FACTORS INFLUECING E-COMMERCE ADOPTION

Organizational innovation was adopted as a theoretical foundation for this study. Organizational innovation can be defined as the development and implementation of ideas, systems, products, or technologies that are new to the organization adopting it (Rogers, 1995). Innovations are means of changing an organization, either as a response to changes in the external environment or as a preemptive action to influence the environment. The adoption of innovation is a process that includes the generation, development, and implementation of new ideas or behaviors (Rogers, 1995). Innovations can be categorized by a broad range of types, including new products or services, new process technologies, new organizational structures or administrative systems, or new plans or programming pertaining to organizational members (Poutsma, Van Uxem & Walravens, 1987). Adoption of e-commerce, hence, can be regarded as one form of innovation adoption.

The innovation literature has identified various groups of variables that are possible determinants of organizational adoption of an innovation (Fichman & Kemerer, 1997; Kimberly & Evanisko, 1981; Tornatzky & Fleischer, 1990; Chau & Jim, 2002). Based on a synthesis of the organizational innovation literature, Kwon and Zmud (1987) identified five sets of factors that may influence IT innovation. These sets include user characteristics, task characteristics, innovation characteristics, organizational characteristics, and environmental characteristics. Kimberly and Evannisko (1981) proposed three clusters of predictors for innovation adoption: characteristics of organization, characteristics of leader, and characteristics of environment.

Recently a number of IT innovation studies (e.g., Boynton, Zmud & Jacobs, 1994; Tornatzky & Fleischer, 1990) have adopted an emerging theory from the strategic management literature—absorptive capacity (Cohen & Levinthal, 1990)—to explain a firm's abilities in adopting and assimilating an innovation. Boynton et al. (1994), for example, argued that a firm's ability to effectively use IT is influenced by the development of IT-related knowledge and processes that bind them together the firm's IT managers and business managers. They pointed to the organizational climate as the key factor influencing the ability of firms to absorb new knowledge and technology. Fichman and Kemerer (1997) found that organizations are more likely to initiate and sustain the assimilation of software process innovations when they have a more extensive existing knowledge in areas related to the focal innovation. Table 1 summarizes factors potentially influencing a firm's decision in adopting information technology.

Table 1. Factors influencing information technology adoption

Organization Factors
• Organization Size • Organization Readiness • Employee IT Knowledge
Leadership Factors
• Top Management's IT Knowledge • Top Management's Innovativeness • Top Management Support
Technology Factors
• Relative Advantage • Compatibility • Complexity
External Factors
• Environment Uncertainty • Information Intensity

Drawing from organizational innovation literature, we identify and test six research variables, representing three major groups, *organizational factors*, *technology factors*, and *external factors*, potentially influencing a firm's decision in e-commerce adoption. First, organizational factors have been the most widely used and tested as the key determinants of innovation (Grover & Goslar, 1993; Thong, 1999). In this study, we focus on three sets of variables: structural variable (size), process variable (top management support for e-commerce), and IT context variables (existence of IT department). Size is one of the most widely investigated variables for innovation adoption. Large firms are more likely to adopt innovation since they are capable of absorbing the risk associated with innovation, and have sufficient resources and infrastructure to facilitate the implementation of innovation (Fichman & Kemerer, 1997). Process factors have also frequently been adopted as a key determinant of IT-related innovation adoption, especially the roles of top management. The IT innovation literature generally reported a positive effect of senior management support on IT-related innovation (Orlikowski, 1993; Rai & Patnayakuni, 1996). The common rationales provided include influencing the allocation of slack resources, and generating enthusiasm and commitment toward changes among organizational members. Finally, evidence from the innovation literature recently suggests that the role of a firm's ability to absorb new knowledge related to innovation can play an important role in innovation adoption (Cohen & Levinthal, 1990). SMEs that are familiar with IT skills and knowledge might find it easier to acquire additional knowledge necessary for adopting e-commerce. Hence, it is conceivable that the existence of IT departments in SMEs could promote e-commerce adoption.

The second group of variables is technology factors. Specific factors related to innovation characteristics are frequently used as a key determinant of innovation adoption intention. This study investigates the effects of two innovation characteristics: perceived compatibility and perceived benefits. Different organizations may face different innovation opportunities. Whether these opportunities can be exploited depends on the degree of match between the innovation's characteristics and the infrastructure currently available in the organization (Rogers, 1995). In addition, not all innovations are relevant to an organization. The degree of relevance depends on the potential benefits organizations received.

The third group of variables is an external factor. Past studies have stressed the importance of environments. When organizations face a complex and rapidly changing environment, innovation is both necessary and justified (Pfeffer & Leblebici, 1977). Environmental factors, especially market factors (i.e., competitiveness), cannot be controlled by organizations; rather, they affect the way

Table 2. Examined variables

Factors	Theoretical Representation	Variables
Organizational Factors	Organizational Structure	Size
	Organizational Process	Top Management Support for E-Commerce
	IT Context	Existence of IT Department
Technology Factors	Technological Context	Perceived Benefits
		Perceived Compatibility
Environmental Factors	Organizational Environment	Competitiveness

Table 3. Pair-wise analysis of the mean difference among the three organization types

Variables	Mean Difference Between		
	Adopters & Laggards	Adopters & Prospectors	Prospectors & Laggards
Size	Significant*	Significant*	Not Significant
Top Management Support for E-Commerce	Significant***	Not Significant	Not Significant
Existence of IT Department	Significant***	Significant***	Not Significant
Perceived Benefits	Significant**	Not Significant	Significant*
Perceived Compatibility	Significant***	Not Significant	Significant***
Industry Competitiveness	Significant**	Not Significant	Not Significant

firms conduct their businesses. Thus, it is conceivable that environmental factors create a need for firms to adopt IT-related innovation such as e-commerce. This study examines the effect of competitiveness on e-commerce adoption. Table 2 summarizes the research variables used in this study.

DATA COLLECTION

Survey was the primary research methodology of this study. The target firms for this study are SMEs in Thailand. Based on the definition accepted by the Ministry of Industrial in Thailand, SMEs are businesses that have overall asset values less than or equal to 200 million baht for manufacturing and service firms, 100 million baht for wholesalers, and 60 million baht for retailers. While not officially being defined, the size of SMEs, reflected by the number of employees, has generally been accepted to be fewer than 200 (Sevilla & Soonthornthada, 2000). We adopt this number as the maximum size of SMEs.

Data was collected through a national survey in several major provinces in Thailand. Respondents were those who influenced or were part of a decision-making process of e-commerce adoption. In total, 1,200 packages of questionnaire were distributed, and 452 questionnaires were returned. Sixty-six questionnaires were unusable. The total response rate of this study is 32.16%.

Respondent firms were subsequently classified based on their e-commerce adoption action. Firms were classified as *adopters* if they had already adopted e-commerce; as *prospectors* if they had not adopted e-commerce, but had a specific plan to adopt e-commerce within one year; and as *laggards* if they neither had a specific plan nor intention to adopt e-commerce. From the total 386 responses, 107 firms (27.7%) were classified as adopters, 52 firms (13.47%) as prospectors, and 227 firms (58.8%) as laggards.

FINDINGS

A post-hoc multiple comparison (Scheffee's) was employed to perform a pair-wise comparison of the mean difference on the key factors among the three organization types (see Table 3). The results suggest that adopters and laggards were significantly different in all factors. However, the results of the mean difference between adopters and prospectors and between prospectors and laggards are mixed. In particular, adopters and prospectors are significantly different in size and existence of IT department. Prospectors and laggards are significantly different in perceived benefits and perceived compatibility.

FUTURE RESEARCH OPPORTUNITIES

For future research, while this study incorporates a number of key variables identified from the literature, future studies may expand the research model by incorporating various variables to cover more comprehensive aspects of the phenomenon, such as variables reflecting key aspects of e-commerce, variables reflecting SME context, and variables representing a gap between Asian and Western cultures.

In addition, this study examines only one aspect of e-commerce adoption, the extent to which an organization is relatively earlier to adopt e-commerce than others. Future study may attempt to test other aspects of e-commerce adoption. The diffusion of innovation literature can be used as a foundation to develop dependent variables. Fichman (2001), for example, identified a number of measures of organizational innovation such as earliness of adoption, infusion, and assimilation. While these variables are widely used specifically in the context of information technology, they can be applied in the context of e-commerce. For instance, future study may develop a research model to test the infusion of e-commerce in SMEs (i.e., the extent to which e-commerce is used in a complete and sophisticated way). By adopting a more sophisticated measure, future study might apply a more sophisticated technique in testing the relationships in the research model, such as linear regression and structural equation modeling techniques (i.e., LISREL, PLS).

CONCLUSION

It is unarguable that e-commerce is becoming one of the key technologies driving businesses in the current dynamic environment. A study of e-commerce would expand our understanding on the rational underlying the thinking logic of firms in adopting the technology.

Results from our statistical analysis reveal an inside look at key factors that influence adoption decision of SMEs in Thailand. Overall, the results strongly support that organizations differ in key variables identified from the innovation literature, reinforcing that key variables identified from the organization innovation theory are applicable in the context of Asian settings and in the context of e-commerce innovation.

A number of conclusions can be drawn based on these results. First, the amount of strategic emphasis firms give to IT (i.e., IT-related knowledge, resources, and capabilities) has an impact on e-commerce adoption intention. Firms that strongly support the use of information technology, by formally establishing an IT department, are more likely to adopt e-commerce earlier than firms with less IT support. Second, we found that prospectors significantly differ from laggards in technology factors—perceived benefits and perceived compatibility—whereas there is no difference between prospectors and adopters in the technology factors. These results imply that technology factors do have an influence on attitudes toward e-commerce (i.e., changing from unfavorable—laggards—to favorable tendency—prospectors), but have no influence on a relative earliness of adoption stage (i.e., no change from prospectors to adopters). Third, e-commerce adopters are more likely to operate in a more competitive environment, compared with the other two organization types. This also implies that SMEs operating in a competitive environment are constantly scanning and implementing new technologies such as e-commerce.

For practitioners, this study highlights the importance of IT skills and knowledge in influencing e-commerce adoption. This study shows that knowledge about IT plays a major role in influencing a firm's adoption decision. SMEs that strongly support IT deployment (i.e., high level of IT investment, existence of IT department) are more likely to adopt e-commerce earlier than those with less IT support. Since e-commerce is a key technology driving businesses in a current competitive environment, the earlier the firms adopt e-commerce, the faster the firms can extend their reach to customers and secure their share in the market by using a market access capability of e-commerce.

KEY TERMS

Absorptive Capacity: The ability to value, assimilate, and apply new knowledge.

Compatibility: The degree to which an innovation is perceived as consistent with the existing values, past experiences, and needs of potential innovation adopters.

Diffusion of Innovation: The process by which an innovation is communicated through certain channels over time among the members of a social system.

Electronic Commerce (E-Commerce): The sharing of business information, maintaining business relationships, and conducting business transactions by means of telecommunication network.

Electronic Data Interchange (EDI): The movement of specially formatted standard business documents, such as orders, bills, and confirmations sent between business partners.

Electronic Readiness (E-Readiness): The aptitude of an economy to use Internet-based computers and information technologies to migrate traditional businesses into the new economy.

Innovativeness: The degree to which an individual or other unit of adoption is relatively earlier in adopting new ideas than others.

Perceived Benefits: The extent of management recognition of the relative advantage that innovation can provide to firms.

End–User Computing Success Measurement

INTRODUCTION

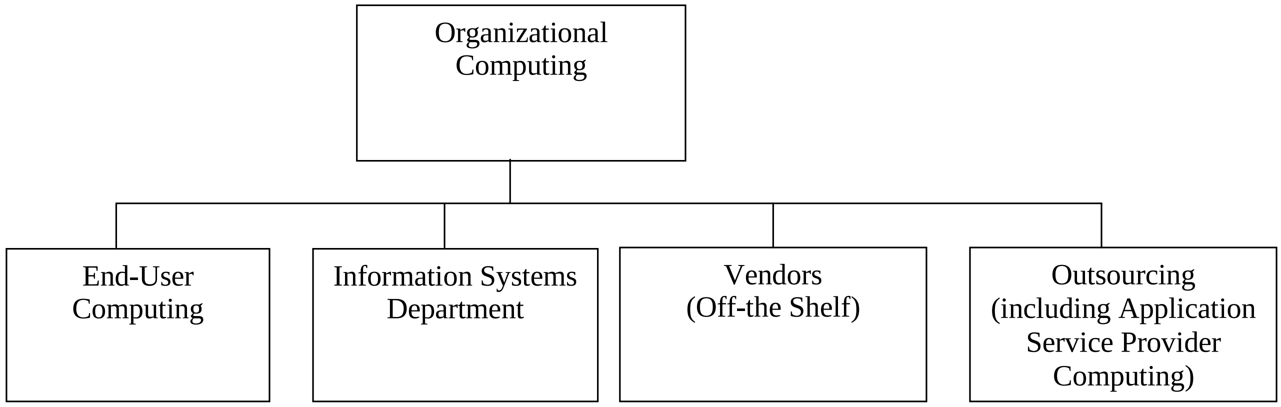
End-user computing (EUC) is the optional development of computer applications and models by personnel (individuals or groups) outside the MIS department. The emergence of EUC in the 80s and early 90s can be traced to the proliferation of computers, increased organizational computing needs, more sophisticated user application development tools coupled with higher computer and information literacy among staff and professional workers. Prior to the arrival of personal computers and graphical user interfaces, end users relied on data processing (now information technology) personnel to assist in meeting their information needs (Inman, 1986). Programming a mainframe was beyond the skills of most workers. Problems identified during this era of computing include:

- Failure to meet end-user needs.
- Cost of developing end-user applications was high.
- Large backlog of end-user applications made the development very slow.

As users required more information for decision making and highly user-friendly applications became available, end users began developing customized solutions to the needs that the data processing departments could not (Ahituv, Neumann & Riley, 1994). Today, EUC has become commonplace. Small, customized applications with spreadsheets and databases are commonplace in end-user departments. At present, EUC is just one contributor to overall organizational computing. As shown in Figure 1, the other sources of computing include applications developed by the information systems department (ISD), applications developed by vendors (off-the-shelf), and outsourcing—including application service providers (ASPs). EUC success is therefore just one contribution to overall organizational computing success. For our purposes, we define EUC success as the degree to which the organizational EUC strategy contributes to individual, group, and organizational computing success in an environment that includes applications developed by the information system department (ISD), application service providers, outsourcing parties, and of-the-shelf vendors. This means EUC complements the other components of organizational computing.

The type of applications developed by end users include transaction processing systems, manufacturing systems, expert systems, executive information systems, decision support systems, and online application processing systems (McLean, Kappelman & Thompson,

Figure 1. Components of organizational computing success



1993). There are problems, however: although end-user developed applications are low risk, localized and quickly meet user needs, unlike applications developed by the ISD or vendors, they lack integration, standardization, documentation and quality control. They also lack security, data consistency, and may result in duplication of effort. Table 1 compares the characteristics one would find in the different types of organizational computing.

In this article, we review the major research studies on EUC success measurement focusing on what has been accomplished and what remains to be done. We conclude that the measurement of EUC success seems to be an intractable problem. For example, we identified among others that there is shortage of longitudinal EUC measurement studies. There is lack of studies that have controlled for task, technology and work context. Also, there is lack of research about the relationship between EUC and other forms of organizational computing.

BACKGROUND

Measuring the Elements of EUC Success

Figure 1 indicates that EUC success should be measured as an embedded unit of organizational computing success. One problem is that the specific objectives of EUC are often invisible to the end user and to the company. The extent to which the objectives are attained is also unknown because end users often develop applications without knowledge of how their actions impact the other embedded units of organizational computing. End-user developed applications are rarely tracked by organizations. At the same time, it is not difficult to find organizations where an end- user developed application (e.g., DSS) is critical to daily operations. Furthermore, end users may be unwilling to allow objective measurement of the

Table 1. Characteristics of types of organizational computing

	End-User Computing	Information Systems Department	Vendors (Off-the-Shelf)	Outsourcing
Cost	Low/None	Moderate	Moderate	High
Schedule	Immediate	Slow	Fast	Slow
Size	Small	Moderate	Large	Moderate/Large
Control	Low	High	High	High
Risk	Low	Moderate	Low	High
Influence	Local	Local to Organizational Levels	Local to Organizational Levels	Local to Organizational Levels
Fit to User Task	High	Moderate	Low	Moderate
Support (help desk, documentation, training)	Low/None	Moderate	Moderate	Moderate

Duplication of Effort	High	Low/None	Low/None	Low/None
Acceptance	High	Low	Moderate	Moderate

efficiency or effectiveness of their applications, especially from an outsider, for fear of job loss. Although benign measures such as end-user satisfaction are less threatening and easier to obtain, this is problematic because end users are asked to place a value on something about which they are far from objective.

According to Gerrity and Rockart (1986), EUC success will occur if there is:

- An increase of effectiveness in the individual using the developed application.
- A move to formalize the informal system that was developed so that it can be used by other end users.
- An increase in learning on the part of the users in their ability to accomplish work.
- An increase in competitive advantage through support of new products, markets, and opportunities.
- An improvement in organizational effectiveness as users access data to improve decisions they make.

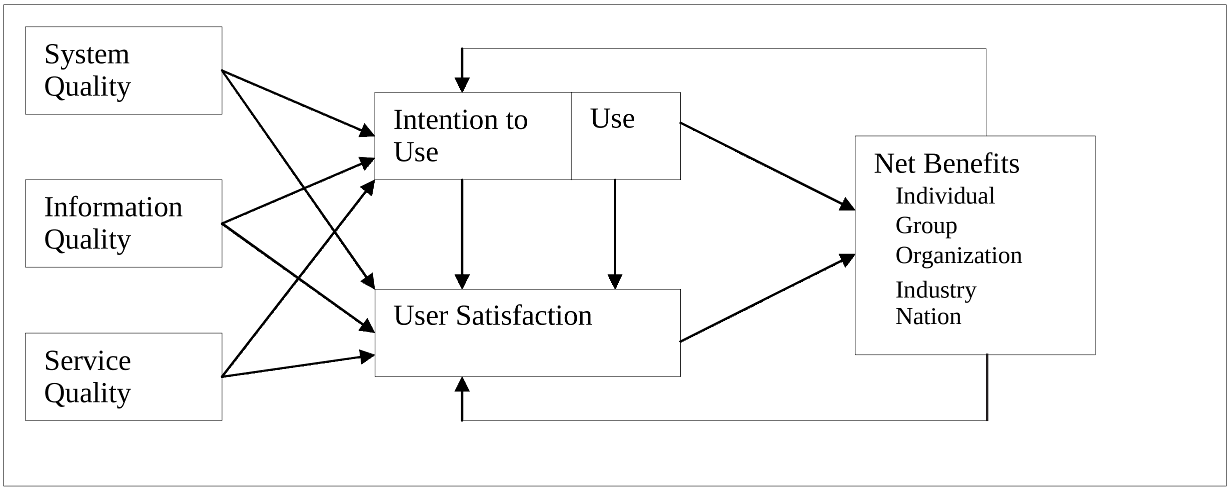
Scott Morton (1990) added a sixth item to this list: EUC success is observed if an overall increase in national wealth due to increase in knowledge of workers and information handlers exists.

The investigation of the payoff from IT investment in general has been relentless (Brynjolfsson, 1993; Seddon, Graeser & Willcocks, 2002). Since EUC became an accepted part of organizational computing, researchers have investigated whether there are significant returns from investment in EUC (Amoroso & Cheney, 1992; Blili, Raymond & Rivard, 1998; Brynjolfsson, 1993; Doll & Xia, 1997; Fabey, Land & Targett, 1999; Smithson & Hirschheim, 1998; Torkzadeh & Doll, 1991). Has the investment of time and money in EUC been worthwhile? Has the investment increased the effectiveness, efficiency and competitiveness of the organization? In reviewing the literature, we found out that most articles that did measure EUC success focused on user satisfaction, system use and end-user productivity. The measurements were mainly based on subjective self-reporting. The dependent and independent variables varied depending on the objectives of the researchers (Brancheau & Brown, 1993; DeLone & McLean, 2003; Seddon et al., 1999). Table 2 presents the independent variables and Table 3 the dependent variables that have been used to measure EUC success. The variables can be captured by the DeLone and McLean's Updated Model for measuring IS success (DeLone & McLean, 2003).

Information Systems Success and EUC Success

Several articles discuss components of IS success though its economic and objective measurement is often elusive (DeLone & McLean, 1992, 2003; Seddon, 1997; Seddon et al., 1999). However, consensus on specific measures of IS success seem to center on intention to use the system, actual system use, user satisfaction, and the net payoffs or benefits that accrue to the various stakeholders. As shown in Figure 2, success measures will depend on the unit of analysis that stands to benefit from the use of the target information system (DeLone & McLean, 2003; Seddon et al., 1999). The literature also indicates that higher levels of system use (intended or actual) and user satisfaction will occur when there is high system quality, high information quality, and high service quality. Higher system use and user satisfaction will lead to higher net benefits, which in turn will encourage more usage and higher user satisfaction.

Figure 2. DeLone and McLean's 2003 model of IS success



DeLone and McLean (2003) conclude that the six categories of success clearly indicate that IS success is a complex, multidimensional and interdependent construct and that it (IS success) should be measured as such. As shown in Figure 2, although "Net Benefits" is seen as the ultimate measure of IS success it also influences system usage and user satisfaction. DeLone and McLean recommend that more field research is needed to investigate and incorporate the "Net Benefit" measures. They also recommend that user satisfaction should always be used when "IS Use" is mandatory. However, the researcher's selection of what IS dimensions to focus on will depend on the objectives and context of the study.

Table 2. Measures used as the independent variable in EUC success measurement

Management Support for Planning and Control ✳ Top Management Understanding of IT ✳ Development of Appropriate Strategies/Policy ✳ Top Management Integration of the organizational EUC strategic plan with the IS master plan ✳ Provide a budget for educational and training programs in-house or at remote location using company personnel (software, OS, communication training, general and functional computer literacy) ✳ Encourage experimentation with various emerging technologies and applications ✳ Encourage use of IT to support a wider variety of tasks ✳ Reward efforts of using IT to meet set goals at sectional, department, divisional and corporate levels ✳ Develop core internal experts who will train and mentor others (local resident experts) ✳ Provide software library services ✳ Access to an Information Center (IC), Help Desk or Hotline **Information Center Support** ✳ Guidance in selecting hardware and software ✳ Hardware setup/configuration ✳ Software installation/backup/recovery ✳ Access to corporate data ✳ Applications maintenance/troubleshooting **Organizational Structure** ✳ Centralized ✳ Decentralized ✳ Distributed **User Characteristics** ✳ Years of Education ✳ Cognitive Style ✳ Computer Skills (command level, programming) ✳ Self-efficacy expectation ✳ Demographics (Gender, Age) ✳ Inputs to EUC: programming time, flow diagram, 4GL, pseudocode, and so forth ✳ Personality ✳ Computer Attitudes ✳ Computer Anxiety ✳ Math Anxiety ✳ Experience ✳ Skill Variety ✳ Autonomy ✳ End-user computing sophistication/Competence: ability, usage intensity, application, customization	**System Characteristics** ✳ High/Low end ✳ Quality: Security, Functionality, Ease of Use, Reliability, Availability, Portability, Importance, Integration, Adaptability, Usability, Response Time, Documentation ✳ Type of Application ✳ Value and Usefulness of system terminology **Information Characteristics** ✳ Quality of output: content, structure, correctness, accuracy, format, ease of use, completeness, timeliness, security, relevance ✳ Number of defects/function point ✳ Quality attribute models ✳ Value and usefulness of screen displays/user interface **User/System/Task Interaction** ✳ End-user participation in analysis and design ✳ End-user involvement in analysis and design: perceived risk, degree of pleasure, status value ✳ End-user usage of the system (frequency, time, number of accesses/transactions, usage pattern, dependency) ✳ Time on project in task categories ✳ LOC/hour ✳ Function points/hour ✳ Outcome expectancy ✳ Perceived usefulness ✳ Intention to use ✳ Perceived fun ✳ Satisfaction **External Support** ✳ Good relationship with hardware/software vendors/consultants (positive feelings, realistic expectations) ✳ Technical support (Service Level Agreements, Resource Level Agreements) ✳ Training by external consultants, friends, vendors, or educational institutions **Task Characteristics** ✳ Task identify ✳ Task significance ✳ Task uncertainty (complexity, volatility) **Service Characteristics** ✳ Quality: Reliability, Responsiveness, Assurance, Empathy **Other characteristics** ✳ EUC stage of growth ✳ Social pressure

FUTURE TRENDS

The Future of EUC Measurement

Measuring EUC success seems to be an intractable problem. Although research studies have contributed to our understanding of the EUC success measures, there is still lack of consistency in the specification of the measures, research design, and technology used. Problems associated with EUC success measurement are:

Control and Clarity—There is a need to control for task, technology and context in studies that measure EUC success. Considerations for task variety and complexity were rarely found in the literature. Given the wide variety of skill, position, and types of computing work, it is imperative that we consider controlling for task complexity. Similarly, the research studies have examined and reported on a wide range of technologies. The problem of control is exacerbated by rapid changes in technology that make it difficult to repeat similar tests and measures over time. Context also needs to be clearly defined so that it is understood whether use of the information system is mandatory or voluntary or whether a competing information system exists.

Creation of Meta and Longitudinal Data—There is shortage of longitudinal EUC measurement studies. Most studies identified in the literature are cross-sectional. Longitudinal studies will enable us to learn how end users perform as they develop higher technology skills and how technology changes impact performance of complex tasks and the other components of organizational computing over time.

Unit of Measurement—Most studies tend to focus on the individual end user as the unit of analysis. However, if we are concerned with the degree to which EUC contributes to overall organizational computing success, we need to apply group, departmental and ultimately organizational measures of EUC. For instance, if satisfaction is a measure of EUC success, that success should be measured at many other levels. A CEO or departmental manager may have a very different perspective on an IS success than a specific end user has.

Lack of Objective Measures of End-User Performance in a field setting—End-user computing activities are rarely visible to the rest of the organization. Such activities are therefore difficult to observe, document and measure unobtrusively (Shore, 1998).

Need for Confirmatory Studies—More studies are needed to test and challenge the new DeLone and Mclean model (2003) using the context variables suggested by Seddon et al. (1999) and Brancheau and Brown (1993), and work system framework variables suggested by Alter (2002).

Lack of Conceptual Definitions—The operational definition of the measuring variables must correspond with the conceptual definition. Researchers should develop and use existing measures that are well established and validated in IS and other disciplines. For example, are we really measuring end-user satisfaction? If so, how is this different from satisfaction with artifacts researched in other fields such as marketing or engineering?

Lack of Interrelationship Studies—There is a lack of research about the relationship between EUC and other forms of organizational computing. EUC development, implementation and maintenance can cause an organization to formalize informal systems, hoping to gain productivity or control where corporate systems have failed. The existence of EUC developed systems may be an important step towards successfully developing more formalized systems. EUC developed systems may play an educational role in moving user groups towards understanding of requirements and acceptance of more formal systems. The growth of EUC communities of practice may accelerate this trend.

Lack of Global View—Most EUC research has been conducted in North America, Europe, and Australia. There is belief that the results obtained from these settings are generalizable to the rest of the world. This belief may be ill advised given differences in culture, socio-work roles, level of IT sophistication and access to technology. Models of EUC need to be checked for external validity across cultures. This is even more important in the future as companies employ a global workforce.

CONCLUSION

When future research uses existing well-defined EUC concepts and measures, it will be possible to conduct meta-analyses and improve our overall understanding of EUC success. There is also a need to pay attention to the contextual factors of end-user computing. Too many studies are focused at the individual level, ignoring departmental, work-group, organizational and even national effects. A broader view of the implications of EUC in organizational computing success could give insight into its contribution to national productivity, quality and competition.

KEY TERMS

End-User Computing (EUC): The optional development of computer applications and models by personnel (individuals or groups) outside the MIS department.

EUC Net Benefits: A measure that captures the balance of positive and negative impacts that result from EUC activities in an organization.

EUC Satisfaction: An affective measure of an end user's opinion about the net benefits derived from EUC activities in an organization.

EUC Success: The degree to which the organizational EUC strategy contributes to individual, group, and organizational computing success in an environment that includes applications developed by the information system department (ISD), application service providers, outsourcing parties, and off-the-shelf vendors.

Information Quality: The success of the information being meaningful and useful to the receiver**.**

Intention to Use: An attitude measure of an end user's goal to use a specific information system.

Service Quality: A measure of end-user opinions on the overall support provided to them by top management, ISD, and others.

System Quality: The reliability and efficiency of an information system.

System Usage: The extent of actual use of a specific information system—(mostly voluntarily).

Engineering Emotionally Intelligent Agents

Penny Baillie-de Byl
University of Southern Queensland, Australia

Mark Toleman
University of Southern Queensland, Australia

INTRODUCTION: EVOLUTION OF EMOTIONAL AGENTS

Traditionally, philosophers have defined emotions to be interruptions to otherwise logical states of being (Smith & Kirby, 2000). The recent resurgence of research in the emotional realm in both psychology and cognitive science agrees with the view developed by the late Charles Darwin who, in the late 1800s, conceived that emotions play an important part in our cognition and serve to provide us with the mechanisms for adaptive behaviour in a dynamically complex world (Smith & Ellsworth, 1985).

One relevant line of research is the realm of affective computing. This relatively new domain examines the effect that emotions have on human intelligence and endeavors to use this to further enhance the field of artificial intelligence (AI). How the concept of emotions might heighten the intelligent functioning of artificial beings is still unclear, but through the variety of research programs that currently exist, areas that might benefit are being identified. In this domain, much work is being done to develop artificial intelligences capable of identifying, processing and synthesizing emotions. Picard (1997) suggests that emotions are an integral part and a natural progression for AI. She further states that: "...the inability of today's computers to recognize, express, and have emotions, severely limits their ability to act intelligently and interact naturally with us".

Emotional decision making provides a good solution for computer systems that face the problem of enumerating and evaluating multitudinous choices within an acceptable time frame. One application of AI that is benefiting by integrating emotional decision making mechanisms is that of intelligent agents. The word *agent* is used within the AI domain to refer to a number of different applications. The most popular use of the term pertains to an autonomous artificial being that has the ability to interact intelligently within a temporally dynamic environment.

BACKGROUND

Much of the current research for achieving these types of results with artificial agents is based on appraisal theories. Models such as the Affective Reasoner (Elliot, 1992, 1998), the Oz project (Bates, Loyall & Reilly, 1992), PETEII (El-Nasr, 1998), Silas (Blumberg, Todd & Maes, 1996), Yuppy (Velasquez, 1999), extensions of the INES intelligent tutoring system (Hospers, Kroezen, op den Akker, Nijholt, & Keylen, 2003; Heylen, Nijholt, op den Akker, & Vissers, 2003) and systems based on PMFserv (Silverman, 2001; Silverman, Cornwell, & O'Brien, 2003) are just a few examples of how appraisals (cognitive and non-cognitive) are used to generate emotional states and behaviors within an artificial intelligence.

Cognitive appraisal theory and the OCC Model developed by Ortony, Clore and Collins (1988), although not originally intended for synthetic generation of emotions, is a basis for several of these projects. Table 1 displays the values used in the OCC model and subsequent AI applications to appraise an event and determine an appropriate emotion. The table is a subset of the OCC appraisals, displaying eight of the possible 22 emotional states mentioned in the theory.

Heylen et al. (2003) report a proposed extension to INES to incorporate social and emotional intelligence skills of human tutors using emotional axes defined in Kort, Reily & Picard (2001). Implementation is still at the conceptual stage. Baillie (2002) developed an emotionally motivated artificial intelligence (EMAI) architecture that has the capacity for decision making influenced by simulated human emotional intelligence. The architecture consisted of several major processing and knowledge representation areas working together in a complex network of information gathering, manipulation and update. A focal point of the architecture was an "affective space" which acted as an emotional filter influencing an EMAI agent's perception of its beliefs about the environment and, as a consequence, how it behaved. EMAI agents have been

Table 1. A subset of the OCC cognitive structure of emotion

Consequential Disposition	Focus Object (self or other)	Consequences for Focus Object	Emotion
pleased	other	desirable	Happy For
pleased	other	undesirable	Pity
displeased	other	desirable	Resentment
displeased	other	undesirable	Gloating
pleased	self	relevant	Hope
pleased	self	irrelevant	*Joy*
displeased	self	relevant	Fear
displeased	self	irrelevant	Distress

implemented and evaluated for reasonableness in their simulation of emotions. Silverman, Cornwell & O'Brien (2003) report on progress towards an open agent architecture (PMFserv) to allow exploration of a range of human attributes, including emotions. The architecture has many similar structural components providing similar functionality to the EMAI architecture, but its application domains and integration efforts hinder experimentation and simulated scenarios have not been evaluated.

AN EMOTIONALLY INTELLIGENT AGENT ARCHITECTURE

The EMAI architecture (shown in Figure 1) is one example of recent emotional agent architectures. It is a complex set of mechanisms that process emotional concepts for their use in affective decision-making and reasoning. There are two types of emotion mechanisms integrated in the EMAI architecture. The first mechanism emulates fast primary emotions (Koestler, 1967) otherwise known as motivational drives. These drives can be classified according to their source, pleasure rating and strength. In an EMAI agent, these drives are used to initiate behaviour in the agent. They can include concepts such as hunger, fatigue or arousal. The strength of the drives is temporally dynamic and at particular threshold levels the agent will set goals, that when successfully achieved, will pacify the drives. For example, over time the strength of the hunger drive will increase. At a certain point, the agent will become so hungry that it will set appropriate goals to ensure it obtains food. On the consuming of food, the strength of the agent's hunger drive will decrease.

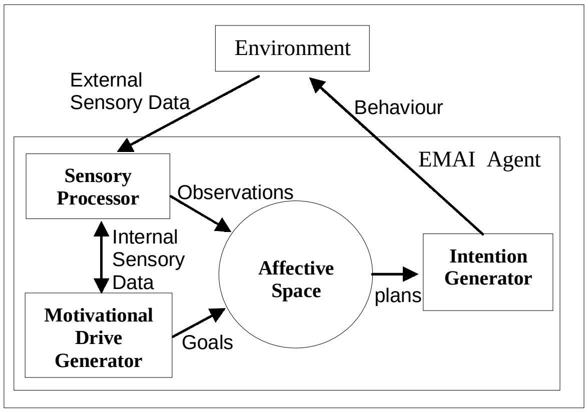
The agent's goals are generated by a motivational drive generator which consists of drive mechanisms and a set of internal state registers representing the primary emotions. Each register is represented by a single gauge and stores the value for a particular drive, for example hunger. The number of internal state registers implemented depends on the application for which the EMAI agent is being used.

The second type of emotion implemented in the EMAI architecture is secondary emotion. This category of emotion refers to the resultant mental (and in turn physical) states generated by attempts to satisfy the goals. These emotions include feelings such as happiness, anger, sorrow, guilt and boredom. Secondary emotions are represented in the EMAI architecture as values in an affective space.

The affective space is a six-dimensional space defined by six appraisal dimensions. The affective space, based on the psychological model of Smith and Ellsworth (1985), defines 15 emotions (happiness, sadness, anger, boredom, challenge, hope, fear, interest, contempt, disgust, frustration, surprise, pride, shame and guilt) with respect to the six dimensions of pleasantness, responsibility, effort, certainty, attention and control.

In addition to representing the agent's emotional state, the agent uses the affective space to associate emotions with all stimuli both internal to the agent (as internal sensory data) and within its environment (as external sensory data). The stimuli are perceived by the agent as part of an event. An event is a behavioral episode executed by the agent. Stimuli can be any tangible element in the agent's environment including the actions being performed, smells, objects, other agents, the time of day or even the weather.

Figure 1. Summary illustration of the EMAI architecture



The sensory processor of the agent is where high level observation takes place. This information is filtered through the affective space before it is used by the agent to generate outward behaviour (determined by the intention generator). It is at this point that the information has been perceived. Therefore, all information perceived by the agent is influenced by the agent's emotional state.

Before a stimulus or event can be perceived by the agent, the agent must calculate an associated emotion for each. The emotion associated with a stimulus is determined by examining each of the appraisal dimensions with respect to the agent's last encounter with the stimulus.

FUTURE TRENDS & KEY ISSUES

Synthesizing and modeling emotions is a complex task. Most affective computing research concentrates on specific, often single-dimensional aspects of generating emotions rather than adopting a holistic view or providing integrated solutions necessary to engineer emotional agents. Various key issues, problems and limitations remain for developers attempting to engineer emotional agents.

- **Emotion Range:** Although humans have a plethora of complex emotional states, research has found that viewers can best recognize six universal emotions, namely, sadness, anger, joy, fear, disgust and surprise (Ekman, Friesen & Ellsworth, 1972). Many current models simply represent these discrete emotions using levels that rise and fall as the agent's state changes. This is a simplistic view and fails to allow complex or mixed emotional states. Current models also lack the ability to maintain a temporally dynamic emotional experience with an environmental element be it an object or another agent. Humans can also express more ambiguous emotions such as pride combined with physical states such as tiredness; however, these are often interpreted in different ways by different people. Agent architectures must allow more flexible representations of emotions if modeling is to reflect reality.
- **Knowledge Representation:** An agent's knowledge representation should be deeply coupled with the knowledge-base rules. Emotions are often processed by a mechanism other than the inference engine, however it may be pertinent to include emotions in the rule-base and adjust inference engine processes to naturally handle emotion with the rules. This way emotion is a fully integrated part of the agent and can be better incorporated with the agent's knowledge and behavior allowing agents to revise their beliefs based on experience gained. Production rules usually associated with agent development (see, for example, Heylen et al., 2003) are not flexible enough for this level of knowledge representation. Contemporary affective agent architectures provide no means of attributing partial blame or credit for resulting emotions to individual elements that were part of an event. However, conceptual graphs have been shown by Baillie (2002) to provide the appropriate interrelated knowledge of goals and known concepts allowing agents to extrapolate to new situations that are related through its ontology.
- **Emotional State Combining and Decay:** The natural decrease in emotion strength or emotional decay in models is usually dealt with by using constant decay rate functions that act over time and require considerable programming and coordination effort. Baillie (2002) used the idea of a mood, represented by a point in an affective space, and modeled changing moods as movement from point to point in that space.
- **Feedback and Adaptation:** For humans, the experiencing of emotional states provides feedback that influences future behavior. Such a mechanism is not provided in many current agent architectures to the extent that it would allow an agent to adapt to its environment on an emotional basis. Extension of the relationships inherent in the Theory of Reasoned Action (Fishbein & Ajzen, 1975), viz., beliefs, assessments and intentions, or consideration of similar theoretical depictions of emotion synthesis is vital if agents are to show these traits.
- **Emotion Emergence:** Models that simulate or evaluate the emergence of emotion in an artificial agent are rare. Contemporary agent models do not apply emotional bias in decision making. While they do provide the means to generate agents with personalities and preprogrammed behaviors associated with differing dispositions, they do not allow the temporal changes in decision making considering emotions.
- **Common Standards:** The natural sciences domain is divided in its definitions and causes of emotion. This could also be a potential problem in the youthful area of affective computing where a plethora of models and theories have arisen. An emotional language standard is needed to gather efforts in the domain and continue the forward thrust in research.

Research on these issues and limitations and consideration of them by agent developers will influence the quality of engineered emotional agents and contribute significantly to the domains of affective computing and artificial intelligence. This will lead to improved affective agent architectures that integrate new approaches to emotion synthesis and affective decision making.

CONCLUSION

What the future holds for the field of affective computing is unclear. Although emotions have been thought to impede rational thinking they are now acknowledged as a vital part of rational intelligent behavior and necessary not only for survival, but also intellectual success. As affective computing is very much in its infancy, researchers need to continue to examine and assess the elementary concepts of emotion generation. No single theory stands out from the rest as being the ideal. The complexities of human emotions may be too extreme to include them holistically within an artificial intelligence at this time. Only those segments of emotional behaviour that are advantageous to the goals of an artificial being should be considered. Further categorization of emotional behaviours is necessary to identify domains where particular aspects of emotions are of advantage.

KEY TERMS

Affective Computing: A domain of computer science research combining fields such as Artificial Intelligence and Human Computer Interaction in the endeavor to develop computers that can recognize, express and have emotions.

Cognitive Appraisal Theory: The categorization of emotions through the evaluation of stimuli.

Emotion: A subjective response, accompanied by a physiological and behavioral change in an individual.

Emotion Blending: The determination of a final emotion being the result of several emotional states being experienced simultaneously an individual.

Emotion Synthesis: The process of representing emotions in computing devices using cognitive appraisal or other emotion classification theories.

Emotional State Decay: The rate at which the valence of an emotion decreases with time.

Valence: The strength of an experienced emotion.

Enhanced Knowledge Warehouse

Krzysztof Węcel

Witold Abramowicz
The Poznan University of Economics, Poland

Pawel Jan Kalczynski
University of Toledo, USA

INTRODUCTION

Enhanced knowledge warehouse (eKW) is an extension of the enhanced data warehouse (eDW) system (Abramowicz, 2002). eKW is a Web services-based system that allows the automatic filtering of information from the Web to the data warehouse and automatic retrieval through the data warehouse. Web services technology extends eKW beyond the organization. It makes the system open and allows utilization of external software components, thus enabling the creation of distributed applications.

The enhanced knowledge warehouse is an add-in to the existing data warehouse solutions that offers a possibility of extending legacy data-based information resources with processed information acquired from Web sources of business information.

eKW is characterized by transparent filtering and transparent retrieval. The system automatically acquires interesting documents from Web and internal sources and enables business users, who view data warehouse reports, to access these documents without the necessity of formulating any document retrieval queries. Instead, the system takes advantages of meta-information stored in business metadata and data warehouse reports, and builds and runs appropriate queries itself. The system also has an event-alerting capability.

eKW, by design, is a part of the semantic Web. The main role of eKW in the semantic Web is mediation between the world (external information) and internal information systems utilized within the organization. One of the most popular ways of conforming to semantics is to use ontologies, which provide a means for defining the concepts of the exchanged data. eKW is a kind of data mediator that employs ontologies as a conceptualization layer (W'cel, 2003).

BACKGROUND

Document management systems may be divided into two major categories: information retrieval (IR) and information filtering (IF) systems.

The classical models of information retrieval systems were defined by Salton (1983). As distinct from structured data management, information retrieval is imprecise and incomplete. This is due to the inaccurate representations of document contents and user information needs. The distinctive feature of information retrieval systems is a relatively constant document collection. The collection stores documents and their representations (indices). When a user submits a query to the information retrieval system, the query is compared against all indices in the collection. Documents whose indices match the query are returned as the resulting subset of the collection. Most search engines on the Web and digital libraries available on the market can serve as examples of information retrieval systems (Baeza-Yates, 1999).

The main objective of information filtering systems is to block unwanted information from the incoming stream of documents. As distinct from IR systems, filters do not have any fixed collection of documents. Instead, they hold a collection of standing queries (profiles). The profiles represent long-term information interests of their owners. When a new document arrives at the filter its representation is created and compared against all profiles in the collection. Some libraries maintain systems that inform users about new volumes included in the library. Such systems are usually based on the server-side filtering architectures and their profiles usually consist of semi-structured elements (e.g., author, subject, title). This idea is referred to as selective dissemination of information (SDI).

JUSTIFICATION

Possessing and maintaining large information resources does not itself provide any guarantees that users will manage to find the piece of information (document) they need. First of all, users must be aware that the particular piece of information already exists in their resources. Yet, even if they are aware, searching may be very labor consuming. Such a situation is highly undesirable for organizations, as they do not exploit their potentials to increase the effects. That is why knowledge management is nowadays considered the capability of re-use of information and is becoming an increasingly vital issue.

Usually, users are not eager to learn how to operate in several different information systems. Integration of information resources enables the exploitation of the capabilities of many systems through a single user interface (UI). Data warehouse users should be capable of finding interesting documents through a single UI. Not only should the users be aware that the desired information does exist, but also relevant documents should be disseminated to them mechanically. Such a mechanical distribution of the relevant information gives more time for other tasks.

Business users have certain problems with finding information sources, building correct retrieval queries and formulating proper filtering profiles. Thus, introducing the system capable of relieving the users from the necessity of formulating queries and solving the most commonly reported problems with accessing information on the Web would increase productivity of those seeking relevant external information.

The constantly growing number of content providers and the exploding volume of business information are not accompanied by the corresponding growth of capabilities of exploitation of the resources by the contemporary organizations. Therefore, automatic acquisition, organization and presentation of information became not only possible but also essential for the performance of today's businesses.

THE IDEA OF eKW

The term *data warehouse* was defined by Bill Inmon in 1992 as *a collection of integrated, subject-oriented databases to support the DSS function, where each unit of data is relevant to some moment in time*. Since then a rapid growth of this relatively new idea has been observed.

In the eKW model, Web documents are assumed to be business news published in English by major content providers on the Web (e.g., Reuters, Cnn.com), because this type of external information is the one in favor of business people (Abramowicz, 2000; Webber, 1999). The solution proposed is based on the existing standards in the area of data warehousing, document management, communication among software agents, internetworking and storage.

The basic idea of data warehousing is to create a data model common for the whole organization (metamodel). The model provides a framework for uploading legacy data, stored in heterogeneous databases across the organization, to the warehouse. Before data are uploaded they need transformation that includes filtering, consistency check, field mapping and aggregation.

Data warehouses proved to be useful for the purpose of legacy data analysis and they are commonly implemented by organizations. They provided novel data processing techniques like data mining, basket analysis, dimensional data analysis, drill-down, drill-through or slice-and-dice. These techniques are based on the characteristic features of data and information stored in the data warehouse: non-volatility, relevance to some moment in time (timeliness), correctness, consistency, completeness, business subject orientation, and business descriptions in metadata (Adelman, 1997; Kimball, 1996).

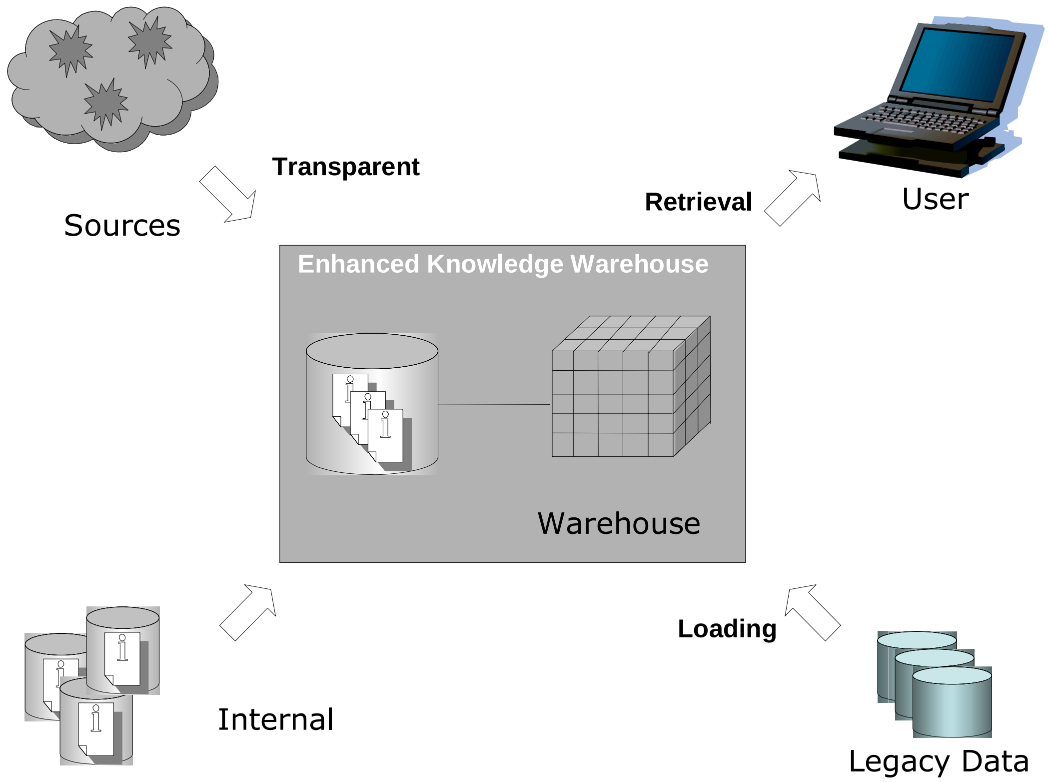
In terms of the data warehouse, metadata1 (warehouse metadata) are data about data. Metadata consist of facts and events concerning database objects. Metadata are usually stored in a database referred to as the metadata repository or the metadata collection. Nowadays, metadata are considered to be an integral part of the data warehouse (Gleason, 1997; Inmon, 1999).

Due to its destination and the sophisticated methods of data processing, the enterprise data warehouse is often claimed to be the corporate knowledge repository. However, we argue that information derived only from structured information (data) produced by the organization is just a fraction of corporate knowledge that may be stored in the repository.

As distinct from database systems, document management systems deal with unstructured and semi-structured information. Because machines are not capable of understanding text, they must rely on mathematical representations of the document content and user information needs.

The most distinctive feature of eKW is that information acquisition, organization and dissemination are performed without any additional actions taken by data warehouse users. In particular, no formulation of keyword-based queries is necessary to access external business news relevant to user information needs. Instead, the queries are formulated mechanically based on business metadata and information stored in the enterprise

Figure 1. Overview of the enhanced knowledge warehouse



data warehouse. The system mechanically collects external documents that are potentially interesting to users and stores them in the local collection. Business users who access corporate data are mechanically supplied with documents that match both the context of the data accessed and user interests at the same time. In this way users have easy access to relevant information resources acquired from outside the organization. These resources are being continuously extended and integrated with the data warehouse. In this way enhanced knowledge warehouse provides a framework for more effective (faster and based on more relevant information) decision making in the organization.

Based on the previous experience with augmenting documents and data, we decided to create a model that would relieve business users from the necessity of connecting to diverse and volatile sources on the Web, formulating queries, and browsing through the results. In order to do this, our system must be capable of mechanical information acquisition from Web sources, adding appropriate descriptions (indices) and precise information retrieval. The first two features imply a continuous series of actions, while the latter requires a trigger that makes the retrieval part of the system run.

The four arrows in Figure 1 represent main processes in the system. The process of loading legacy data to the data warehouse is a typical warehouse loading process defined by the organization. The process of loading internal documents is based on the principles of loading a digital library. In other words, there are two processes that distinguish the enhanced data warehouse model: transparent filtering (continuous) and transparent retrieval (spontaneous). The prefix "transparent" indicates that both processes are see-through for business users.

The enhanced knowledge warehouse is composed of the following Web services that can act independently:

a) Library Service, an implementation of data warehouse library
b) Profiling Service, responsible for data warehouse profiling
c) Filtering Service, responsible for retrieving business information from the Web utilizing filtering machine
d) Indexing Service, responsible for organizing the documents in DWL (Indexing parser)
e) Reporting Service, the front office of the system, responsible for delivering the results to the users.

FUTURE TRENDS

Although both document management and data warehousing systems are designed to supply business users with relevant information that is necessary to solve business problems, they are usually implemented and used separately. Most often, there is no system to store, organize and disseminate information published on the Web. This forces users, who need a broader view of business, to switch between data warehouse applications and content providers on the Web. The latter are usually overloaded with information, require navigation and formulating queries, entering passwords and flood users with commercials. Researchers report that the two most wanted attributes of external information sources are speed and convenience (Webber, 1999), whereas most sources cause frustration and discourage business users from taking any advantages of information available on the Web.

Therefore, the main future trend will be the integration of documents and data. In the eKW model, the problem of consistency of warehouse data and Web documents is addressed.

CONCLUSIONS

Enhanced knowledge warehouse model has certain advantages for business users over non-integrated solutions: instant/extended search, cross-organizational knowledge exchange, personalized event-alerting, and continuous information acquisition.

Because the amount of information produced by content providers on the Web is growing, it is impossible for a human user to process it in the traditional way. Web searches cause frustration, rarely lead to success and waste precious time. eKW was designed to help business people extend their knowledge about the organization by supplying them automatically with documents acquired from Web sources, relevant to their current context and information needs. Transparent filtering function mechanically collects documents potentially interesting to the organization, describes them with commonly accepted terms, and organizes them according to the existing business metadata. Transparent retrieval function supplies data warehouse users with documents relevant to their contexts and their personal interests in business information. The contexts are mechanically extracted from the state of the currently browsed report and personal needs are based on implicit feedback.

The enhanced knowledge warehouse system supplies business users with information based on the legacy data extended by information acquired from the business environment. This gives additional possibilities of business data analysis and provides a framework for better understanding of business processes related to the organization.

E

KEY TERMS

Common Semantic Layer: The ontology for eKW is implemented with common semantic layer (CSL). CSL is a relatively stable set of concepts (key words and phrases) with hierarchical and non-hierarchical relations utilized by the organization to describe information. A typical CSL consists mostly of proper names (e.g., products, shares, vendors or competitors). It is a foundation for building structures that facilitate the access to information resources (Abramowicz, 2001c).

Consistency of Warehouse Data and Web Documents: In order to introduce consistency among documents and data, data warehouse library must enjoy data warehouse features. Hence, documents are never removed from DWL; all documents are properly described with metadata and linked to data warehouse objects. There are four levels of consistency between DWL and DW that enable the eDW system to build retrieval queries: subject consistency, temporal consistency, semantic consistency and personalization. These four levels together provide constraints for sub-setting DWL and producing relatively small ranked lists of relevant documents associated with data warehouse reports.

Context Query: Context query represents the short-term user information needs. It is created each time a business user launches a data warehouse report. The context query consists of three parts: subject constraints, time constraints and semantic constraints. Subject constraints define the warehouse objects that are part of the report. Time constraints are represented by the actual time range grasped by the most current state of the report. Semantic constraints are represented as a set of CSL-based weighted keywords. The context query is executed on the data warehouse library and personalized results are immediately returned to the user.

Data Warehouse Library: The data warehouse library (DWL) is a repository of documents acquired from Web sources or located within the organizational intranet.

Apart from the contents, the repository stores additional metadata about the documents, mainly temporal and semantic indices. Basically, DWL is an extensive digital library (DL) and enjoys all capabilities of a typical information retrieval system. However, there are three distinctive features that make DWL something more than a typical DL: temporal indexing, CSL-based indices and direct links to warehouse business metadata. All these features provide novel possibilities of sub-setting the collection of documents to be searched and establishing links among documents and data.

Data Warehouse Profiling: Data warehouse profiling is a way of discovering the information needs of the data warehouse users. It is the first stage of the transparent filtering. The profiling action is triggered by a change in business metadata. The process results in a set of warehouse profiles that represent long-term information needs of data warehouse objects logically represented in metadata. It is assumed that warehouse profiles are transitive; that is, they represent information needs of users who utilize the objects while looking for information (Abramowicz, 2001a; W'cel, 2002).

Filtering Machine: Filtering is performed autonomously by a set of specialized source agents dispatched by the agent-based filter. The filter has access to the current warehouse profiles. It stores the list of sources subscribed to by the organization with their properties (Abramowicz, 2001). We introduced a new automatic navigation technique: information ants. The ant-like agents carry the warehouse profiles. New documents are parsed, indexed and matched with all profiles respectively. If a document matches the profile, it is downloaded and re-indexed in order to store it in DWL.

Indexing Parser: Because of the heterogeneous nature of Web documents, we argue that indexing must also be performed at the stage of parsing Web documents. Hence, each source agent has a built-in indexing parser capable of building a document representation (index) based on the internal structure and the content of a given Web document. Typically the hierarchy of tags is taken into account while building the document index. Another important part of the process is taking into account source-specific lists of stop words, thesauri and ontologies. Each resulting index consists of a weighted set of terms that occurred in the analyzed document. This format is a standard vector space model format that is commonly utilized in document filtering and retrieval.

Temporal Indexing: Extracting temporal references from documents (Llido, 2001), also referred to as temporal indexing or time indexing, aims at describing the content of textual documents with a set of time ranges (Abramowicz, 2001a; Kalczynski, 2002). The time ranges may be weighted. Time index is based not only on firm dates extracted from the content, but also on weaker references, like "next Monday," "last month" or "today," and inexplicit references such as tense operators "will," "was" or "is". Weaker references are resolved according to the date the document was published (reference date). The final outcome of temporal indexing is the time index associated with the document. The index consists of a finite number of non-overlapping weighted time ranges. Detailed description of the time indexer applied in the eKW system is given in Kalczynski (2003).

Transparent Filtering: Transparent filtering is a continuous process, transparent for business users, in which documents are acquired from Web sources and stored in the data warehouse library with appropriate descriptions. The principle of filtering is that documents are analyzed only once; hence only new documents are processed by the system. Transparent filtering can be further divided into profiling and filtering. Those two sub-processes are mutually independent.

Transparent Retrieval: Transparent retrieval is a spontaneous process triggered by data warehouse users each time they launch a data warehouse report. In this process the data warehouse library is mechanically searched for documents that match the current context of a given data warehouse report. The context is extracted from the report metadata and data. The ranked list of matching documents is compared against the user profile and presented to the business user as an extension of structured information displayed on the report.

ENDNOTE

Enhancing Competitiveness of B2B and B2C E-Commerce

Henry Aigbedo
Oakland Unversity, Michigan, USA

INTRODUCTION

A framework that is often used to describe the transformation of society relates to the percentage of people involved in or impacted by a given paradigm at some point in time. Even though some of these paradigms co-exist at a given point in time, one of them tends to dominate and exert considerable influence on the others. Several authors have described such evolution in different contexts. For example, Fitzsimmons and Fitzsimmons (2004) suggest that societies have undergone the following transformation, one leading to the next in succession: agrarian, manufacturing, service, and information. Since its introduction a little over a decade ago, the Internet, which exemplifies the leap into the information age, has had a profound impact on many areas of human endeavor, indeed, far more than had been imagined or anticipated. This impact on society is apparent through its widespread use in government, education, medicine, engineering, as well as in business. Considering the number of people involved and the dollar amount of sales transacted over the Internet, it seems reasonable to infer that it has had the greatest impact in business during the past millennium. The Internet continues to play a significant role in making enterprises to be more competitive.

The progression of the information age is underscored by projections about its growth and impact on the economies of many countries. For example, Forrester and Gartner research groups project unprecedented growth in Internet-related business transactions globally in the coming years. In particular, Gartner estimated that worldwide B2B e-commerce will surpass 7.3 trillion dollars by 2004 (Noyce, 2002). It is interesting to observe that the order of growth in electronic transactions is similar to the projected growth in computer processing speed. Further, technological advancements in the computer and communication industries have led to reduced prices of computers and Internet service, respectively. These developments are playing a significant role in facilitating the use of the Internet for commerce. For example, several polls indicate that more than half of Americans own personal computers. While not all people who own computers have Internet connectivity at home, many gain access through secondary means such as public libraries and work computers. University of California Los Angeles (UCLA) Internet-related studies indicate that over 70% of Americans are online (Lebo & Wolpert, 2004; UCLA, 2001). Also, Barnes (2003) reports that, as of fall 2002, estimates for people around the world who use the Internet were about 600 million, about 10 percent of the world population.

This article discusses how firms are using Business-to-Business (B2B) and Business-to-Consumer (B2C) e-commerce strategies to gain competitive advantage. Several related initiatives that firms can avail themselves of in order to be more effective will also be briefly examined. The article is organized as follows. First, we provide some background by describing some issues that have been identified in the literature concerning the subject. Next, we discuss the importance of B2B and B2C e-commerce to firms and their clientele. We then examine the future of B2B and B2C e-commerce initiatives as potent weapons and how they should be deployed to foster success. Finally, we summarize and conclude with our final thoughts on B2B and B2C e-commerce.

BACKGROUND

Several models of electronic commerce have been developed to represent or formalize the various practices of various entities (Aigbedo, 2004; Barua, Prabhudev, Winston, & Yin, 2001; Mahadevan, 2000). Also, Kaplan and Sawhney (2000) present a two-by-two matrix that describes activities among businesses along two dimensions: “What businesses buy” (operating inputs or manufacturing inputs) and “How businesses buy” (systematic sourcing or spot sourcing). Under this classification scheme, Internet exchanges such as e-STEEL fall within the manufacturing inputs/spot sourcing quadrant.

From a definitional perspective, electronic commerce includes Internet-based and non-Internet-based means of transmitting business information. However, we restrict our discussion to Internet-based e-commerce because of its ubiquity and potential for growth in the coming years. The principal users of Internet-based e-commerce can be classified as Consumers, Businesses, and Governments, with interactions occurring among pairs of these classes or between a class and its like. The two major areas that have experienced the most growth and that are projected to capture a significant proportion of Internet use for commerce are Business-to-Business (B2B) and Business-to-Consumer (B2C) e-commerce. Now let us see two examples of these transactions. When an Original Equipment Manufacturer places orders for parts from its suppliers through the supplier's Web site, the parties are engaged in B2B e-commerce. On the other hand, when a consumer purchases a book through an online bookstore such as Barnes and Nobles' Web site, the interaction between this customer and the company is B2C e-commerce.

Amazon.com was one of the firms that blazed the trail in e-commerce, in general, and B2C e-commerce, in particular, by selling books through its Web site. Since its inception, it has expanded its offerings to include a wide variety of items such as compact disks, electronic appliances, apparel, and accessories. Following Amazon's success, many "brick-and-mortar" firms have either fully or partially transferred their operations online. For example, Wal-Mart, the retail giant, now also offers for sale through its Web site many items that it sells through its conventional stores (Wal-Mart, 2004) Also, the Internet has greatly facilitated Dell Computer's direct business model, which entails sale of computers directly to consumers, as the company generates a significant proportion of its sales through its Web site. In 1999, Dell Computer earned over 1 billion dollars through its B2C e-commerce initiative (Chopra & Van Mieghem, 2000).

So far, B2C e-commerce appears to have had the greatest impact from the point of view of the number of people directly affected. However, as Kenjale and Phatak (2003), for example, observe, B2B e-commerce has a greater potential as far as number of transactions and dollar volumes are concerned. A case in point is DaimlerChrysler's 2001 purchase of highly engineered parts for two future car models through Covisint for more than 3 billion dollars under a B2B reverse auction framework (Konicki, 2001).

From the foregoing discussions, it would seem that it is only well-known, large corporations that are engaged in e-commerce. However, this is not the case, as many companies, including small ones, are transforming part or all of their operations to the virtual environment. Chen, Haney, Pandzik, Spigarelli, and Jesseman (2003) report on the initiatives taken by a small firm in implementing e-commerce. They also describe some critical success factors that need to be followed by such companies. These include gradual transformation into e-commerce (especially considering cost implications and unavailability of technical expertise in small firms), proper allocation of resources, outsourcing of critical startup services, modification of business practices, collection and analysis of customer-related data to help monitor buying patterns, thus facilitating promotions and better service offerings.

Just as understanding consumer behavior has been the focus of traditional marketing research for decades, it is extremely important to understand it in the context of e-commerce as well. By synthesizing several published work in this respect, Saeed, Hwang, and Yi (2003) proposed an integrative framework for understanding the basic factors that influence customer behavior in e-commerce environments. They identified four predictor variables: system quality (relates primarily to web design and technological features that facilitate the customer's shopping experience), information quality (relates primarily to content accuracy, relevance, and reliability), service quality (relates to the customer's perceptions of the experience), and vendor and channel characteristics (e.g., size and reputation).

B2B E-COMMERCE INITIATIVES

Companies are finding the Internet a very useful tool for facilitating transactions among themselves. It is gradually replacing traditional methods such as facsimile and Electronic Data Interchange (EDI). Although B2C applications spurred the use of the Internet for commerce, a far greater volume of transactions occurs among companies. There is much more to transactions among companies than simply buying and selling, which are central to B2C applications. Customer relationship management, exchange of product and production-related information, and collaboration in product design and development are some of the areas where B2B e-commerce is deployed. More and more companies now understand that they have reached their limits in terms of improvements in performance and profits that they can achieve by themselves. Therefore, in recent years we have seen increased emphasis on supply chain management, as companies seek to work more closely with their partners on the downstream side of the chain (towards the customer) and the upstream side of the chain (towards the parts suppliers). In the retail industry, for example, Wal-Mart's tremendous success in pursuing its low-cost strategy is due largely to its supply chain initiatives that provide for effective exchange of information among its distribution centers, the manufacturers, and its stores, in relaying real-time demand information. Dell Computer has also achieved similar success by building powerful links with its suppliers, thus creating what is generally referred to as the virtual supply chain, characterized by virtual integration between Dell and its partners. Based on the results of a study of ten companies in Australia, Power and Sohal (2002) discuss the firms' perspectives on the benefits of e-commerce to their operations. Tangible benefits included reduction of finished goods and work-in-process inventories, increased flexibility, and overall cost reductions. Some intangible benefits were also identified that included the ability to promote improvement in various operations with their business partners.

In recent years, there has been a move in certain industries to form Internet exchanges – virtual locations on the Internet where buyers and sellers meet to exchange information and carry out transactions. A classic example is Covisint, the automotive exchange formed a couple of years ago by the "Big Three" US automotive companies and Nissan, Renault, Commerce One, and Oracle. In addition to the fact that this arrangement provides visibility to both buyers and sellers, it has facilitated auctions and reverse auctions of products or capacity. As noted above, DaimlerChrysler spent more than 3 billion dollars to purchase parts for two future car models through Covisint. (Konicki, 2001). Industry experts are increasingly recognizing how important it is for exchanges to provide sustainable value propositions to their members—value that transcends only technological offerings. Indeed, exchanges that have thrived so far (e.g., Pantelos Group for the utility and energy industry in the United States and Worldwide Retail Exchange) have put mechanisms in place that facilitate this laudable objective (Ulfelder, 2004). Volkswagen is also following suit with the exchange it has established to streamline processes with its numerous suppliers (Hofmann, Sloan, & Malykhina, 2004).

As of now, there is no general agreement about how these exchanges will evolve over the next couple of years. For example, Wise and Morrison (2000) had argued that competitive bidding practice, which places emphasis only on price, does not account for many other important factors such as quality, delivery speed, and customization, in certain manufacturing environments. Furthermore, such arrangements often offer little benefits to the suppliers (Aigbedo & Tanniru, 2002; Wise & Morison, 2000). Talluri and Ragatz (2004) discuss various types of auction arrangements that can be used to facilitate B2B e-commerce, and they propose an Analytical Hierarchy Process (AHP) framework for practical application of the concepts when auction is based on multiple attributes such as price, quality, and flexibility. On the other hand, Wyld (2002) used recent data compiled by the Institute of Supply Management (ISM) to analyze the state of industry in the application of the Internet for procurement. He observes that there has been steady growth, especially in the use of the Internet to procure indirect goods and services. Other areas of use emerging from that study included identification of new suppliers and collaboration with suppliers.

Although not all companies use the Internet as the medium to coordinate with their partners, the enhanced information flow that the Internet provides has several benefits. This includes reduced cost of modification of product and pricing information, since a central system such as an exchange can make the same information available to all parties at the same time without the need for duplication. Furthermore, the hub-and-spoke connection that a central system provides reduces linkage costs, as only one link needs to be made each time a new member is included in the supply network. This will result in savings in setup and maintenance costs. Increased visibility that is enabled by the Internet is very crucial for environments where product mixes change very rapidly; examples include fashion goods, electronic equipment such as computers, and automobiles. The Internet helps substitute information for inventory, thus reducing operational costs. This visibility also reduces or eliminates the "bullwhip effect" (upstream amplification of demand requirements) in supply chains. The bullwhip phenomenon, which has begun to gain attention lately, results mainly from information asymmetry among companies in the successive stages of the supply chain.

B2C E-COMMERCE INITIATIVES

The airline industry is a major sector that has seen tremendous growth in B2C e-commerce. Most would-be passengers now purchase airline tickets online. Some airlines offer better prices or provide incentives to customers purchasing tickets online as compared to those purchasing through their sales representatives (Southwest Airlines, 2004). Recently, airlines such as Northwest Airlines have even gone as far as making it possible for customers to print their boarding passes from the airline's Web site, thus saving on check-in time at the airport. Other sectors that have experienced the benefits of B2C e-commerce include the hospitality industry (Carroll & Siguaw, 2003), the mail-delivery industry such as Federal Express, United Parcel Service, and the United

States Postal Service, the print media (Rose, 2003), and the retail industry (Karp, 2003; Merrick, 2003).

B2C e-commerce provides value propositions to customers as well as the companies engaged in it. Among other things, it offers customers the opportunity of comparing features and prices and purchasing items from the comfort of their own homes. In addition to vast savings that can be realized in operational costs, this provides a company with the opportunity to reach a very large customer base. Furthermore, it reduces errors that could arise from multiple handling of data and provides a convenient way of aggregating and analyzing customer-related information. One novel way companies started using e-commerce initiatives to improve their profits is working with online companies to aggregate service offerings in the form of packages that would be more attractive to customers. For example, Marriot Hotel chains recently entered into such an agreement with Expedia and Hotels.com (Binkley, 2004).

The above examples may seem to suggest that e-commerce initiatives are always successful. However, this is not the case as shown by the failure and subsequent bankruptcy of Webvan (an online grocer) in 2001. Among other things, Starr (2003) analyzed the operations of Webvan over a three-year period, 1998-2000, and sought to understand the reasons for Webvan's failure and whether or not it could have been averted. He observes that Webvan relied too much on its technological prowess without adequately assessing operational factors, including inventory-related issues for their short-lifespan products. This result corroborates Porter's (2001) assertion that it is extremely important for firms to perform adequate groundwork, as the use of the Internet does not obviate the need for sound business models.

THE FUTURE OF B2B AND B2C E-COMMERCE

Just as it is with the adoption of any new technology or method of operation, e-commerce has had its challenges, failures, and successes. Since 2000, we have seen the demise of many dot.com companies that proved to be unviable. Many others are learning from mistakes they made in the past, and others are waxing stronger by appropriately positioning themselves and adopting strategies that are consistent with the dynamic nature of the business environment.

Further, one important issue that needs to be borne in mind is that the Internet and the e-commerce technology that comes along with it are simply tools. Porter (2001) aptly describes this issue by observing that moving over to the Internet to transact business should not replace sound business principles. In other words, doing so would simply amount to transferring the problems of the system into a virtual environment. In a similar light, Kendall (2003) discusses the importance of planning in making e-commerce initiatives successful. This can be especially important when one understands that the Internet, by virtue of its ubiquity, essentially lowers the barrier to entry for firms in many industries. Thus, while it is true that the Internet potentially provides some operational advantages, the key for any firm is not just the use of the Internet, but how to use it in innovative ways, thus creating distinctive competency.

The above no doubt underscores the need for firms to spend a considerable amount of time in developing suitable business models that will yield significant value propositions and that are operationally effective and efficient before implementing them. Adequate market research to assess potential for viability, as well as performing appropriate simulation studies, where applicable, will certainly prove to be very invaluable in this respect.

One of the key issues that will increasingly become important in B2B e-commerce is effective coordination among various firms in the supply chain. Coordination here means information sharing and visibility relating to the spectrum of individual and inter-firm activities. While there have been advances in this area over the past couple of years, with firms such as Dell Computer leading the way with virtual integration, there is still a lot that can be done in many other industries such as the automotive industry. Information can be used to replace inventory thus enabling the firms in the supply chain to maintain the appropriate amounts of inventory at the appropriate locations. A major area of difficulty in some industries, especially the automotive industry, is that of trust among the partners. In some cases, shared information has been used in a detrimental way by partnering firms to leverage their competitive position or when asking for price concessions. Still along this line, the formation of consortium exchanges by firms in certain industries (such as Covisint in the automotive industry) is useful. However, there is need for them to be more proactive in articulating the value that all participants (especially low leverage participants such as suppliers) stand to gain. Otherwise, many supplier firms will be reluctant to participate, thus negatively impacting the benefit to the entire supply chain.

More than ever, quality management will play a very vital role in the success of B2C e-commerce in the coming years. For example, amidst the many firms providing similar products over the Internet and the numerous brick-and-mortar competitors, a company will need to pay particular attention to on-time delivery and e-fulfillment.

Although the customer is aware that there is need for trade-off between convenience and delivery time offered by an e-tailer (retailer who operates using the Web and Internet technology), a company needs to make the necessary efforts to ensure that the difference is not so much as to outweigh the advantages. Particular attention should be given to building partnerships with efficient logistic firms and designing effective inventory management systems. Depending on the circumstances, it may even be more cost-effective for a firm to partner with local stores as outlets, requiring the customer to "complete the last mile" of the transaction by going to pick up the items (Lee & Whang, 2001). This phenomenon is sometimes referred to as a "click-and-mortar" framework.

Another important issue is how an e-tailer presents information to would-be customers on its Web site. Just as proper layout of facilities is important in a brick-and-mortar setting, it is essential that would-be customers have little difficulty locating the items they want to purchase. Furthermore, procedures relating to purchase transactions (such as shipping costs and return policies) need to be clearly indicated and appropriately placed on the Web site, otherwise it could lead to customer dissatisfaction, which will have serious negative impact on the firm.

The process of tracking customer or prospective customer behavior in e-commerce transactions has continued to receive attention (Moe & Fader, 2001). Not all customers who visit a company's Web site or check on a product eventually make purchases. Effectively forecasting demand for a given product or related products has continued to be a daunting endeavor. Development of sophisticated data-mining techniques, coupled with their integration with forecasting techniques, should lead to better forecasting, thus enabling a firm to respond faster, without having to hold excessive amounts of items in inventory.

B2B and B2C companies need to be increasingly vigilant in the area of Internet security, as recent events has shown substantial losses incurred by many firms due to the activities of miscreants. Investments in appropriate technology, proper training of personnel, and constant monitoring of these systems will go a long way in preserving them so they can perform as desired. Heightened interest in the development and deployment of intrusion-detection devices for addressing these issues is an important step in this direction (Richmond, 2002).

CONCLUSION

The significant growth that has been experienced in B2B and B2C e-commerce in recent years suggests great potential for continued growth in the coming years. Many companies have now introduced, to varying degrees, the use of the Internet for commerce, and several studies have indicated that many more are following suit. However, it is important for managers to recognize that the Internet is primarily a means to facilitate business transactions, and by no means does it obviate the need to develop and operate models that are based on sound business principles. In the B2B e-commerce arena, special attention needs to be accorded to effective coordination across the supply chain, appropriately replacing inventory with information in ways that will lead to better value for the entire supply chain. Firms involved in B2C e-commerce should especially pay attention to quality of services to their customers, especially as it pertains to fulfillment of their needs. Furthermore, the issue of Internet security needs to be given high priority, as it appears to pose the most serious threat to success of e-commerce operations.

KEY TERMS

B2B E-Commerce: Business-to-Business (B2B) e-commerce is transaction that occurs between and among firms that are related to the procurements of goods and/or services through electronic medium. The typical medium of transaction is the Internet and World Wide Web.

B2C E-Commerce: Business-to-Consumer (B2C) e-commerce is transaction that occurs between a firm and individual consumer or user of the firm's goods and/or services through electronic medium. The typical medium of transaction is the Internet and World Wide Web.

Brick-and-Mortar: Operations that take place in conventional off-line settings as opposed to those that take place online. For example, offering items for sale at a conventional store as opposed to selling them online.

Bullwhip Effect: Demand amplification from its source across the supply chain. This is largely caused by information asymmetry among the entities in the supply chain.

Click-and-Mortar: A firm that operates both online and off-line or a hybrid operation that requires a combination of online and off-line aspects to complete a transaction. For example, a company offers items for sale online and requires that the customers pick up the items from a nearby store.

Consortium Exchange: A group formed by companies in the same industry, bringing their supply chains together for the purpose of facilitating transactions among themselves over the Internet.

E-Fulfillment: A company meets the needs of its customers with whom it carries out some transactions through the Internet. It is most often associated with B2C e-commerce.

Internet Security: The phenomenon by which a company assures that its data and entire Internet infrastructure are protected from damage caused by miscreants through activities such as hacking.

Original Equipment Manufacturer (OEM): A company that manufactures the main equipment or product that is used by the final consumer. An OEM can be considered as the core or focal organization that bridges the supply side and the demand side of the full supply chain linking all the way from the raw materials to the final consumer.

Supply Chain: A network of companies interacting among themselves with the ultimate aim of providing needed goods and/or services to the final consumer. Three main items that flow among the entities are goods/services, information, and funds.

Virtual Supply Chain: A supply chain with little or no ownership bond, but so closely linked together and operations very well coordinated as though the various entities in the chain were all part of the same company.

Enhancing Workplaces with Constructive Online Recreation

Jo Ann Oravec
University of Wisconsin-Whitewater, USA

INTRODUCTION

Organizations have become more permeable— integrating more influences from the outside world— as participants engage in such online diversions as trading stocks, engaging in multiplayer games, or viewing images of their children in daycare. Ready availability of these activities has brought the potential for abuse but also new opportunities. Constructive uses of online recreation and play can enhance many workplaces (especially high-tech and information-saturated ones) and perhaps ultimately make them more productive. This article proposes that these complex issues be resolved through participatory approaches, involving workgroups in discussions as to what constitutes "constructive recreation" as well as in development and dissemination of effective and fair policies. This discourse can also ultimately increase levels of trust among team members and between employees and management.

BACKGROUND

Issues concerning the boundaries between work and play have provided continuing struggles for managers and employees. Workplaces have become more "porous" and permeable— integrating more influences from the outside world— as individuals engage in such online diversions as trading stocks, playing games, or viewing images of their children in daycare. Everyday workplace life is becoming more diverse and chaotic. Although many organizational roles today demand high levels of creativity and mental flexibility, they can also fail to provide the means through which individuals can gain fresh perspectives. In the "information age," playful, exploratory, and spontaneous interaction can also facilitate the exchange of ideas for tackling workplace problems. Managers who expect employees not to use the Internet for some amount of off-task activity severely misjudge the nature of workplace life— which is solidly infused in online interaction. Depriving employees of opportunities for Internet recreation in some cases excludes the possibility of nearly any form of diversion from assigned responsibilities.

Workplace use of the Internet for activities that are not directly authorized by management is often considered as the "theft" of human and computer resources, while construed as a just reward by employees (Lim, 2002). Even though many managers consider the personal use of the Internet as an ethical lapse (Greengard, 2000), the "moral high ground" concerning these issues is not entirely clear. Much of the rhetoric and advertising copy associated with workplace computing incorporates recreational imageries and motifs, which can send misleading signals to employees. A number of individuals have already had significant experience combining work with online recreation; convincing them that hard work cannot be combined with online play is thus a tough sell. Telecommuters returning to organizational settings are often not entrusted with the autonomy to engage in online breaks at appropriate times— latitude they take for granted when doing the same tasks in their home offices. Many young people became comfortable with computing through video games and online interpersonal interaction and took online breaks during their demanding college studies (Colkin & George, 2002). Individuals must find ways to cope psychologically with increased pressures on the job (Weil & Rosen, 1997) and management should explore creative but feasible ways to assist them in these efforts.

Wireless Internet applications add more complexities, further increasing the porousness of organizations and making employees' access to recreation less dependent on systems controlled by their managers. Daniels (2000) reports how wireless technologies (such as PDAs with Internet access) are used within meetings to amuse and distract participants, often resulting in productivity losses. Since wireless technologies are still in the early stages of adoption in many organizational contexts, placing severe restrictions on their use (and penalties for misuse) could be counter-productive. Personal computers became familiar workplace additions in the 1980s in part because of their use for gaming, an activity that encouraged employees of a variety of ages and backgrounds to explore the various dimensions of the devices and to become more comfortable with them.

If engaged in constructively, online recreation can aid in awakening creativity and increasing wellbeing, just as appropriate and timely face-to-face diversions have restored employees' energies over the past decades. However, some individuals may not be able to deal with online recreation constructively. They indeed will use it in ways that affect their organizations and themselves negatively, just as some individuals cannot perform adequately on the job for other reasons. Forms of "positive discipline" can be utilized if employees choose to exceed reasonable, agreed-upon limits; implementing such discipline "requires that the supervisor and employee work together to correct the problem behavior" (Guffey & Helms, 2001). Managers and employees should strive together to harness online recreation toward positive ends, rather than condemning or seeking to stifle it completely.

WHAT IS "CONSTRUCTIVE RECREATION"?

Online recreation has already served many supportive purposes in organizations; games can be used to help decrease computer anxiety as well as encourage experimentation and the early stages of learning (Kendall & Webster, 1997; Oravec, 1999; Webster & Martocchio, 1992). What would make online recreation optimally beneficial to individuals, project teams, and the organization as a whole? To start the discussion: recreation is "constructive" when it is in synch with pending work responsibilities, allowing individuals to use time not consumed by workplace demands in ways that equip them to face future tasks with greater energy and expanded perspectives. Constructive recreation is also in keeping with technological constraints, as exemplified by the organizations that allow online recreation but place limits during certain hours to avoid system overload (Verton, 2000). Policies established are developed in participatory ways, and are disseminated broadly. Constructing ways of assigning tasks and evaluating employees so that significant and meaningful measures of productivity are involved can lessen an emphasis on the "surface" behavior of employees. Other characteristics of constructive recreation initiatives include:

- ***fostering flexibility:*** A major impetus behind constructive recreation initiatives is facilitating the rapid adaptation of individuals to changing circumstances. Constructive recreation affords individuals the means to maintain their flexibility in workplace environments that place increasing demands on their capacities to withstand change.
- ***manifesting sensitivity to cultural concerns:*** Workplace recreation is also "constructive" to the extent in which it is responsive to the overall culture of the organization and sensitive to the needs and values of other organizational participants (including freedom from harassment). Requirements of project team members in terms of scheduling are especially critical to recognize since the synchronization and sustained involvement of everyone are required during critical periods.
- ***providing stimulation and refreshment:*** Along with its other aspects, recreation is constructive if it provides intellectual and psychological stimulation or support, the sustenance often needed to take on tough challenges. "Reclaimed moments" that individuals spend in such activity can allow them to reestablish senses of control in otherwise stressful and constraining contexts. Ability to access such recreation and thus momentarily escape can provide a safety valve for those who face unyielding situations or put in long work hours, thus putting the porousness of today's Internet-supported workplaces to good use.

FUTURE TRENDS

The value of recreation and play in adult realms is not well understood. Play has been given an assortment of definitions in the academic and research literatures (with examinations in the fields of social psychology, philosophy, and anthropology); it is often considered in both its adult and child modes as a "cognitive and symbolic act that is fundamental to the human representational process" (Myers, 1999). Across species as well as cultures, play has been shown to help individuals prepare for the unexpected by presenting varying streams of novel or challenging situations (Spinka, 2001). Play is generally considered as a support for children's intellectual and social development, but its role in adult lives is less clear. Research initiatives on what kinds of recreation and play are most efficacious in different workplace environments—as well as on individual and group "play styles"—could enlighten constructive recreation efforts (although they cannot be expected to provide definitive results).

Simulation is indeed an aspect of play that has some direct implications for employee readiness in the workplace, and it has received some research treatment (Myers, 1999). Michael Schrage's (1999) *Serious Play* examines how simulations expand the intellectual capacities of knowledge workers; forms of online play may equip individuals to utilize an organization's "serious" computer simulations more effectively, thus reinforcing skills applicable in many workplace contexts. Many powerful simulation games with societal or political themes are widely available to the public and have considerable audiences;

the Sims series and other popular single- and multiplayer games have been used to entertain and educate in a variety of contexts (Pillay, Brownlee & Wilss, 1999).

Constructive recreation initiatives will also be a part of many organizational efforts to build cohesion. Managers have often used organizationally sanctioned recreation as a perquisite, a bonus for acceptable conduct. It has served as an extension of the workplace, providing a form of "social capital" (part of the "glue" that holds the at-work community together). Through the past century, many organizations have sponsored picnics and celebrations with the strategy of increasing workplace cohesion (Putnam, 2000).

As employees (including many white collar as well as knowledge workers) telecommute or put in long and irregular hours, the adhesive that binds organizations has been increasingly conveyed through electronic channels. However, it is unclear what kinds of online activity can foster social capital (Uslaner, 2000). Just as human resource experts struggled early in the twentieth century to integrate face-to-face recreation into workplace contexts, organizations should attempt similar feats in online realms, thus making online recreation a shared and open resource rather than a secretive endeavor. Unlike many early human relations experiments, the recreational activities involved should be developed in a participatory (rather than patriarchal) fashion. Whether organization-approved fantasy football, discussion group and collaborative filtering forums, joke-of-the-day contests, or other recreations are ultimately successful will depend on how they fit into everyday working experiences.

CONCLUSION

Can we indeed construct a "level playing field"? As workplaces have evolved, so have the issues that have divided employers and managers. Conflict has ensued for decades on an assortment of matters relating to the quality of worklife, often leading to dysfunctional confrontations. Today, employees who guess wrong about online recreation standards— or choose to violate them— often pay large penalties, even being demoted or fired. Some managers have devised negative sanctions for these infringements far more severe than those applied to comparable face-to-face interaction. Office workers paging through paper catalogues in idle minutes rarely face the harsh penalties that those caught shopping online often encounter.

Hard-line positions against forms of online recreation may be required in some instances and directly related to important organizational goals. For instance, air traffic controllers should be expected to keep focused on landing real airplanes rather than escape into fantasy games during assigned hours. However, some hard-line restrictions can reflect fear or lack of understanding of online realms. Management may assume that online recreation will foster or encourage Internet addiction or related concerns. "Internet addiction" has become a widely identified syndrome, although its medical underpinnings are still in question (Beard, 2002; Oravec, 1996, 2000).

Ambiguities concerning online work and play in virtual realms are increasingly adding complexities to these issues (Broadfoot, 2001). It is often difficult to tell which Web sites are related to business needs and which are recreational; many have dual purposes, combining amusement with news and other serious pursuits. Slashdot.org has humorous material as well as valuable technical commentary, and abcnews.com has stories on upcoming movies as well as current economic results. Helpful intelligent agents (some with cartoon-like manifestations) can add levity to everyday tasks. Surfing the Internet for an answer to a question or fiddling with various programs can interfere with productive effort, as individuals dwell on technological nuances. Managers and employees need to deal not only with recreational concerns but also with broader issues of how to integrate computing into workplaces in ways that are engaging yet productive. However, online recreation should not be exploited as a means to keep individuals glued to workstations for indefinite periods in lieu of reasonable work schedules and functional work-life balances.

Solutions as to how to couple online work and play are emerging in organizations that are tailored to specific workplace contexts. Managers and employees are gaining important experience in resolving these issues as individuals perform activities away from direct supervision via mobile computing or virtual office configurations. Managers are learning how to perform their functions without direct employee surveillance. Employees are learning higher levels of self-discipline and the skills of balancing on-line work and play— just as they have learned to balance face-to-face schmoozing with task orientation in the physical world. Thus setting severe restrictions on online recreation can serve to slow down the process of understanding how to migrate the organization into virtual realms and establish trust. Responsibility and respect for others in these realms can be difficult to acquire, and many employees will indeed need direction.

Allowing for reasonable and humane amounts of online recreation can indeed have considerable advantages, both for the individuals involved and the organization as a whole. It can serve to open blocked creative channels and possibly relieve stress as well. Online recreation can also extend the limits of individuals' working days by providing extra dimensions to workplace activity.

Rather than going through the emotional labor of looking busy, employees can utilize spare moments on the job in recharging their mental batteries. Constructive use of recreation will require a number of changes, such as increases in managerial flexibility and employee empowerment (Boswell, Moynihan, Roehling & Cavanaugh, 2001; Kanter, 2002). Organizational participants must learn how to handle the distractions and opportunities of increasingly porous workplaces, with their many external influences. Education and training can be useful in these initiatives: novice employees can be aided to couple work and recreation in ways that increase overall effectiveness. Constructive recreation strategies can bring these complex matters into the open, rather than allow them to be objects of rumor and fear.

Forms of online diversion are already becoming integral elements of everyday workplace life, often serving to humanize and enhance organizations. Negotiation and discourse on constructive recreation issues can increase mutual trust and respect concerning online as well as face-to-face activity. With effort on everyone's part, the constructive use of online recreation can help the entire organization work harder and play harder.

KEY TERMS

Flexible Workplace: Organizational settings that can quickly take external and internal changes into account in their processes.

Internet Addiction: Use of the Internet and network resources that undermines the fulfillment of some of an individual's basic human needs.

Organizational Policies: Openly-stated, officially-sanctioned rules for organizational resource usage and other kinds of organization-related conduct.

Participatory Management: Management in which the input of employees as well as managers is thoughtfully taken into account in setting organizational policies and developing organizational structures.

Play: Activities in which individuals and groups engage that stimulate various aspects of personal and social functioning without necessarily being related to particular utilitarian outcomes.

Simulation Games: Games in which important aspects of a system are modeled so that game participants can engage in activities and deal with events that are comparable to those that system participants would encounter.

Social Capital: Social closeness, mutual knowledge, and cohesion that are a product of a wide assortment of different kinds of informal, volunteer, and partially-structured social interactions.

Enterprise Resource Planning and Integration

Karl Kurbel
European University Viadrina Frankfurt (Oder), Germany

INTRODUCTION

Enterprise resource planning (ERP) is a state-of-the-art approach to running organizations with the help of comprehensive information systems, providing support for key business processes and more general, for electronic business (e-business). ERP has evolved from earlier approaches, in particular, materials requirement planning (MRP) and manufacturing resource planning (called MRP II) in the 1980s.

The focus of MRP and MRP II was on manufacturing firms. The essential problem that MRP attacked was to determine suitable quantities of all parts and materials needed to produce a given master production schedule (also called a "production program"), plus the dates and times when those quantities had to be available. Application packages for MRP have been available from the 1960s on. In the beginning, they were mostly provided by hardware vendors like IBM, Honeywell Bull, Digital Equipment, Siemens, etc.

MRP was later expanded to *closed-loop MRP* to include capacity planning, shop floor control, and purchasing, because as Oliver Wight (1884) puts it: "Knowing what material was needed was fine, but if the capacity wasn't available, the proper material couldn't be produced" (p. 48).

The next step in the evolution was *MRP II (manufacturing resource planning)*. According to the father of MRP II, Oliver Wight, top management involvement in the planning is indispensable. Therefore, MRP II expands closed-loop MRP "to include the financial numbers that management needs to run the business and a simulation capability" (Wight, 1984, p. 54).

Enterprise resource planning (ERP) has its roots in the earlier MRP II concepts, but it extends those concepts substantially into two directions. ERP takes into account that other types of enterprises than those producing physical goods need comprehensive information system (IS) support as well, and even in the manufacturing industry, there are more areas than those directly related to the production of goods that are critical for the success of a business.

BACKGROUND OF ERP: THE NEED FOR INTEGRATION

The key issue of ERP is integration (Langenwalter, 1999). Whereas stand-alone solutions—sometimes sophisticated information systems for various areas of a business—have been available before, ERP takes an holistic approach. Instead of isolated views—on procurement, on manufacturing, on sales and distribution, on accounting, etc.—the focus is now on integrating those functional areas (Scheer & Habermann, 2000).

The need for integrated systems has been recognized by many, but Germany-based SAP AG was the first to put them into reality. SAP's early success as worldwide market leader comes largely from the fact that this company actually designed and implemented business-wide integrated information systems.

The lack of integration of information systems has created a variety of problems. The most serious ones among those problems are the following:

- Redundancy, i.e., the same information is stored and maintained several times.
- Inconsistency, i.e., information about the same entity stored in different places is not the same.
- Lack of integrity, i.e., databases where such information is stored are not correct.

Mistakes, wrong decisions, and additional work are some of the consequences resulting from these problems. Consider, for example, data about customers. Such data are often entered and maintained in a sales and distribution information system (customer orders), then again in the dispatching system (delivery orders), and perhaps once more in a financial accounting system (invoices). Not only is this redundant and mean additional work, but also the same attributes may even stand for different things. For example, an "address" field in the sales and distribution system may represent the address of the customer's procurement department, whereas "address" in the dispatching system is the place where the goods have to be delivered.

Integration of information systems can be considered from several perspectives: from the data, the functions, the operations, the processes, the methods, and the software perspectives. The most important aspects are data integration, operations integration, process integration, and software integration:

- Integration of *data* means that data models and databases are unified so that all departments of an enterprise use the same data entities, with the same values.
- Integration of *operations* requires connecting individual operations, or steps of a business process, with preceding or succeeding operations, respectively.
- Integration of *processes* means that interfaces between different business processes are explicitly considered (e.g., connections between order processing and flow of material control).
- Integration of *software* means that different programs, e.g., information systems for different business functions, can run together and use each other's data and operations.

Those aspects of integration have always been considered important requirements for effective business information processing, but how does one actually obtain enterprise-wide integrated information systems?

Because most organizations have been using information systems in various business areas for quite some time, one way is to integrate those stand-alone systems subsequently. This approach has been discussed and practiced under the concept of "software reengineering," often related to the term "legacy systems" for the information systems to be integrated (Miller, 1997; Seacord et al., 2003).

The other approach to obtain integrated information systems is obviously to start developing them from scratch. In such a situation, information structures can be modeled and designed on the drawing board in an enterprise-wide manner, at least in theory. Practical experiences have shown that developing comprehensive information systems for all areas of a business is a giant task. That is why such systems have rarely been developed as individual solutions. Not only is the investment needed very high, but also manpower and know-how to develop such systems are often beyond the means of a single company. Therefore, comprehensive integrated information systems have mostly been developed by dedicated software and consulting companies. In the 1970s and 1980s, those systems were named with rather general terms, like standard packages or integrated business information systems, until the terms "enterprise resource planning" and "ERP system" emerged in the 1990s. In fact, the term "enterprise resource planning" has been coined by the software industry and not by academia.

Today there is a common understanding of what the term stands for. The definition used in this chapter is as follows: An *enterprise resource planning system (ERP system)* is a comprehensive information system that collects, processes, and provides information about all parts of an enterprise, automating business processes and business rules within and across business functions partly or completely.

Alternatively, an ERP system may be defined as a set of integrated information systems rather than as one system. This depends on the perspective of the viewer. For the user, an ideal ERP system will behave like *one* enterprise-wide information system, with one database, and one common user interface. Nevertheless, such a system may be composed of many subsystems and many databases, as long as they are well integrated.

COMPONENTS OF AN ERP SYSTEM

Horizontal and Vertical Views of Enterprise Resource Planning

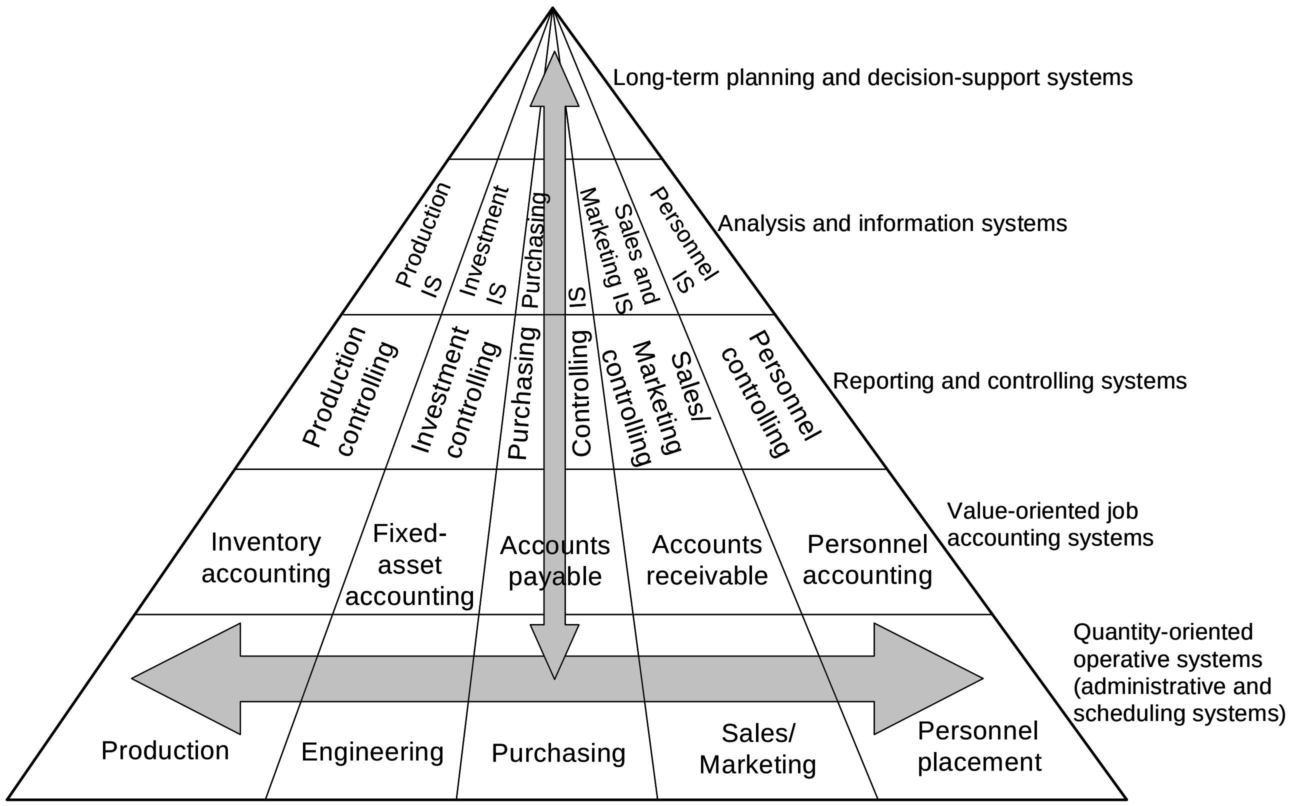
An ERP system integrates information, processes, functions, and people into one coherent system (Brady et al., 2001). Such a system supports all horizontal business functions and all vertical levels of a business (operational, tactical, and strategic). Figure 1 illustrates this view in a simplified information systems pyramid. Each component may be seen as a functional subsystem. In a horizontal perspective, systems are integrated along the value chain. The vertical direction asks for integration of operative systems with their corresponding value-oriented accounting systems; reporting and controlling systems; analysis and management information systems; and long-term planning and decision support systems (Scheer, 1994, p. 5).

A typical ERP system provides components like the ones shown in Figure 1, arranged and extended in one way or another. As an example of integrated information systems, the mySAP ERP system is described subsequently.

An Example: mySAP ERP

mySAP ERP is the market leader's current ERP system. This system encompasses all levels of the pyramid. It is structured into the following modules (short descriptions are taken from SAP, 2003, 2004):

Figure 1. Integrated business information systems (Source: Scheer, 1994, p. 5)



Analytics

- Strategic enterprise management: Supports the top level of the pyramid in Figure 1: integrated strategic planning, performance monitoring, business consolidation, and stakeholder communication; provides tools for planning and executing the strategies: balanced scorecard, value-based management, financial statement planning, risk management, investment planning, and more.
- Business analytics: Supports managers with methods and tools for financial and management reporting, financial planning, budgeting and forecasting, profitability management, product and service cost management, overhead cost management, working capital and cash-flow management, etc.; provides analytical functions for procurement, inventory and warehouse management, manufacturing, transport, sales, customer service, quality management, enterprise asset management, program and project management, and more. [In Figure 1, those functions, tools, and methods belong mostly to levels 2 (analysis and information systems) and 3 (reporting and controlling information systems).]

Figure 2. Application domains and modules of mySAP ERP (Source: SAP, 2004)

Analytics	Strategic Enterprise Management	Financial Analytics	Operations Analytics	Workforce Analytics	
Financials	Financial Accounting	Management Accounting	Financial Supply Chain Management	Corporate Governance	
Human Capital Management	Employee Life-Cycle Management	Employee Transaction Management	HCM Service Delivery	Workforce Deployment	
Operations: Value Generation	Procurement	Inventory & Warehouse Management	Manufacturing	Sales Order Management	Customer Service
Operations: Support	Life-Cycle Data Management	Program & Project Management	Quality Management	Enterprise Asset Management	
Corporate Services	Travel Management	Environment, Health & Safety	Incentive & Commission Management	Real Estate Management	

Financials

The Financials module supports several application areas that are located first on level 4 of the pyramid:

- Financial accounting: Processing of incoming and outgoing payments, cash flows; provides general ledger, accounts receivable, accounts payable, fixed assets accounting, inventory accounting, tax accounting, financial statements, and more; helps to monitor financial transactions; supports business analysis through combined planning, reporting, and analysis of competitive measures.
- Managerial accounting: Provides profit center accounting, cost center and internal order accounting, project accounting, product cost accounting, profitability accounting; supports investment management, revenue and cost planning, transfer pricing, etc.
- Financial supply chain management: Supports financial collaboration within the enterprise and its business networks; provides credit management, cash and liquidity management, treasury and risk management, and more.
- Manager self-service: Provides managers with access to all relevant business information as well as related services.

Human Resources

The Human Resources module is comprehensive, including functionalities of the operative, administrative level (level 5) and the value-oriented level (level 4).

- Employee life cycle management: Supports recruiting and talent management, performance management, compensation management for various modes

(e.g., performance- and competency-based pay)
- Employee transaction management: Provides the central repository for employee data; integrates the information with other SAP business applications, especially Financials and Operations; supports time and attendance processing (planning, managing, and evaluating the working times and activities of internal and external employees); handles working-time provisions determined by companies themselves, by standard agreements, or required by law; handles all payroll processes, supports current legal regulations and collective agreement specifications, and ensures compliance with regulatory changes
- Workforce deployment: Provides project resource planning, resource and program management (i.e., resource management, project portfolio management, project execution, and skills management), and specific solutions for retail personnel and call centers
- HCM (human capital management) self-services: Provides self-services for managers and employees

Operations

This module supports mainly the bottom level through quantity-oriented operative subsystems for daily operations, including support for planning and execution.

- Purchase order management: Provides conversion from demands to purchase orders, issuance, and confirmation of purchase orders; supports purchasing of materials and services (for example, subcontracting for components).
- Inventory and warehouse management: Comprises inbound processing (all the steps of an external procurement process that occur when the goods are received) and outbound processing (all steps to prepare and ship goods to their destination), warehousing and storing (warehouse-internal movements and storage of materials); manages physical inventory for the company's own stocks (periodic, continous, etc.).
- Manufacturing planning: Provides typical MRP (materials requirement planning) functionality: computing quantities and due dates for production orders and purchase requisitions through lead-time scheduling, depending on buffers, operation times, lot-sizing rules and so on.
- Manufacturing execution: Supports the process of capturing actual production information from the shop floor to support production control and costing processes; supports a variety of concepts: make-to-order, repetitive manufacturing, flow manufacturing, shop-floor manufacturing, lean manufacturing, process manufacturing, and batch manufacturing.
- Transportation: Provides transportation planning (routing, carrier selection, etc.) and execution (shipment orders), freight costing, and legal services.
- Sales order management: Supports quotation and order management (creating and processing orders, including pricing and scheduling orders for fulfillment) including inquiries and follow-up orders; provides mobile-sales, billing, and contract-management functionalities.
- Customer service: Helps to manage a customer's product configuration (installation and configuration management, including definition of the product hierarchy, management of serial numbers, measurements, document management, and engineering change management), service contracts, planned services, warranties, and so on.
- Life cycle data management: Provides document management, product structure management (including bills of materials), recipe management, integration of CAD (computer-aided design), PDM (product data management), and GIS (geographical information system) data, and more.
- Quality management: Supports quality engineering according to the ISO 9000 standard, quality assurance and control (quality inspections, statistical process control, traceability, etc.), quality improvement (audit management according to ISO 19011, problem/complaint management, corrective and preventive action, etc.).
- Project management: Provides functions for project planning (project structures, costs, budgets, workforce and resource planning, scheduling activities, etc.), project execution (monitoring project progress, progress analysis/earned value analysis, progress tracking, etc.).

Corporate Services

The Corporate Services module provides comprehensive support for resource-intensive corporate functions:

- Real estate management: Provides tools to support real-estate property acquisition and disposal, property portfolios, functions to help users lease and manage the real estate portfolio, etc.
- Incentive and commission management: Helps to design incentive compensation plans, calculate vari-

able compensation (e.g., direct sales commissions), carry out evaluations of performance and cost results, and more.
- Travel management: Provides functions for travel request and pre-trip approval, travel planning and online booking, travel expense management, services for mobile staff, and more.
- Environment, health, and safety: Supports a variety of functions for product safety, handling of hazardous substances, transportation of dangerous goods, waste management, etc.; allows companies to take preventive care of their employees' health; schedules medical examinations and testing for workers; manages emissions for air, water, and soil; monitors and controls plant emission sources.

This overview of components of the mySAP ERP system illustrates the wide range of functions that support ERP nowadays. The reader interested in details of ERP functionality is encouraged to study the products' Web sites. Descriptions of the above functions can be found on SAP's Web site (SAP, 2003, 2004). ERP systems by other vendors' ERP systems are outlined below.

THE MARKET FOR ERP

ERP systems have been around for about two decades now. All large and medium-size companies use such systems today, and more small companies are catching up. Well-known ERP systems in use include R/2, R/3, R/3 Enterprise, and mySAP ERP (all by SAP AG, Germany), Oracle's E-Business Suite (by Oracle, USA), iBaan Enterprise (formerly by Baan, Netherlands, now SSA, USA), Movex (by Intentia, Sweden), System21 (by GEAC, Canada), J.D. Edwards (USA), PeopleSoft (USA), Navision (by Microsoft, USA), Business Solutions (by Sage, UK), and infor:COM (by infor, Germany).

However, names and vendors are changing, as there is plenty of dynamic in the ERP market. Mergers and acquisitions and an ongoing market concentration can be observed year by year. Some of the above-mentioned systems will have been renamed because of those processes, or will have gone up in the new parent company's ERP system by the time this article is published.

Although there is still a fairly large number of ERP vendors, a handful of them dominate the ERP market worldwide. The global market leader by far is SAP AG from Walldorf (Germany). Followers are Oracle Corp., PeopleSoft (having completed the acquisition of J.D. Edwards), Sage, and Agilisys (haven taken over infor:COM).

FUTURE TRENDS: EXTENDING AND ENHANCING ERP

While ERP continues to be the core of any integrated business software, the focus has shifted toward advanced user support, like Business Intelligence (Biere, 2003) and Knowledge Management (Davenport et al., 1998; Earl, 2001), and interorganizational support of electronic business, in particular, supply chain management and customer relationship management. As those areas are closely related to ERP, all major vendors have extended their systems to support them as well.

Customer Relationship Management (CRM) is an approach to develop a coherent, integrated view of all relationships a firm maintains with its existing and potential customers (Laudon, 2004, p. 61). Nowadays, many channels are available for enterprises and customers to be in contact with each other: retail stores, telephone, e-mail, electronic shopping on the Web, mobile devices, etc. CRM systems try to consolidate customer information from all those channels and integrate the firm's diverse customer-related processes.

The major focus of ERP is to support the internal business processes of an organization. However, business activities do not end at the limits of one's own company. A natural extension of ERP is, therefore, s*upply chain management* (SCM; Ayers, 2001). SCM looks at the organization's business partners, in particular at the suppliers and their suppliers. In addition, many methodological and technical shortcomings of ERP have been removed or at least improved in SCM. Those improvements have been discussed in the literature under "Advanced Planning and Scheduling" (e.g., Meyr et al., 2002) and were implemented in SCM solutions by SCM vendors.

One example of such improvements is the use of optimization methods, like linear programming, mixed-integer programming, constraint propagation, and heuristics like genetic algorithms to solve production and distribution planning problems. Another example is pegging, i.e., creating, maintaining, and evaluating relationships between purchasing orders, production orders, transportation orders, and customer orders across entire supply networks worldwide.

CONCLUSION

ERP is a comprehensive approach to running organizations with the help of computer-based information systems. Such systems, so-called ERP systems, support all major areas of a business. ERP systems are integrated systems, with respect to information, processes, functions, and people. Usually, those systems are very large, developed by specialized software firms. The worldwide market leader is, by far, Germany-based SAP AG, with its current systems R/3 Enterprise and mySAP ERP. Except for small enterprises, almost all of today's companies use ERP systems for their ongoing business.

Extensions of ERP systems can be observed at the former limits of ERP: in CRM, the focus is on dedicated customer support; the focus of SCM is to help organizations plan worldwide supplier–buyer networks and to act successfully within such networks; business intelligence enables enterprises to behave in an "intelligent" way (e.g., addressing the most promising customers well-aimed); knowledge management helps to formalize and preserve important knowledge in an organization; and information system support for key areas, like the before-mentioned areas, is provided both by ERP vendors and by specialized software and consulting firms.

KEY TERMS

Data Integration: Unifying data models and databases so that all departments of an enterprise use the same data entities, with the same values.

Enterprise Resource Planning (ERP): The current state-of-the-art approach to running organizations with the help of information systems that provide support for key business processes and, more general, for electronic business (e-business).

ERP System (Enterprise Resource Planning System): A comprehensive information system that collects, processes, and provides information about all parts of an enterprise, automating business processes and business rules within and across business functions, partly or completely.

Operations Integration: Creating logical connections of individual operations, or steps of a business process, with preceding or succeeding operations, respectively.

Process Integration: Defining and automating interfaces between different business processes explicitly.

SAP: Software company based in Walldorf (Germany); market leader in ERP software worldwide. SAP is an abbreviation of the company's German name "Systeme, Anwendungen, Produkte in der Datenverarbeitung" (systems, applications, products in data processing).

Software Integration: Connecting different programs so that they can run together and use each other's data and operations.

Enterprise Resource Planning and Systems Integration

Mark I. Hwang
Central Michigan University, USA

INTRODUCTION

Systems integration has been an important topic ever since businesses started using mainframes to run their back-office operations. These systems specialized in common tasks found in functional areas such as accounts receivable and accounts payable, inventory, purchasing, and ordering. However, getting information from these fragmented systems to get a whole picture view of the business was extremely difficult if not impossible. By integrating back-office operations into a single system, enterprise resource planning (ERP) was supposed to solve that problem. In reality, however, very few companies fully implement all the modules of an ERP package and most continue to rely on legacy systems and other specialized software for their processing needs Integration of ERP with various enterprise applications remains a challenge. Moreover, it is not uncommon to have ERP software from different vendors or multiple copies of ERP software from the same vendor running in the same company. Integrating multiple instances of ERP software will be the predominant ERP project in most large corporations in the next half decade. Finally, many companies pursue merger and acquisition as a major growth strategy. A critical task in merging two companies nowadays involves integrating their ERP systems. This paper addresses these integration issues involving ERP systems. Common tools for integration and success factors for integration projects are discussed.

NEED FOR SYSTEMS INTEGRATION

The trends in globalization, mergers and acquisitions, and the advent of e-commerce and e-business have all contributed to the intensification of the competitive landscape. Companies need to find better ways to interact with their customers and provide better services. More than ever before, customers require information on various relations they have with a business; information about their accounts, their balances, recent purchases, and bills (Slater, 2000a). Traditionally, all that information, even if available, was locked in disparate systems. Consequently, companies that succeeded in integrating their systems enjoyed tremendous competitive advantage and reaped huge rewards in sales and market shares by offering unprecedented customer values. A good example is Dell, who was able to integrate not only its internal but also suppliers' systems. As a result, it has cut down its inventory to four day's worth of supplies, compared with from 30 to 50 days of its competitors. Its integrated supply chain system is a major contributor to its number one position in the worldwide PC market (Hildebrand, 2003).

Systems integration has been an important topic ever since businesses started using mainframes to support their back-office operations (Kumar & Hillegersberg, 2000; Hildebrand, 2003). Companies developed computer systems to automate common tasks in functional areas such as accounts receivable, accounts payable, inventory, purchasing and ordering. However, for the most part, these departmental systems were un-integrated and, therefore, not capable of providing a whole picture view of the business. Integration traditionally was done in a piece meal fashion and required custom coding that was both difficult and expensive. Attempts to develop enterprise-wide integrated systems for the most part have failed (Kumar & Hillegersberg, 2000). Commercial enterprise resource planning (ERP) systems, first appeared in the 1980s, were considered a major solution to the integration problem. However, it was soon found out that ERP could create its own integration problems, as discussed next.

Integration through ERP

ERP represents a major commercial solution that enables companies to integrate business operations across functions. Expanding from their roots in manufacturing and operations, vendors such as SAP and Baan continue to add business processes to their ERP offerings in areas including order management, marketing, purchasing, warehouse management, human resources and finance. In the mid-1990s sales of ERP software got a major boost as corporations rushed to replace their homegrown systems with Y2K compliant ERP systems. The implementation of ERP, however, was enormously difficult and expensive. Due to the extreme complexity of the software and the major changes required in the associated business processes, many ERP projects were abandoned or had their scope dramatically reduced. As a result, a typical company only implements a very small portion of an ERP package. Many companies continue to rely on their legacy systems or special software to support their operations. Integration of ERP with various enterprise applications remains a challenge (*Themistocleous, Irani, & O'Keefe, 2001)*.

ERP Consolidation

Many companies have also adopted the best-of-breed approach to the implementation of ERP: Picking and choosing the best modules on the market to create their ERP system. For example, a company may use PeopleSoft for human recourses, SAP for finances and manufacturing, and JD Edward (now part of PeopleSoft) for purchasing. In fact, some have estimated that as many as 90 percent of companies have ERP software from different vendors (Worthen, 2003). A 2003 Hackett Group survey, for example, found that an average company had 2.7 copies of ERP systems (2003). Integrating various ERP systems with each other and with other enterprise applications makes systems integration an even more daunting job.

Even if there is only one ERP package from one vendor, integration can be complicated. In the rush to meet the project deadline, especially during the Y2K crisis, many companies made another mistake: Instead of having one instance or copy of, say SAP, serving the whole company, they installed multiple instances of the software for different business units, different geographical locations, etc. Due to a lack of time or will, instead of standardizing, companies allowed different units and locations to keep their idiosyncratic work processes, which required customization of the software in different ways in different units and locations. This has resulted in a proliferation of ERP systems that, even when purchased from the same vendor, are unable to talk to each other. One company reportedly has as many as 64 copies of SAP running in different business units (Sliwa, 2000)! Integration of these multiple instances of ERP is very expensive and will be the major systems implementation project for large corporations in the next decade (Berinato, 2003).

Mergers and Acquisitions

As more and more companies deploy ERP systems, their integration becomes a top priority in mergers and acquisitions (Stedman, 2000). Because these systems are very complex and difficult to implement, their integration with different cultures and management styles from two merging companies presents enormous hurdles (Radcliff & LaPlante, 1999; Stedman, 1999). In addition, since this kind of projects is so resource intensive, it may compromise the implementation of other IT initiatives. Exxon/Mobil's merger in 1998 was especially noteworthy as it resulted in the largest SAP systems integration project at a time when the two companies had to contend with the Y2K issue (King & Nash, 1998).

Due to customizations and release variance, merging ERP systems from even the same vendor can be extremely difficult if not impossible (Kubilus, 2003; Stedman, 1999). Consequently, some firms chose not to integrate their ERP systems initially (Caldwell, 1998; Sliwa, 2000). The decision on which ERP system to keep has also been made irrespective of technical or even financial considerations. When Standard Register acquired Uarco, the former had PeopleSoft's ERP whereas the latter had Baan's. After the merger the new company stayed with Standard Register's legacy system because it was Y2K compliant. After 2000, the company moved to Baan's because the combined company had more experience with it than with PeopleSoft (Caldwell, 1998). Another example is the merger of Dow Chemical with Union Carbide. Dow was, and still is, an SAP R/2 user whereas Union Carbide had implemented SAP R/3. Some industry observer believed that the new company would move to R/3 since it was the newer version (Collett, 1999). In the end, however, the merged company decided to standardize on R/2, which has been an integrated system that supports Dow Chemical's global business operations in 135 countries since 1998.

To summarize, ERP is a solution to the systems integration problem. However, the installation of an ERP package does not create an integrated enterprise (Slater, 2000a). In fact, as discussed above, ERP amplifies the need for systems integration. It is, therefore, imperative that ERP implementers understand systems integration issues and be involved in integration projects. The next two sections discuss tools and success factors for systems integration.

TOOLS OF THE TRADE

Like all information systems project, systems integration takes people, resources and proper project management, some of which will be discussed in the next section. For the software component, most companies rely on middleware to integrate various applications. Middleware may be defined as software products that connect applications to enable data sharing (Slater, 2000b). The advantages of middleware and different types of middleware are discussed next.

Advantages of Middleware

Technically, middleware offers three advantages (Slater, 2000b):

- *Simplicity*: In the past the dominant approach to integration was point-to-point integration, which involved custom coding two or more programs so that they could talk to each other. If one of these programs needed to talk to another program, another point-to-point integration was created. Instead of connecting every application with every other application, the middleware approach allows one connection only from each application—to the middleware. Systems integration becomes much cleaner and more robust. The savings in development and maintenance rapidly multiply when the number of applications in need of integration increases.
- *Persistence*: Some middleware can capture and then hold data until it is processed by the applications or databases involved. This allows asynchronous or batch integration, which is usually easier and cheaper to implement then real-time integration (Hildebrand, 2003).
- *Services*: Middleware can offer commonly needed services such as data checking, validation, and manipulation. Using middleware means companies don't have to duplicate those functions in every application that needs them. Again, the savings in development and maintenance quickly multiply as the number of applications involved increases. As the middleware market evolves, more services will become available to companies that use them. The most promising framework for providing services is web services, which will be discussed in the next section.

Types of Middleware

Middleware can be loosely classified into four groups (White, 2003). Table 1 lists the four groups and their respective integration foci.

- *Object- and Component-Oriented Middleware*: This type of products is based on object-oriented architectures such as Common Object Request Broker Architecture (CORBA), Object Request Brokers (ORBs) and platforms such as Java 2 Platform Enterprise Edition (J2EE) and .NET. Object-oriented architectures describe the interactions between applications and networks and are a key part in building services and interoperable applications (Slater, 2000b). Iona Technologyies' Orbix 2000 is a middleware product based on CORBA release 3.0.
- *Message-Oriented Middleware*: This type of products relays messages or data from one application to another by putting them in a queue waiting for delivery. This is an example of persistence mentioned above and it also allows the receiving application to retrieve the message at a later time, thus permitting asynchronous integration of data. An example is a customer who may have several accounts with a bank, which are tracked in different databases. When the customer updates his address in one account, the middleware can update his other accounts automatically (Slater, 2000b). IBM's MQSeries is a prime example of message-oriented middleware.
- *Web-based Middleware*: This type of products utilizes web technologies such as web browsers, web servers and Extensible Markup Language (XML) as the data exchange protocol. In the business-to-business (B2B) space, XML is expected to replace the current standard, electronic data interchange (EDI), as the data exchange method (White, 2003).

Currently, the most important class of web-based middleware is known as web services, technologies that allow easy integration of applications over the Internet or Internet protocol based networks. In addition to XML, three other standards are involved in web services (Kalin, 2002):

- *Simple Object Access Protocol or SOAP*: Describes how an application talks to a Web service and asks it to perform a task and return an answer,
- *Universal Description, Discovery and Integration or UDDI*: A virtual yellow pages for Web services that lets software discover what Web services are available and how to hook up to them, and

Table 1: Types of middleware

Middleware Grouping	**Integration Focus**
Object- and component-oriented middleware	Sharing (reuse) of business logic
Message-oriented middleware	Data integration
Web-based middleware	Data and user interface integration; newer web services also provide application integration
Application integration middleware	Application integration

- *Web Services Description Language or WSDL*: The little blurb associated with each entry in the UDDI that describes what kind of work a Web service can do.

Web services offer tremendous potential as an integration tool (Kalin, 2002). First, they run on the Internet or Internet protocol based networks, which are the preferred media for e-commerce and e-business. Second, they have the backings of major technology vendors including BEA systems, IBM, Hewlett-Packard, Microsoft, Sun, and Oracle. Some consider web services one of the two dominant ways to consolidate ERP systems; the other being one instance ERP, a monolithic system from one vendor, say SAP or Oracle, that runs all enterprise-wide systems including ERP, customer relations management (CRM), and supply chain management (SCM) (Worthen, 2003).

- *Application Integration Middleware*: This group includes older technologies such as screen scraping, database gateways, and transaction processing monitors. It also includes a new class of software products known as enterprise application integration (EAI), which incorporate technologies for communications/messaging, XML, data transformation, brokers, process models and development frameworks, and business rules. EAI products are comprehensive software suits that allow connection to an array of applications including ERP, CRM and to various databases. Using EAI, big corporations with a large number of applications to integrate can save as much as 80 percent over custom coding (Slater, 2002). EAI has also received the most attention in academic journals as an enterprise integration tool (e.g., Lee, Siau, & Hong, 2003; Themistocleous, Irani, & *O'Keefe*, 2001). It should be noted that the term "EAI" or simply application integration (AI) has been used broadly to refer to an approach to systems integration or narrowly to mean a type of software products. For example, Lee, Siau, and Hong (2003) defined EAI as "a business computing term for plans, methods, and tools aimed at modernizing, consolidating, and coordinating the overall computer functionality in an enterprise" (P. 57). Themistocleous, Irani, and *O'Keefe* (2001), on the other hand, reported various middleware products including EAI that have been used to integrate ERP systems with other applications.

SUCCESS FACTORS FOR SYSTEMS INTEGRATION

In addition to proper software, other factors affect the success of systems integration. Summarized below are guidelines that have appeared in practitioners' journals. Some success factors such as human capital are common to all IT implementation projects while others such as the will to share information and work processes are specific to integration efforts. Empirical validation of these and other factors in a more systematic way seems a promising research avenue.

1. Robust infrastructure: The volume of data to be stored, transported and processed will grow greatly so plan for storage, bandwidth and processing power accordingly (Slater, 2000a).
2. The will to share information and work processes: Integration means free flow of information across organizational boundaries. People must be willing to unlock their information vaults or all the investments in technology will not create an integrated enterprise (Slater, 2000a). Integration also brings new ways of doing things or more tasks for existing users. Consequently, users must be educated and trained properly for them to accept the new responsibilities (Hildebrand, 2003).
3. Clearly defined and communicated vision: Total integration is great but it's also very expensive. Different companies have different integration needs. For companies that are technology laggards, a better strategy may be to choose an ERP from a big enterprise software vendor such as SAP or PeopleSoft and wait for them to roll out add-on modules to integrate additional functions (Hildebrand, 2003). For technology leaders and large companies that have a vast number of existing applications, the payoffs from integration can be huge so EAI or web services make better sense, but the ROI must be communicated to and accepted by business executives. (Slater, 2000a)
4. Prioritization: Analyze each business area and process to determine which should be integrated first and the level of integration. Customer facing applications such as e-commerce and e-business are good candidates for initial integration. Also, some applications require real-time integration whereas others make do with batch or asynchronous integra-

tion, which is cheaper and easier to implement than the former (Hildebrand, 2003).

5. Human capital: Regardless of technology, it is people that make a system work. Retention of integration expertise in house is the key to integration success (Iansiti, 2003). An integration project can fail due to inexperienced project managers (Bass, 2003). Many companies have also created a program office to help manage systems integration projects (Slater, 2000a). A program office is a high-level group that brings visibility to systems integration and creates a forum for knowledge sharing and issues resolution across business areas.

CONCLUSION

Systems integration is an on-going issue in the use of information technology by businesses. Whereas in the past, integration may be viewed as part of the maintenance and upgrade of software and performed in a piece meal fashion, competitive pressures dictate that companies take a proactive view today and develop a comprehensive strategy for integrating all applications in a systematic way. The introduction of ERP is a first step towards integration but it also brings new challenges in creating a truly integrated enterprise. Companies that have the vision, strategy, and support mechanisms for achieving integration of all applications including ERP will be rewarded with sizable increases in sales, profits and market share; those that don't will fall into oblivion.

KEY TERMS

Enterprise Application Integration: Comprehensive middleware software suits that allow connection to an array of applications including Enterprise Resource Planning, Customer Relationship Management and to various databases.

Enterprise Resource Planning: Configurable enterprise software that integrates business processes across functions.

Middleware: Software that connects different applications to allow data sharing.

Simple Object Access Protocol or SOAP: Describes how an application talks to a Web service and asks it to perform a task and return an answer.

Systems Integration: The process of tying together two or more computer systems for sharing data and functionality.

Universal Description, Discovery and Integration or UDDI: A virtual yellow pages for Web services allowing software to discover what Web services are available and how to hook up to them.

Web Services: Technologies that allow easy integration of applications over the Internet or Internet protocol based networks.

Web Services Description Language or WSDL: The little blurb associated with each entry in the Universal Description, Discovery and Integration that describes what kind of work a Web service can do.

XML (Extensible Markup Language): The de facto standard for data exchange among different applications, especially over the Internet.

Enterprise Resource Planning for Intelligent Enterprises

Jose M. Framinan
University of Seville, Spain

INTRODUCTION

Enterprise resource planning systems can be defined as customizable, standard application software that includes integrated business solutions for the core processes and administrative functions (Chan & Rosemann, 2001). From an operative perspective, ERP systems provide a common technological platform, unique for the entire corporation, allowing the replacement of mainframes and legacy systems. This common platform serves to process automation as well as to simplify current process either by an explicit reengineering process or by the implicit adoption of the system 'best practices' (Markus & Tanis, 2000). Finally, the common centralized platform allows the access to data that previously were physically or logically dispersed. The automation of the processes and the access of data allows the reduction of the operating times (thus reducing operating costs) while the latter serves to better support business decisions (see, e.g., Umble, Haft & Umble, 2003, for a detailed review of ERP benefits).

A widespread critique to ERP systems is their high total cost of ownership (Al-Mashari, Al-Mudimigh & Zairi, 2003) and hidden costs in implementation (Kwon & Lee, 2001). Besides, ERP systems impose their own logic on an organization's strategy and culture (Davenport, 1998), so ERP adopters must adapt their business processes and organization to these models and rules. Consequently, organizations may face difficulties through this adaptation process, which is usually carried out without widespread employee involvement. This may cause sore employees, sterile results due to the lack of critical information usually provided by the employees, and also that the new system is delivered late, with reduced functionality, and/or with higher costs that expected (Kraemmeraard, Moeller & Boer, 2003). Additionally, some analysts have speculated that widespread adoption of the same ERP package in the same industry might lead to loss of competitive advantage due to the elimination of process innovation-based competitive advantage (Davenport, 1998). This has been observed, for instance, in the semiconductor manufacturers sector (Markus & Tanis, 2000).

The early stage of ERP was carried out through Materials Requirement Planning (MRP) systems (Umble et al., 2003). The next generation of these systems, MRP II (Manufacturing Resources Planning), crossed the boundaries of the production functionality and started supporting not only manufacturing, but also finance and marketing decisions (Ptak & Schragenheim, 2000). Current ERP systems appeared in the beginning of the '90s as evolved MRP II, incorporating aspects from CIM (Computer Integrated Manufacturing) as well as from EDP (Electronic Data Processing). Therefore, ERP systems become enterprise-wide, multi-level decision support systems. ERP systems continue evolving, incorporating Manufacturing Execution Systems (MES), Supply Chain Management (SCM), Product Data Management (PDM), or Geographic Information Systems (GIS), among others (Kwon & Lee, 2001).

BACKGROUND

Most enterprise resource planning systems share a number of common characteristics, both from a technological as well as a business perspective. These include:

- **Client/server, open systems architecture.** Most ERP packages adopt an open systems architecture that separates data (database server), application (ERP server), and presentation (user interface/ERP client) layers, guaranteeing cross-platform availability and systems integration. In order to interoperate with existing business applications or information systems, most ERP packages adhere to the majority of common standards for data exchange or distributing processing.
- **Enterprise-wide database.** One of the most distinguishable characteristics of ERP is the strong centralization of all relevant data for the company (Al-Mashar et al., 2003). When physical centralization is not possible, communication and/or replication protocols among the different databases should be implemented in order to ensure data consistency and accessibility throughout the entire enterprise.
- **Kernel architecture.** Some ERP systems support more than 1,000 different business functionalities (Bancroft, Seip & Sprengel, 1998), covering nearly

all relevant business aspects for most of the enterprises. As all these functionalities cannot be loaded in the ERP server at the same time, the majority of ERP systems employ a so-called 'kernel architecture'. In this architecture, most functionalities are stored in the ERP database, usually in the form of source code of a proprietary, fourth-generation, programming language. When certain functionality is required by an ERP client, the ERP server loads it from the database and compiles the corresponding code so the functionality is made available for the clients. Once it is not required, the functionality is removed from the ERP server. Note that this mechanism also allows for an easy enhancement/updating of existing functionalities, as well as for the construction of new ones.

- **Process-oriented, business reference model.** ERP is process-oriented software that has been developed, starting from an implicit or explicit business reference model in order to appropriately describe the relevant business functions covered by the ERP system. For most ERP vendors, this model is explicit and takes the form of the 'best practices' extracted form the ERP vendor experience (Markus & Tanis, 2000). This can be used to analyze and evaluate current business processes in the enterprise prior to the implementation of the ERP package, serving thus as benchmark processes for business process reengineering (BPR).
- **Adaptation to the enterprise.** In order to meet the specific requirements of different enterprises, ERP systems are highly configurable. This potential for customization is considered to be one of the main differences between ERP and other standard software packages (Kraemerand et al., 2003). The customization process may take several months, or even years, depending on the enterprise.
- **Modularity.** Although the term 'ERP system' is usually employed to design a system covering all corporate functions (Slater 1998), generally an ERP system is composed of a set of ERP modules. An ERP module is a group of function-oriented, tightly integrated functionalities, which in many cases can be separately purchased and installed. Typical ERP modules are the financial-accounting module, production-manufacturing module, sales-distribution module, or human resources module. This allows enterprises to purchase only these modules, strictly required, as well as offers the possibility of integrating them with existing information systems.

An intelligent enterprise is an organization that acts effectively in the present and is capable of dealing effectively with the challenges of the future (Wiig, 1999). Since most enterprises operate today in a complex and dynamic environment, characterized by increasing competition and continuous changes in products, technology and market forces, an intelligent enterprise should be proactive, adaptable, knowledgeable, and well resourced (Kadayam, 2002). In order to achieve this behavior, it is expected that all employees in the intelligent enterprises not only deliver the work products that are directly associated with their functions, but that they also innovate to improve customer relationships and enterprise capabilities, and to envision opportunities for new products and services (Wiig, 1999). Therefore, it is clear that an intelligent organization should have timely access to all critical information in order to gain insight into its performance and should be able to provide effective decision support systems. Hence, one of the requisites for the intelligent enterprise is the availability of all relevant data in the organization. Indeed, access to the right information is considered to be one of the key characteristics of intelligent enterprises (Smirnov, Pashkin, Chilov & Levashova, 2003).

FUTURE TRENDS

If we adopt the generic intelligent enterprise architecture by Delic and Dayal (2002), ERP addresses issues of supply chain efficiency and back-office optimization, and provides the basis for Enterprise Knowledge Management (EKM). At the same time, the evolution of enterprises to the form of intelligent organizations requires the cooperation of independent companies into a virtual multi-tier enterprise (Olin, Greis & Kasarda, 1999), the Internet providing the glue for their heterogeneous information systems (Delic & Dayal, 2002). In order to achieve this, one of the main trends followed by most ERP systems vendors is the introduction of the Internet (Chan & Rosemann, 2001; Kwon & Lee, 2001). The adoption of the Internet can be seen from two viewpoints—the user interface viewpoint, and the internal/external communication viewpoint.

With respect to the user interface, ERP systems are transaction oriented. However, the connectionless nature of the Internet protocols (i.e., the connection between the Web server and the browser is not maintained after the former has sent the requested data to the later) makes it not well suited for transactions. Therefore, it is intrinsically difficult to adapt the ERP internal structure to the Internet. As a consequence, most of the ERP vendor's effort is on creating reliable gateways between the ERP system and an Internet server.

Regarding the internal or external communication of the ERP system, the emphasis is on the adoption of Internet standards for data exchange. This is done with respect to both the exchange of data among the different ERP modules and to the exchange of data among the ERP system and external applications. Hopefully, this effort will result in the adoption of a common communication standard that will allow the integration of the information systems of customers and/or providers in a supply chain. Additionally, it will make feasible the so-called 'component ERP'—that is, the acquisition of the 'best-of-breed' modules from every ERP vendor (Fan, Stallaert & Whinston, 2000). Since communications among ERP modules has been driven by proprietary protocols, the ERP market has been forcing the enterprises to purchase all modules of the ERP system from the same vendor or face huge costs in developing interfaces for modules from different ERP systems. This may be greatly simplified by the adoption of a public, common, protocol standard such as those on the Internet. Even in the most likely case that interfaces between modules from different vendors are still required, the decrease in the cost of their development may render it affordable for the enterprises (Appleton, 1997; Kwon & Lee, 2001).

THE ERP MARKET: VENDORS AND MARKET TRENDS

About 40% of large companies worldwide and 60% of smaller companies are deploying ERP systems, and 70% of Fortune 1,000 companies have implemented core ERP applications (Bingi, Sharma & Godla, 1999; Yen, Chou & Chang, 2002). The world ERP market has been growing at a rate higher than 30%, and most forecasts predict keeping the figures. Actually, the ERP market is the largest segment of a company's application budget (34%), and it is expected to remain so through 2004 (Scott & Shepherd, 2002; Somers & Nelson, 2004). This growth has been boosted by a number of reasons, such as globalization, market maturity in developed countries, and advances in information and communication technologies, among others.

With respect to the market players, it is not easy to offer precise information about market shares, since the comparative analysis of the published results show a great dispersion depending on the sources. All these analyses show the enormous fragmentation of the ERP market, where more than 100 products are available (see APICS, 2000). Additionally, there is consensus that SAP AG is the world market leader with the product SAP R/3, although its market share oscillates between 16% and 32%, depending on the sources. Along with SAP AG, five other products keep a market share oscillating around 2%. These are PeopleSoft, Oracle, Computer Associated, JD Edwards, and Baan.

THE ERP IMPLEMENTATION PROJECT: RISKS AND KEY SUCCESS FACTORS

ERP acquisition and implementation constitutes a risky project that may result, in a high number of cases, in unsatisfactory, if not failed, system implementations. It has been reported that nearly three-fourths of ERP implementation projects are judged unsuccessful by the ERP implementing form (Griffith, Zammuto & Aiman-Smith, 1999). Cases of failures in well-known organizations such as Boeing (Stein, 1997) or Siemens (Seidel & Stedman, 1998) have been described. Furthermore, these reported instances involve the software of all primary ERP vendors (Motwani, Mirchandani, Madan & Gunasekran, 2002). More detailed reports (Booz & Allen's 1999 report on ERP, cited by Buckhout, Frey & Nemec, 1999) confirm that nearly 35% of ERP implementation projects are cancelled, while in 55% of the projects, the final budget is doubled from the original one, and so happens with respect to the estimated project due dates.

Key success factors stem from the consideration of the ERP implementation project as a strategic project, in terms of time, costs, and expected benefits. Therefore, as with any strategic project, a commitment of the enterprise with the project is required (Appleton, 1997). The influence of the different success factors is discussed, for example, in Clemons (1998), Brown & Vessey (1999), Holland & Light (1999), Sumner (1999), Markus & Tanis (2000), and Parr & Shanks (2000).

The causes of failures can be fitted in three major groups:

- **Inherent complexity of ERP implementation project.** Implementation projects are extremely complex projects affecting key functional areas of the enterprise, usually carried out by a team composed of personnel external to the enterprise, supported by some company staff. To adequately handle this complexity, companies must be willing to dedicate some of their best employees with the right personal, business, and/or technological competencies, and hire external consultants who combine these qualities (Kraemmeraard et al., 2003).
- **Implementation strategy.** In some companies, big-bang implementation strategies (also known as all-at-once) have been followed, seeking to implement

all required features and modules at once, thus reducing the overall implementation time and minimizing the transient period between the former and the new information systems (Gill, 1999). However, this approach delays the visibility of the results for a very long time, leading in some cases to distrust in the overall ERP implementation project (Motwani et al., 2002). Instead, in a phased implementation strategy, the project is divided into milestones, each one representing an ERP package module or set of related functionalities. Then, these modules or sets are implemented one by one, not starting the implementation of a module until the previous one has been satisfactorily implemented and tested.

- **Organizational/cultural clash.** Since the implementation of ERP systems requires disruptive organizational changes (Hammer & Stanton, 1999), it is not surprising that some 60% of the failed implementation experiences arise from cultural or organizational clashes (Wheatley, 2000). Reports point at poor training as the main cause, due to underestimations on the hours of training, or to a training more focused on the technical aspects of the new information system, rather than in clearly explaining the new business processes. The solution to the poor training is obviously a higher awareness of the importance of the ERP training in the success of its implementation (Kraemmeraard et al., 2003). Optimal figures for training costs are between 15-20%. Besides, training must be more focused on a system's business processes rather than on a system's screens, so the users can sufficiently understand the logic of the new system (Wheatley, 2000).

CONCLUSION

ERP systems have been considered one of the most noteworthy developments in information systems in the past decade. ERP systems are present in most large companies that operate in the new millennium. Their advantages in terms of access to information or the integration of business functions has been outlined. However, ERP implementation projects are not risk-free: rates of ERP implementation failures are rather high. Although the failure figures may be partly explained by the intrinsic complexity of the ERP implementation project, some others may be minimized by the consideration of the ERP implementation as a strategic decision in the enterprise, resulting in a principal, long-term project rather than a 'single' information system change.

ERP systems will play a central role in the intelligent enterprise of the future. ERP vendors are continuously adding new features and providing an easy integration with other information systems, as well as among modules from different vendors. Success in the latter issue is claimed to be crucial for maintaining the now outstanding ERP position in the new enterprise.

KEY TERMS

Best Practices: Process procedures of recognized excellence, usually obtained from companies' experience and or process optimization analysis.

Big-Bang ERP Implementation: ERP implementation strategy consisting of implementing all required modules and features at once.

Business Process Reengineering (BPR): Radically re-thinks key enterprise process in order to achieve substantial process improvement.

Client/Server Architecture: Computer network model separating computers providing services (servers) from computers using these services (clients).

Enterprise Knowledge Management (EKM): Aimed to inject knowledge into business processes and to enable reuse of human expertise through the creation of common data objects and definitions that can be used with equal ease and success by all employees in the enterprise.

Enterprise Resource Planning (ERP): Packaged software to support corporate functions such as finance, human resources, material management, or sales and distribution.

Intelligent Enterprise: Organization capable of acting effectively in the present and dealing effectively with the challenges of the future by being proactive, adaptable, knowledgeable, and well resourced.

Modularity: Most ERP packages decompose their functionality in modules grouping typical business functions such as finance, sales, and manufacturing, among others.

Process Orientation: Recognition of series of functions that carry out an overriding task by providing the customer with a meaningful result.

Enterprise Resource Planning Maintenance Concepts

Celeste See-pui Ng
Yuan Ze University, Taiwan R.O.C

INTRODUCTION

Enterprise resource planning (ERP) is packaged software, and the accompanying set of best practices designed to integrate and serve different departments' needs, and to automate a corporation's business functions and processes on a single management system, database, and interface. ERP allows business to operate in a real-time, more effective and responsive manner and can facilitate better identification, storage, analysis, reuse and distribution of a company's business intelligence (e.g., performance, productivity, customer satisfaction, availability, inventory management, communication). SAP, Oracle, and PeopleSoft are the top three ERP software vendors. ERP software installation and popularity have grown over the past decade, especially in the late 1990s (it was once thought to be the panacea for Y2K problem). The motivations for ERP use are internal business integration, best business practices, competitive advantage, and operational cost reduction. Following the market trend, a large number of ERP implementation projects were conducted, especially by large enterprises. However, multi-million dollar ERP implementation projects are not without problems. In some companies, implementation takes much longer and requires a larger budget than expected, and a large number of modifications and configurations to the software are necessary. Some businesses have to change their existing processes to adapt to the software, and thus have to deal with significant internal resistance and change management. A few companies have even been bankrupted by unsuccessful ERP implementation projects.

A typical packaged software lifecycle, from the client perspective, involves implementation and installation, maintenance, and upgrade. Traditional software maintenance has been acknowledged by many researchers as the longest and most costly phase in the software lifecycle. This is also the case for the ERP context. It has been observed from experience and from the literature that there are inconsistencies in and confusion surrounding the terms used to describe the same ERP maintenance activity and tailoring options. Determining the most accurate and appropriate terms, together with their meaning, is a worthwhile endeavor as it can facilitate better communication among researchers and practitioners, and enable research results to be transferred more effectively to the real world. This paper aims to emphasize better understanding of ERP maintenance activities, and attempts to clear confusions and inconsistencies in the use of terms commonly applied in the ERP maintenance context. The discussion in this text focuses on SAP's ERP software. A Yankee Group survey of 350 business decision makers found that SAP is the most recognized name, followed by Oracle and PeopleSoft (Westervelt, 2004). The survey also revealed that 50% of the respondents preferred a large vendor. This indicates that the present paper will have relevance for a wide audience. In addition, the majority of research done to date has been based on the SAP software. This allows comparisons to be made with existing studies.

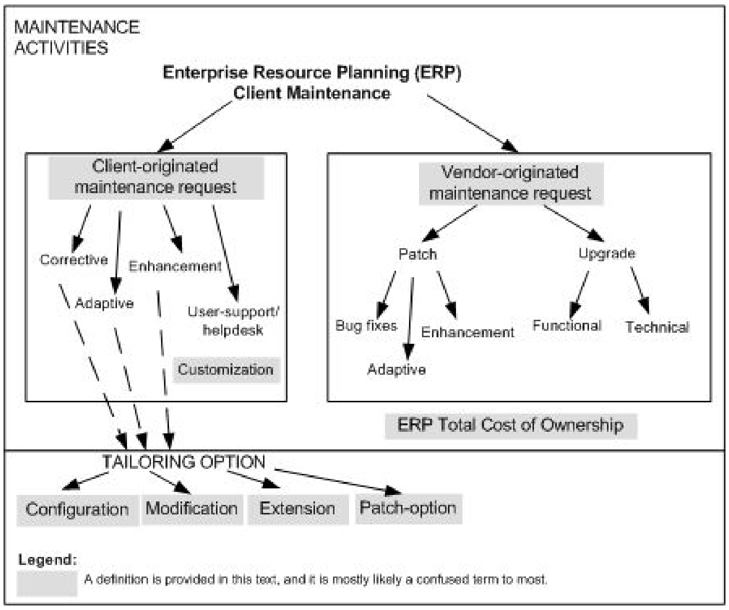
BACKGROUND

Overall, confusion about the terms used in the context of ERP maintenance, as well as inconsistencies in the terms used to refer to the same ERP maintenance activities and tailoring options, are observed in practice, in the trade press and in academic literature. For example, are patch maintenance and upgrade parts of the clients' ERP maintenance activities? Is ERP enhancement similar to ERP modification, and can the term "customization" be used interchangeably with "configuration"?

Client-Originated Maintenance Request Types

In an ERP environment, maintenance requests include those initiated both by the ERP client, and by the vendor (Ng, Gable, & Chan, 2002), see Figure 1. A survey conducted by Glass and Vessey (1999) on ERP maintenance has indicated that most maintenance requests introduced within an ERP-using organization are enhancement-driven. Enhancement is needed to change existing functionality in order to operate in a way that is desired and/or better than that offered by the original 'vanilla-flavored' software. Although in reality the clients' ERP maintenance also includes corrective, adaptive, and user-support (Ng et al., 2002), to the knowledge of the author

Figure 1. Terms defined in this text



very little has been researched and written about them. Previous research has been focused on the costly, lengthy, failure and critical success factors of ERP implementation projects. However, relative to maintenance that includes upgrading (even though some are supported by the vendor – at a cost), implementation issues are likely to be the tip of the iceberg of ERP software lifecycle costs and issues.

According to Ng et al., ERP maintenance is defined as:

post-implementation activities related to the packaged application software undertaken by the client-organization from the time the system goes live until it is retired from an organization's production system, to: keep the system running; adapt to a changed environment in order to operate well; provide help to the system users in using the system; realize benefits from the system; and

Table 1: SAP categorization of tailoring options

Tailoring option	Description*
Customization	— involves changes made within the standard vendor code by setting system parameters via SAP's configuration tables. In SAP R/3, the configurable elements are central functions, organizational elements, control elements, data validation, and system control (Bancroft, Seip, & Sprengel, 1998).
Enhancement using customer exits	— is for requirements that are not included in the standard SAP. Customer exits are incorporated in the standard as empty modification 'shells'. Customers fill the 'shell' with their own coding.
Enhancements using business add-ins	— allows ERP client organizations to add their custom code or the standard supplemental solutions provided by SAP, and also permits third-party software development to be incorporated in the standard code (Kessler, 1999).
Assisted modifications	— is done using the modification assistant to create customer-specific objects within the customer name range; e.g. screen layout, and function key assignment.
Modifications to the SAP standard	— involves modifying SAP standard objects.

**Source: Kessler, 1999; SAP, 1998*

Table 2: Researchers categorization of SAP software tailoring options

Tailoring option*	**Description***
Configuration	Setting of parameters (or tables) in order to choose between different executions of processes and functions.
Bolt-on	Implementation of a third-party package designed to work with the ERP system and to provide industry-specific functionality.
Screen masks	Creating new screen masks for input and output of data.
Extended reporting	Programming of extended data output and reporting options.
Workflow programming	Creating non-standard workflow.
User exits	Programming additional software codes in an open interface.
ERP programming	Programming additional applications without changing the original source code.
Interface development	Programming interfaces to legacy systems or third party products.
Package code modification	Changing the source-codes.

**Source: Brehm et al., 2001*

keep the system a supported-version and meet the vendor's requirements for standard code. These activities include: implementing internal change-requests; responding or handling user-support requests; upgrading to new versions/releases; and performing patches. (pg. 100)

Solutions: Tailoring Options

In order to implement an enhancement, corrective or adaptive maintenance request, knowledge of the tailoring options available and/or provided by the vendor is important. According to SAP (1998) and consultant Kessler (1999), there are five fundamental choices for tailoring to the SAP standard. The list and description of the SAP tailoring options are given in Table 1.

SAP tailoring categorization is technical-oriented and emphasizes to the performance of particular tailoring tasks, and what tool to use. A more detailed analysis of the tailoring option is given in the academic literature (see Brehm, Heinzl, & Markus, 2001). Brehm et al. (2001) describe the tailoring options from multi perspectives — how they are done, what is changed/modified, and the layers (i.e. interface, application and database) involved (see Table 2). This categorization is obtained from an analysis of the implementation literature and from the authors' interviews with MIS directors (from SAP client-organizations).

In another version of tailoring options given by Glass and Vessey (1999), the SAP term "customization" is used to refer to those configuration activities which involve changes made to ERP functionality via internal configuration switches. On the other hand, "extension" in (Glass & Vessey, 1999) is used to describe changes associated with user exits, bolt-ons and custom code add-ons.

Vendor-Originated Maintenance Request Types

The externally-originated maintenance activities comprise support packages or patches and upgrade versions, which are distributed by the vendor but implemented by the ERP client on its ERP system. A support package or patch contains corrections and further adjustments for an already installed version. ERP client organizations obtain maintenance support services through a maintenance contract with an ERP vendor, for example SAP. The annual maintenance fee is usually between 12 and 20% of the initial software license fee (Butler, 2001). In providing efficient maintenance support to its clients, SAP posts the patch support on the online system. This system offers various patch types dedicated to fixing program bugs in particular areas.

An ERP upgrade is part of ERP post-implementation activities. It involves replacing an installed ERP version with a newer version that is readily available (nearly always) from the same vendor in the market. In contrast to patch maintenance (which is meant for bug fix and, occasionally, minor enhancements), organizations typically upgrade to a new ERP version in order to realize the benefits of substantial new functionality (SAP, 2002; Stein, 1999), and new technologies or business opportunities (Callaway, 2000). There are basically two types of upgrade: functional and technical. Upon implementing a functional upgrade, the system users will experience new and/or additional functionality in the system. On the other hand, no added functionality is usually found from a technical upgrade. This type of upgrade is usually triggered by the need to migrate to a better software platform, to obtain better performance, and to maintain a viable migration path. A technical upgrade is a "like to

Table 3. ERP upgrade cost factors

Cost factor	Description*
Software	A new version that has more functionality, flexibility, and extensibility, will generally cost more to upgrade.
Hardware	Additional and more powerful hardware, or new hardware that is compatible with the new system (Jakovljevic, 2000).
User training	It is driven by changes in user interface and/or new functionality in a new system (Ohlson, 2000).
Consultant	Knowledge and expertise required in an ERP upgrade are not always readily available internally. Hence, most of the time, external consultants are required.
Upgrade implementation	Upgrade implementation involves the cost of data conversion, system analysis, system integration and testing, and post-implementation turmoil (Jakovljevic, 2001).

**Source: Ng, 2001*

like functionality replacement". On the other hand, a functional upgrade delivers major business improvements and enhancement benefits (Ng, 2001).

Unlike internally-originated maintenance, client organizations do not have to determine which tailoring option to adopt in performing a patch-maintenance or an upgrade. Specific program, tools, and methodology are provided by the vendor to assist clients in these activities.

In making the decision to upgrade, one has to consider several factors. These include the availability of the desired functionality (Collins, 1999; Ohlson, 2000), the right and sufficient personnel, the comfort and familiarity of its users with the system (400-Group, 1998), and the vendor's upgrade path availability and support window (Collins, 1999). Similar to the initial ERP implementation and acquisition cost, upgrade expenses are as shown in Table 3.

MAIN THRUST OF THE ARTICLE

This section will attempt to provide a clearer definition of which terms are appropriate to which situation. Figure 1 depicts the commonly encountered, and yet confusing, terms in the context of ERP client maintenance. A client-originated maintenance request originates within a client organization. It is meant to fix bugs, adapt internal and external changes to business processes, make enhancement to the installed system to meet new user requirements, and provide helpdesk/user-support. On the other hand, vendor-originated maintenance requests are maintenance needs that are created by a vendor in order to fix bugs in the packaged software, adapt to new legal requirements, impose the vendor's maintenance-support strategy and upgrade path availability, and provide additional enhancement to business process functionality and meet user requirements. In some cases, the terms "customization" and "enhancement" are used interchangeably, but, is this appropriate? "Customization" is more suitable as a generic term to refer to the need for changes, modifications or configurations to the standard ERP system. It should not be mistakenly associated with enhancement request or "configuration" tailoring options.

Also, as has been observed from the literature in the previous section, inconsistent use of terms to refer to the same tailoring option exists between the top ERP vendor and researchers, and among researchers. This is likely to

Table 4. Match between researchers and SAP tailoring typologies

Brehm et al. (2001) tailoring option	Corresponds to SAP's definition of
Configuration	Customization
User exits	Enhancement using customer exits
Bolt-on	Enhancement using business add-in
Screen masks, Extended reporting, Workflow programming, ERP programming, Interface development	Assisted modifications
Package code modification	Modifications to the SAP standard

Table 5. ERP tailoring options versus client-originated maintenance requests

		ERP client-originated maintenance request		
		Corrective	Adaptive	Enhancement
Tailoring option	Configuration	✓	✓	✓
	Modification	✓(for custom code only)	✓	✓
	Extension		✓	✓
	Patch-option	✓	✓	✓

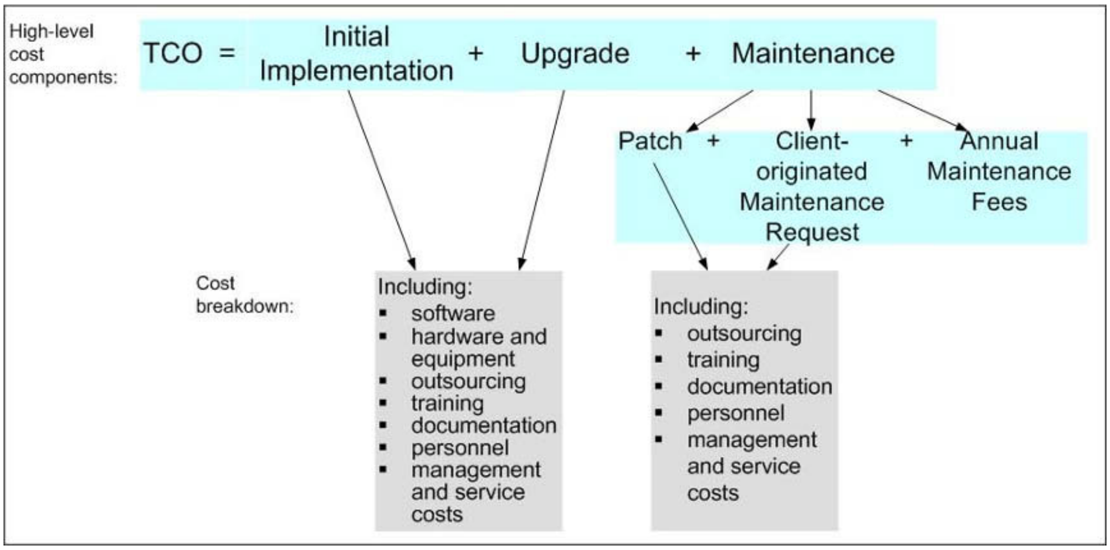
be due to a lack of a common understanding and a formal definition for ERP tailoring options among researchers. Moreover, in the author's opinion, this inconsistency exists because sometimes people associate a maintenance activity with a tailoring option and vice versa (e.g., "enhancement" with "modification", "customization" with "configuration").

By comparing the description of each tailoring option from the SAP (1998) and Brehm et al. (2001), overlaps are observed. The extent of correspondence in terms between Brehm et al. and SAP is illustrated in Table 4.

It is proposed that only the term "configuration" (as it is more intuitive than "customization") be used to refer to the tailoring option where changes are done, within the standard vendor code, by setting system parameters via vendor provided configuration tables. "Modification" is used to refer to the tailoring option where a vendor's standard objects and/or code are changed or modified. On the other hand, for tailoring options that involve adding custom or third-party codes to user-exits, add-ons, reports or user interfaces, without changing the vendor code, the proposed term is "extension". It is of note that the tailoring options reviewed here are non request-type specific or applicable only to enhancement requests. Besides this, an additional tailoring option – "patch-option" – is introduced. This is because occasionally general enhancement, adaptation, and correction requests can be satisfied by implementing the patches supplied by the vendor. Table 5 is a cross-tabulation between the four types of tailoring option and the three fundamental types of maintenance request. It shows the possible tailoring options that can be applied to the three maintenance request types.

In light of the typical packaged software lifecycle, the total cost of ownership (TCO) for ERP software comprises three main components: initial implementation, maintenance, and upgrade. This is illustrated in Figure 2.

Figure 2. ERP total cost of ownership



FUTURE TRENDS

Like other software systems, ERP is not a panacea for all. ERP is built to be generic, in order to meet a wide range of clients needs. Thus, while some clients try to change their business processes, some change the standard code in order to incorporate their unique business processes where they perceive critical for competitive advantages. Also, although ERP software provides a comprehensive set of business applications that can serve different departments under a single system, most companies still maintain their idiosyncratic legacy systems and some buy best-of-breed packaged software from different vendors. This is the result of their unwillingness to replace a system that is still working, and the packaged software does not meet their requirements or simply not good enough. Besides, such hesitancy could also be the result of an economic slowdown, wanting to avoid vendor lock-in, waiting for the web-application to mature, and so forth. However, multi-systems lead to integration problems. As a consequence, time and effort need to be invested in order to make disparate systems 'talk' to each other. Some perceive that the answer to this is through Web applications. But, as far as Web applications are concerned, there are a number of issues yet to consider and address, including cost, benefit, network bandwidth and infrastructure, threats and risks, security, and ethics. Moreover, in light of the growing customer base of the ERP system, it is valuable to investigate how ERP maintenance and upgrades could be better managed. How can the implementation of patches be better queued and implemented to achieve economies-of-scale? And what process model will best describe activities in ERP maintenance and upgrades?

CONCLUSION

ERP maintenance and upgrade issues become immediate important topics after client organizations have their ERP system in place – if not sooner. This paper suggests that inconsistency and confusion in some terms commonly used in the ERP maintenance environment can be minimized by avoiding the association between maintenance request types and tailoring options. The tailoring option called patch-option is introduced to better reflect the actual ERP maintenance environment. In light of the current ERP market situation, integration, Web-application, and maintenance and upgrade process model issues will remain and get more attention from researchers and practitioners in the future.

KEY TERMS

Client-Originated ERP Maintenance Request: Originated from within a client organization. It is intended to fix bugs, adapt internal and external changes to business processes, make enhancements to the installed system to meet new user requirements, and provide helpdesk supports.

ERP Configuration: A tailoring option, which involves setting or configuring a generic/industry-specific ERP system using the switches/tables provided by the vendor in order to personalize the ERP system to support an organization's business practices, and requirements.

ERP Customization: Customization simply means that changes, modifications or adaptations are needed in order to meet some user-requirements. It can be carried out via configuration tables, adding extensions or making modifications to the standard code (but cannot be done by applying any patch provided by the vendor).

ERP Extension: A tailoring option, which involves adding custom or third-party codes to user-exits, add-ons, reports or user interfaces, without changing the vendor/standard code.

ERP Modification: A tailoring option, which results in changes being made to the existing ERP (standard) code and custom objects being created.

ERP Patch-Option: A tailoring option, where vendor's patch(es) are used to service a maintenance request.

ERP Total Cost of Ownership (TOC): ERP software lifecycle cost covering the initial implementation and installation, continuous maintenance, and upgrades to the system until the software is retired from the production system. It includes all the software, hardware and equipment, annual maintenance fees, outsourcing, training, documentation, personnel, management and service costs.

Tailoring Option: Describes how changes can be incorporated into the ERP system or how maintenance request can be serviced.

Vendor-Originated ERP Maintenance Request: Created by a vendor in order to fix bugs in the packaged software, adapt to new legal requirements, impose the vendor's maintenance-support strategy and upgrade path availability, and provide additional enhancement to business process functionality and meet user requirements.

ERP Adoption in Indian Organizations

Monideepa Tarafdar
University of Toledo, USA

INTRODUCTION

Enterprise resource planning (ERP) systems integrate various functions and processes in organizations. ERP software is developed in the form of different modules, each of which helps to perform distinct functions within the company. The modules interface with the same database and are integrated so that workflows can be designed across different modules. The software helps standardize business processes and ensures organization-wide availability of transaction data. ERP software evolved from earlier manufacturing resource planning (MRP) systems, which included inventory management, procurement and production planning functions. The implementation of ERP software started in the early 1990s and during the late 1990s, the growth rate of the ERP market was between 30 to 40%. As of 2001, 30,000 companies around the world had implemented ERP and the total value of the ERP market was at $25 billion. There is not much literature relating to ERP implementation and adoption in companies in Asia and other parts of the developing world. These organizations face issues that are significantly different from those faced by organizations in the developed world, because of differences in the sophistication of IT use, and in the cultural and social contexts. In this article, we describe some experiences that companies in India have gone through in implementing ERP systems. We present a framework for analyzing the critical factors and issues that influence the ERP adoption process, and highlight the areas of opportunity and risk. The framework is sufficiently general so as to be extended to other developing countries.

BACKGROUND

The implementation of ERP software is quite different from traditional software development. ERP software is a single program that is bought off the shelf and then configured to include the specific characteristics of processes of individual companies. Parts of the software have to be customized such that they can correctly represent the workflow and processes of the particular company. This is a complex process, requiring many activities to be carried out. Most studies have described the implementation process in terms of stages.

Ross and Vitale (2000) suggest that ERP implementation is done in five stages. The *design* phase deals with planning and standardization, where an organization chooses the specific package and decides on the extent of customization required. In the *implementation* stage, the software is implemented and goes live. In the *stabilization* phase, the firm adjusts to the new system and integrates it into its existing operations by identifying and smoothing out integration hiccups. The *continuous improvement* stage is marked by additions to the existing functionality of the ERP package through add-ons from other vendors. Organizations typically implement data warehousing, data mining, customer relationship management (CRM) and supply chain management (SCM) software to augment the transaction-based capabilities of the ERP software. In the *transformation* stage, the organization starts to see the benefits of the ERP system, in terms of more efficient processes and possibly better information exchange with partners, leading to flexibility and responsiveness.

Rajagopal (2002) proposes a six-stage model. In the *initiation* stage, organizations study possible business benefits, such as IT infrastructure integration and business process re-engineering, which might make ERP adoption necessary. The *adoption* stage consists of activities such as investment decisions and cost-benefit analysis related to choice of the package and the vendor. In the *adaptation* stage, the system is implemented and becomes available for use. In the *acceptance* stage, users become more comfortable with using the ERP system, their requirements are incorporated, and the overall benefits of the system become apparent. In the *routinization* stage, system integration is realized, users fully accept the system and its use becomes a routine activity. Finally, during the *infusion* stage, the organization looks to the next level of benefits that might be available. The organization moves beyond "just" using the system—it uses the available information to enhance the performance of different functions.

In the model proposed by Markus and Tannis (1999), the *chartering* stage comprises review and selection of the package and consultants, and clarifying the business related factors that make ERP a necessity. The *project* stage describes different aspects of the implementation process and consists of project management, software customization and process re-engineering. During the *shakeout*, managers familiarize themselves with the software. System bugs are reported and fixed and the operational effects on the business are felt. Finally in the *upward and onward* phase, strategic business benefits from ERP occur, additional technical skills are built and upgrades are planned for.

ERP implementation results in significant changes in the IS architecture, redesign of process, increased managerial competence and comfort with new technology and a greater role for IT in critical processes (Scott et al., 2000). A number of factors influence the ERP adoption process. First, strong leadership support is important for ensuring the availability of resources and manpower, and for signaling to the employees the importance of the software (Baskerville et al., 2000; Bingi et al., 1999; Markus, 1999; Parr et al., 1999; Sarkar et al., 2000). Second, open and honest communication about the ERP initiative results in greater understanding of organizational needs and hence quicker acceptance of the software (Davenport, 1998; Holland et al., 1999; Mendel, 1999). It also helps employees understand the rationale for ERP implementation and enables them to appreciate problems in existing systems. A third influencing factor is the skill and competencies of the implementation team. Implementation teams that are technically strong, empowered to make decisions, politically close to important people in the organization and have a good understanding of end-user needs, enable organizations to minimize implementation difficulties and time and cost overruns (Askenas et al., 2000; Baskerville et al., 2000; Ferranti, 1998).

THE ADOPTION OF ERP SOFTWARE IN INDIA: A PROCESS MODEL

Issues and Problems

The first ERP systems were adopted in India in the mid 1990s and the Indian ERP market grew at an average rate of 70% over the years 1995 to 20011. As of 2001, about 800 companies had implemented ERP software2. The study of ERP implementation experiences in Indian companies is an interesting case of new technology adoption because many Indian companies go from very rudimentary IT-based systems to sophisticated ERP systems in one quantum jump (Sharma, 2001). We studied the ERP adoption processes of 25 companies from 10 different industries in the manufacturing and service sectors, which had implemented ERP software, to understand the factors that characterize the ERP adoption process in Indian companies. This article presents the findings in the form of an overarching framework that describes different aspects of the ERP implementation process of companies in India.

A Framework for Analyzing the Adoption of ERP in Indian Organizations

The ERP implementation process in Indian companies can be modeled as a *phase-stage* process framework, as shown in Figure 1. Each cycle in the spiral represents a single phase of implementation, in which a given number of modules are implemented. The innermost cycle represents the first phase and subsequent phases are introduced as more modules are implemented. The number of cycles or phases that are required depends on the characteristics of the individual organization, like annual turnover, size, complexity of organizational processes and IT readiness. Each phase has three stages and the activities carried out within a stage are shown alongside the section representing the stage.

The *planning stage* consists of activities before the ERP software is implemented. These include drawing up a business case and providing justification for the implementation of ERP, such as improvement of critical operational parameters. They also involve making decisions about whether to re-engineer processes using the *"best practices"* feature of the software or to customize the software to existing needs and processes. Planning activities revolve around the functioning of the IS department. In many cases, the IS function is not considered a very important one, prior to the implementation of the ERP software. Since ERP systems have great reach and are technically very complex software, it is essential to change the status of the IS function. Related planning activities therefore include giving greater powers to existing IS functional heads or instituting new CIO positions, which are powerful and visible, and can take charge of the implementation process. IS professionals trained in both technology and business are recruited. On the technology front, anticipated changes involve migration of data from legacy systems into an integrated platform, integration of existing application programs into the ERP system, and connection of separate servers and terminals into a single networked configuration. There is also an accompanying need for training and technical skill acquisition for maintaining the new systems. External consultants are recruited in order to help with software configuration, customization and expertise transfer. Since the ERP project is usually much larger than any previous IS project in terms of the scale of resource commitment, range of operations affected, and the number of people involved, the risk of failure is perceived to be high. Therefore it is essential to plan ahead for extra resource allocation and increases in IT budget, in case of unforeseen problems during implementation.

The *implementation* stage deals with issues that are required to be addressed once the implementation pro-

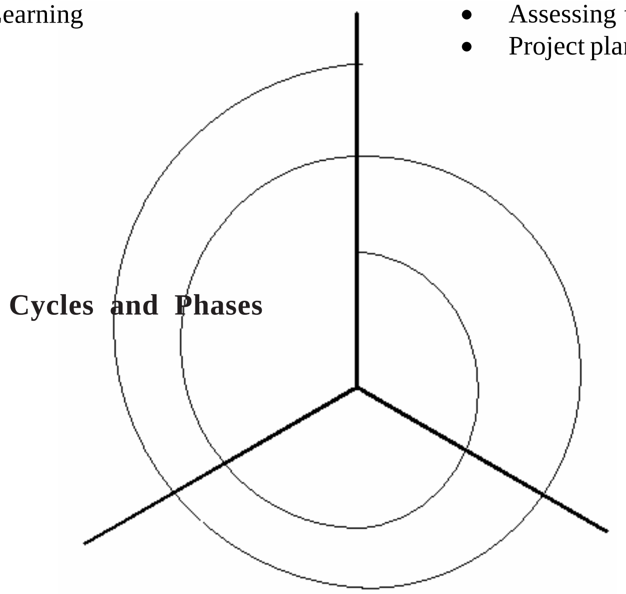
- Assimilating Phase Learning

Planning Stage

Activities:
- Drawing up a business case
- Understanding business characteristics
- Assessing the IT readiness of the organization
- Project planning



Implementation Stage

Activities:
- Management of technical aspects
- Organizational change management

cess is underway. The ERP system is significantly different from existing systems, and requires advanced technical skills. Hence the implementation process is a joint exercise between external consultants and company employees. These consultants also train the IS professionals, who later become responsible for the maintenance of the system. Those IS professionals who are not directly involved in the ERP project or have not trained on the software are often cynical of the possible benefits of the projects and refuse to co-operate. This is attributed to a lack of motivation and a feeling of alienation amongst these employees. Hence there is a need for making sure that these employees support the project requirements and help in the overall effort.

ERP results in significant changes at various levels. Task definitions are changed and employees require new skills and understanding as different tasks are combined. Reorganization of tasks also results in changes in the reporting structure. These transformations are often difficult for employees to accept quickly because of the magnitude of change involved. We found that senior managers were apprehensive that if they were not able to communicate clearly the nature of, and rationale behind, the changes, software would be rejected. Hence the primary risk of failure of the ERP system stems from human change acceptance issues, and not technical problems.

The *post-implementation review* stage is concerned with analysis of benefits and changes accruing from the ERP system. It also includes an examination of key learnings and skills acquired from the implementation process, and their application to subsequent rounds of implementation of the software. In most of the organizations that we studied, there were significant changes in business processes and reduction in the number of overlapping activities, coupled with greater understanding of task requirements because of multi-tasking and the combination of different stages of tasks into single steps. There was an overall shift from being function driven to process driven. There were also enhancements in the technical capabilities of employees and IS professionals. Operational benefits included improved customer service, reduced costs, better inventory management, and the facilitation of real-time processing, flow and availability of financial and other information. All of this led to better decision-making and greater accountability. Overall, ERP was used to create a systematic structure for storing and retrieving information seamlessly across functions.

Differences between Developed and Developing Nations

In this section we describe differences in the ERP implementation process between companies in the developed and developing nations, as illustrated by the phase-stage model.

1. ***The Phase-Stage Framework:*** The most important aspect of the framework is the presence of phases. In each phase, a company selects specific modules, implements them and leverages the key learnings in subsequent phases of implementation. The process of phasing has allowed Indian companies to limit exposure to implementation risks. While the presence of stages has been described in existing studies from developed countries, the presence of phases has not been mentioned. This is probably because most companies in developed countries have had a relatively longer history of organization-wide IT usage and the level of general awareness and societal acceptance is higher. Hence they have taken a big-bang approach, implementing all major modules in one go, in order to reap the benefits of integration quickly. Indian companies, and possibly those in other developing nations, because of their low level of IT usage prior to ERP, have had to adopt a conservative approach towards implementation. This has allowed them to avoid committing vast resources that a full package implementation would have demanded, to infuse changes gradually and minimize the risks of failure. The phased implementation, in concept and in spirit, is similar to the spiral software development lifecycle model of Boehm (1986), which suggests a risk-driven approach to software development.

2. ***The Existence of Stages within each Phase:*** The second important aspect of the framework is the existence of different stages within a phase. The presence of stages is in broad theoretical agreement with the stage theories described in the earlier section. In addition, the phase-stage model also describes specific aspects of each stage that are typical for companies in India and possibly in other developing economies, and has described the implications of these aspects for managers.

3. ***Changes in the Information Systems Function:*** ERP implementation has resulted in significant changes in the skill sets and organizational importance of the IS department in many organizations in India. IS professionals who had earlier worked with very basic systems have acquired highly marketable implementation skills. This has resulted in a high attrition rate of IS professionals and a high level of turbulence in the IT humanpower pool. This aspect is not as pronounced in existing models of ERP adoption based on studies in developed societies.

FUTURE TRENDS

Future developments in ERP software need to be analyzed in the light of two contexts. The first relates to the enhancement of technical and functional capabilities of the ERP software. ERP packages now provide Web-enabled functionalities and e-business suites for use in B2B and B2C transactions. In this context, SAP has launched mySap.com, Baan has a product called iBaan, and Oracle has incorporated e-business functionalities into their new ERP software called Oracle 11i. Moreover, many ERP vendors have positioned themselves as one-stop vendors for different integration requirements, and are adding CRM and SCM functionalities into their software. This is in response to integration problems that organizations have had when they have tried to interface different best of breed solutions. Therefore, basic ERP packages are expected to serve as the back-end transaction-processing database, to which e-business modules incorporating functions relating to e-procurement, CRM and SCM would be added.

The second context that is expected to shape the future of the ERP industry, especially in developing nations, is the decreasing cost of ERP solutions. Between 1995 and 2000, most customers have been large companies who are market leaders with considerable slack resources. Most of the large companies have already implemented ERP. The future market is represented by companies in the small and medium enterprise (SME) segment. The phase-stage framework would be important for these companies because the financial outlay required for full-scale ERP implementation is significantly larger than the normal IT budget, for these companies. Hence a gradual and risk driven approach to ERP implementation is required. This framework would also be important for global companies with facilities located in developed and developing nations. Using this framework would help them find an implementation pace that suits both kinds of settings.

Future research efforts would therefore need to be directed at analyzing ERP adoption as part of an overall framework for adoption of e-business, along with the implementation of other packaged software such as CRM and SCM. The study of ERP adoption by SMEs and the accompanying specific problems and issues is another area of potential investigation.

CONCLUSION

Over the last few years, many organizations in India have benefited from improved processes and better information availability as a consequence of the implementation of ERP solutions. For many others, the adoption of ERP has resulted in a very painful transition and adaptation period, while the benefits have not been immediate or tangible. This model presents a general conceptual framework and serves as a useful starting point from where the ERP experience of Indian companies can be analyzed. It also presents some practical implications for managers for managing and controlling relevant aspects of different stages of the implementation process. The generality of the framework has been further enhanced because of the number of industries covered in the study. The framework can be used for organizations in other developing societies, as well as in SMEs.

KEY TERMS

Best Practices: Generic business processes that are programmed into ERP software. They are based on cumulative knowledge about widely accepted practices that have been seen to work effectively across organizations in generic industries.

Customer Relationship Management (CRM): An approach that manages in an integrated manner all business processes that directly involve customers, in an effort to build long-term and sustainable relationships with customers. A CRM system is a central repository of customer information that records information from all contact points with customers, and generates "customer profiles" available to everyone who wishes to "know the customer".

Developing Nations: Those nations, particularly in Asia and Latin America, which are not as industrially developed as countries in Europe and North America. They are characterized by underdeveloped and uneven infrastructure in areas of telecommunications, roads, transportation and electricity distribution. Other features of such societies include low-cost labor and a large portion of the population living in rural areas and employed in the agriculture sector.

Enterprise Resource Planning (ERP) Systems: Integrated systems that support a wide range of transaction processing functions common to most organizations. Applications are designed around modules, which are linked to a central database in such a manner that data entered once through one module are available to applications of all other modules.

Enterprise Software Configuration: The process of implementing customized information flows, business logic and database design in an ERP software. This requires activities such as designing forms, reports and screen layouts, modifying existing programs, writing code for add-on applications, designing and implementing databases, and converting data from legacy systems.

Process Re-engineering: An exercise by which organizational processes are radically re-designed and changed. Instead of automating existing processes, organizations are encouraged to question existing practices, eliminate unnecessary steps in the workflow, streamline activities and introduce a paradigm shift in the organization.

Small and Medium Enterprises: Companies that have an annual turnover of less than $6 million and less than 250 to 300 employees.

Supply Chain Management (SCM): The integration of all activities in the value chain that provide products, services and value to customers. These activities include purchasing, materials management, production planning and control, inventory control and distribution and delivery.

Ben-Gurion University, Israel

INTRODUCTION

Background on Traditional Approach to Information System Development

Many paradigms for system analysis and design have been proposed over the years. Early approaches have advocated the functional approach. Common methodologies that support this approach are SSA and SSD (DeMarco, 1978; Yourdon & Constantine, 1979). SSA is based on the use of data flow diagrams (DFDs), which define the functions of the system, the data stores within the system, the external entities, and the data flows among these components. Early SSA and similar methodologies emphasized the functional aspects of system analysis, neglecting somehow the structural aspects, namely the data model. This was remedied by enhancing those methodologies with a conceptual data model, usually the entity-relationship (ER) model (Chen, 1976), that is used to create a diagram of the data model, which is later mapped to a relational database schema.

SSD is based on the use of structure charts (SCs), which describe the division of the system to program modules as well as the hierarchy of the different modules and their interfaces. Certain techniques have been proposed to create SCs from DFDs (Yourdon & Constantine, 1979). The main difficulty of an approach where functional analysis is followed by structured design lies in the transition from DFDs to SCs. In spite of various guidelines and rules for conversion from one structure to the other, the problem has not been resolved by those methodologies (Coad & Yourdon, 1990).

Shoval (1988, 1991) developed the ADISSA methodology that solved this problem. It uses hierarchical DFDs during the analysis stage (similar to other functional analysis methodologies), but the design centers on *transactions* design. A transaction is a process that supports a user who performs a business function, and is triggered as a result of an event. Transactions will eventually become the application programs. Transactions are identified and derived from DFDs: A transaction consists of elementary functions (namely functions which are not decomposed into sub-functions) that are chained through data flows; and of data stores and external entities that are connected to those functions. A transaction includes at least one external entity, which serve as its trigger. The process logic of each transaction is defined by means of structured programming techniques, for example pseudo-code. Based on the hierarchical DFDs and the transactions, ADISSA provides structured techniques to design the user-system interface (a menus-tree), the inputs and outputs (forms and reports), the database schema, and detailed descriptions of the transactions, which will eventually become the application programs. The menus-tree is derived from the hierarchy of DFDs in a semi-algorithmic fashion, based on functions that are connected to user-entities. The design of the forms and reports is based on data flows from user-entities to elementary functions and from elementary functions to user-entities. The design of the relational database schema is based on the analysis of dependencies among the data elements within the data-stores. The data flows from elementary functions to data stores and from data stores to elementary functions serve as a basis for defining access steps, namely update and retrieval operations on the relations. Access steps are expressed as SQL statements that will be embedded in the program code of the respective transactions. The products of the design stages can be easily implemented using various programming environments.

Background on Object-Oriented Approach to Information System Development

The development of object-oriented (OO) programming languages gave rise to the OO approach and its penetration into system analysis and design. Many OO methodologies have been developed in the early 90s (e.g., Booch, 1991; Coad & Yourdon, 1990, 1991; Jacobson, 1992; Rumbaugh, Blaha, Premerlani, Eddy & Lorensen, 1991;

Shlaer & Mellor, 1992; Wirfs-Brock, 1990). In the OO approach the world is composed of objects with attributes (defining its state) and behavior (methods), which constitute the only way by which the data included in the object can be accessed. When using the OO approach, a model of the system is usually created in the form of a class diagram consisting of data classes with structural relationships between them (e.g., generalization-specialization), and each class having its attributes and methods.

While there are no doubts about the advantages of the OO approach in programming, as it supports information hiding (encapsulation), software reuse and maintenance, there are doubts with respect to the effectiveness of the approach for analyzing business-oriented information systems (as opposed to real-time systems). The early OO methodologies tended to neglect the functionality aspect of system analysis, and did not show clearly how to integrate the application functions (transactions) with the class diagram. Another difficulty with those methodologies was that they involved many types of non-standard diagrams and notations.

The multiplicity of diagram types in the OO approach has been a major motivation for developing the UML (Booch et al., 1999; Clee & Tepfenhart, 1997; Fowler, 1997; Larman, 1998; Maciaszek, 2001; UML-Rose, 1998). UML provides a standard ("unified") modeling language. It

Figure 1. The initial class diagram of Music Programs system

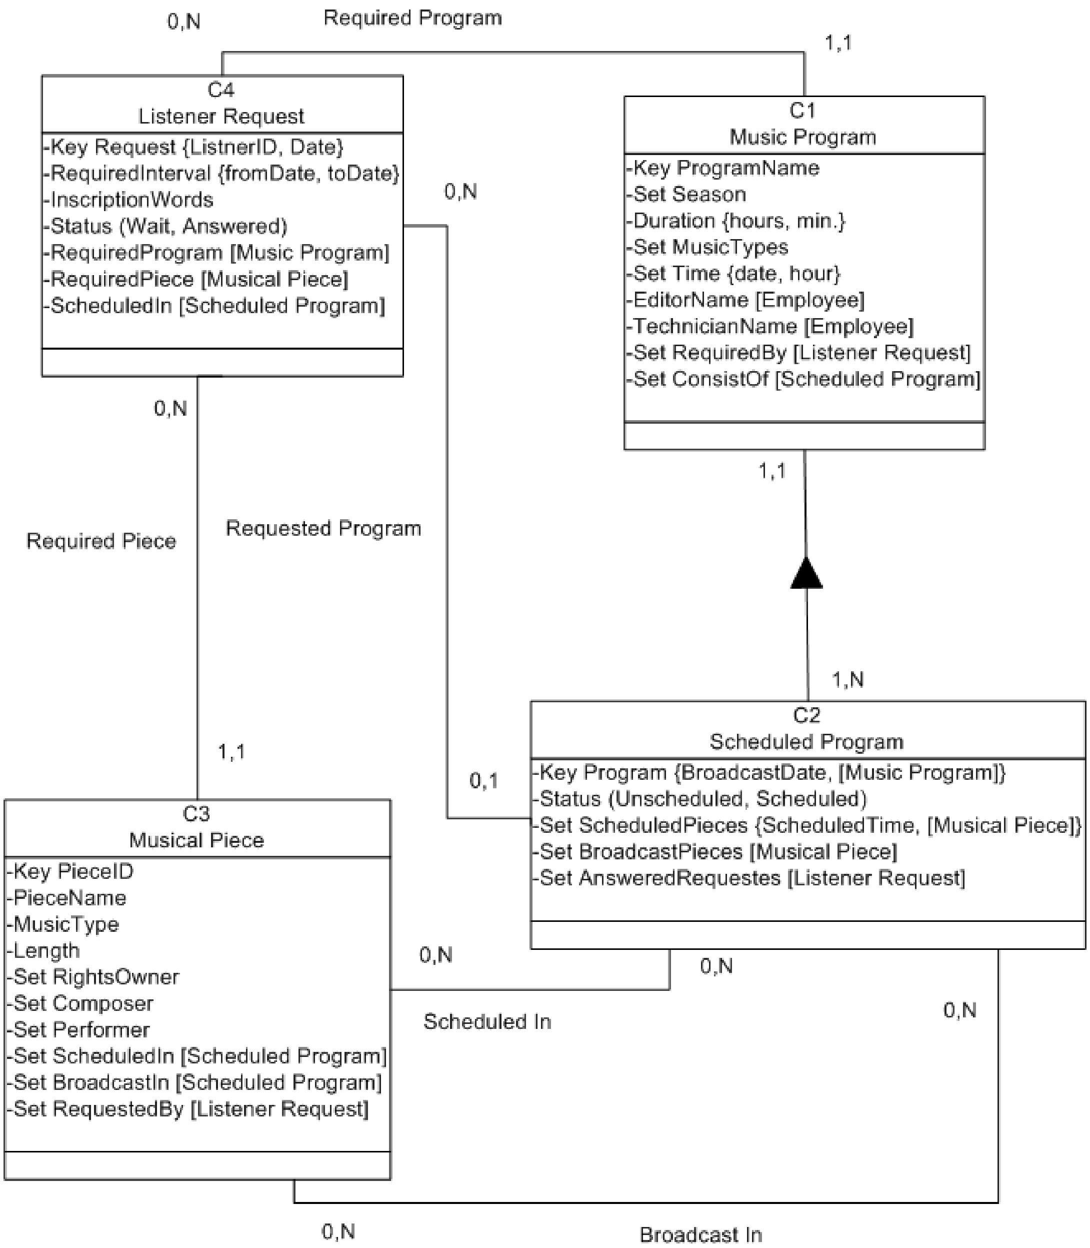

Figure 2. The top-level OO-DFD of Music Programs system

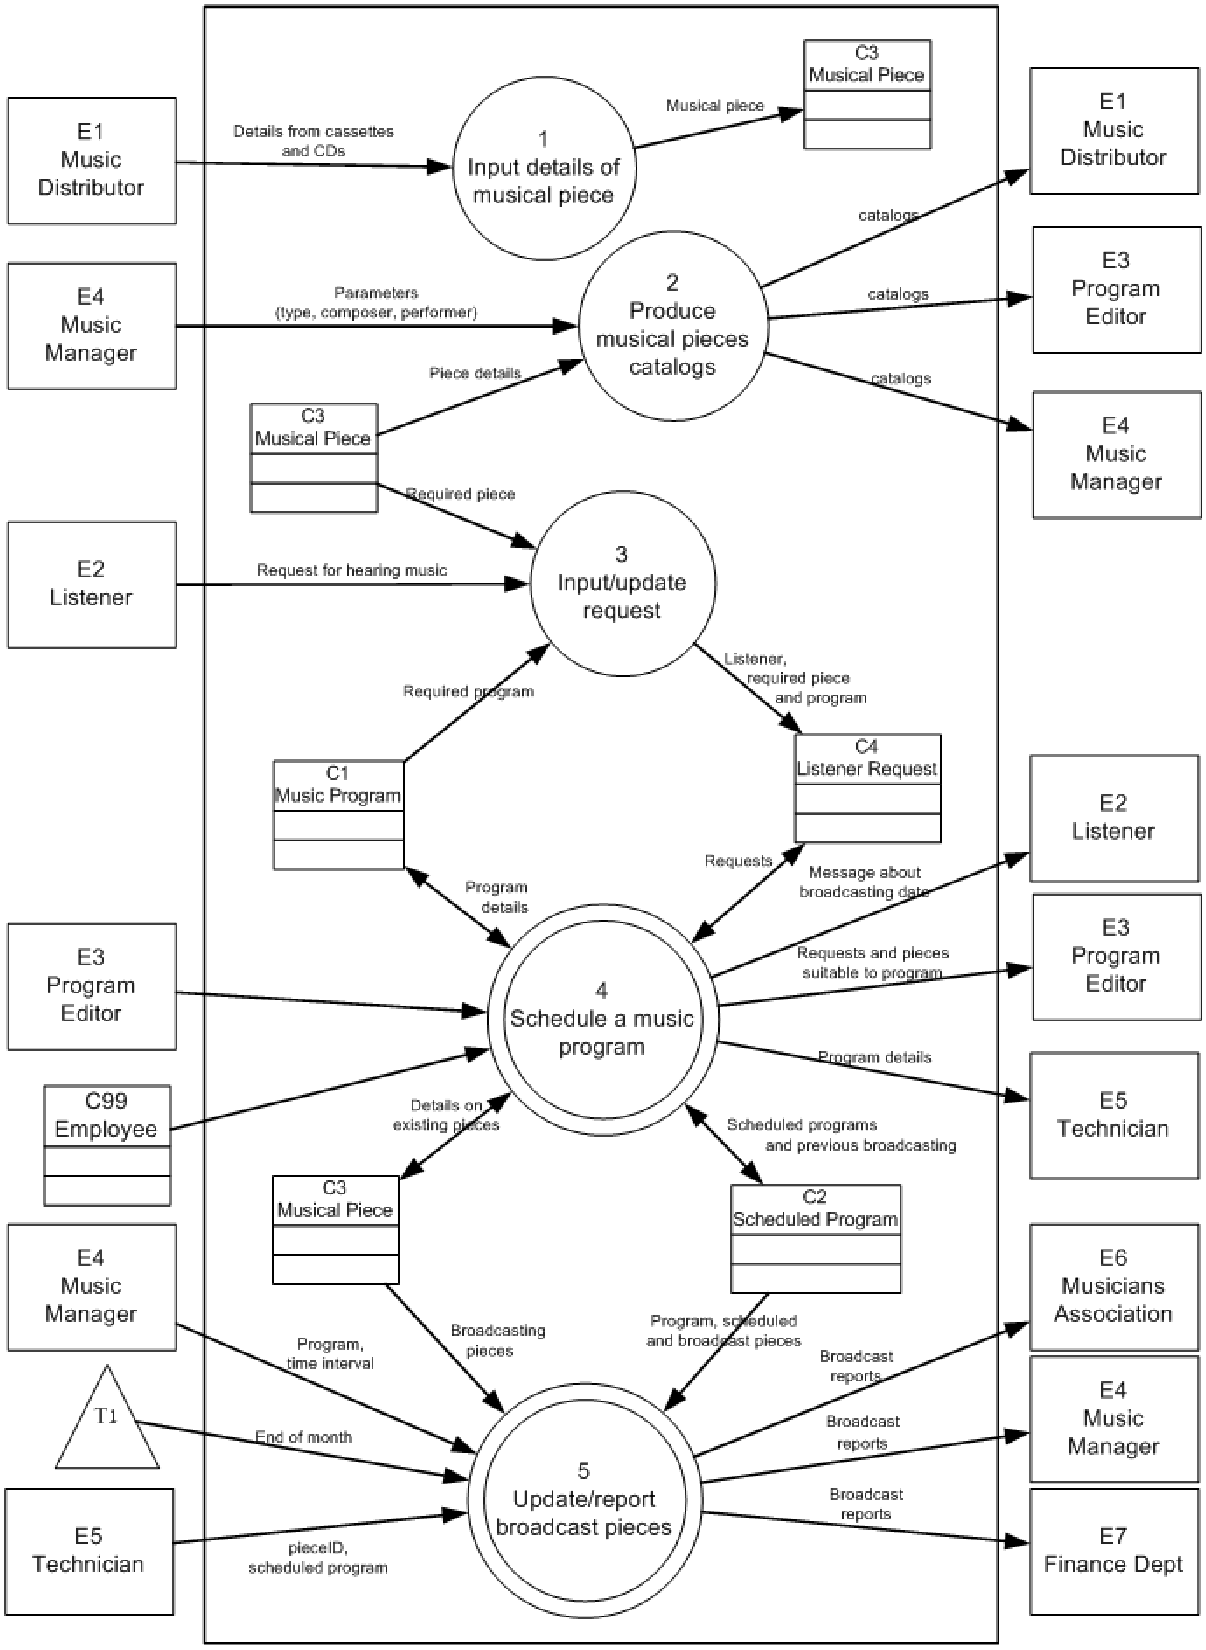

consists of several types of diagrams with well-defined semantics and syntax, which enable a system to be presented from different points of view. But UML does not offer a development methodology that guides the developer on *how* to do and which techniques to use. Moreover, some of the diagram types are redundant, and it is not always clear if and when they should be used in system development (e.g., sequence diagrams vs. collaboration diagrams).

Our approach is to integrate the two paradigms of system development. In our view, functions are as fundamental as objects, complementing each other, and a development methodology should combine the functional and the object-oriented approaches. FOOM is a system analysis and design methodology that presents this combination.

ESSENTIALS OF FOOM METHODOLOGY

FOOM is an integrated methodology for the development of business-oriented information systems, which combines the functional and the OO approaches. The essential steps of the methodology are as follows (for more details see Shoval & Kabeli, 2001):

The Analysis Phase

The analysis phase consists of two main activities: data analysis and functional analysis. The products of this stage are a data model, in the form of an initial class diagram, and a functional model, in the form of hierarchical OO-DFDs.

The initial class diagram consists of data (entity) classes, namely classes that are derived from the application/user requirements and contain "real world" data. Each class includes attributes of various types (e.g., atomic, multi-valued, sets, and reference attributes). Association types between classes include "regular" relationships, generalization-specialization (inheritance) links between super and subclasses, and aggregation-participation (part-of) links. Relationships are signified by links between respective classes, and by reference attributes to those classes. The initial class diagram does not include methods; these will be added at the design phase. An example of an initial class diagram is shown in Figure 1.

The OO-DFDs specify the functional requirements of the system. Each OO-DFD consists of general or elementary functions, external entities – mostly user-entities, but also time and real-time entities, data classes (instead of the traditional data stores), and data flows among them. An example of an OO-DFD is shown in Figure 2; it is the top-level OO-DFD. For each general function, signified by a double circle, there is a separate OO-DFD that details its sub-functions and related entities and classes (not shown).

Data analysis and functional analysis may be performed in any order. When starting with functional analysis, the analyst elicits the user requirements and based on that creates the OO-DFDs, which include (besides other components) data class rather than data stores. Then the analyst can create an initial class diagram – using the classes already appearing in the OO-DFDs. This means mainly defining proper class associations and attributes. Alternatively, the analyst may first create an initial class diagram (based on user requirements), and then create OO-DFDs, using the already defined classes. We investigated the pros and cons of the two alternative orders in an experimental setting, and found out that an analysis process that starts with data analysis provides better products and is preferred by analysts (Kabeli & Shoval, 2003). At any rate, the two product of the analysis stage are synchronized so that all classes appearing in the class diagram appear also in the OO-DFDs, and vise versa.

The Design Phase

Top-Level Design of Transactions

This stage is performed according to ADISSA methodology, where the application transactions are derived from DFDs. The products of this stage include transactions diagrams, as extracted from the OO-DFDs, and top-level descriptions of the transactions. In addition, a new class - Transactions – is added to the class diagram. This abstract class does not contain objects – it will contain transaction methods (which will be designed from the transactions' descriptions). Figure 3 shows an example of a "simple" transaction consisting of an elementary-function, a class and a user-entity; this transaction is derived from OO-DFD (Figure 2).

A top-level transaction description is provided in Structured-English (pseudo-code), and it refers to all components of the transaction: every data-flow from or to an external entity is translated to an "Input from..." or "Output to..." command; every data-flow from or to a class is translated to a "Read from..." or "Write to..." command; every data flow between two functions is translated to a "Move from... to..." command; and every function in the transaction is translated into an "Execute function.." command. The process logic of the transaction is expressed by standard process-logic patterns (e.g., if... then... else...; do-while...). The analyst and the user, who presents the requirements, determine the process logic of each transaction. This cannot be deducted automatically

Figure 3. A "simple" transaction diagram

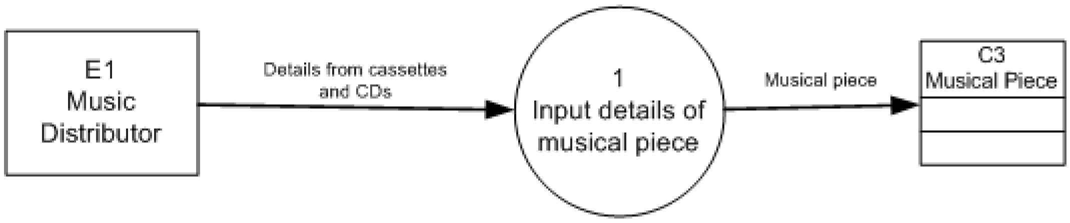

Figure 4. Top-level description of the transaction

Begin transaction_1
/ Input details of a Musical Piece */*
1. Input from E1: Music Distributor – details from cassettes and CDs.
2. Execute Function 1 – Input details of musical piece
3. Write to Class C3: Musical Piece – details of musical piece.

End transaction.

from the transaction diagram alone, because a given diagram can be interpreted in different ways, and it is up to the user to determine its proper semantics. The top-level description of this transaction is shown in Figure 4. This description will be used in further stages of design, namely input/output design and behavior design, to provide detailed descriptions of the application-specific class methods.

Design of the Interface – the Menus Class

As in ADISSA, the menus tree is derived in a semi algorithmic way from the hierarchy of OO-DFDs (Shoval, 1990). An example of a menus tree that is derived from our example is shown in Figure 5. The main menu contains five lines/items; three marked by "T" (for "trigger"), indicating lines that trigger transactions; and two marked by "S" (for "selection"), indicating lines that call other menus. (The numbers next to each line indicate the functions included in the transaction being triggered by the respective menu line). The menus tree is translated into a new class – Menus; the instances (objects) of this class are the individual menus. Note that at run time, a user who interacts with the menu of the system actually works with a certain menu object. He/she may select a menu line that will cause the presentation of another menu object, or invoke a transaction, which is a method of the Transactions class.

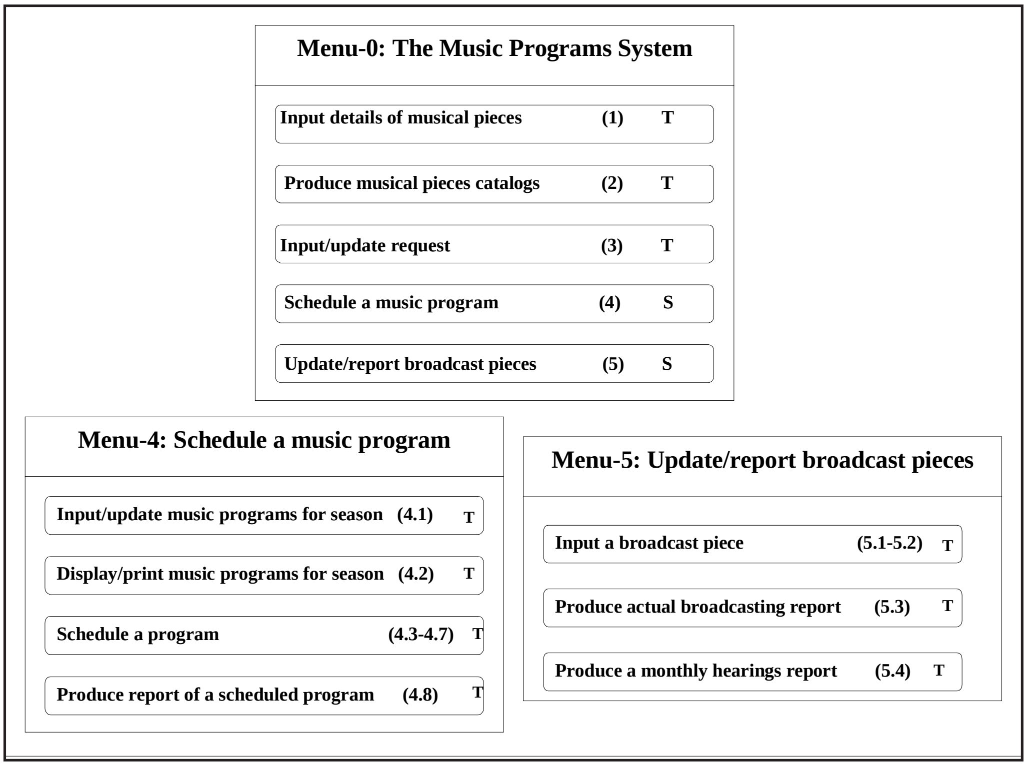
Design of the Inputs and Outputs – The Forms and Reports Classes

This stage is also performed according to ADISSA and is based on the input and output commands appearing in each of the transaction descriptions. For each "Input from..." command, an input screen/form will be designed, and for each "Output to..." command an output screen/report will be designed. Depending on the process logic of each transaction, some input or output screens may be combined. Eventually, two new classes are added to the class diagram: Forms - for the inputs; and Reports - for the outputs. Obviously, the instances (objects) of each of these classes are the input screens and output screens/reports, respectively.

Design of the System Behavior

In this stage, the top-level descriptions of the transactions are converted into detailed descriptions of application programs and class methods. The transition from a top-level description of a transaction to detailed descriptions of methods is done as follows: Every "Input from..." and "Output to..." command in the top-level description is translated to a message calling an appropriate method of the Forms or Reports class. Every "Read from..." or "Write to..." command is translated to a message calling a "basic" method of the appropriate class. Basic methods include Create, Read, Update and Delete (CRUD), and are assumed to exist in every class. Every "Execute-Function..." command can be translated to a basic method of certain classes, or to a "specific" method that will be attached to a proper class. A specific method may perform a procedure/function that is specific to the application/transaction, beyond any basic method (e.g., comparisons, computations). Each procedure that is defined as a basic or specific method of some class is removed from the transaction's description and replaced by a message to that class-method. A procedure/function that encom-

Figure 5. Interface design – the Menus tree



passes several classes must not be defined as a specific method of a certain class; rather it may remain part of the transaction. The remaining parts of the transaction's description are defined as "transaction method". This method is actually the "main" part of the transaction's program, and belongs to the Transactions class. Hence, when a user asks the system to perform some program/transaction, he/she fires the "main" method of the transaction (via proper menus selections); that method executes, and may call (send messages to) other methods (basic or specific) of respective classes – according to the process logic of the transaction.

Each transaction method or specific method can be described in two complementing forms: pseudo-code and message chart. Figure 6 shows the pseudo-code of the transaction. This description must not be too "formal"; it should include comments that will clarify the transaction to the programmer who will implement it in the proper programming language. A message chart (Figure 7) shows the classes, methods and messages included in a method, and the order/process logic of their execution. A message chart is actually a combination of a program flowchart and class diagram that includes only the classes involved in the method. Message charts supplement the pseudo-code; they must not be created for all transactions.

To summarize, the products of the design phase are: a) a complete class diagram, including Data, Menus, Forms, Reports and Transactions classes, each with various attribute types and method names (and parameters), and various associations among the classes; b) detailed menu objects of the Menus class; c) detailed form and report objects of the Forms and Reports classes; d) detailed descriptions of the transaction and specific methods, in pseudo-code and/or in message charts. At the implementation stage, the programmers will use these design products to create the software with any common OO programming language.

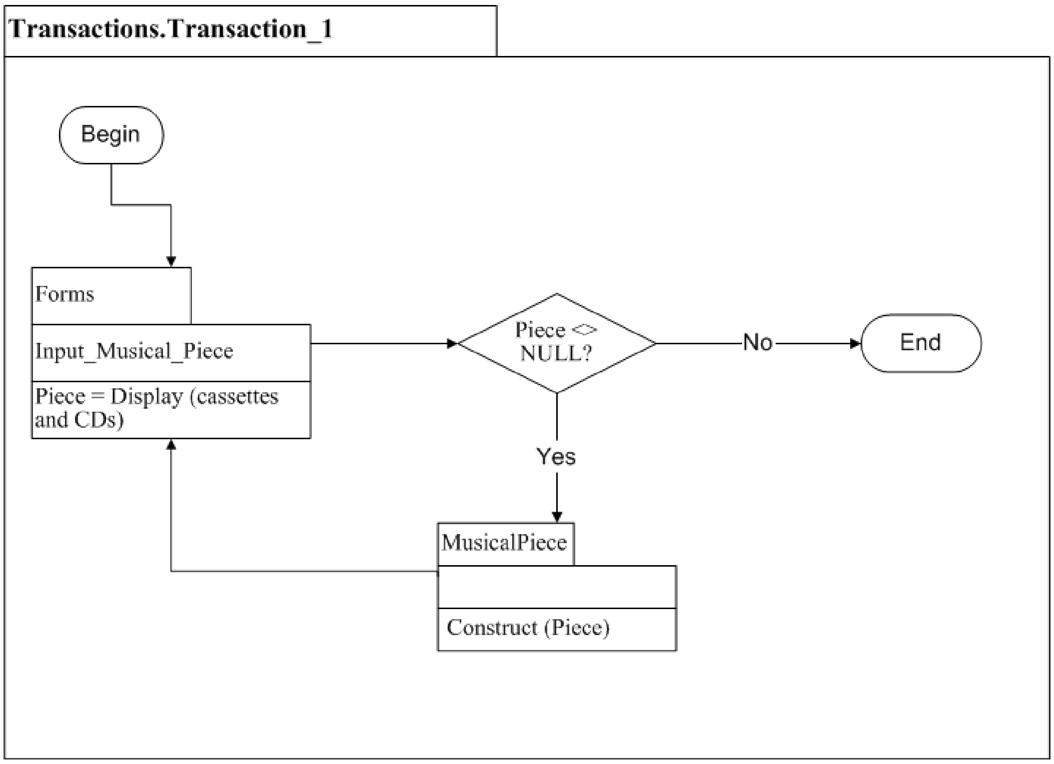
CONCLUSION

The advantages of the FOOM methodology are: (a) System analysis is performed in functional terms via OO-DFDs - a natural way for users to express their information needs, and in data terms via an initial class diagram. (b) System design follows the analysis and uses its products. The class diagram is augmented with a Menus class that is derived from the menus designed earlier from the OO-DFDs. Inputs and Outputs classes are also derived from the input forms and the outputs of the system (earlier

Figure 6. Pseudo-code of the transaction

```
Begin Transaction_1
   Repeat
      Piece=Forms.Input_Musical_Piece.Display (cassettes and CDs)
         /* Input_Musical_Piece is a form, which enable the user to fills in details of a musical piece. When
                                   the user completes the form it returns the filled piece object */
      If Piece <> NULL then        /* if the user selects to add a piece*/
               Musical_Piece.Construct(Piece)    /*Construct an object of Musical Piece*/
      End if
   Until Piece = NULL                    /* the user selects to stop adding pieces
End
```

Figure 7. Message chart of the transaction



products of the design stage). The transactions are defined as basic methods, specific methods and transaction methods. (c) The end products of the design phase can be easily implemented with any OO programming environment.

FOOM methodology is supported by a set of CASE tools. These include tools that enable creating and checking the correctness of class diagrams, hierarchical OO-DFDs and the menus of the application, and identifying transactions from DFDs. Other tools, which are under development, will enable designing the forms and reports, and creating pseudo-code and message charts of the methods – as based on the transactions.

KEY TERMS

ADISSA - Architectural Design of Information Systems based on Structured Analysis: An analysis and design methodology. In the analysis stage it utilizes hierarchical DFDs. In the design stage the DFDs are used to design the various components of the system. These include: a) top-level descriptions of the transactions, which eventually become detailed descriptions of the applications programs; b) the user interfaces (menus); c) the input and output screens and reports; d) the database schema in the form of normalized relations, and SQL commands for retrieving and updating the database.

DFD - Data Flow Diagram: A diagram used in functional analysis that specifies the functions of the system, the inputs/outputs from/to external (user) entities, and the data being retrieved from or updating data stores. There are well-defined rules for specifying correct DFDs as well as for creating hierarchies of interrelated DFDs.

ER - Entity-Relationship: A conceptual data model that defines the domain in terms of entities, attributes and relationships. ERD is an ER diagram, in which entities are represented as rectangles, attributes as ellipses and relationships between entities as diamonds.

OO-DFD – Object-Oriented DFD: A variant of DFDs introduced in FOOM methodology, which include object (data) classes rather than data stores.

SSA - Structured System Analysis: A traditional, functional-oriented methodology for analyzing information systems, which utilized data flow diagrams.

SSD - Structured System Design: A traditional methodology for designing information systems, which utilized structure charts.

SQL – Structured Query Language: A standard language for querying and updating a relational database.

UML – Unified Modeling Language: An "industrial standard" notation for object-oriented development. It consists of a several types of (mostly) diagrams that enable describing systems from different perspectives, including managerial, structural and behavioral (functional).

Ethical Implications of Investigating Internet Relationships

Monica T. Whitty
Queen's University Belfast, Northern Ireland

INTRODUCTION

The focus on Internet relationships has escalated in recent times, with researchers investigating such areas as the development of online relationships (e.g., McCown, Fischer, Page & Homant, 2001; Parks & Roberts, 1998; Whitty & Gavin, 2001), the formation of friends online (Parks & Floyd, 1996), representation (Bargh, McKenna & Fitzsimons, 2002), and misrepresentation (Whitty, 2002) of self online. Researchers have also attempted to identify those addicted to accessing online sexual material (Cooper, Putnam, Planchon & Boies, 1999). Moreover, others have been interested in Internet infidelity (Whitty, 2003a) and cybersex addiction (Griffiths, 2001; Young, Griffin-Shelley, Cooper, O'Mara & Buchanan, 2000). Notwithstanding this continued growth of research in this field, researchers have neglected to consider the more ethical ways in conducting this type of research.

While it is acknowledged here that some of the discussions in this article might be equally applied to the study of other Internet texts, such as religious or racial opinions, the focus in this article is on the concomitant ethical concerns of ongoing research into Internet relationships. Given that the development and maintenance of online relationships can be perceived as private and very personal (possibly more personal than other sensitive areas), there are potential ethical concerns that are unique to the study of such a topic area (Whitty, 2004). For a broader discussion of virtual research ethics, refer to Ess and Jones (2004).

REVIEW OF RESEARCH ON INTERNET RELATIONSHIPS AND SEXUALITY

Early research into this area has mostly focused on the similarities and differences between online and offline relationships. Researchers have been divided over the importance of available social cues in the creation and maintenance of online relationships. Some have argued that online relationships are shallow and impersonal (e.g., Slouka, 1995). In contrast, others contend that Internet relationships are just as emotionally fulfilling as face-to-face relationships, and that any lack of social cues can be overcome (Lea & Spears, 1995; Walther, 1996). In addition, researchers have purported that the ideals that are important in traditional relationships, such as trust, honesty, and commitment, are equally important online, but the cues that signify these ideals are different (Whitty & Gavin, 2001). Current research is also beginning to recognize that for some, online relating is just another form of communicating with friends and lovers, and that we need to move away from considering these forms of communication as totally separate and distinct entities (e.g., Vayreda, Galvez, Nunez & Callen, 2002). Moreover, McKenna, Green, and Gleason (2002) have found that when people convey their 'true' self online, they develop strong Internet relationships and bring these relationships into their 'real' lives.

Internet friendships developed in chat rooms, newsgroups, and MUDs or MOOs have been examined by a number of researchers. For example, Parks and Floyd (1996) used e-mail surveys to investigate how common personal relationships are in newsgroups. After finding that these relationships were regularly formed in newsgroups, Parks and Roberts (1998) examined relationships developed in MOOs. These researchers found that most (93.6%) of their participants had reported having formed some type of personal relationship online, the most common type being a close friendship.

Researchers have also been interested in how the playful arena of the Internet impacts on the types of relationships formed in these places (e.g., Whitty, 2003b; Whitty & Carr, 2003). Turkle's (1995) well-known research on her observations while interacting in MUDs found that the role-playing aspect of MUDs actually creates opportunities for individuals to reveal a deeper truth about themselves. Whitty and Gavin (2001) have also contended that although people do lie about themselves online, this paradoxically can open up a space for a deeper level of engagement with others.

Cybersex addiction and the available treatment for these cybersex addicts and their partners has been an area of research and concern for psychologists (e.g., Schneider, 2000; Young, Pistner, O'Mara & Buchanan, 1999). Research has also focused on what online acts might be considered as an act of infidelity. For example, Whitty (2003a) found that acts such as cybersex and hot-chatting were perceived as almost as threatening to the offline relationship as sexual intercourse. In addition to the above concerns, Cooper et al. (1999) identified three categories of individuals who access Internet erotic material, including recreational users, sexual compulsive users (these individuals are addicted to sex *per se*, and the Internet is but one mode where they can access sexual material), and at-risk users (these individuals would never have developed a sexual addiction if it were not for the Internet).

ETHICAL ISSUES PERTINENT TO THE STUDY OF INTERNET RELATIONSHIPS

Much of the research, to date, on Internet relationships and sexuality has been conducted online—either through interviews and surveys, or by carrying out analysis on text that is readily available online. There are many advantages to conducting research online, as well as collecting text or data available online for analysis in one's research (see Table 1).

In spite of the numerous advantages to conducting research online, investigators also need to be aware of the disadvantages (see Table 2).

What all studies that research Internet relationships have in common is that they are researching a sensitive topic, which requires individuals to reveal personal and often very private aspects of themselves and their lives. Given the sensitive nature of this topic area, it is crucial that researchers give some serious thought to whether they are truly conducting research in an ethical manner.

A common form of using the Internet for researching online relationships is to analyze the text produced by people online. The text can be produced in a number of different forums, including chat rooms, MUDs, newsgroups, and online dating sites. One way researchers collect data is by lurking in these different spaces in cyberspace. The development of online relationships (both friendships and romantic) and engaging in online sexual activities, such as cybersex, could easily be perceived by those engaging in such activities as a private discourse. Given the nature of these interactions, social researchers need to seriously consider if they have the right to lurk in online settings in order to learn more about these activities—despite the benefits of obtaining this knowledge.

There are fuzzy boundaries between what constitutes public and private spaces online, and researchers need to acknowledge that there are different places online. For example, a chat room might be deemed a more public space than e-mail. It is contended here that lurking in some spaces online might be ethically questionable. We must, as researchers, debate how intrusive a method lurking potentially is. As Ferri (1999, cited in Mann & Stewart, 2000) contends: "Who is the intended audience of an electronic communication—and does it include you as a researcher?" (p. 46).

Researchers also need to consider how the participant perceives the spaces online. As Ferri suggests, private interactions can and do indeed occur in public places. It has been theorized that the Internet can give an individual a sense of privacy and anonymity (e.g., Rice & Love, 1987). The social presence theory contends that "social presence" is the feeling that one has that other persons are involved in a communication exchange (Rice & Love, 1987). Since computer-mediated relating (CMR) involves less non-verbal cues (such as facial expression, posture, and dress) and auditory cues in comparison to face-to-face communication, it is said to be extremely low in social presence. Hence, while many others might occupy the space online, it is not necessarily perceived in that way. As researchers, we need to ask: Can researchers ethically take advantage of these people's false sense of privacy and security? Is it ethically justifiable to lurk in these sites and download material without the knowledge or consent of the individuals who inhabit these sites? This is especially relevant to questions of relationship development and sexuality, which are generally understood to be private matters. Therefore, good ethical practice needs to consider the psychology of cyberspace and the false sense of security the Internet affords.

Table 1. Practical benefits of conducting research online

-	Easy access to a population of individuals who form relationships online and who access sexual material
-	Internet provides researchers with a population that is sometimes difficult to research (e.g., people with disabilities, agoraphobia)
-	Contact people in locations that have closed or limited access (e.g., prisons, hospitals)
-	Requires relatively limited resources
-	Ease of implementation

Table 2. Disadvantages of conducting research online

- Security issues
- Possible duplication of participants completing surveys
- Difficult to ascertain how the topic area examined impacts on the participant
- Restricted to a certain sample

It is suggested here that researchers need to maintain personal integrity as well as be aware of how their online investigations can impact on the Internet relationships they study. For example, given researchers' knowledge of online relationships, interacting on online dating sites, chat rooms, and so forth could potentially alter the dynamics of these communities.

While it might be unclear as to how ethical it is for lurkers to collect data on the Internet, there is less doubt as to whether it is acceptable to deceive others online in order to conduct social research, especially with respect to online relationships and sexuality. Ethical guidelines generally state that deception is unethical because the participant is unable to give free and fully informed consent. For example, according to the Australian National Health and Medical Research Council (NHMRC), which set the ethical guidelines for Australian research:

"…as a general principle, deception of, concealment of the purposes of a study from, or covert observation of, identifiable participants are not considered ethical because they are contrary to the principle of respect for persons[,] in that free and fully informed consent cannot be given." (NHMRC, 1999)

Generally, ethical guidelines will point out that only under certain unusual circumstances is deception unavoidable when there is no alternative method to conduct one's research. However, in these circumstances individuals must be given the opportunity to withdraw data obtained from them during the research that they did not originally give consent to.

PRACTICAL CONSIDERATIONS

As with any other research conducted within the social sciences, some important ethical practices need to be adhered to when we conduct research on Internet relationships and sexuality (see Table 3).

Informed consent requires researchers to be up front from the beginning about the aims of their research and how they are going to be utilizing the data they collect. In offline research, individuals often sign a form to give their consent; however, this is not always achievable online. One way around this is to direct participants to a Web site that contains information about the project. This Web site could inform the participants about the purpose of the study, what the study entails, as well as contact details of the researcher and the university Human Ethics Committee.

In some cases, spaces on the Web are moderated. In these instances, it is probably also appropriate to contact the moderators of the site prior to contacting the participants. This is analogous to contacting an organization prior to targeting individuals within that organization. Researchers also need to be aware that some European countries require written consent. If written consent is required, then the participant could download a form and sign it offline, and return it by fax or postal mail (Mann & Stewart, 2000).

In research about relationships and sexuality, in particular, there is the risk that the interview or survey has created too much stress for the participant to continue. As with offline research, we need to consider up until what point a participant can withdraw consent. The end point of withdrawal of consent might be, for instance, after the submitting of the survey or at the conclusion of the interview, the interviewer might find confirmation that the participant is happy to allow the researcher to include the transcript in the study. Social scientists should also be aware that the lack of social cues available online makes it more difficult for them to ascertain if the participant is uncomfortable. Thus one should tread carefully and possibly make an effort to check at different points in the interview if the individual is still comfortable with proceeding.

There are other issues unique to Internet research with respect to withdrawal of consent. For example, the computer could crash midway through an interview or survey. Mechanisms need to be put into place to allow participants to rejoin the research if desired, and consent should not be assumed. In circumstances such as the computer or server crashing, we might need to have a system to enable debriefing, especially if the research is asking questions of a personal nature. Nosek, Banaji, and Greenwald (2002) suggest that debriefing can be made available by providing a contact e-mail address at the beginning of the study. They also suggest providing "a 'leave the study' button, made available on every study page, [which] would allow participants to leave the study early and still direct them to a debriefing page" (p. 163). In

Table 3. Ethical practices

- Informed consent
- Withdrawal of consent
- Confidentiality
- Psychological safeguards

addition, they suggest that participants be given a list of frequently asked questions (FAQs), since, they argue, there is less opportunity to ask the sorts of questions participants typically ask in face-to-face interviews.

There are various ways we might deal with the issue of confidentiality. As with offline research we could elect to use pseudonyms to represent our participants or even request preferred pseudonyms from them. However, a unique aspect of the Internet is that people typically inhabit the Web using a screen name, rather than a real name. Can we use a screen name given that these are not real names? While they may not be people's offline identities, individuals could still be identified by their screen names if we publish them—even if it is only recognition by other online inhabitants.

As mentioned earlier in this article, research into the areas of relationships and sexuality is likely to cause psychological distress for some. It is perhaps much more difficult to deal with psychological distress online and with individuals in other countries. Nevertheless, it is imperative that we ensure that the participant does have counseling available to them if the research has caused them distress—which sometimes might be delayed distress. This could mean that there are limits to the kinds of topics about which we interview participants online, or that we restrict our sample to a particular country or region where we know of psychological services that can be available to our participants if required.

Given that research into Internet relationships and sexuality is a relatively new area, future research might also focus on how to improve ethical practices. For instance, future studies might interview potential participants about how they would prefer social scientists to conduct research. Moreover, gaining a greater understanding of how individuals perceive private and public space could also influence how we conduct future studies in this topic area.

CONCLUSION

In concluding, while this article has provided examples of ways forward in our thinking about virtual ethics in respect to the study of online relationships, it is by no means prescriptive or exhaustive. Rather, it is suggested here that debate over such issues should be encouraged, and we should avoid setting standards for how we conduct our Internet research without also considering the ethical implications of our work. The way forward is to not restrict the debate amongst social scientists, but to also consult the individuals we would like to and are privileged to study.

KEY TERMS

Chat Room: A Web site, or part of a Web site, that allows individuals to communicate in real time.

Cybersex: Two or more individuals using the Internet as a medium to engage in discourses about sexual fantasies. The dialogue is typically accompanied by sexual self-stimulation.

Discussion Board/Group: A Web site, or part of a Web site, that allows individuals to post messages, but does not have the capacity for interactive messaging.

Hot-Chatting: Two ore more individuals engaging in discourses that move beyond light-hearted flirting.

Lurker: A participant in a chat room or a subscriber to a discussion group, listserv, or mailing list who passively observers. These individuals typically do not actively partake in the discussions that befall in these forums.

MUDs and MOOs: Multiple-user dungeons, or more commonly understood these days to mean multi-user dimension or domains. These were originally a space where interactive role-playing games could be played, very similar to Dungeons and Dragons.

Online Sexual Activity: Using the Internet for any sexual activity (e.g., recreation, entertainment, exploitation, education).

Screen Name: A screen name can be an individual's real name, a variation of an individuals' name, or a totally made-up pseudonym. Screen names are especially required on the Internet for applications such as instant messaging.

E

Ethics of New Technologies

Joe Gilbert
University of Nevada Las Vegas, USA

INTRODUCTION

Information processing has been done through telling stories, drawing on cave walls, writing on parchment, printing books, talking on telephones, sending messages via telegraphs, broadcasting on radio and television, processing data in computers, and now by instantaneous network dissemination. Since the mid-1990's, personal computers have been the instrument of choice for sending and receiving information, and for processing much of it. The technology is the latest in a long series, but social issues involved have not really changed. Issues of content (is it true? obscene?), ownership (whose picture/text/idea? whose parchment/telephone system/computer?), and impact (anti-government, anti-social, harmful to children) appear today just as they did hundreds or thousands of years ago.

BACKGROUND

New technologies enable people to do new things (send 20 copies of a memo at once) or to do old things in new ways, such as storing files (Freeman & Soete, 1997). Improvements in technology that are incremental do not usually introduce major social issues, but radical innovations frequently present new kinds of social opportunities and threats (Brown, 1997). Ethics is the branch of philosophy that studies interpersonal or social values and the rules of conduct that follow from them. Ethics deals with questions of how people should treat each other on a basic level (Berlin, 2000). It considers such issues as rights and duties and fairness or justice. Because ethics concerns itself with fundamental rules, its applications to specific new technologies might require both knowledge of the new technology and reasoning about its possible applications based on established principles of ethics (Burn & Loch, 2001; Halbert & Ingulli, 2002).

Philosophers have pondered and written about issues of ethics for thousands of years. Some of their writings on this subject continue to be read and debated generation after generation (LaFollette, 2000). Three basic approaches have been most common and most accepted in discussions of ethics.

- Utilitarianism maintains that the ethical act is the one that creates the greatest good for the greatest number of people.
- Rights and duties maintain that the ethical act is the one that acknowledges the rights of others and the duties which those rights impose on the actor.
- Fairness and justice hold that the ethical act is the one that treats similarly situated people in similar ways with regard to both process and outcome.

ETHICS AND TECHNOLOGY

John Stuart Mill and Jeremy Bentham are the two philosophers most closely associated with utilitarianism. This view of ethics puts a high value on results, and holds that we must consider whether and to what degree our actions will bring pain or pleasure not only to ourselves but to all others who will be impacted by what we do (Frey, 2000; Mill & Bentham, 1987). A utilitarian would argue that the harm done to many individuals and businesses by viruses and worms far outweighs any happiness brought to their authors, and thus creating and disseminating such code is unethical. Similarly, a utilitarian analysis of music file-sharing would consider whether widespread free file-sharing might result in composers and artists deciding that it is not in their financial interest to continue writing and performing music. If this result occurred, not only the composers and artists but also their listeners would end up suffering harm that might outweigh the good that they enjoy from free file-sharing. Finally, a utilitarian analysis would favor products and policies that increase the spread of computer literacy and availability, since the Internet can bring great good to its users and computer literacy and availability makes such use possible.

Many philosophers have written about rights and duties (Sumner, 1987). The basic idea of this approach is that individuals do have rights, and that these rights are, practically speaking, worthless unless someone or some group has a corresponding duty. Thus, if I have a right to privacy, you have a duty not to monitor my every move (Kelly & Rowland, 2000). There are four basic sources of rights, and we will consider each in turn.

Human rights are possessed by every human, simply by virtue of being human. Among these rights are the right to live (not to be randomly killed), to be told the truth, to own property, and to basic dignity (Ignatieff, 2001). Among these, the one that most often causes confusion is the right to be told the truth. Humans could not interact with each other in any meaningful way if lying and truth-telling were equally valid. Promises, contracts, and interpersonal relations all depend on the fact that the default setting for conversation is truth-telling. This does not mean that everyone always will or even should tell the whole truth all the time. It does, however, mean that we can and do start with an assumption of truth-telling (Bok, 1999). A right to property, whether physical or intellectual, means that others have a duty not to take or use my goods without compensating me.

Since property rights are human, they apply whether a given country's laws regarding such things as copyright and intellectual property are specific on a given issue or not. Music companies and movie studios, on behalf of individual artists, have a right to control and charge for distribution of their products. This right imposes a duty on individuals not to take such property without paying for it and recognizing the terms of distribution. Similarly, software companies have a right to charge for and control the distribution of their intellectual property. They paid programmers to develop a software product; others have a duty to respect the rights to this intellectual property.

Some rights are given to individuals by law. These citizen rights come by reason of membership in a community (nation, state, county, etc.). The right of citizens of the United States to free speech is not recognized by some other countries. Typically, dictatorships grant few citizen rights to those under their rule. These rights often coincide with human rights (right to live, to property, etc.) but frequently go beyond basic human rights. Copyright, as it exists in the United States, is not recognized equally in all countries. This is why it is important that the basic right to own property is a human right—it is valid whatever the laws of a particular jurisdiction.

A third source of rights is position. Policemen may apprehend and incarcerate suspected criminals. CEO's can speak for their companies on many issues. Purchasing agents can spend a company's money on goods or services within some limits. Managers can set rules for computer usage at work. People have these rights not just because they are human, or because they are particularly wise or knowledgeable, but because of the position they occupy. Since individuals have these rights, others have duties to respect the rights and follow their direction.

The fourth and final basic source of rights is by contract. Individuals or organizations can agree to contractual relations that create rights and impose duties that would not otherwise exist. If I agree to pay a certain amount of money each month in order to use an online service, I have a duty to pay and the service provider has a duty to make the service available to me under the terms of the contract.

The third basic approach to ethics is fairness and justice: it is ethical to be fair and unethical to be unfair. It is not fair that some individuals should purchase software and others obtain it free through sharing or piracy. It is fair for those who invest time, talent and money in producing software to be paid for the products resulting from their efforts and investments by all of those who use them, not just by some. Issues of fairness sometimes arise in the area of using computer technology for purposes of employee monitoring (Alder, 1998). In general terms, fairness involves treating similarly situated people in similar ways with regard to both process and outcome. However, justice is sometimes defined as equality, and at other times, as based on contribution, on needs and abilities, or on maximum freedom (Velasquez, 2002).

An issue that often arises in considering fairness and justice is the question of which individuals or groups are similarly situated. In the sense that all who access the Internet can view unrestricted sites, all who access the Internet are similarly situated. In the sense that some who access the Internet may choose to view pornography and others may choose not to (even inadvertently), we have at least two groups that are not similarly situated. Using this approach, one might argue against unrestricted availability of pornography on the Internet, but in favor of restricted access to Internet pornography. All who receive e-mail might be viewed as similarly situated. Spam reaching all e-mail accounts thus reaches similarly situated people. However, if most individuals who receive e-mail do not wish to receive spam, then this group (the unwilling) might be seen as not similarly situated with those who do wish to receive it. Such an argument could serve as the basis for something like an e-mail equivalent of the do-not-call list recently introduced for telemarketing.

The different approaches to ethics often produce the same result. If we consider the issue of hacking or gaining unauthorized access to another's system, utilitarianism concludes that more harm than good results from this activity. Those whose system is wrongfully accessed are faced with revising controls, checking to see what harm if any has been done, and correcting any problems caused by the hacking. Only the hacker gains. Those who have created or purchased the system have a right to limit access; the hacker has a duty to respect this right. It is not fair or just that some people go through the appropriate authorization to access or use a system while others hack into it. Thus from all three perspectives, hacking as defined can be judged unethical. If one does not accept the basic premises of the prevailing capitalist system, however, a defense of hacking can be devised (Halbert, 1994).

When the three approaches provide different results, rights and duties usually prevails as a way of determining whether an act is ethical, because rights are so basic. However, this is not always the case. In American copyright law, there is a "fair use" provision that allows an individual to make one copy for personal use of a copyrighted article without obtaining permission of the copyright holder. Whether this copy is made from a printed article on a photocopy machine or downloaded from a computer, the same basic principle applies (Halbert & Ingulli, 2003). A utilitarian analysis suggests that this provision allows the greatest good for the greatest number of people, because single-copy permissions for personal use would involve excessive transaction costs to both users and copyright owners. One could argue from a rights and duties perspective that the copyright owner has a right (and the user a corresponding duty) to payment for each and every copy made of the material, even for a single copy. Fairness and justice would suggest that the "fair use" exception is ethically acceptable as long as each owner and user play by the same rules.

FUTURE TRENDS

Each of the three views can be used to analyze issues regarding new information technology and its applications (Gilbert, 2001). Because information technology has developed so quickly in the last quarter century, and appears to be poised for continued rapid development, a good deal of ethical analysis is and will be needed of specific questions and issues. The basic approaches are clear from a long history of ethical theory. The specific issues are and will be fresh, but those concerned with using information technology ethically can find answers to their questions. The collecting, storing, transmitting and analysis of information will continue to be central to both commerce and society. Issues of ownership, access, privacy and social impact will continue to concern individuals and society.

It seems safe to assume that laws will evolve and court decisions will help to illuminate legal issues involved with information processing technology. Individual managers, technicians and citizens will ponder and debate the ethics of various uses of this technology. Basic philosophical approaches will remain the same; their application to individual situations will continue to require that thoughtful individuals work through the journey from abstract principles to particular applications and decisions.

CONCLUSION

Much of the discussion of right and wrong concerning information technology is based either on personal opinion or on legal interpretations of such topics as intellectual property rights and individual privacy. Philosophers have thought about, discussed, and written about right and wrong for thousands of years. While the history of philosophy has unfolded before the invention of electronic information technology, issues such as privacy, property ownership, truthfulness, and government intrusion on individual liberties have been the subjects of ethical inquiries for well over two thousand years. In attempting to cope with social issues raised by new technologies, the best thoughts of many generations of humans can be usefully brought to bear on current controversies. Doing this requires both knowledge of the discipline of ethics and at least some knowledge of new technologies and their social impacts. The application of such knowledge connects us with our ancestors who wrote on cave walls, told stories over campfires, printed books, and used the other means of processing information described at the beginning of this article.

KEY TERMS

Citizen Rights: Those rights that an individual has by virtue of being a member of a government unit (country, state, province, etc.). They vary from government unit to government unit.

Contract Rights: Those rights that an individual has by reason of a valid contract that imposes duties on the other contracting party or parties. They are enforceable under legal systems, but are not the same as citizen rights.

Duties: The correlative of rights, since rights by their nature impose duties.

Ethics: The study of social or interpersonal values and the rules of conduct that follow from them.

Fairness and Justice: The philosophical view that the moral act is the one that treats similarly situated people in similar ways with regard to both process and outcome.

Human Rights: Those rights that all humans have simply by reason of being human, without regard to an individual government unit's laws.

Philosophy: The study of basic principles including what and how we know, rules for language and reasoning, and the basis for social interaction.

Position Rights: Those rights that an individual has by reason of the position that he or she occupies, such as police officer, chief financial officer, or parent.

Rights and Duties: The philosophical view that the moral act is the one that recognizes the rights of others and the duties that those rights impose on the actor.

Utilitarianism: The philosophical view that the moral act is the one that results in the greatest good or happiness for the greatest number of people.

Evaluating Computer–Supported Learning Initiatives

John B. Nash
Stanford University, USA

Christoph Richter
University of Hannover, Germany

Heidrun Allert
University of Hannover, Germany

INTRODUCTION

The call for the integration of program evaluation into the development of computer-supported learning environments is ever increasing. Pushed not only by demands from policy makers and grant givers for more accountability within lean times, this trend is due also to the fact that outcomes of computer-supported learning environment projects often fall short of the expectations held by the project teams. The discrepancy between the targets set by the project staff and the outcomes achieved suggests there is a need for formative evaluation approaches (versus summative approaches) that facilitate the elicitation of information that can be used to improve a program while it is in its development stage (c.p., Worthen, Sanders & Fitzpatrick, 1997). While the call for formative evaluation as an integral part of projects that aim to develop complex socio-technical systems is widely accepted, we note a lack of theoretical frameworks that reflect the particularities of these kind of systems and the ways they evolve (c.p., Keil-Slawik, 1999). This is of crucial importance, as formative evaluation will only be an accepted and effective part of a project if it provides information useful for the project staff. Below we outline the obstacles evaluation faces with regard to projects that design computer-supported learning environments, and discuss two promising approaches that can be used in complimentary fashion.

BACKGROUND

According to Worthen et al. (1997), evaluation is “the identification, clarification, and application of defensible criteria to determine an evaluation object’s value (worth or merit), quality, utility, effectiveness, or significance in relation to those criteria.” In this regard evaluation can serve different purposes. Patton (1997) distinguishes between judgment-, knowledge- and improvement-oriented evaluations. We focus on improvement-oriented evaluation approaches. We stress that evaluation can facilitate decision making and reveal information that can be used to improve not only the project itself, but also outcomes within the project’s target population. The conceptualization of evaluation as an improvement-oriented and formative activity reveals its proximity to design activities. In fact this kind of evaluative activity is an integral part of any design process, whether it is explicitly mentioned or not. Accordingly it is not the question if one should evaluate, but which evaluation methods generate the most useful information in order to improve the program. This question can only be answered by facing the characteristics and obstacles of designing computer-supported learning environments.

Keil-Slawik (1999) points out that one of the main challenges in evaluating computer-supported learning environments is that some goals and opportunities can spontaneously arise in the course of the development process and are thus not specified in advance. We believe that this is due to the fact that design, in this context, addresses ill-structured and situated problems. The design and implementation of computer-supported learning environments, which can be viewed as a response to a perceived problem, also generates new problems as it is designed. Furthermore every computer-supported learning experience takes place in a unique social context that contributes to the success of an intervention or prevents it. Therefore evaluation requires that designers pay attention to evolutionary and cyclic processes and situational factors. As Weiss notes, “Much evaluation is done by investigating outcomes without much attention to the paths by which they were produced” (1998, p. 55).

For developers designing projects at the intersection of information and communication technology (ICT) and the learning sciences, evaluation is difficult. Evaluation efforts are often subverted by a myriad of confounding variables, leading to a “garbage in, garbage out” effect;

the evaluation cannot be better than the parameters that were built in the project from the start (Nash, Plugge & Eurlings, 2001). Leaving key parameters of evaluative thinking out of computer-supported learning projects is exacerbated by the fact that many investigators lack the tools and expertise necessary to cope with the complexity they face in addressing the field of learning.

We strongly advocate leveraging the innate ability of members of the computer science and engineering communities to engage in "design thinking" and turn this ability into a set of practices that naturally becomes program evaluation, thereby making an assessment of the usefulness of ICT tools for learning a natural occurrence (and a manifest activity) in any computer-supported learning project.

Design-Oriented Evaluation for Computer-Supported Learning Environments

There are two approaches that inherently relate themselves to design as well as to evaluation. Therefore they are useful tools for designers of computer-supported learning initiatives. These two perspectives, discussed below, are scenario-based design and program theory evaluation. Both approaches assume that the ultimate goal of a project should be at the center of the design and evaluation discussion, ensuring a project is not about only developing a usable tool or system, but is about developing a useful tool or system that improves outcomes for the user. Beyond this common ground, these approaches are rather complementary to each other and it is reasonable to use them in conjunction with one another.

Scenario-Based Approaches

Scenario-based approaches are widely used in the fields of software engineering, requirements engineering, human computer interaction, and information systems (Rolland et al., 1996). Scenarios are a method to model the universe of discourse of an application, that is, the environment in which a system, technical or non-technical, will be deployed. A scenario is a concrete story about use of an innovative tool and/or social interactions (Carroll, 2000). Scenarios include protagonists with individual goals or objectives and reflect exemplary sequences of actions and events. They refer to observable behavior as well as mental processes, and also cover situational details assumed to affect the course of actions (Rosson & Carroll, 2002). Additionally it might explicitly refer to the underlying culture, norms, and values (see Bødker & Christiansen, 1997). That said, scenarios usually focus on specific situations, only enlighten some important aspects, and generally do not include every eventuality (e.g., Benner, Feather, Johnson & Zorman, 1993).

Beside their use in the design process, scenarios can also be used for purposes of formative evaluation. First of all, as a means of communication, they are a valuable resource for identifying underlying assumptions regarding the program under development. Stakeholder assumptions might include those related to instructional theories, the learner, the environmental context, and its impact on learning or technical requirements. Underlying assumptions such as these are typically hidden from view of others, but easily developed and strongly held within individuals developing computer-supported learning environments. Scenarios help to reveal the thinking of designers so that others can participate in the design process and questionable assumptions can come under scrutiny. The use of scenarios also allows identification of pros and cons of a certain decision within the design process. In this vein Carroll (2000) suggests employing "claim analysis." Claims are the positive or negative, desirable and undesirable consequences related to a certain characteristic of a scenario. Assuming that every feature of a proposed solution usually will entail both positive and negative effects helps to reflect on the current solution and might provoke alternative proposals. The analysis of claims is thereby not limited to an intuitive ad hoc evaluation, but also can bring forth an explicit hypothesis to be addressed in a subsequent survey.

Program Theory Evaluation

Program theory evaluation, also known as theory-based evaluation, assumes that underlying any initiative or project is an explicit or latent "theory" (or "theories") about how the initiative or project is meant to change outcomes. An evaluator should surface those theories and lay them out in as fine detail as possible, identifying all the assumptions and sub-assumptions built into the program (Weiss, 1995). This approach has been promoted as useful in evaluating computer-supported learning projects (Strömdahl & Langerth-Zetterman, 2000; Nash, Plugge & Eurlings, 2001) where investigators across disciplines find it appealing. For instance, for designers (in mechanical engineering or computer science), program theory evaluation reminds them of their own use of the "design rationale." And among economists, program theory evaluation reminds them of total quality management (TQM). In the program theory approach (Weiss, 1995, 1998; Chen, 1989; Chen & Rossi, 1987), one constructs a project's "theory of change" or "program logic" by asking the various stakeholders, "What is the project designed to accomplish, and how are its components intended to get it there?" The process helps the project stakeholders and the evaluation team to identify and come to consensus on the project's theory of change. By identifying and describing the activities, outcomes, and goals of the program, along with their interrelationships, the stakeholders are then in position to identify quantifiable measures to portray the veracity of the model.

Theory-based evaluation identifies and tests the relationships among a project's inputs or activities and its outcomes via intermediate outcomes. The key advantages to using theory-based evaluation are (Connel & Kubisch, 1995; Weiss, 1995):

- It asks project practitioners to make their assumptions explicit and to reach consensus with their colleagues about what they are trying to do and why.
- It articulates a theory of change at the outset and gains agreement on it, by all stakeholders reducing problems associated with causal attribution of impact.
- It concentrates evaluation attention and resources on key aspects of the project.
- It facilitates aggregation of evaluation results into a broader context based on theoretical program knowledge.
- The theory of change model identified will facilitate the research design, measurement, data collection, and analysis elements of the evaluation.

Both scenario-based design and program theory stress the importance of the social context while planning computer-supported environments. They also represent means to facilitate the communication among the stakeholders and urge the project team to reflect their underlying assumptions in order to discuss and test them. Furthermore, both approaches are particularly suitable for multidisciplinary project teams. Scenarios and program logic maps are not static artifacts; they are a starting point for discussion and have to be changed when necessary. With these similarities there are also differences in both approaches. The major difference between them is that program theory offers a goal-oriented way to structure a project, while scenario-based design proffers an explorative approach that opens the mind to the complexity of the problem, alternatives, and the diversity of theories that try to explain social and socio-technical process. That is, scenario-based design highlights the divergent aspects of project planning, and evaluation program theory stresses the convergent aspects. Program theory evaluation helps to integrate each scenario, decision, and predefinition into the whole process. Scenarios force users not just to use terms, but to give meaningful descriptions. They force users to state how they actually want to instantiate an abstract theory of learning and teaching. This helps to implement the project within real situations of use, which are complex and ill structured. Program theory helps to focus on core aspects of design and prevent getting 'lost in scenarios'. Scenarios and program theory evaluation can be used in an alternating way. Thereby it is possible to use both approaches and improve the overall development process.

The program theory of an initiative can be a starting point for writing scenarios. Especially the interrelations between the goals and interrelation between ultimate goal and inputs can be described with a scenario. The scenario can help to understand how this interrelation is meant to work and how it will look in a concrete situation. Scenarios on the other hand can be used to create program theory by pointing out main elements of the intended program. They can also be used to complete already existing program theory by presenting alternative situations of use. For developers of computer-supported learning environments, scenario-based design and program theory represent complementary approaches, which when used together or separately, can add strength to the implementation and success of such projects.

FUTURE TRENDS

It is clear that formative evaluation will become more important in the future, and it will be especially crucial to think about how to integrate evaluation into the design process. Essentially, designers will need to answer the question "Why does the program work?" and not just "Did it work?" It becomes obvious that the design of a computer-supported learning environment, like the development of any other complex socio-technical system, is a difficult process. In fact the necessity for changes in the original plan is practically preordained due to the ill-structured and situated nature of the domain. The mere act of engaging in a design process suggests that designers will engage in planned as well as evolutionary, unplanned activities. Therefore it is important that the project designers use methods that support divergent thinking and methods that support convergent processes. While scenario-based design and program-theory evaluation represent complementary views on the design and evaluation of computer-supported learning environments that can facilitate these processes, there is still room for improvement.

CONCLUSION

Formative evaluation is an important means to ensure the quality of an initiative's outcomes. Formative evaluation directed towards improvement of an initiative can be understood as a natural part of any design activity. While this is widely recognized, there is still a lack of program evaluation frameworks that reflect the uniqueness of the design process, the most crucial of which is the inherent ambiguity of design. In spite of great inspiration portrayed by project teams, usually manifested by visions of a certain and sure outcome, no project can be pre-planned completely, and midcourse corrections are a certainty. Scenario-based design and program theory evaluation provide a theoretical foothold for projects in need of collecting and analyzing data for program improvement and judging program success.

In sum, scenario-based design and program theory hold many similarities. The major difference between them is that program theory offers a goal-oriented way to structure a project, while scenario-based design provides an explorative approach that opens the mind to the complexity of the problem, alternatives, and the diversity of theories that try to explain social and socio-technical process.

Scenario-based design highlights the divergent aspects of project planning, and evaluation program theory stresses the convergent aspects. For developers of computer-supported learning experiences, scenario-based design and program theory represent complementary approaches, which when used together or separately can add strength to the implementation and success of ICT learning projects.

KEY TERMS

Computer-Supported Learning: Learning processes that take place in an environment that includes computer-based tools and/or electronically stored resources. CSCL is one part of this type of learning.

Evaluation: The systematic determination of the merit or worth of an object.

Formative Evaluation: The elicitation of information that can be used to improve a program while it is in the development stage.

Program: A social endeavor to reach some predefined goals and objectives. A program draws on personal, social, and material resources to alter or preserve the context in which it takes place.

Program Theory: A set of assumptions underlying a program that explains why the planned activities should lead to the predefined goals and objectives. The program theory includes activities directly implemented by the program, as well as the activities that are generated as an response to the program by the context in which it takes place.

Scenarios: A narrative description of a sequence of (inter-)actions performed by one or more persons in a particular context. Scenarios include information about goals, plans, interpretations, values, and contextual conditions and events.

Summative Evaluation: The elicitation of information that can be used to determine if a program should be continued or terminated.

Evaluating IS Quality as a Measure of IS Effectiveness

Carla Wilkin
The University of Melbourne, Australia

INTRODUCTION

An enduring question in information systems research and practice concerns evaluation of the impact of information systems (IS). It endures, as to date there is no ready solution. Focusing on one aspect, measuring IS success or effectiveness, there are ranges of measures available. At one end of the scale we have perceptual measures like use and user satisfaction; somewhere along that scale we have the more objective measures like quality; whilst at the other end we have objective measures like increased market share, price recovery and increased product quality.

Measurement of IS success or effectiveness has been shaped by DeLone and McLean (1992), who proposed a taxonomy and an interactive model that conceptualized and operationalized IS success. However, this was based on theoretical and empirical work from the 1970s and 1980s, published in the period 1981-1988. Information systems, not being a static phenomenon, have progressed and changed. DeLone and McLean (2002, 2003) themselves acknowledged this in their recent revisitation, reexamination and reformulation of their IS success model. Their view correctly affirms that we cannot leave people outside this equation; meaning objective measures alone are not appropriate. Furthermore, the subjectivity of perceptual measures mean they are of questionable usefulness. Taking the middle ground, where quality is the measure, the question then becomes how best to measure quality of a delivered IS.

In an equation that seeks to define our understanding of the value of information technology (IT) to the business process, the system as a stand-alone object is worthless. The worth of the system lies in its role in the business process: and it is people who make it work in these processes. What is therefore required is a measure that takes account of human reactions to delivered systems. This can be evaluated by considering a variety of end-user stakeholder expectations and/or perceptions as measures of quality. In fact, much insight can be gained by measuring the disconfirmation of expectations of ideal service and perceptions of reality (Wilkin, 2001), particularly if this is assessed at various levels of seniority.

MEASURING QUALITY

Debate has surrounded measuring quality from a disconfirmation perspective (Carr, 2002; Peter, Churchill & Brown, 1993; Van Dyke, Prybutok & Kappelman, 1999). Justification for including expectations (Cronin & Taylor, 1992, 1994; Teas, 1993, 1994; Van Dyke, Kappelman & Prybutok, 1997) centred on the insight it provided about how users formulated perceptions or how significant such users saw each dimension or statement (Carman, 1990; Kettinger & Lee, 1997; Parasuraman, Zeithaml & Berry, 1986; Pitt, Watson & Kavan, 1995). Moreover, expectations are seen as essential to both understanding and achieving IS effectiveness, particularly given the different internal opinions held by different user stakeholders where a low or high perception rating could provide misleading information. A measure that includes expectations provides insight regarding changes in the system environment (Watson, Pitt & Kavan, 1998; Wilkin, 2001).

The perception's only measure, another approach to defining and evaluating quality, was proposed in a belief that a measurement of service quality derived by the difference score only captured factors that were related to service quality and did not measure customers' view of the concept itself (Cronin & Taylor, 1992). However, support can be found for the view that a single measure of performance provides little information about a user's thoughts in relation to product features, nor the process by which performance is converted into understanding by the consumer (Oliver, 1989; Spreng, MacKenzie & Olshavsky, 1996).

A definition of quality could have many contradictory functions: sometimes implicit/sometimes explicit; at times mechanistic/at times humanistic; and sometimes conceptually/sometimes operationally understood. In an IT context, there is not any single understanding of the term. Quality, being concerned with the totality of features, is best evaluated as a multi-dimensional construct using multiple statements to capture the quality of each dimension.

Applying a measure of quality to evaluate something as complex as a delivered IS requires consideration and understanding of the mechanisms that underpin an IS. The DeLone and McLean model conceptualized system quality (not system) and information quality (not information). Despite the complexity and technical nature of some IT products, in order to achieve success, we need to look beyond the process and delivery of the product, to the system as a whole, and ask whether benefits can be gained by focusing on customer views of the quality of the product, product delivery and associated concerns (Wilkin, 2001).

Quality has many elements. If we put this human evaluation of a delivered system into context, then it is not just measurement of the system itself (system quality), nor the information so generated (information quality) that is important, but a balanced evaluation that also takes account of service (service quality) and the role of an IS unit in contributing to the effectiveness of delivered IS, which is important (Wilkin, 2001). Support for the argument to include service quality in this evaluation can be found in the work of other researchers too (DeLone & McLean, 2002, 2003; Kettinger & Lee, 1994; Li, 1997; Pitt, Watson & Kavan, 1995; Wilkin & Hewett, 1999).

Assuming a multi-dimensional approach to evaluating quality of delivered IS encompassing the system, information and service aspects, the issue then is which dimensions are important for each aspect (component). Table 1 summarizes the important dimensions (Wilkin, 2001) in measuring each component (system quality, information quality and service quality). Following on, what are then required are indicators capable of measuring aspects of each component. These are many and vary from "*responds quickly to all commands*" (system quality), to "*quickly interpreted*" (information quality) and "*delivers support in a timely manner*" (service quality).

Under this multi-dimensional approach, ratings for the various aspects of quality, 1, 2 and so on, captured on a Likert scale of 1 to 7 (strongly agree to strongly disagree), highlight problematic areas, which when viewed in conjunction with organizational goals and objectives, can facilitate the establishment of priorities.

At a strategic level, the merits of this approach, where multiple dimensions and statements are used to evaluate the quality/effectiveness of an information system, relate to the ease and simplicity with which insight into the system in question is provided. Predecessors have captured quality or surrogates of quality in a single statement, thereby limiting insights provided to interested parties on the aspects of the business system/application stakeholders perceive as problematic. Thinking beyond the impact on the individual and organization, the value provided by such an approach is significant in light of the advancement of organizations to what Drucker (1988) forecast as the third period of change in organizational structure, namely to an information-based organization. Herein, "information is data endowed with relevance and purpose and knowledge, by definition, is specialized" (Drucker, 1988, p. 58). Thus, it is accordingly vital that the IS delivers information of the required quality.

In line with Drucker (1988), this multi-dimensional approach allows the evaluator to directly target and compile the views of a broad cross-section of stakeholders regarding the quality of the IS with respect to the performance of their duties.

At an operational level, the merits of the approach include:

- the flexibility to add and subtract dimensions for each component according to users requirements;
- the use of different dimensions to measure the different components of quality;
- the capability for benchmarking where expectations, measured at intermittent intervals, is balanced with more timely assessment and reassessments of perceptions;
- the opportunity, because of the use of dimensionality, to discover specific problematic areas, and then "drill down" into those areas; and
- improvement in the "usefulness" of the results through the addition of statements specific to the situation – something that is offset to a degree against the increase in length.

FUTURE TRENDS

Despite much work having been done on evaluation of the impact of IS, further investigation is warranted to balance subjective and objective measures of quality of these systems. The answers to this investigation will probably flow from the debate concerning the relative merits of

Table 1. Important dimensions in measuring system quality, information quality and service quality

System Quality	Information Quality	Service Quality
Functionality	Accuracy	Expertise
Integration	Availability	Credibility
Usability	Relevance	Availability
Reliability	Presentation	Responsiveness
Security	Promptness	Supportiveness

considering the desirability and relevance of monetary evaluations balanced with subjective judgments related to end-user stakeholder evaluations of IS performance and productivity.

CONCLUSION

Iacocca's (1998) words, quality "doesn't have a beginning or a middle. And it better not have an end" (p. 257), are as valid today as ever, since the realization of high quality/effectiveness is only achievable when it becomes an intrinsic part of business operations through every stakeholder's mindset.

The quality-based, multi-dimensional approach to evaluation of a delivered IS outlined here (comprising components, dimensions and indicators), enables problematic areas to be more accurately pinpointed. The magnitude of organizations' investment and commitment to IT, compounded by the increasingly complex and interwoven nature of IS, make evaluation of quality of a delivered IS a significant issue. In this regard, this article has discussed a number of critical issues, which offer to business and researchers alike implications and challenges. Hence, despite persistent difficulties in measuring the quality of these delivered systems (Davis, 1989), we should pursue work on balancing subjective and objective measures of quality in a timely manner.

KEY TERMS

Component: A term used to describe an information system and its composition for the purposes of this work. Specifically, the components in this work are: system quality, information quality and service quality.

Dimension: Refers to the determinants of quality of each of the three components, namely, system quality, information quality and service quality.

Expectations: These have a future time perspective and a degree of uncertainty. Expectations are a set of beliefs, held by targeted users of an information system, associated with certain attributes, beliefs or outcomes. They are associated with the eventual perception of a system and with the performance of the system.

Indicator: A term used to refer to something that would point to quality or a lack thereof.

Information Quality: A global judgment of the degree to which these stakeholders are provided with information of excellent quality with regard to their defined needs, excluding user manuals and help screens (features of system quality).

IS Success: A global judgment of the degree to which these stakeholders believe they are better off. The term is sometimes used interchangeably with IS effectiveness.

Perceptions: Contingent upon prior expectations, perceptions have been used by some as a reality check of expectations, where an assessment of quality is derived by the disconfirmation of the two. Moreover, they have also been proposed as a measure of adequacy (perceptions)/importance.

Quality: An elusive and indistinct construct defined in terms of customer perceptions and expectations. In arriving at a definition, one must take account of both audience and circumstance. There has been some attempt to define it as a global judgment about a product's (or service's) overall excellence. Quality can be measured on the basis of customer expectations and perceptions, along the lines of Brown's (1992, p. 255) definition: "[t]he totality of features and characteristics of a product or service that bear on its ability to satisfy stated or implied needs".

Service Quality: A global judgment or attitude relating to an assessment of the level of superiority or excellence of service provided by the IS department and support personnel.

System Quality: A global judgment of the degree to which the technical components of delivered IS provide the quality of information and service as required by stakeholders, including hardware, software, help screens and user manuals.

INTRODUCTION

Educational goals have generally shifted from knowing everything in a specific domain to knowing how to deal with complex problems. Reasoning and information processing skills have become more important than the sheer amount of information memorized. In medical education, the same evolution occurred. Diagnostic reasoning processes get more strongly emphasized. Whereas previously knowing all symptoms and diseases was stressed, reasoning skills have become educationally more important. They must enable professionals to distinguish between differential diagnoses and recognize patterns of illnesses (e.g., Myers & Dorsey, 1994).

BACKGROUND

Authentic or realistic tasks have been advocated to foster the acquisition of complex problem-solving processes (Jacobson & Spiro, 1995; Jonassen, 1997). In medical education, this has led to the use of expert systems in education. Such systems were initially developed to assist practitioners in their practice (NEOMYCIN, in Cromie, 1988; PATHMASTER in Frohlich, Miller, & Morrow, 1990; LIED in Console, Molino, Ripa di Meanan, & Torasso, 1992). These systems simulate a real situation and were expected to provoke or develop students' diagnostic reasoning processes. However, the implementation of such expert systems in regular educational settings has not been successful. Instead of developing reasoning processes, these systems assume them to be available. They focus on quickly getting to a solution rather than reflecting on possible alternatives. Consequently, it was concluded that students need more guidance in the development of diagnostic reasoning skills (Console et al., 1992, Cromie, 1988; Friedman, France, & Drossman, 1991); instructional support was lacking.

KABISA is one of the computer programs that, among other things, aims at helping students to develop their diagnostic reasoning skills (Van den Ende, Blot, Kestens, Van Gompel, & Van den Enden, 1997). It is a dedicated computer-based training program for acquiring diagnostic reasoning skills in tropical medicine.

DESCRIPTION OF THE PROGRAM

KABISA confronts the user with cases or "virtual patients". The virtual patient is initially presented by three "characteristics"[3], randomly selected by the computer. After the presentation of the patient (three characteristics), students can ask additional characteristics gathered through anamnesis, physical examination, laboratory and imaging.

If students click on a particular characteristic, such as a physical examination test, they receive feedback. Students are informed about the presence of a certain symptom, or whether a test is positive or negative. If students ask a "non-considered" characteristic, that is, a characteristic that is not relevant or useful in relation to the virtual patient, they are informed about this and asked whether they want to reveal the diagnosis they were thinking about. When they do so, students receive an overview of the characteristics that were explained by their selection and which ones are not. Additionally, they get the place of the selected diagnosis on a list that ranks diagnoses according to their probability given the characteristics at hand. If students do not want to show the diagnosis they were thinking about, they can just continue asking characteristics.

A session is ended with students giving a final diagnosis. KABISA informs them about the correctness. If it is correct, students are congratulated. If the diagnosis is not correct, students may be either informed that it is a very plausible diagnosis but that they do not have enough evidence, or they may get a ranking of their diagnosis and an overview of the disease characteristics that can and cannot be explained by their answer.

Additionally, different non-embedded support devices, that is, tools, are made available to support learners. These tools allow students to look for information about certain symptoms or diseases, to compare different diagnoses, or to see how much a certain characteristic contributes to the certainty for a specific diagnosis. Students decide themselves when and how they use these devices (for a more detailed description, see Clarebout, Elen, Lowyck, Van den Ende, & Van den Enden, 2004).

FUTURE TRENDS

In this section, some critical issues are put forward that raise discussion points for the future design and development of open learning environments.

A Learning Environment vs. a Performance Environment

KABISA is designed as an open learning environment, that is, students are confronted with a realistic and authentic problem; there is a large amount of learner control and tools are provided to learners to guide their learning (Hannafin, Land & Oliver, 1999). However, the performed evaluation study revealed some interesting issues. A first revelation was that students do not follow a criterion path when working on KABISA. Prior to the evaluation, two domain experts in collaboration with three instructional designers constructed a criterion path. This path represented the ideal paths students should go through to optimally benefit from KABISA (following the “normative approach” of Elstein & Rabinowitz, 1993), including when to use a specific tool. Only five out of 44 students followed this path.

A second issue relates to tool use. KABISA offers different tools to support students. These tools can help students in their problem-solving process. Results suggest that students consult some help functions more than others, but overall they do not consult them frequently and if they use them they do not use them adequately. Students also tend to not use the feedback that they can obtain when asking for a “non-considered” characteristic.

Although this environment can be described as an open learning environment, it seems that students do not perceive it as a learning environment, but rather as a performance environment. Thinking aloud protocols reveal that students think they are cheating or failing when consulting a tool. Giving the limited use of these tools, it becomes difficult to gain insight in the effect of tool use on the learning process.

However, in spite of the observation that in only a small number of consultations the criterion path was followed, students do find in 80% of the consultations the right diagnosis. It seems that by trial and error, by not following the criterion path, students can also obtain the right diagnosis.

The results of this evaluation suggest that students do not use KABISA to foster their diagnostic reasoning skills. Rather, KABISA enables them to train readily available skills.

The Use of Design Models for Designing Open Learning Environments

This evaluation shows the importance of an evaluation phase in the design and development of computer-based training programs. It reveals the valuable contribution of (linear) design models, such as the so-called ADDIE-model (Analyse-Design-Development-Implementation-Evaluation). Although it is argued that in open learning environments a linear design process cannot longer be applied, this evaluation shows that it still can contribute to the design. For instance, a more thorough analysis (first phase) of student characteristics could have provided a means to adapt the difficulty level to the level of the students or to identify what guidance students actually need. Apparently, the feedback given to students does not encourage them to adapt their problem-solving process. Being product- rather than process-oriented, feedback may not be adapted to students’ actual needs. Or, students’ instructional conceptions about computer-based learning environments or their perceptions about KABISA (game versus an educational application) may influence the use of the program. Students’ instructional conceptions should be taken into account through the design process of the program. One possible way to influence these conceptions might be the introduction of the program. In the introduction, the aims of the program, the different functionalities and the relationship with the different courses should be clearly defined (see Kennedy, Petrovi, & Keppell, 1998, for the importance of introductory lessons). This relates to the implementation phase.

Given the difficulty of anticipating potential problems and difficulties students might encounter in open learning environments, it might be considered to break the linearity of such design models and to introduce a formative evaluation after each phase. This would enable the redirection of the program while developing it, rather than after the implementation of the program. Rather than only evaluating a final product, the development process should be taken into consideration as well. Rapid prototyping for testing the program at different phases of the development might be indicated. This leads to a more spiral cycle rather than a linear design process.

Amount of Learner Control in Computer-Based Programs

In the design and development of KABISA, a lot of time and effort is spent in the development of tools, similar to other computer-based programs. However, results show that students do not (adequately) use these tools. Other authors have found similar results (see for instance, Crooks, Klein, Jones, & Dwyer, 1996; Land, 2000). This raises questions about the amount of learner control in open learning environments. Should the environment be made less open and provide embedded support devices instead of tools so that students cannot but use these devices? Or should students receive some additional advice towards the use of these tools? In the first case, support might not be adapted to the learners need. This might cause problems, given that either too much or too less support can both be detrimental (Clark, 1991). The second option leaves the environment open. But also here it can be questioned whether this advice should not also be adapted to the learners' needs. A possible solution with respect to this issue might come out of the animated pedagogical agent-research. These agents are animated figures that aim at helping learners in their learning process and adapt their support based on the paths learners followed (Moreno, 2004; Shaw, Johnson, & Ganeshan, 1999).

CONCLUSION

The evaluation of KABISA addressed some general issues important to consider in the design, development and implementation of open learning environments. Although these environments are advocated to foster the acquisition of complex problem-solving skills, there seems still to be gap between the intention of the designers and the use by the learners. This relates to the issue addressed by Winne and Marx (1982) about calibration. In order for an instructional intervention to be effective, calibration is needed between the conceptions of the different people involved. The introduction of a pedagogical agent might help to calibrate the conceptions of students to those of the designers. Moreover these agents might help in encouraging students to adequately use tools without reducing the openness of the learning environment.

KEY TERMS

Animated Pedagogical Agents: Animated figures operating in a learning environment and aiming at supporting learners in their learning process and capable of adapting their support to the learners' paths.

Criterion Path: A representation of an "ideal path" to go through a specific learning environment. It specifies for each possible step in the program what the most ideal subsequent steps are.

Embedded Support Devices: Support devices integrated in the learning environment. Learners cannot but use these devices (e.g., structure in a text).

Instructional Conceptions: Conceptions about the functionalities of (elements of) a learning environment. These conceptions can relate to the effectiveness or efficiency of specific features in a learning environment (e.g., tools) or to the environment as a whole (e.g., KABISA as a learning environment).

Non-Embedded Support Devices (synonym: Tools): Support devices that are put to the disposal of learners. Learners decide themselves when and how to use these tools.

Open Ended Learning Environments: A learning environment that aims at fostering complex problem solving skills by confronting learning with a realistic or authentic problem in a learning environment with a large amount of learner control and different tools.

Perceptions: Students' perceptions relate to how they perceive a specific environment (c.q., KABISA), they are the results of an interaction between students' instructional conceptions and a specific learning environment.

ENDNOTES

[1] A more extended version of this manuscript was published in Armstrong, A. (Ed.). (2004). *Instructional design in the real world. A view from the trenches.* Hershey, PA: Idea Group Inc.

[2] The authors express their gratitude to Stefano Laganà who spend a lot of effort in the adaptation of KABISA and in the development of a log file system.

[3] The term 'characteristic' refers to either a symptom or disease characteristics, either a request for results of a physical examination, laboratory test, or imaging. An example of a characteristic can be 'the patient has severe headache' or 'the palpation of the abdomen is negative.'

Evolution of ERP Systems

Mohammad A. Rashid
Massey University–Albany, New Zealand

INTRODUCTION

The functional units of today's complex business environment require more and more interfunctional data flow for decision making, timely and efficient procurement of product parts, management of inventory, accounting, human resources, and distribution of goods and services. Management of such organizations need efficient information systems to improve competitiveness by cost reduction and better logistics. Enterprise resource-planning systems (ERP), or enterprise systems (Brady, Monk, & Wagner, 2001; Grant, 2003; Hamilton, 2002; Hossain, Patrick, & Rashid, 2002; O'Leary, 2000), are such software systems for business management encompassing modules supporting functional areas such as planning, manufacturing, sales, marketing, distribution, accounting, finances, human resource management, project management, inventory management, service and maintenance, transportation, and e-business. The architecture of the software facilitates transparent integration of modules providing flow of information between all functions within the enterprise in a consistently visible manner. Corporate computing with ERPs allows companies to implement a single integrated system by replacing or reengineering their mostly incompatible legacy information systems.

The concept of the ERP system as "one database, one application and a unified interface across the entire enterprise" (Tadjer, 1998) can be illustrated, following Davenport (1998), with the diagram in Figure 1. The American Production and Inventory Control Society (APICS, 2001) has defined ERP systems as "a method for the effective planning and controlling of all the resources needed to take, make, ship and account for customer orders in a manufacturing, distribution or service company." An ERP system "comprises of a commercial software package that promises the seamless integration of all the information flowing through the company—financial, accounting, human resources, supply chain and customer information" (Davenport, 1998). They are "configurable information systems packages that integrate information and information-based processes within and across functional areas in an organisation" (Kumar & Van Hillsgersberg, 2000).

ERP systems surfaced in the market in the late 1980s and the beginning of the 1990s, targeting mainly large complex business organizations. During the 1960s, most organisations designed, developed, and implemented centralised computing systems, mostly automating their inventory control systems using inventory control (IC) packages. Material requirements planning (MRP) systems were developed in the 1970s and involved mainly planning the product or parts requirements according to the master production schedule. Following this route, new software systems called manufacturing resources

Figure1. ERP systems concept

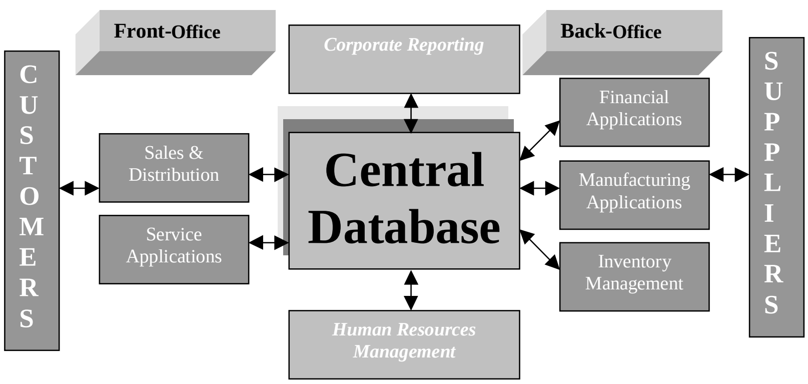

Figure 2. ERP evolution

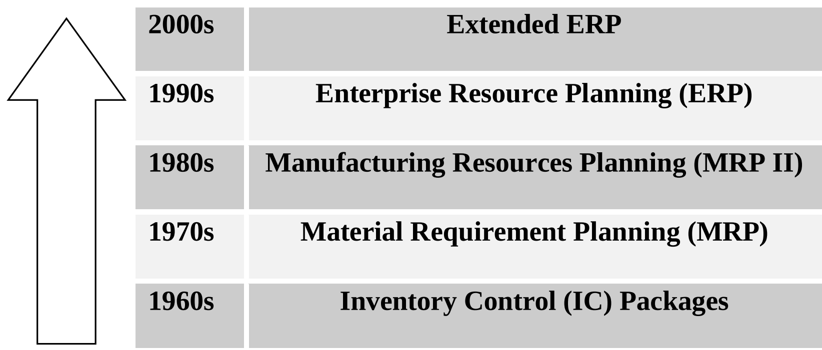


planning (MRP II) were introduced in the 1980s with an emphasis on optimizing manufacturing processes by synchronising the materials with production requirements. MRP II included areas such as shop floor and distribution management, project management, finance, human resource, and engineering. Based on the technological foundations of MRP and MRP II, ERP systems integrate business processes including manufacturing, distribution, accounting, finances, human resource management, project management, inventory management, service and maintenance, transportation providing accessibility, visibility, and consistency across the enterprise.

During the 1990s, ERP vendors added more modules and functions as "add-ons" to the core modules, giving birth to the "extended ERPs." These ERP extensions include advanced planning and scheduling (APS), e-business solutions such as customer relationship management (CRM), and supply chain management (SCM). Figure 2 summarises the historical events related with ERP.

Organisations choose and deploy ERP systems for many tangible and intangible benefits and strategic reasons. In many cases, the calculation of return on investment (ROI) is weighted against the many intangible and strategic benefits. The benefits that an ERP system may bring to organizations are shown in Table 1 while Table 2 shows the problems and disadvantages organisations need to overcome to reap the benefits.

Table 1. Advantages of ERP systems

What Benefit	How
Reliable information access	Common DBMS (database management system), consistent and accurate data, improved reports
Avoid data and operations redundancy	Modules access same data from the central database, avoid multiple data input, and update operations
Delivery- and cycle-time reduction	Minimizes retrieving and reporting delays
Cost reduction	Time savings, improved control by enterprise-wide analysis of organisational decisions
Easy adaptability	Changes in business processes, easy to adapt and restructure
Improved scalability	Structured and modular design with add-ons
Improved maintenance	Vendor–supported, long-term contract as part of the system procurement
Global outreach	Extended modules such as CRM and SCM
E-commerce, e-business	Internet commerce, collaborative culture

Table 2. Disadvantages of ERP systems

Disadvantage	How to Overcome
Time consuming	Minimize sensitive issues, internal politics, and raise general consensus
Expensive	Cost may vary from thousands of dollars to millions, business process reengineering cost may be extremely high
Conformity of the modules	The architecture and components of the selected system should conform to the business processes, culture, and strategic goals of the organisation
Vendor dependence	Single vendor versus multivendor consideration, options for "best of breeds," long-term committed support
Feature and complexity	ERP system may have too many features and modules that the user needs to consider carefully and implement the needful only
Scalability and global outreach	Look for vendor investment in R&D, long-term commitment to product and services, consider Internet-enabled systems
Extended ERP capability	Consider middleware add-on facilities and extended modules such as CRM and SCM

An ERP system is required to have the following characterisitics:

- Modular design comprising many distinct business modules.
- Use centralized common database management system (DBMS).
- The modules are integrated and provide seamless dataflow.
- They are generally complex systems involving high cost.
- They are flexible and offer best business practices.
- They require time-consuming tailoring and configuration setups.
- The modules work in real-time: on-line and batch processing capabilities.
- They are or soon they will be Internet-enabled.

Different ERP vendors provide ERP systems with some degree of specialty, but the core modules are almost the same for all of them. Some of the core ERP modules found in the successful ERP systems is the following.

- Accounting management
- Financial management
- Manufacturing management
- Production management
- Transportation management
- Sales and distribution management
- Human resources management
- Supply chain management
- Customer relationship management
- E-business

COMMERCIAL ERP SYSTEMS

The dominating ERP software suppliers in 2003 were SAP, PeopleSoft, Oracle, SSA Global, Microsoft, and Sage. According to IDC (International Data Corp), the top-ten vendors in 2003 had a market share of 46% of the $25 billion ERP market. Each vendor, due to historic reasons, has a specialty in one particular module area such as SAP in logistics, PeopleSoft in human resources management, Oracle in financials, and SSA Global's SSA Baan ERP in manufacturing. There are also about 50 established and a few more newly emerging smaller and midsize ERP vendors and third-party developers competing for the ERP market. The result is stiff competition and feature-overlapping products difficult to differentiate. Long-term vision, commitment to service and support, module features, specialty, experience, and financial strength for R&D are the major vendor qualities for product selection and turnkey implementation. Table 3 shows the brief profile of these dominating ERP vendors.

Table 3. Brief profile of the dominating ERP vendors

Vendor Name	*Founding Year*	*Flagship Product*
SAP AG	Germany, 1972	R/3, mySAP.COM
PeopleSoft Inc.	USA, 1987	PeopleSoft8
Oracle Corporation	USA, 1977	*Oracle Applications* Oracle11i
SSA Global	USA, 1981	*SSA Baan ERP*
Sage	UK, 1980	Sage Line 500
Microsoft (Microsoft Business Solutions)	USA, 1981	Great Plains, Navision, Axapta, and Solomon

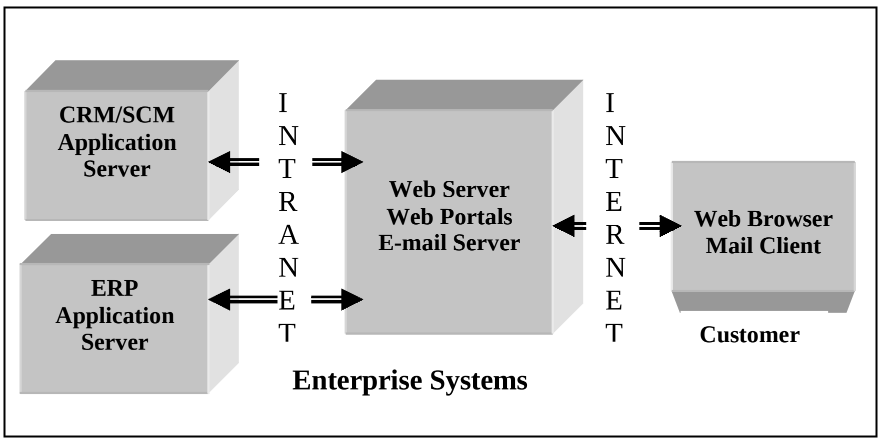
The continued growth of the ERP systems market is attributed to the fact that the vendors are adding applications such as supply chain management, customer relationship management, and the integration of Internet-enabled applications for e-business. ERP vendors are targeting the untapped SME (small and medium-sized enterprise) market with supposedly scaled-back systems suitable for smaller firms by offering simple, cheaper, and preconfigured, easy-to-install solutions within budget and time constraints. For some vendors, this may lead to offering centrally managed, Internet-enabled, ERP-system-based services for SMEs to access and use anytime from anywhere.

ERP systems are becoming more and more Internet-enabled (Lawton, 2000), extending legacy ERP systems to integrate with newer external business modules such as supply chain management, customer relationship management, sales-force automation (SFA), advanced planning and scheduling, business intelligence (BI), and e-business capabilities. In fact, ERP is becoming the e-business backbone for organisations doing online business transactions over the Internet. Adoption of e-commerce and e-business solutions, especially business-to-business (B2B) solutions, is seen by many as the wave of current and future extensions of traditional ERP systems of most small, medium, and large vendors. The front-end, Web-based Internet-business applications are integrated with the back-office, ERP-based applications enabling business transactions such as order placement, purchasing, inventory updates, employee benefits, and so forth to take place between the customers, suppliers, and the enterprise based on reliable, relevant data and applications instantly in a borderless domain. Examples of such Internet-enabled, extended ERPs are available from most of the ERP vendors. The concept of the Internet-enabled, extended ERP system is shown in Figure 3.

CONCLUSION

The unprecedented growth of computing power and the proliferation of the Internet brings new challenges to ERP vendors for redesigning their products, breaking the barrier of proprietorship and customisation, and embrac-

Figure 3. Web-enabled extended ERP system



ing the collaborative business over intranet, extranet, and the Internet in a seamless manner. A sign of acceptance of these challenges is the appearance of new add-on modules that follow open architecture, provide interchangeable modules, and allow easy customisation and user interfacing.

There are scopes for emerging ERP vendors to contribute to the field, especially in the aerospace industry, the finance industry, and the logistics industry. Analysis of the market penetration of ERP systems shows clearly that the current players have to downsize their products and offerings to be attractive to SMEs. Changes in ERP software architecture taking advantage of the smaller but powerful hardware platforms can provide significant opportunities to smaller players to bring new small, robust, easy-to-use systems into the market suitable for SMEs. Future successful vendors will capture large markets of smaller businesses by providing a more consistent and enduring income stream.

KEY TERMS

APICS: American Production and Inventory Control Society. A not-for-profit international, educational organization founded in 1957, respected throughout the world for its education and professional certification programs.

Customer Relationship Management (CRM): Software systems that help companies to acquire knowledge about customers and deploy strategic information systems to optimize revenue, profitability, and customer satisfaction

Extended ERP: Extends the foundation ERP system's functionalities such as finances, distribution, manufacturing, human resources, and payroll to customer relationship management, supply chain management, sales-force automation, and Internet-enabled integrated e-commerce and e-business

Fat Client/Server Architecture (C/S): A client/server network architecture where the client (PCs or workstations on which users run applications) performs the bulk of the data-processing operations while the data itself is stored on the server

Graphical User Interface (GUI): A software interface based on the computer's graphics capabilities with pointing devices such as the mouse that free the user from learning complex commands for using programs

Return On Investment (ROI): An estimate expressed as a ratio comparing the net benefits (the "return") to its total cost (the "investment") for measuring operating performance and efficiency in utilizing the assets of the company

Small and Medium-Sized Enterprise (SME): A business enterprise independently owned by contributing most of the operating capital and managed by the owners or managers, having fewer than 250 employees and a small-to-medium market share

Supply Chain Management (SCM): Software systems for procurement of materials, transformation of the materials into products, and distribution of products to customers, allowing the enterprise to anticipate demand and deliver the right product to the right place at the right time at the lowest possible cost to satisfy its customers

Exception Rules in Data Mining

Olena Daly
Monash University, Australia

David Taniar
Monash University, Australia

INTRODUCTION

Data mining is a process of discovering new, unexpected, valuable patterns from existing databases (Frawley, Piatetsky-Shapiro, & Matheus, 1991). Though data mining is the evolution of a field with a long history, the term itself was only introduced relatively recently, in the 1990s. Data mining is best described as the union of historical and recent developments in statistics, artificial intelligence, and machine learning. These techniques are then used together to study data and find previously hidden trends or patterns within.

Data mining is finding increasing acceptance in science and business areas that need to analyze large amounts of data to discover trends, in which they could not otherwise find. Different applications may require different data mining techniques. The main kinds of knowledge that could be discovered from a database are categorized into association rules mining, sequential patterns mining, classification and clustering.

In this article, we concentrate on exception rules mining.

BACKGROUND

Exception rules mining has attracted a lot of research interest (Déjean, 2002; Grosof & Poon, 2002, 2003; Hellerstein, Ma, & Perng, 2002; Hussain, Liu, Suzuki, & Lu, 2000; Keogh, Lonardi, & Chiu, 2002; Liu, Hsu, Mun, & Lee, 1999; Padmanabhan & Tuzhilin, 2000; Suzuki, 2002a, 2002b; Yamada & Suzuki, 2002; Zhang, Zhang, Yan, & Qin, 2002). Exception rules have been defined as rules with low support and high confidence (Hussain et al., 2000). A traditional example of exception rules is the rule Champagne=>Caviar. The rule may not have high support but it has high confidence. The items are expensive so they are not frequent in the database, but they are always brought together so the rule has high confidence. Exception rules provide valuable knowledge about database patterns.

Exception rules discovery can be classified as either directed or undirected. A directed search obtains a set of exception rules each of which contradicts to a user-specified belief (Liu et al., 1999; Padmanabhan, 2000). An undirected search obtains a set of pairs of an exception rule and a general rule (Hussain et al., 2000; Suzuki, 2002a, 2002b; Yamada & Suzuki, 2002).

Directed search of exception rules will be described next. User-specified beliefs are obtained first. Each of the discovered exception rules contradicts to user-supplied beliefs.

In Liu et al. (1999), post-analysis of the discovered database patterns is performed to identify the most interesting patterns. The technique is characterized by asking the user to specify a set of patterns according to his/her previous knowledge or intuitive feelings. This specified set of patterns is then used by a fuzzy matching algorithm to match and rank the discovered patterns. The assumption of this technique is that some amount of domain knowledge and the user's interests are implicitly embedded in his/her specified patterns. In general, the discovered patterns are ranked according to their conformities to the user's knowledge or their unexpectedness, or their actionabilities.

In terms of unexpectedness, patterns are interesting if they are unexpected or previously unknown to users. In terms of actionability, patterns are interesting if users can do something with them to their advantage. With such rankings, a user can simply check the few patterns on the top of the list to confirm his/her intuitions (or previous knowledge), or to find those patterns that are against his/her expectation, or to discover those patterns that are actionable.

Padmanabhan and Tuzhilin (2000) focus on discovering unexpected patterns and propose methods for discovering a minimal set of unexpected patterns that discover orders of magnitude fewer patterns and retain most of the interesting ones. The approach has been experimentally tested using a case study application in a marketing domain.

The rule A=>B is defined in Padmanabhan and Tuzhilin (2000) to be unexpected with respect to the belief X=>Y on the dataset D if B and Y logically contradict each other, the antecedents of the belief and the rule hold on the same statistically large subset of D, and the rule A, X=>B holds.

Now the undirected method of searching exception rules will be explained. Exception rules will be obtained based on general rules or common sense rules.

In Hussain et al. (2000), a method for mining exception rules is presented based on a novel measure which estimates interestingness relative to its corresponding common sense rule and reference rule. Common sense rules are rules with high support and high confidence. Reference rules are rules with low support and low confidence. Exception rules are defined as rules with low support and high confidence.

The formula for the relative interestingness measure RI in Hussain et al. (2000) is derived based on information theory and statistics. The measure has two components, which are interestingness based on the rule's support and interestingness based on the rule's confidence.

Suzuki (2002a) introduces undirected discovery of exception rules, in which a pattern represents a pair of an exception rule and its corresponding strong rule. Proposed scheduled discovery and exception rule discovery guided by a meta-pattern are described and tested on data sets.

Suzuki (2002b) presents an algorithm for discovering exception rules from a data set without domain-specific information. The method is based on sound pruning and probabilistic estimation. The normal approximations of the multinomial distributions are employed as the method for evaluating reliability of a rule pair. The method has been validated using two medical data sets and two benchmark data sets in the machine learning community.

The main contribution of Yamada and Suzuki (2002) is the formalization of spiral discovery for interesting exception rules and a method that employs initial knowledge, MDL-based discretization and reduction of the number of discovered rule pairs. The experimental evaluation was performed on meningitis data set.

EXCEPTION RULES MINING

A new approach to mine exception rules will be proposed in this section. The approach belongs to the category of directed search. An interconnection between exception rules and strong association rules will be considered. As opposed to the research work described in the previous section, both strong positive and negative association rules are considered.

Based on the knowledge about positive and negative association rules in the database, the candidate exception rules will be generated. A novel exceptionality measure will be proposed to evaluate the candidate exception rules. The candidate exceptions with high exceptionality will form the final set of exception rules.

In order to formulate the proposed approach, a few data mining terms have to be defined. Itemset is a set of database items. For example, itemset XY means a set of two items X and Y. Association rule is an implication of the form X=>Y, where X and Y are database itemsets. An example of an association rule could be supermarket items Chips=>Coke purchased together frequently.

The rule X =>Y has support s, if s% of all transactions contain both X and Y. The rule X =>Y has confidence c, if c% of transactions that contain X, also contain Y. In association rules mining user-specified minimum support (minsup) and minimum confidence (minconf) are given.

Association rules with support greater or equal to minsup and confidence greater or equal to minconf are referred to as strong rules (Agrawal, Imielinski, & Swami, 1993; Agrawal & Srikant, 1994).

Itemsets that have support at least equal to minsup are called frequent itemsets. Negative itemsets are itemsets that contain both items and their negations. For example, consider the negative itemset X~Y. In this itemset ~Y means negation of item Y (absence of item Y in the database record).

Negative association rule is an implication of the form X=>~Y, ~X=>Y, ~X=>~Y, where X and Y are database items, ~X, ~Y are negations of database items. An example of a negative association rule is Coke=>~Pepsi, which means that people do not buy Coke and Pepsi together.

In our approach, the search for exception rules will be based on the knowledge about strong association rules in the database. An example: we discover a strong association rule in the database, for instance, shares of companies X and Y most times go up together X=>Y. Then those cases when shares of the companies X and Y do not go up together, X=>~Y or ~X=>Y, we call *exceptions* when satisfying the proposed *exceptionality* measure explained next. An algorithm for mining exception rules based on the knowledge about association rules will be proposed in as well.

We explain a few proposed definitions first. For exception rules mining instead of minsup we employ *lower* and *upper bounds*, satisfying the conditions: 0<lower bound<upper bound<minsup;

Low support belongs to the range [lower bound; upper bound]. *Infrequent itemsets* have low support. Note that the lower bound is always greater than 0, as we are not interested in rules with 0 support or close to 0. Upper bound is lower than minsup. The lower and upper bounds are chosen specifically for each data mining application.

Exception Rules are rules with *low* support and high *exceptionality* values. Infrequent itemsets with high exceptionality are called *exceptional* itemsets.

In the proposed exception rules mining the confidence measure is not applicable to evaluate the exception rules.

$$\text{Exceptionality(CandExc/AssosRule)} = \text{FuzzySup(CandExc)} + \text{FuzzyFraction(CandExc/AssosRule)} + \\ + \text{Neglect(CandExc/AssosRule)}$$

For example, we obtain a strong rule A=>B and would like to evaluate a potential exception rule A=>Not B. The strong rule A=>B has high confidence, implying that A=>Not B cannot have high confidence. Let us say the minimum confidence is 60%. The strong rule A=>B satisfies the minimum confidence constraint, so at least 60% of database records containing A also contain B. It means that maximum 40% records containing A do not contain B. The exception rule A=>Not B has maximum 40% confidence. As confidence is not applicable for evaluating exception rules, we propose a special measure *exceptionality* to evaluate the exception rules.

Exceptionality of a candidate exception rule given the corresponding association rule is defined by the above formula.

Refer to Daly and Taniar (2004) for the details of our proposed exceptionality measure.

We propose a novel exception rules classification and explain the premises of mining exceptions based on the negative association rules in data bases. We suggest two general types of exception rules, which are exceptions in positive sense and exceptions in negative sense. Exceptions in negative sense will be descried next.

After basic mining for positive and negative association rules in a database we obtain steady patterns of database items that occur together frequently. Let us say X and Y are database items and

$$\left.\begin{array}{l} X \\ Y \end{array}\right\} \text{frequent} \qquad XY = \text{fre} \qquad (1)$$

$$X => Y \qquad \text{high confidence}$$

Also we obtain that

$$\left.\begin{array}{l} X\sim Y \\ \text{or} \\ \sim XY \end{array}\right\} \text{infrequent} \qquad (2)$$

So we have a strong association rule (1), and we make sure that (2) are infrequent. Rules (1) and (2) are our premises to check if one of the rules (3) has a high exceptionality, which would prove it is an exception in negative sense.

$$\left.\begin{array}{l} X=>\sim Y \\ \text{or} \\ \sim X=>Y \end{array}\right\} \text{high exceptionality — (Exception)} \qquad (3)$$

For example, consider two oil companies X and Y. Their stock normally goes up at the same time: X=>Y. In the case when their shares do not go up at the same time X=>~Y, we call the rule X=>~Y an exception if X~Y is infrequent and has high exceptionality measure.

Exceptions in positive sense will be descried next. After basic mining for positive and negative association in a database, we obtain a steady pattern of database items. Let us say X and Y are database items and

$$\left.\begin{array}{l} X \\ Y \end{array}\right\} \text{frequent} \qquad X\sim Y = \text{frequent} \qquad (4)$$

$$\left.\begin{array}{l} X=>\sim Y \\ \text{or} \\ \sim Y=>X \end{array}\right\} \text{high confidence}$$

Also we obtain that

$$XY = \text{infrequent} \qquad (5)$$

We have a strong negative association rule (4), and we make sure that (5) is infrequent. (4) and (5) are our premises to check if one of the rules (6) has a high exceptionality, which would prove it is an exception rule in positive sense.

$$\left.\begin{array}{l} X=>Y \\ \text{or} \\ Y=>X \end{array}\right\} \text{high exceptionality — (Exception)} \qquad (6)$$

For example, consider two oil companies X and Y. Their stock never goes up at the same time: X=>~Y. In the case when their shares do go up at the same time X=>Y, we call the rule X=>Y an exception if XY is infrequent and has high exceptionality measure.

In Figure 1, we present an algorithm for mining exception rules based on strong association rules. Association rules are generated from frequent itemsets with high confidence. The confidence calculation is a straightforward procedure after all frequent itemsets have been generated. We do not consider the confidence calculation as it is easy and conceptually proven correct. The input of the exception rules mining algorithm are frequent 1-itemsets. The output of the algorithm is exceptional itemsets. Exceptional itemsets will become exception rules after the confidence of association rules has been checked.

Figure 1. Exceptional itemsets generation algorithm

```
k=1
1-freq_itemsets                 // generate frequent 1-itemsets
k=2
2_candidate_itemsets            // generate candidate 2-itemsets
forEach c in 2_candidate_itemsets
 if (c frequent)                // verify the condition (1)
        if (negative_sets infrequent)   // verify the condition (2)
                {generate_2_Exc_cand_negative
                 check_Exceptionality: true: //condition(3): if high Exceptionality
                          ExceptionalItemsets.Add()  //to array of exceptional itemsets
             }
     else
         if (negative_sets frequent)     // verify the condition (4)
                {generate_2_Exc_cand_positive
                check_Exceptionality: true://condition (6): if high Exceptionality
                         ExceptionalItemsets.Add() //to array of exceptional itemsets

              }
k++
```

We generate frequent itemsets and on each step k (k = length of the itemset) we check the conditions (1), (2) or (4), (5) described previously and if they hold true, we check the exceptionality values for candidate exceptions.

Refer to Daly and Taniar (2004) for details of our proposed algorithm and performance evaluation on a data set.

FUTURE TRENDS

The overview of the future trends or open research questions in exception rules mining is presented in this section.

Future Trends:

- Develop a novel approach in addition to directed/ undirected search
  Directed search of exception rules has been recognized as a subjective search method. It is up to the user to define the system of the beliefs and expected patterns. Based on the obtained belief system, the contradicting patterns will become exception rules in the given domain. Therefore, the generated exception rules may be contradictive given different user input.
  On the other hand, undirected search generates exception rules independently from domain knowledge or user experience. Exception rules are based on the common sense rules (strong patterns).
  There could be another way of mining exception rules, independently of user beliefs or strong patterns in the database. One of open research areas is to identify such a novel method of mining exceptions rules in databases.

- In directed search
  One of the research issues is to create a uniform user belief system for the given domain. It may involve a lot of data collecting from a number of experienced users/decision makers. Obviously, the uniform belief system would have to be updated on regular basis. Besides, it may be possible to develop a limited system applicable to a number of domains.

- In undirected search
  Develop novel interest measures for exception rules evaluations. Develop new resource-efficient algorithms for mining exception rules

CONCLUSION

Exception rules mining has attracted a lot of research interest. A lot of interesting works have been published and a lot to appear. This is an open research area.

The main approaches in exception rules mining have been highlighted and potential future research directions have been discussed. There are two main approaches in mining exception rules. The first approach is directed discovery of exception rules relying on user-specified beliefs. The second approach generates pairs of common sense rules and corresponding exception rules.

This article is a review of the research that has been done in the exception rules mining and a good starting point for people who desire to contribute in research in the area.

KEY TERMS

Association Rules: An implication of the form A=>B, where A and B are database itemsets. Association rules have to satisfy the pre-set minimum support (minsup) and minimum confidence (minconf) constraints.

Confidence: The rule A=>B has confidence *c*, if *c%* of transactions that contain A, also contain B.

Exception Rules: Rules with low support and high confidence.

Frequent Itemsets: Itemsets that have support at least equal to minsup.

Itemset: A set of database items.

Negative Association Rules: An implication of the form X=>~Y, ~X=>Y, ~X=>~Y, where X and Y are database items, ~X, ~Y are negations of database items.

Negative Itemsets: Itemsets that contain both items and their negations.

Support: The rule A=>B has support *s*, if *s%* of all transactions contain both A and B.

Executive Judgment in E-Business Strategy

Valerie Baker
University of Wollongong, Australia

Tim Coltman
University of Wollongong, Australia

INTRODUCTION

One of the main strategic challenges for organizations today is to effectively manage change and stay competitive in the future. Change appears to be the only constant in contemporary business and is present in every industry and in every country (Brown & Eisenhardt, 1998). Moreover, the key area of importance, current within many organizations, is how to effectively leverage technology within such a complex and dynamic business environment (Sauer & Willcocks, 2003). The alignment or fit approach, which has its roots in contingency theory, has long been promoted as the way to get high returns from technology investment. However, the realization of advantage from the Internet and related e-business technology investment has long been a source of frustration for corporate executives. Impressive performance returns by companies such as Dell Computers, Cisco Systems and General Electric illustrate that returns can be achieved by linking the Internet and related e-business technologies to firm strategy. These companies have shown that successful management of their IT investments can generate returns as much as 40% higher than those of their competitors (Ross & Weill, 2002). Yet, many executives view the Internet and related e-business technologies with intense frustration. They recollect investment in the great speculative bubble of the 1990s and excessive expenditure on year 2000 (Y2K) compliant systems (Keen, 2002). They recall high profile examples of botched enterprise resource planning (ERP) systems that have consistently run over time and budget and report that customer-relationship management (CRM) initiatives were largely a flop (Reinartz & Chugh, 2002). Unfortunately, it is not yet clear how firms should go about capturing the potential that exists in e-business, as few normative frameworks exist to guide practitioner investment.

BACKGROUND

One area of scholarly activity where consistent advances have been made regarding the determinants of firm performance is in structural contingency theory. Here, the contingency factor (i.e., environment-structure) has enabled predictions to be made in a relatively unambiguous manner (Donaldson, 1995). Applied to an e-business setting, contingency theory argues that performance increases can be expected whenever information technology is applied in an appropriate and timely way, in harmony with business, environmental and organizational conditions. Consider a typical scenario where an executive wants to make a strategic investment in information systems. They have two choices: (1) a system to support backend operations using ERP technology, and (2) a CRM support system. How do they prioritise between these competing investments? Contingency literature would argue that it depends upon the organization's strategy and decision-making information requirements (Chandler, 1962; Child, 1972; Galbraith & Kazanjian, 1986). Manufacturing excellence strategies associated with companies like Carrefour or Ford Motor Company would get greater value from ERP systems. Customer intimacy strategies at companies like CitiBank or IBM Global Services would benefit most by customer feedback systems.

As simple as this observation may appear, the application of alignment has proven elusive. Despite 20 years of effort and investment in consulting advice, CIOs are still struggling with the same set of alignment problems. A recent survey by CIO Insight (Patterson, 2001) highlights the point that only 34% of organizations considered the link between their IT priorities and their enterprise strategy to be "strong." While these statistics reflect the difficulties of coordinating complex organizations, they provide evidence that most managers are not using the basic tools of alignment that have been developed over several decades of research.

Priem and Cycyota (2000) equate the process of alignment between IT strategies and business goals with executive judgment. The literature regarding judgment theory argues that firm success can be explained by the judgments executives make concerning the current state of the environment and the vision of the organization. In uncertain times, where market pressures and time constraints dominate the business landscape senior manager's perceptions, skill and vision often form the basis on which strategic choices regarding IT investments are made. For example, it takes little more than a browsing of the management section of the local bookstore—blazoned with titles such as Inside the Minds: Leading CEOs—or a visit to the local news agent to pick up a recent copy of Forbes, Fortune or Business Week to recognize the importance that publishers and managers place on the philosophies and actions of even some of the least successful or most unlikely of management leaders. Perhaps more relevant is that often the appointment of "higher quality CEOs" leads to immediate stock market reactions and greater long term performance. One such example was the reappointment of Steve Jobs as CEO of Apple Computer. Jobs has been widely praised for his skill in judging the commercial potential of convergent Internet technologies and his return to the company was considered instrumental in its reversal of bad fortunes (Stevens, 1997).

The corollary here is that judgment is an essential skill for setting the overall direction of the organization. In turbulent environments, often the context of e-business, quick trade offs need to take place, as the strategic direction of the firm enables it for the future. This being the case management discretion becomes increasingly important, as decisions are made "on the fly" with little information or understanding of the decision problem. Management play a vital role in "trading off" elements of organization control, that is, structure for better adaptation, a view supported by complexity theory (Brown & Eisenhardt, 1998). This theory views strategy as a process which constantly changes, and thus needs a type of structure or execution method that is dynamic and will allow the organization to be ready for the future.

Thus, although judgment appears to be important to organizational success, scholars have largely ignored executive intentions and no empirical link between executive choices and firm outcomes has been established. Instead, strategic outcomes are presumed to be due to strategic choice (Preim & Harrison, 1994). This omission may account in some part, for why practitioners continue to pay little attention to the large amount of published work concerning the antecedents of strategy and performance. This concern provided the motivation for a special issue of the Academy of Management Journal (AMJ, 1998, p.746) that sought greater understanding of the way knowledge is transferred between academics and practitioners. The issue again surfaced in a recent issue of the Academy of Management Executive, providing evidence that practitioners still typically turn to sources of information other than academics or the scientific literature when searching for ways to improve performance (Ford, Duncan et al., 2003).

FUTURE TRENDS

Clearly, we need greater understanding of the conditions which lead executives to make strategic choices if we are to develop research that has an impact on practitioners.

Existing research into the change process and the implementation of e-business related technology is limited because it fails to measure the link between strategic choices and firm outcomes. As we have suggested, the judgments that executives make provides important insight into how IT strategic change or e-business change is approached given different situations and organization contexts.

Peterson (2002) suggests that it is the processing of information and the judgments that are made by top management that leads to critical decisions being made about how firms deal with IT-related strategic change. As the business environment rapidly changes, the variance in possible outcomes ranges from failure to unparalleled success. These differences can largely be explained by the "mythical relationship between technology ecology, human nature, decision cycles, IT and the speed and veracity of their interactions" (Peterson, 2002, p.485). Executives process information about these relationships and form critical strategic judgments regarding the future direction of their organization through its e-business strategy.

Managers face conditions such as dynamic markets, casual ambiguity and path dependence that make it extremely difficult to predict the outcomes of their IT strategic investments. As this illustration suggests, it is imperative that managers have in place strategies to cope with changes as they occur. Faced with external environmental changes (e.g., new rates of Internet adoption, killer mobile commerce applications, etc.), managers need to be able to adjust their strategic choices accordingly "just as water shapes itself according to the ground, an army should manage its victory in accordance with the enemy. Just as water has no constant shape, so in warfare there are no fixed rules and regulations" (Sun Tzu in Hussey, 1996, p.208)

What Sun Tzu highlights is the requirement that strategies be flexible in order to manage strategic change. Mintzberg, Ahlstrand, and Lampel (1998) describe this as an emergent strategy, where rather than pursuing a strategy, an organization makes decisions based on the situation, effectively testing the market as they go.

Thus strategic decisions regarding IT management need to be a mixture of both deliberate and emergent strategies. "Real-world strategies need to mix these in some way: to exercise control while fostering learning" (Mintzberg et al., 1998, p.11). The importance of strategic alignment between the organization and its environment becomes even more critical given recent environmental turbulence and the evolving importance of technology and e-business to competitive advantage.

Executive Judgment and Strategic Alignment

Priem and Cycyota (2000) state that understanding judgments by strategic leaders is essential to determine the role of mental processes in strategy development and how these strategies and processes affect firm performance. They suggest that a number of theoretical platforms commonly found in the strategy literature provide a solid platform from which we can examine strategic judgement. The "fit" or "alignment" paradigm is perhaps one of the most pervasive in strategy. Good strategy requires at a minimum alignment with changing external conditions. In simple terms, the proposition is that there is an organizational structure that fits the level of contingency factor whether it is environmental uncertainty, organizational characteristics, technological characteristics or strategy design interdependence so that an organization in fit creates significant and positive implications for performance. This idea that fit between organization structure and contingency factor leads to superior performance has been empirically supported in both qualitative and quantitative studies (Donaldson, 1995). Given this distinguished history, it might reasonably be expected that executives would frequently make decisions based on the principles of organization congruence (Priem, 1994).

Most early theories of structural contingency focused on how the fit between bivariate variables (i.e., structure-environment alignment, strategy-structure alignment or strategy-environment alignment) are associated with increased firm performance. However, information technology (IT) is becoming an important substitute for organization structure in modern organisation (Sauer & Willcocks, 2003). For example, Oracle's ability to transform itself into an Internet-enabled business would not have been possible without an appropriate technology base. The wrong technology base would have made such an initiative a massive technological and organizational challenge because of the custom integration required. Emerging evidence indicates that structure and technology are complementary. Where structures create boundaries for management control, technology permits those boundaries to be traversed thereby enabling more complex commercial activities to be effectively integrated and managed.

EMPIRICAL INVESTIGATION OF STRATEGIC JUDGMENT

The "integrative framework" developed by Lee (1989, 1991) in a series of papers regarding the management of information systems provides a suitable approach to the study of judgment. Lee's integrative framework formally presented in his 1994 paper combines three levels of "understandings": the subjective, the interpretive and the positivist. According to Lee, the three understandings are "far from being mutually exclusive and irreconcilable"; in fact, "they may be utilised as mutually supportive and reinforcing steps in organisational research". Priem and Cycyota (2000) also support this view by claiming that both qualitative and quantitative studies are necessary to increase our understanding of strategic judgement.

In the case of e-business, qualitative work can be useful in exploratory investigation that may highlight issues more formal approaches may miss. For example, case studies of the most spectacular strategic information systems initiatives Baxter Healthcare and American Airline's SABRE indicate that these IT/e-business systems were largely accidental success stories (Clemons, 1986). However, these subjective and interpretive studies cannot test hypotheses adequately, because of the close contact needed with research subjects and the resulting small sample size. Quantitative studies provide the crucial positivist link that complements exploratory work in a way that can generate more widely generalizable insights. Notable examples, include the study of IT's contribution to performance in the retail industry (Powell & Dent-Micallef, 1997), and the investigation of organizational antecedents to e-business adoption (Srinivasan, Lilien, & Rangaswamy, 2002).

The following sections focus on measurement techniques, which can be used to examine individual judgment. These techniques can be grouped into two categories: (1) composition methods, and (2) decomposition methods (Priem & Harrison, 1994).

Composition Methods

Composition methods focus on the processes that underlie individual judgments. Composition involves methods such as verbal protocol analysis, information searches and cause mapping to gather interpretive information from executives about the processes that lead them to make certain judgments. These types of techniques would be useful in identifying the variables that executives use in their strategic decision making, but which are not included in current management theory (Priem & Harrison, 1994).

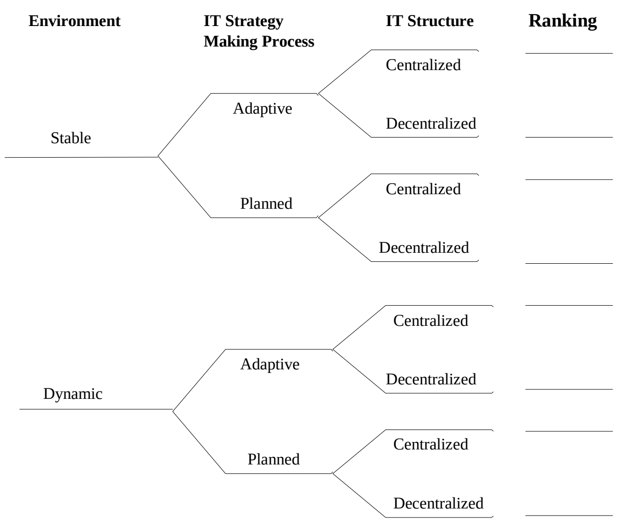
Decomposition Methods

Decomposition techniques focus on the interactions that take place surrounding the judgment itself. The technique requires that the variables or judgment attributes be known a priori. The substantive nature of those variables must come from existing strategy theory (Priem & Harrison, 1994), and contingency theory provides an excellent starting point.

In this case, decomposition methods are required to focus on executive choices in response to a series of decision scenarios (i.e., behavioural simulations regarding the environment, firm structure and the strategy making process). The variance in executive choice is evaluated against these factors of interest, which can be manipulated across scenarios, using conjoint or choice analysis techniques.1 Figure 2 shows the way we can manipulate the important choices outlined in structural contingency theory. Paired comparisons (or stated preferences) are collected and then used to evaluate direct and interaction effects. In this way, we reveal the direction and strength of the three factors considered central to contingency theory. For example, an executive faced with a stable environment would lean towards a planned strategy and decentralized structure according to contingency prescriptions. Respondent rankings on each path reflect the perceived utility respondents have for each combination of variables.

This combination of composition and decomposition techniques enables one to test whether the prescriptions of at least one well-known theory (i.e., contingency theory) influences executive judgment. The extent to which these prescriptions are already "obvious" to, or widely known by, practising executives will shed new light on the role of judgment in IT strategy and change.

Figure 2. Judgment evaluation survey



CONCLUSION

We have outlined the importance of executive judgment to the strategic choice process and its particular relevance to the study of e-business, where environmental turbulence increases the relevance of managerial discretion. By separating the outcomes from the actual decision choice, we can begin to more fully understand how these strategic choices influence firm performance. Until now the process of strategic choice has largely been treated as a "black box" where it is assumed that measured outcomes are the result of deliberate choices.

One of the reasons contingency theory has become so popular is that it provides managers with prescriptive advice regarding which configurations lead to higher performance. Further examination of executive judgments to ascertain whether executives are making decisions based on the idea of alignment or fit is required. This will help in our understanding of whether material taught by academics in business schools is actually being used by students in industry. Are executives using the ideas of alignment or fit as prescribed in theory or are they making judgments based on other factors? The answer to this question has important implications for relevance and improving the linkage between theory and practice.

Understanding the processes that occur in strategy development will lead to greater knowledge of the decisions that executives make in uncertain environments and hyper-turbulent contexts. This understanding is important if we want to develop e-business related research that is applicable to practitioners. It is this type of research that will guide executives in the strategic management of change and allow them to gain advantage from leverage their investments in e-business technology.

KEY TERMS

Contingency Theory: A meta-theory, which argues that firm performance is defined by the environment-strategy-structure relationship, where the organization's strategy is contingent on the external environment and the organization structure is contingent on the firm's strategy.

E-Business Technology: Any technology, which enables an organization to conduct business electronically, with the overall aim of improving firm performance.

Executive Judgment: A decision that an executive makes, when they do not have a full understanding of the decision problem, based on their mental models of the environment and their vision for the organization.

External Environment: Factors which are external to an organization, such as new technology or product developments, changing rates of market growth, which an organization must respond to.

Fit/Alignment: Terms used to explain the relationship between IT and strategy. The IT strategy should work in synergy with the organizations strategy. These terms have their roots in the meta-theory contingency theory.

Strategic Choice: The choices that executives make which impact on the strategic direction of the organization. These choices exist as the intended strategies of the organization.

Strategic Decision-Making: The process of making important decisions (usually made by the top management team) to put executive choices into action by implementing strategies.

ENDNOTE

[1] There are a number of conjoint analysis methods, which can be used to test executive judgments. Each of the methods uses a variation of regression to decompose an executive's judgment. The most appropriate for evaluating executive judgments is metric conjoint analysis. For example, Priem (1994) used metric conjoint analysis to examine the judgments of CEO's in manufacturing firms. The outcome of this research was that the executives in manufacturing firms often make contingent judgments, regarding key strategy variables.

Expanding Data Mining Power with System Dynamics

Edilberto Casado
Gerens Escuela de Gestión y Economía, Peru

INTRODUCTION

Data Mining

Business intelligence (BI) is a key topic in business today, since it is focused on strategic decision making and on the search of value from business activities through empowering a "forward-thinking" view of the world. From this perspective, one of the most valuable concepts within BI is the "knowledge discovery in databases" or "data mining," defined as "the process of discovering meaningful new correlations, patterns, and trends by sifting through large amounts of data stored in repositories, using pattern recognition technologies as well as statistical and mathematical techniques" (SPSS, 1997).

The usage of data mining as we currently know dates back to 1995 (Pyle, 2003). Since then, many applications were developed, and now it is a critical discipline to gain business insight. Table 1 shows a list of current data mining applications.

Table 1. A short list of data mining applications

- Credit scoring
- Customer behavior prediction
- Customer segmentation

System Dynamics

System dynamics was created by Jay W. Forrester, Germeshausen Professor Emeritus of Massachusetts Institute of Technology (MIT), in 1956. It is defined by the System Dynamics Society (www.systemdynamics.org) as "a methodology for studying and managing complex feedback systems, such as one finds in business and other social systems."

System dynamics evolved from prior work in feedback control systems, and progressively its application was extended to fields other than engineering. Though its primary application is focused in the understanding of complex systems, it is also used as a predictive tool (Sterman 2000; An, Uhm, Kim & Kwak, 2002; Forrest, 1998). Table 2 shows a list of some fields where system dynamics has found applications.

LIMITATIONS OF DATA MINING FOR PREDICTIVE APPLICATIONS

Regarding data mining techniques and algorithms, Table 3 summarizes the most commonly accepted classification (Berson & Smith, 1997; Thearling, 2003; The Pilot Software's Data Intelligence Group, 1995).

As predictive tools, the data mining techniques listed in Table 3 have the following shortcomings:

1) *The statistical foundation of data mining:* Most of the current BI methods and tools, such as rule induction, decision trees, neural networks, and so forth, are extensively used to develop predictive models; and their conceptual foundation are a combination of mathematical, statistical, and artificial intelligence techniques. It is here where we find a source of limitation for a wider set of real-world applications, since statistics works with historical data and there is no full guarantee about predictions based on such data. A change in the characteristics

Table 3. Main categories of data mining techniques and algorithms

Decision Trees
Building of tree-shaped structures that represent sets of decisions.

Rule Induction
Extraction of useful if-then rules from data, based on statistical significance.

Nearest Neighbor
Classification of each record in a dataset based on a combination of the classes of the k record(s) most similar to it in a historical dataset (where $k > 1$).

Neural Networks
Statistical analysis tools that, through a "learning" process, build a model of the dependencies between the descriptive variables and the behavior to be explained.

Genetic Algorithms
Building of models using processes such as genetic combination, mutation, and natural selection in a design based on the concepts of evolution.

of a market from a developing to a mature phase, for example, is enough to invalidate the use of statistical methods to forecast customer behavior (An et al., 2002).

2) *Explanation of results:* Another limitation of some data mining methods like neural networks, genetic algorithms, and so forth is their inability to provide an adequate explanation of their results, because they are not easily mapped into human terms (Moxon, 1996), or they are seen as black boxes and no explanation of the results is given, which inhibits confidence, acceptance, and application of results (Parallel Computer Centre at The Queen's University of Belfast, 1997).

3) *The thinking paradigm under the application of data mining methods:* As consequence of their statistical foundation, data mining methods provide information about trends and patterns in the context of a "straight-line thinking" paradigm (i.e., an outcome is expressed as a function of one or more independent variables). However, real world is a feedback system made of interacting elements in a closed-loop context, where an action leads to a result that affects current conditions, and the changed conditions become the basis for future action (Forrester, 1991). A growth strategy executed only relying in trends provided by data mining methods, for example, can lead to failures in achieving the desired goals, because the feedback effects in the business system were ignored (Avila, Mass & Turchan, 1995).

TOOLS OF SYSTEM DYNAMICS: BASIC CONCEPTS

There are two fundamental tools in system dynamics to represent the structure and behavior of a system: causal loop diagrams and stock-and-flow diagrams.

Causal Loop Diagrams

A causal loop diagram is a tool to represent the feedback structure of a system. It is a closed representation of the links between causes and effects involved in it, and also contains an identification of their most important feedback loops (Kirkwood, 1998; Sterman, 2000). Figure 1 shows an example of a causal loop diagram.

Stock-and-Flow Diagrams

A stock-and-flow diagram is another way to represent the feedback structure of a system. But, unlike a causal loop diagram, it can include more precise and detailed information about the nature of the system it represents. Figure 2 shows the following basic elements in a stock-and-flow diagram (Kirkwood, 1998; Sterman, 2000). While causal loop diagrams are more oriented to a qualitative description of a system, stock-and-flow diagrams allow relating mathematical functions to their elements and, therefore, they represent a quantitative description.

Figure 1. Causal loop diagram and its elements

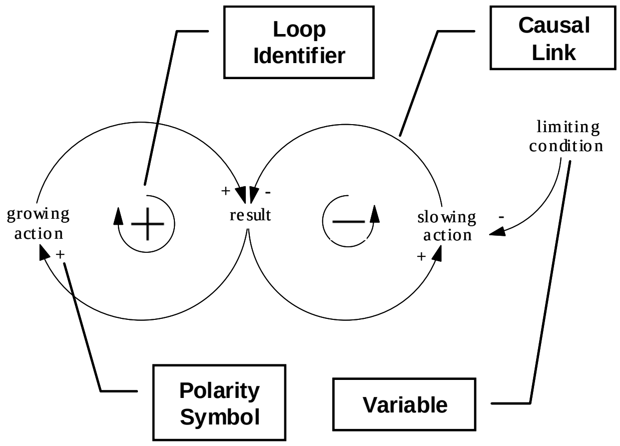

Figure 2. Stock-and-flow diagram and its elements

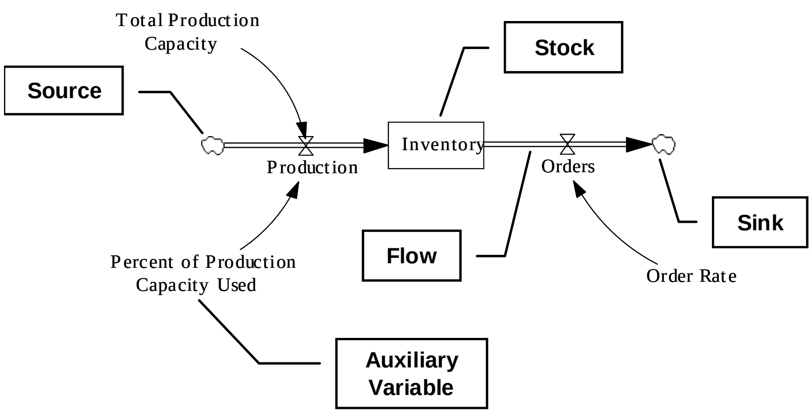
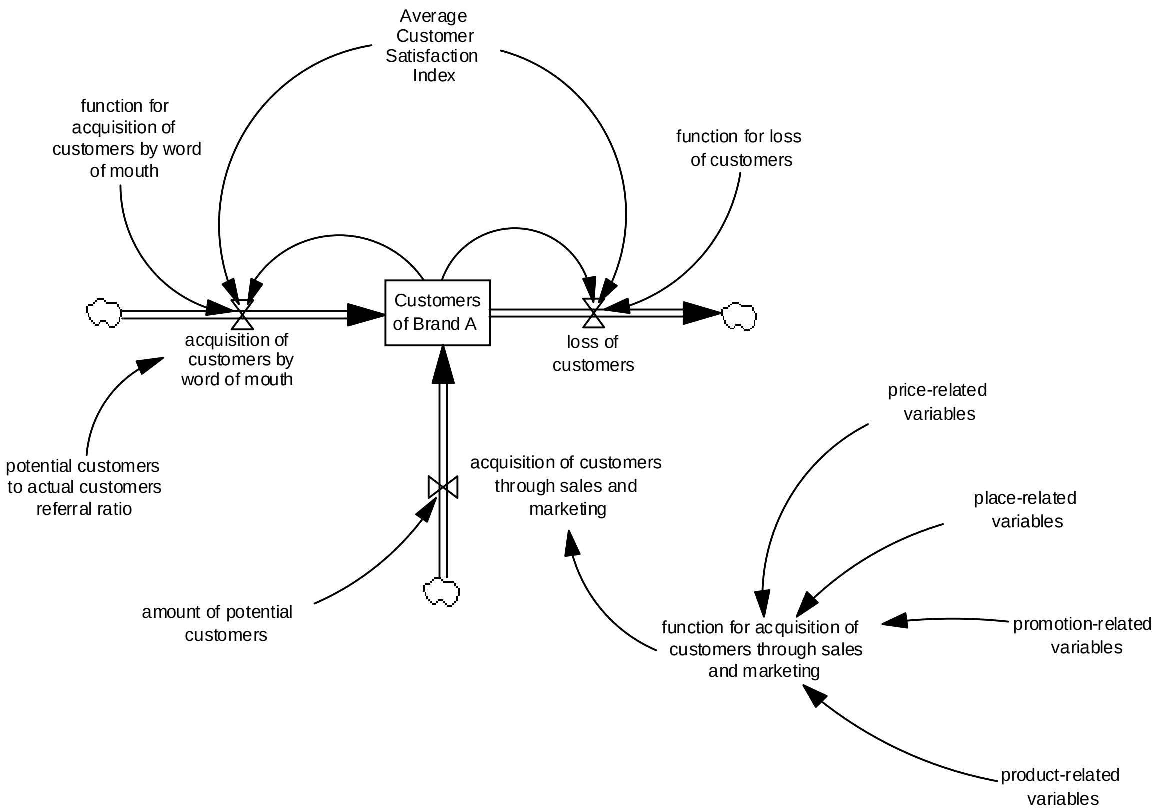


LIMITATIONS OF SYSTEM DYNAMICS

The limitations of system dynamics come from its primary application as modeling tool, and this fact is reflected in the expression "any model is only as good as its assumptions." The following shortcomings of simulation models are cited by Sterman (1991):

- *Accuracy of the decision rules:* Every system dynamics model must be constructed beginning with two processes: the problem articulation or purpose, which must be oriented to solve a specific problem; and the proposal of a dynamic hypothesis, which is a supposition about the behavior of the system to model (Sterman, 2000). The main problem resides in the decision rules under the dynamic hypothesis, which cannot be determined directly from statistical data. Decision rules must be discovered from observation, and this task is limited by the perception of the modeler about the system to study.
- *Soft variables:* Reputation, customer satisfaction, employee motivation, and other soft or intangible variables are fundamental to understand complex systems. Unfortunately, in most cases there is not measures of these data, and under this circumstance these variables are usually discarded from the model. At present, the development of fields like Intellectual Capital and Knowledge Management are contributing to a better estimation of soft variables; in the meantime, the best approach is to include at least reasonable estimates of such variables instead of ignoring them.

Figure 3. Simplified system dynamics model of a CRM application



- *Model boundary:* The model boundary is an important factor that affects its validity. This concept involves which variables will be treated as exogenous (outside the boundary) or endogenous (inside the boundary), and what feedback will be incorporated. As with decision rules, the definition of the boundary will be limited by the perception of the modeler about the system.

DATA MINING AND SYSTEM DYNAMICS TOOLS WORKING TOGETHER

With the current availability of computer power and software tools, there is a great opportunity to take the best of data mining and system dynamics to improve decision-making processes. This approach involves the creation of a system dynamic model to represent the target system. Later, those relationships without a mathematical expression available (because there is not any theory or formula available for them) will be represented by rules or equations obtained from data mining processes. The advantage of this approach is that, once validated, the system dynamics model is a powerful tool for decision making, since it reflects the nature of the target system and provides better insights about its behavior, without the limitations of data mining tools described earlier. In contrast, this approach is affected by the limitations of system dynamics tools, and the direct inclusion of rules or equations into the model could hide important causal relationships that need to be discovered.

AN APPLICATION EXAMPLE

Figure 3 shows a simplified system dynamics model of a Customer Relationship Management (CRM) application related to a brand A, where the processes of customer acquisition and retention are represented. Acquisition is made through sales and marketing or through the phenomena of "word of mouth," and retention is related to a loss of customers' rate.

The average customer satisfaction index for the brand A is calculated through surveys and other data (like frequency of repeated purchases, for example); then, data mining tools provide a set of rules or equations that define mathematical relationships between customer satisfaction and acquisition (or loss) of customers in the form of functions that could be integrated in expressions like the following examples:

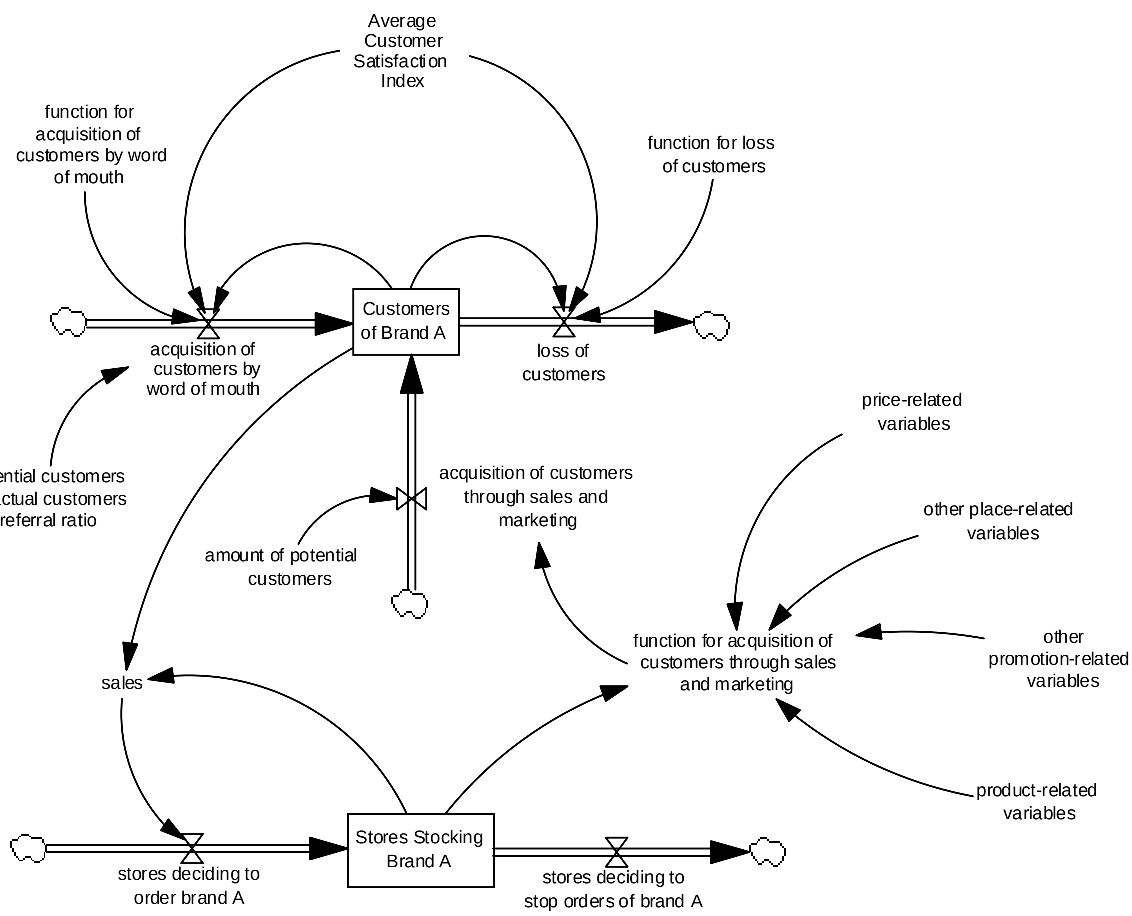
1) acquisition of customers by word of mouth = customers of brand A * potential customers to actual customers referral ratio * function for acquisition of customers by word of mouth (average customer satisfaction index)
2) loss of customers = customers of brand A * function for loss of customers (average customer satisfaction index)

In the equations (1) and (2), "customers of brand A" is the amount of actual customers of brand A, and "potential customers to actual customers referral ratio" is the estimated proportion of potential customers that could be referred by actual customers. The "function for acquisition of customers by word of mouth" and the "function for loss of customers" are derived from data mining processes.

In a similar fashion, another function for the acquisition of customers through sales and marketing is obtained incorporating variables related to the well-known components of the "marketing mix": price, product, promotion, and place (Kotler, 1999, p. 31). As a better understanding of the cause-and-effect relationships of the CRM process is achieved, such function can be reformulated as a new set of stock-and-flow diagrams which include, if needed, a new set of functions obtained via data mining methods. To clarify these concepts, a simplified example is described below.

We suppose that the "function for acquisition of customers through sales and marketing" involves, in addition to other marketing-mix related variables, the amount of money spent in advertising (X) and the amount of stores having the brand A in stock (Y). Through a

Figure 4. Redesign of the model in Figure 3 to incorporate concepts of the dynamic brand value management framework



neural network algorithm, a function of the form $Z = f(X, Y)$ is obtained, and thus we know a mathematical relationship between such variables. However, this expression does not explain conceptually the real effect and impact of X and Y on Z.

To overcome this issue, we could incorporate the principles of an approach known as "dynamic brand value management" or DBVM (Desmet et al., 1998), which takes into account the factors that influence brand value and also dynamic elements such as time delays and feedback loops. Figure 4 shows the redesigned model for the CRM application, where a "virtuous reinforcing loop" is visible: when a product sells well (see variable "sales"), more retailers are motivated to order it (see variable "stores deciding to order brand A"), and the product sells even better.

As more valid cause-and-effect relationships are added, the model will provide more insights for the CRM processes, and it will be possible to apply the intrinsic knowledge contained here to formulate new strategies when a change in the underlying conditions occurs, and when there is not enough available data to mine.

FUTURE TRENDS

The cooperation between data mining and system dynamics tools will progress with a framework that facilitates the model creation process and the integration of their respective elements. A starting point could be the concept of "complex analytic layer" (Oguz 2002), where system dynamics tools would be integrated.

Another way to improve the cooperation between data mining and system dynamics tools is the definition of a common methodology to create and evaluate models that incorporate elements from both approaches. The "Catalyst" methodology (Pyle, 2003), which explicitly incorporates system dynamics with data mining techniques, is an example of this concept.

CONCLUSION

System dynamics is a powerful complement for business intelligence in general. With a clear vision of the features, advantages, and limitations of these tools, we can expect important improvements in decision making and consequently in organizational performance.

The application of system dynamics implies the need to adopt the "systems thinking" paradigm as a new way to see business dynamics. A gradual process is suggested for this purpose, combining skills development exercises with the support of modeling software, if this is available (Casado, 2002). Another concern is the need to trace continuously the developments in knowledge management and intellectual capital, because it is necessary to improve the quantification and representation of intangible variables to be included in system dynamics models.

In the near future, the use of BI tools will be so wide that organizations will not find significant advantages with respect to their competitors. At this point, only a clear understanding of the behavior of systems, far away from discovery of trends and patterns only, will bring back competitive advantage in the business world.

KEY TERMS

Causal Link: An arrow that denotes the cause-effect relationships between two variables in a system dynamics model.

Flow: A representation of the rate of change in the condition of a variable in a system dynamics model.

Intellectual Capital: The set of intangible assets that enable a company to function.

Knowledge Management: The set of processes to manage the creation, dissemination, and utilization of knowledge.

Loop Identifier: A symbol that denotes the nature of each important loop in a system dynamics model. It can be "reinforcing" (positive loop) or "balancing" (negative loop).

Polarity: A positive or negative sign that denotes the sense of the effect between variables connected by a causal link.

Stock: A representation of the state of a variable at a given time in a system dynamics model.

Sink: A representation of a stock into which flows are leaving the boundary of the system.

Source: A representation of a stock from which flows are originated outside the boundary of the system.

Experiential Perspective on Knowledge Management

V.P. Kochikar
Infosys Technologies Ltd., India

J.K. Suresh
Infosys Technologies Ltd., India

INTRODUCTION

The last few decades have seen a growing proportion of organizational wealth being represented by intangible assets, i.e., assets with value that cannot be measured in terms of any physical attribute. Management thinking, conditioned over centuries to extract the greatest value out of physical assets, has had to bring within its ambit the leveraging of these intangible assets in building the capabilities required to deliver superior products and solutions. The discipline of knowledge management (KM) was born and came to encompass the gamut of organizational processes, responsibilities, and systems directed toward the assimilation, dissemination, harvest, and reuse of knowledge. In simpler terms, KM is the answer to the question, "How can the organization update and use its knowledge more effectively?" (Kochikar, 2000).

Some of the world's most successful organizations, be they corporate, academic, or government, invest considerably in KM. McKinsey & Co. spends at least 10% of revenues on managing knowledge. The World Bank's annual KM budget is $50 million. IBM has one of the oldest formal KM initiatives, dating back to 1994.

Substantial benefits have been reported across industries. Johnson & Johnson has implemented KM for speeding up the FDA application process and reported savings of $30 million on one product alone (Berkman, 2001). British Petroleum has estimated savings of $400 million a year, while Chevron has discovered operational cost savings of $2.5 billion over 8 years (Infosys, 2002). Tufts University's school of medicine has used KM to integrate its curricula and has been hailed as a national model for medical education (Genusa, 2001). KM is, however, not an unmixed blessing, as Storey and Barnett (2000) noted. Each organization must fashion a KM strategy that takes cognizance of its unique competencies, aspirations, and business context.

Infosys Technologies (*NASDAQ: INFY*) has conceived, developed, and deployed internally an elaborate architecture for KM that aims to empower every employee with the knowledge of every other employee. The company's success on the knowledge-sharing front has been affirmed by the fact that the company has been a Global MAKE (most admired knowledge enterprises) winner in 2003 (Chase, 2003) and Asia MAKE winner for 2002, 2003. Key elements of the KM architecture include the *Knowledge Currency Unit* scheme, a comprehensive mechanism for reward, recognition, and measurement of KM benefits; *KShop*, the corporate knowledge portal built in-house; and the *knowledge hierarchy*, a four-level taxonomy of 1800 subject areas that constitute knowledge in the Infosys context.

Along the KM journey, we also accumulated a sizeable body of thought on what organizations need to do in order to implement KM successfully, and it is the intention of this article to communicate some of that thought.

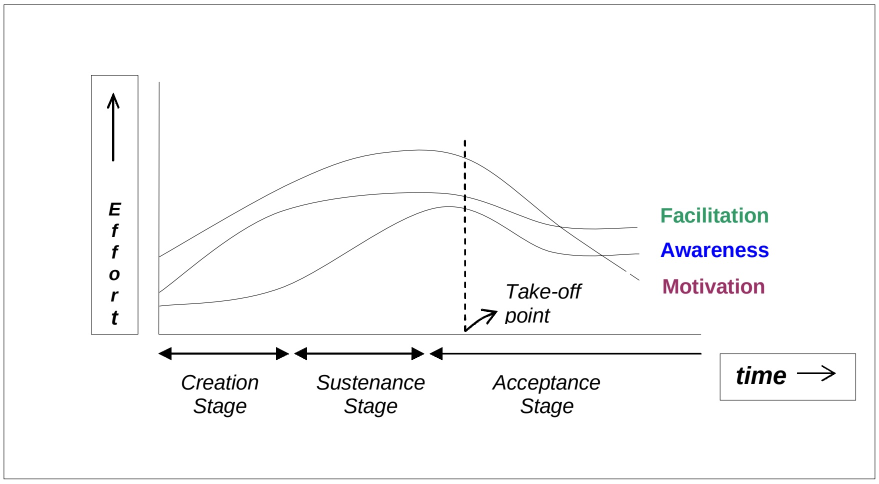
BACKGROUND—THE BUSINESS CASE FOR KM

In achieving its goal, KM needs to percolate into every corner of the organizational mind and create a culture of sharing within the organization. The following definitive statement of Lew Platt, Hewlett-Packard's former CEO, sums up the case for KM: "If HP knew what HP knows, we would be three times as profitable." A strong focus on KM has paid undeniable dividends to leading organizations wordwide. This year's Global MAKE winners have delivered a total return to shareholders of 19.6%, twice the Fortune 500 median of 9.1% (Chase, 2003). Similarly, these leading KM practitioners have shown a return on capital employed of 30.4% versus a Fortune 500 median of 18.5%. These winners also figure prominently in other honor lists, such as *Fortune* magazine's Most Admired Companies list (Hjelt, 2003) and *Business Week* magazine's list of the world's top brands (*Business Week*, 2003).

Chard (1997) and Bartlett (1998) have identified the following drivers for KM: the *pace of change* in a knowledge-driven age, which makes constant learning an imperative; *globalization*, which means acquiring knowledge about new environments and cultural and economic

E

Figure 1. Relative organization-wide effort devoted to motivation, facilitation, and awareness, as a KM initiative evolves over time



Source: Infosys Research

issues; the emergence of *new technologies* that offer new leverage if used well; the increase in *virtual work*, which needs much better knowledge sharing; *rising expectations* from all stakeholders, to meet the companies that need to be proactive and agile; and *growth*, which accentuates the challenge of leveraging the knowledge of individuals for corporate advantage.KM Review magazine's survey of 400 global corporations revealed that the following are key objectives of KM programs (KM Review, 2002):

1. Increasing organizational communication
2. Gaining competitive advantage
3. Increasing collaboration among employees
4. Improving customer relationships
5. Becoming more efficient
6. Innovating
7. Learning from previous mistakes and successes
8. Capturing and retaining tacit knowledge

Using the framework of Nahapiet and Ghoshal (1998), the above objectives can be classified as improving *financial capital* (2, 5); improving *social capital* (1, 3, 4), and improving *intellectual capital* (6, 7, 8). While KM activity, as enumerated below, focuses strongly on the social and intellectual capital aspects, the success of KM must necessarily be measured in terms of improving financial capital. As our extracts from Chase (2003) above demonstrate, successful KM adopters have found that this is the case.

BUILDING AN ORGANIZATIONAL KM ARCHITECTURE: CHALLENGES

An organizational architecture for KM must exhibit the following properties:

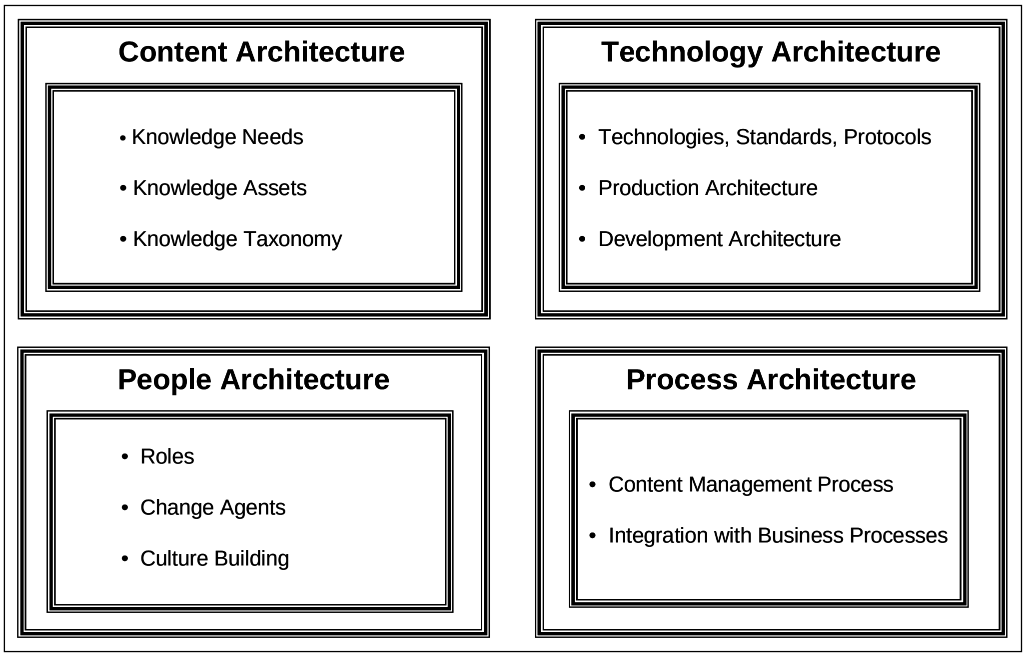
- *Motivation*: It must make people *want* to share knowledge.
- *Facilitation*: It must make it *easier* for them to do so.
- *Awareness*: It must make people *aware* of the KM architecture that has been created, and their roles in using it.

Figure 1 depicts conceptually the relative organization-wide effort required to be devoted to each of the above as the KM initiative evolves over time.

KM success hinges on an architecture that is designed specifically to suit each organization's business and cultural context. Such an architecture must address four key dimensions: *people*, *process*, *content*, and *technology*. Figure 2 outlines the key considerations to be addressed by a KM architecture along these four dimensions.

Enumerated below are a few key challenges on the people, process, content, and technology dimensions that must be addressed when creating a KM architecture.

Figure 2. Sample people, process, content and technology considerations to be addressed by a KM architecture



Deciding How Much Effort Should be Devoted to Technology

As its name implies, information technology (IT) is a mechanism for classifying, storing, and presenting information, as well as ensuring its speedy and effective flow across the organization. Because these capabilities are so critical for KM, it is difficult to conceive of any successful KM implementation that does not lay significant emphasis on the use of IT.

It is, however, necessary to guard against excessive reliance on IT—a tendency that has been liberally fostered by vendors of various hues. Clearly, the use of IT must be judicious, appropriate, preferably ROI-driven, and most importantly, backed by a clear strategy and ownership within the organization (Kochikar, 2000).

A popular yardstick is that not more than a third of the effort and investment of implementing KM should go into technology (Davenport & Prusak, 1998)—any excess makes it highly likely that the "softer" issues related to people, content, and process are being neglected. The extent of IT focus is governed by the target audience's familiarity with, and willingness to use, IT tools.

In the Infosys experience, because *KShop* has been built internally by the central KM group's technology team without the use of any special hardware or software products, the monetary investment in IT for KM has been extremely small. In terms of effort, the investment hovers around the one-third mark.

Table 1 provides a classification typology of technologies for KM and summarizes some of the key technologies.

Deciding the Degree of Centralization of Responsibility

A key question related to the people architecture for KM is, whose responsibility is it to make KM happen? Although every individual and group in the organization must work to make KM successful, there must clearly be an identified group of some form that will "own" KM in the organization. At the same time, this argument must not be taken to the absurd extreme of saying that this central group will have complete responsibility for all aspects of making KM happen. The question thus reduces to, what is the most appropriate position to occupy on the centralization–decentralization spectrum?

The answer to this question is, of course, dependent on issues deeply embedded in the organization's specific context. The extent of senior management's willingness to commit resources for KM is a key determinant. Expectations of KM in the organization also strongly determine the degree of centralization; in general, as more "guarantees" are expected, the more the onus shifts onto the central group.

Source: Infosys Research

In our experience, a "facilitated decentralized approach" works best: the technology architecture management for KM—development, deployment, and maintenance—is done by a central KM group. All stages of the content management process are anchored by the KM group; however, creation of internal content must happen in the field and is *facilitated* by the KM group. The conception and implementation of the KM strategy is also anchored by the central KM group.

This approach entails considerable investment in training and development of staff in the central KM group and in orienting all other roles in the organization to their knowledge-sharing aspect. One practice that we have found useful has been to "catch them young"—sensitize every fresh employee joining the organization to the mechanics of using the organizational KM infrastructure, within the first 2 weeks. In this manner, they learn the KM ropes at a time when their need to acquire knowledge about the organization is very high.

The "Buy versus Build" Decision

There is an abundance of packaged IT solutions for KM on the market. Some of these have been conceived by their vendors with the KM paradigm in mind, and thus support organizational KM requirements to a fair degree. Others are existing products repackaged with a "KM" label, and thus, they meet only a subset of an organization's requirements.

Organizations interested in reaping the full benefits of KM must, as said earlier, invest in designing a customized KM architecture that fits their context. For the technology dimension then, the "build" route becomes inevitable, as the technology solution must fit well into the people, process, and content dimensions of the KM architecture. Clearly, the economics of the buy versus build decision are also influenced in significant degree by relative costs.

In the Infosys experience, the decision to build was influenced largely by the fact that our proprietary knowledge hierarchy referred to earlier was a central mechanism for accessing content and expertise, and it needed to be supported by the technology system. Similarly, the unique knowledge currency unit (KCU) mechanism needed to be supported. The system was required to compute and use *composite KCU ratings* (a quality measure for documents) and provide interfaces for users of documents to award KCUs and manage their individual KCU accounts. Further, the system needed to exchange data with a number of existing corporate databases that store employee and project data in disparate schemas. A key requirement, the ability to control access based on organizational role, needed to be supported. Another strong need was for the technology architecture to evolve in response to changes in the other KM architectural elements, and an extraordinary degree of flexibility was a must.

Deciding the Degree of Centralization of Content

From a practical angle, the degree of distribution of content is another challenge to be surmounted. Does all content need to be centralized in one repository, or does it live and evolve in different pockets across the enterprise? The former choice appears attractive, because it offers features such as simplicity of architecture, administration, usage, change management, etc. However, the fact that specialized knowledge continues to develop in pockets—and that the responsibility (and pride) associated with ownership is the best driving force for its continued currency and relevance—indicates a distributed content architecture.

Using Synchronous versus Asynchronous Mechanisms for Knowledge Sharing

Another important aspect is the relative focus on direct, people-to-people collaborative sharing vis-à-vis sharing through codification of knowledge. Collaboration is characterized by its reliance on bringing people "in touch" for knowledge transfer through synchronous mechanisms. The latter approach (also called content management) is asynchronous, depends on repositories, and emphasizes defined ways of explicating knowledge. Conventional KM wisdom associates collaboration with the potential for tacit knowledge transfer and content management with explicit knowledge transfer. However, our experience suggests that technology, used innovatively, can help blur the boundaries between the two. For example, collaboration through technology systems is largely synchronous, and yet, as for example in the open source movement, is capable of creating exciting possibilities for knowledge transfer in virtual teams. The knowledge represented by the content can also be viewed as providing the live context for the exchange of implicit knowledge. It may, therefore, be said that the conversion of the implicit knowledge of the organization into content is a property of mature KM programs. Technology systems that sit atop the e-mail system, and content mining agents on collaborative forums, are further examples indicating the blurring distinctions between collaboration and content management.

Measuring the Benefits of KM

As KM implementations mature, it becomes imperative that mechanisms to evaluate the benefits must emerge. A complete treatment of KM metrics is beyond the scope of this article, and the interested reader may refer to Skyrme (2003).

In our experience, there are three forms of evidence that can be used in assessing the benefits of a KM program, in increasing order of reliability and difficulty: anecdotal, survey-based, and metrics-based (Kochikar & Suresh, 2003). Anecdotal evidence—"*Thanks to using good KM, my project saved 12 weeks and saved 15% of cost to the customer*"—although it may represent the viewpoint of a few opinion leaders, can be used to great effect. Surveys are generally more convincing, as they represent the view of a sample carefully chosen to represent the views of the entire target population. For example, an internal survey at Infosys found that more than 99% of the respondents believed KM is essential for the company, and 70% said good knowledge-sharing practices had helped in delivering tangible benefit to customers.

The metrics-based approach is the most powerful, and yet the most difficult to implement, demanding a high degree of maturity of the KM implementation. Our approach has been to measure in quantitative terms the impact of knowledge sharing on traditional indicators of project performance, using the KCU mechanism. Several projects have been able to quantify savings in dollar terms, and also report various other benefits, such as improved quality, faster turnaround times, etc.

FUTURE TRENDS

A heartening trend observed over the past few years is the increasing geographical uptake of KM. Of the 1998 MAKE winners, 73.3% were from North America, 17.7% from Europe, and 4.4% from Asia. In the 2003 MAKE study, North America's representation had dropped to 55%, Europe's had risen to 22.4%, while Asia's had surged to 20.4%. Clearly, Europe's and Asia's acceptance of KM has grown at the expense of North America, and this is likely to be a continuing trend.

Over the coming years, KM will continue to be imperative for organizational effectiveness. There is likely to be greater focus on tacit knowledge sharing, evolution of standards for KM solutions, and sharing through communities of practice. These developments will continue to be supported by evolving technologies: the integration of content management and collaboration products, development of agent technologies to provide proactive services, increased role for multimedia content, automated knowledge capture in collaboration products, automatic content classification, and enterprise-level support for mobile application access (reducing the reliance on speech and voice recognition systems).

CONCLUSION

Creating a culture of sharing is governed by principles that have much in common with Metcalfe's law—as more people grow convinced of the benefits of participating in the knowledge-sharing movement, it becomes easier to convince still more people to buy in. Thus, as long as steady progress is made on the road toward achieving greater sharing, the pace of adoption accelerates with time. Once a "critical mass" of users has been reached, the movement reaches a *take-off stage* (Figure 1), beyond which it becomes self-sustaining, without significant effort being devoted toward building up the motivation and awareness properties. Until this point is reached, it is crucial to understand and manage KM adoption as a process of organizational change.

KEY TERMS

Intangible Assets: Organizational assets that do not have any physical manifestation, or that have physical measures with no bearing on their value. The following is a typical list of intangible assets that an organization may have:

- Fragmented knowledge residing with individuals, or encapsulated in artifacts such as documentation and software code
- Codified and classified knowledge residing in repositories
- Unique systems, processes, methodologies, and frameworks that the organization follows
- "Formalized" intellectual property, such as patents, trademarks, and brands
- Relationships and alliances that the organization may have shaped

Intellectual Capital (IC): The "stock" of knowledge that exists in an organization at a particular point in time that can be used to generate value for its stakeholders (Bontis, Crossan, & Hulland, 2002).

Knowledge Currency Units (KCU): A mechanism defined at Infosys Technologies to convert all knowledge-sharing activities to a common denominator, in order to enable their measurement in quantitative terms.

Knowledge Management (KM): The gamut of organizational processes, responsibilities, and systems directed toward the assimilation, dissemination, harvest, and reuse of knowledge.

Metcalfe's Law: States that the utility of a network rises in proportion to the square of the number of its users. This means that as more users get connected into a network, the marginal utility perceived by new users increases dramatically.

Social Capital: The resources available through, and derived from, the network of relationships possessed by an individual or social unit within an organization (Nahapiet & Ghoshal, 1998).

Extensions to UML Using Stereotypes

INTRODUCTION

The Unified Modeling Language (UML) allows to visualize, to specify, to build and to document the devices of a system that involves a great quantity of software. It provides a standard form for writing the models of a system, covering so much of the conceptual aspects (such as processes of the business and functions of the system) as the concrete ones (such as the classes written in a specific programming language, schemas of databases and software components).

In 1997, UML 1.1 was approved by the OMG becoming the standard notation for the analysis and the design oriented to objects. UML is the first language of modelling in which a metamodel in its own notation has been published. It is a strict subset called Core. It is a self-referential metamodel.

It is a very expressive language that covers all of the necessary views to develop and to deploy systems. UML is a language that provides three extension mechanisms (Booch, Rumbaugh, & Jacobson, 1999): stereotypes, tag values, and constrains. The stereotypes allow to create new types of elements of model based on the elements that form the metamodel UML extending the semantics of the same one, the tag values are an extension of the properties of an element of UML, allowing to add new information to the specification of the same one, and the constrains are an extension of the semantics of UML that allow to add new rules or to modify the existent ones.

The organization of this overview is given in the following way: first, we present the stereotypes according to the standard of OMG; second, we expose the analysis of works that extend UML using stereotypes in diverse real domains; third, we make an analysis of the stereotypes of UML; and we finish giving a general conclusion where we focus ourselves in the distinction of the works according to their inclusion or not of the created stereotypes in the metamodel of UML.

STEREOTYPE ACCORDING TO THE STANDARD OF OMG

A stereotype provides a form of classifying elements in such a way that they work in some aspects as if they were instances of a new constructor of the "virtual"

Attributes	
BaseClass	This specifies the names of one or more elements from UML modeling to which the stereotype is applied, such as classes, associations.
Icon	This is the geometric description of the icon that will be used to present an image of the element of the marked model with the stereotype.

metamodel. A stereotype could also be used to indicate a meaning or different use between two elements with identical structure. A stereotype can also specify a geometric icon to be used to present elements with the stereotype.

USING STEREOTYPES IN DIVERSE REAL DOMAINS

UML adapts to any technique, because it has extension mechanisms that don't need to redefine the nucleus UML, allowing to obtain a modeling more appropriate to the different particular domains. All of the extensions should follow the standard proposed by the OMG (2001).

Modeling of Business with UML

UML was initially designed to describe aspects of a software system. For the modeling of business, UML needed to be extended to identify and to visualize resources, processes, objectives and rules more clearly. These are the primary concepts that define a business system. The Eriksson-Penker Business Extensions (Eriksson & Penker, 1999) provide new stereotypes for their model. In a diagram of class of UML, they represent a process through a specific symbol that corresponds to an activity stereotyped in an activity diagram. The resources used by the process are modeled with a stereotyped dependence *«supply»* and the resources controlled by the process are modeled with a stereotyped dependence *«control»*.

Modeling of Web Applications with UML

In Baresi, Garzotto, and Paoloni (2001), they propose a framework denominated W2000, for the design of Web applications. They combine the use of UML and HDM (Hypermedia Model). The Web applications require the integration of two different, but interrelated, activities: the design hypermedia that is focused in the navigation way and the structure of the information, and the functional design that is focused in the operations. Among their main purposes is the extension to the standard of UML of the dynamic diagrams.

It uses *«node type»* like stereotype of UML to define a node type that allows to reach different structures of information and defines the symbol "@" to indicate that a node stereotyped with *«node type»* will be the node for defect where all the users begin to navigate.

They propose a symbol called "index" that allows the users of a navigation to select one of the elements from a list of indexes.

The "collection links" define how the users can navigate between the core and the members of a collection, and they add a symbol to graphically represent the pattern "Index + Guided Tour".

For the functional design, they define the diagrams of scenarios, and these are represented through an extended sequence of diagrams of UML. The extensions refer as much to objects as to the step of messages. The objects are organized in entities (components and nodes), semantic associations and collect. The "free navigation" is represented with dotted lines and the "constrained navigation" is represented with a line with a diamond in it.

In 1999, Jim Conallen, Principal Consultant of Conallen Inc., Object Oriented Application Development in Conallen Inc., presented in their paper an extension to UML, in a formal way, to model applications Web.

The extension was presented at several other conferences in 1999, including the Rational Users Conference in Seattle (July 1999), and two Wrox Press ASP conferences in Washington, DC (September 1999) and in London (November 1999).

Various summaries and introductions to the extension have or will appear in the *Communications of the ACM* (ASPToday, *http://www.asptoday.com/articles/19990517.htm*), and in the UML Resources Web site at Rational Software. A full explanation of this work is currently being prepared for the book, *Building Web Applications with UML* (Conallen, 2002), published in the Object Technology Series of Addison-Wesley Longman.

This article presents an extension of UML for Web application designs. Part of the extension mechanism of UML is the ability to assign different icons to stereotyped classes. A list of prototype icons for the most common class stereotypes can be found as an appendix. It defines two new stereotypes to model the difference between the executed methods in the server and the executed functions in the client. In a page, a method that executes on the server will be stereotyped as *«server method»* and functions that run on the client *«client method»*. This solves the problem of distinguishing attributes and methods of a page object. It proposes the modeling of a page with two stereotyped classes, *«server page»* and *«client page»*. They define several stereotypes to represent the associations, such as: *«builds»* that is modeled with an unidirectional association from the server page to client page, *«redirects»* to model the redirection to other *«server page»*, *«links»* for defined associations between pages clients and other pages (client or server). Also, they define stereotypes to model components, *«server component»* and *«client component»*, for Forms *«form»*, for Framesets *«frameset»*. Other defined stereotypes, *«scriplet»* for cached client page, and *«xml»* for a hierarchical data object that can be passed to and from a Web server and client browser.

In Gorshkova and Novikov (2001), a UML extension capable to refine the design of the client part of Web application is defined. Several new diagrams are specified which provide a precise definition of the content of Web pages and navigation between them. The composition diagram is a special case of class diagram. We use it to express the structure of the Web pages and identify their content: how they are connected together and what data is carried from one page to another. The main notion of the composition diagram is the page, defined as an autonomous block of screen. Each screen in the navigation diagram is mapped into several pages in the composition diagram. The tool may provide links from pages to screens and vice versa to show their relationship. A page is modeled in the composition diagram as a class stereotyped *«page»*. A page may play the role of container for other pages. Nested pages are modeled as aggregated classes. The page has elements like buttons, links and input fields. They are modeled as attributes of the corresponding page. The *«form»* stereotype is a child of *«page»*. It is used to model HTML forms. The navigable association between source and target pages is stereotyped *«link»*. Each *«link»* has a tag context with expression as value.

In Koch, Baumeister, and Mandel (2000), the authors define a set of stereotypes that are used in the construction of intuitive analysis and design models in the development of Web applications. These models are the navigation space model, the navigation structure model, and the static presentation models.

The basis of the navigation design is the conceptual model, and the outcome is a navigational model, which can be seen as a view over the conceptual model. The navigational model is defined in a two-step process. In the first step, the navigational space model is defined, and in the second, the navigational structure model is built. The navigation space model defines a view on the conceptual model showing which classes of the conceptual model can be visited through navigation in the Web application. The navigational structure model defines the navigation of the application. It is based on the navigation space model, but also additional model elements are included in the class diagram to perform the navigation between navigational objects: menus, indexes, guided tours, queries, external nodes, and navigational contexts.

The static presentational model is represented by UML composition diagrams that describe how the user interfaces are built. They define stereotypes to be able to build these diagrams.

The set of defined stereotypes is the *«Navigational Class»*. It represents a class whose instances are visited during navigation. The *«Direct Navigability»* are associations in the navigation model. These associations are interpreted as direct navigability from the source navigation class to the target navigation class. An *«Index»* is modeled by a composite object which contains an arbitrary number of index items. A *«Guided Tour»* is an object which provides sequential access to the instances of a navigational class. A *«Query»* is represented by an object which has a query string as an attribute. This string may be given, for instance, by an OCL select operation. A *«Menu»* is a composite object which contains a fixed number of menu items. A *«Presentational class»* models the presentation of a navigational class or an access primitive, such as an index, a guided tour, query, or menu. A *«Frameset»* is a top-level element which is modeled by a composite that contains (lower level) presentational objects but may also contain an arbitrary number of nested framesets. An area of the frameset is assigned to each lower level element, so called *«frame»*, the same stereotype is also used in Eriksson and Penker (1999). A *«window»* is the area of the user interface where framesets or presentational objects are displayed, and also defined are *«text»*, *«anchor»*, *«button»*, *«image»*, *«audio»*, *«video»* and *«form»*. A *«collection»* is a list of text elements that is introduced as a stereotype to provide a convenient representation of composites. An *«anchored collection»* a list of anchors.

Real-Time Systems Modeling with UML

In Selic and Rumbaugh (1998), a set of constructs that facilitate the design of software architectures in the domain of real-time software systems is described. The constructs, derived from field-proven concepts originally defined in the ROOM methodology (http://wwweb.org/smo/bmc/mb/mb35.html) are specified using the UML standard. In particular, it showed how these architectural constructs can be derived from more general UML modeling concepts by using the powerful extensibility mechanisms of UML. The following stereotypes are defined as UML extension: *«protocol»*, *«protocolRole»*, *«port»*, *«capsule»*, and *«chainState»*.

A protocol role is modeled in UML by the *«protocolRole»* stereotype of Metamodel Class ClassifierRole. A protocol is modeled in UML by the *«protocol»* stereotype of Metamodel Class Collaboration with a composition relationship to each of its protocol roles representing the standard relationship that a collaboration has with its “owned elements”. A port object is modeled by the *«port»* stereotype, which is a stereotype of the UML Class concept. A capsule is represented by the *«capsule»* stereotype of Class. The capsule is in a composition relationship with its ports, sub-capsules (except for plug-in sub-capsules), and internal connectors. A state whose only purpose is to “chain” further automatic (triggerless) transitions onto an input transition is defined as a stereotype *«chainState»* of the UML State concept.

In Toetenel, Roubtsova, and Katwijk (2001), the paper shows an extension UML with mechanisms for specifying temporal constrains and properties. It defines schemes for the translation of UML specifications into semantically equivalent XTG-based (eXtended Timed Graphs) specifications such as the properties given on UML specification can be proved on the XTG specification. The realization of the approach uses the extensibility interface of the Rational Rose UML Tool (Rational Rose 98i, 2000).

ANALYSIS OF UML STEREOTYPES

In Gogolla and Henderson-Sellers (2002), the paper takes up ideas from Gogolla (2001) where stereotypes have been introduced for relational database design. The expressiveness of UML stereotypes has been analyzed, and some concrete suggestions have been made for the improvement of the UML metamodel. Use OCL to define precise stereotypes.

In Riesco, Martellottto, and Montejano (2003) and Riesco, Grumelli, Maccio, and Martellotto (2002), proposals of "evolutionary stereotypes" are presented. These are incorporated into the modeling tool in such a way that they can extend the UML metamodel, including the new elements with their corresponding semantics. In this way, the environment of a tool can dynamically change its appearance and functionality to allow software engineers to use the stereotypes previously defined in the diagrams.

The Clark, Evans, Kent, Brodsky, and Cook study[1] proposes a new metamodelling facility (MMF) containing: Metamodelling Language (MML); Metamodelling Tools (MMT); a satisfaction checker (for instance, does X satisfy constraint C from model M?); to check that a model satisfies its metamodel; to check that a metamodel satisfies the MML rules; to check that MML satisfies the MML rules.

CONCLUSION

UML is a universal language adopted for the modeling of applications in a wide range of domains. It is an open language, which provides extension mechanisms in order to extend the metamodel. The UML extension mechanisms include: Tag values, Constrains and Stereotypes.

In particular, the stereotypes should be carefully declared and should only be used when the message to be communicated could not be expressed in any other UML terms. In order to achieve a better use of stereotypes, there are certain necessary conditions. The UML metamodel should be adjusted and support tools should be provided for the complete part of the UML metamodel dealing with stereotypes.

The papers analyzed in this work propose a varied number of stereotypes to extend UML, with the purpose of using this language to model particular domains, such as Web applications, real-time systems, business modeling, XML, and so forth.

After the reading and the analysis of these papers, it has been detected that only in three of them (Gogolla, 2001; Riesco, Grumelli, Maccio, & Martellotto, 2002; Selic & Rumbaugh, 1998) the addition of stereotypes is defined as a UML complete extension. This occurs through the incorporation of new elements to the metamodel with new semantic that assures the consistency of the metamodel UML.

In the other analyzed papers, the stereotypes are presented being used in their specific context, but without extending the metamodel UML. This is a clear deficiency in their definitions, since the maintenance of the metamodel UML in a consistent way is very difficult, or even impossible, as their stereotypes are not explicitly added to the metamodel UML. Besides, this means that the stereotypes won't be available to be used in generic solutions to problems belonging to the selected particular domain.

KEY TERMS

Class Diagram: Show the classes of the system, their interrelationships, and the collaboration between those classes.

Extension Mechanisms: Specify how model elements are customized and extended with new semantics.

Metamodel: An abstraction which defines the structure for a UML model. A model is an instance of a metamodel. Defines a language to describe an information domain.

Object Constraint Language (OCL): A notational language for analysis and design of software systems. It is a subset of the industry standard UML that allows software developers to write constraints and queries over object models.

OMG: Has been "Setting The Standards For Distributed Computing™ through its mission to promote the theory and practice of object technology for the development of distributed computing systems. The goal is to provide a common architectural framework for object-oriented applications based on widely available interface specifications (OMG, 2001).

Real Domains (Particular or Specific): The different application areas that can require to be modeled with UML. For example: Web applications, real-time system, XML, business modeling, frameworks, communication protocols, workflows, geographical information systems, and so forth.

Stereotype: Allows to create new types of elements of modeling, based on the elements that form the goal-pattern UML, extending its semantics.

ENDNOTE

Face Expression and Motion Analysis over Monocular Images

Ana C. Andrés del Valle
VICOMTech Research Center, Spain

INTRODUCTION

As computers evolve towards becoming more human-oriented machines, human-computer interfaces, behavior-learning robots, and disable-adapted computer environments will use face expression analysis to be able to react to human action. Furthermore, faces play an essential role in human communication. Consequently, they have been the first objects whose motion has been studied in order to recreate animation on synthesized models or to interpret motion for a posteriori use. The analysis of motion and expression from monocular (single) images is widely investigated because non-stereoscopic static images and videos are the most affordable and extensively used visual media (i.e., Webcams).

Synthetic faces are classified into two major groups: avatars and clones. Generally, avatars are a rough and symbolic representation of the person, and their animation is speaker independent because it follows generic rules disregarding the individual that they personify. Clones are more realistic and their animation takes into account the nature of the person and his real movements. Whether we want to animate avatars or clones, we face a great challenge: the automatic generation of face animation data. Manually generated animation has long been used to create completely virtual characters and has also been applied to animate avatars. Nevertheless, many computer applications require real-time and easy-to-use face animation parameter generation, which means that the first solutions developed using motion-capture equipment prove to be too tedious for many practical purposes. Most applications utilizing Talking Heads aim at telecommunication uses. In such a context, real-time capabilities and low computing cost for both analysis and synthesis are required. Current trends in research tend to use speech analysis or synthesized speech from text as a source of real-time animation data. Although these techniques are strong enough to generate parameters to be used by avatars, they cannot provide realistic data for face animation.

BACKGROUND

Systems analyzing faces from monocular images are designed to give motion information with the most suitable level of detail, depending on their final application. Image input is analyzed in the search for general facial characteristics: global motion, lighting, and so forth. At this point, some image processing is performed to obtain useful data that can be afterwards interpreted to obtain face animation synthesis (see Figure 1).

We have categorized the most performing techniques for facial analysis on monocular images in three groups: “those that retrieve emotion information,” “those that obtain parameters related to the Face Animation synthesis used,” and “those that use explicit face synthesis during the image analysis.”

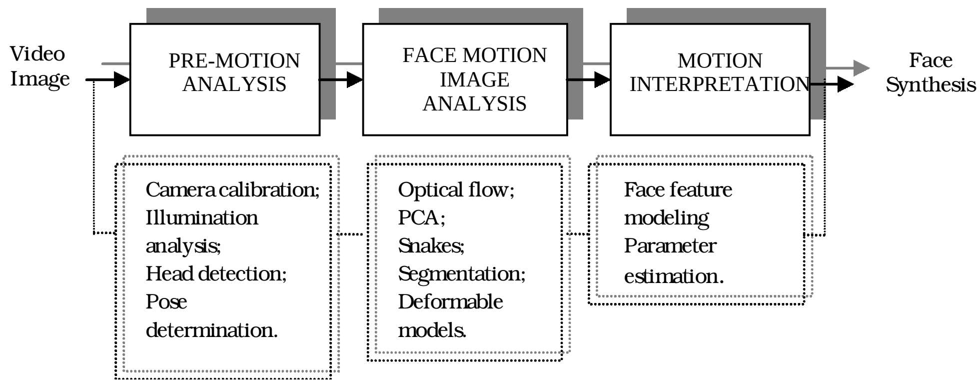
RETRIEVING EMOTION INFORMATION

Humans detect and interpret faces and facial expressions in a scene with little or no effort. The systems we discuss in this section accomplish this task automatically. The main concern of these techniques is to classify the observed facial expressions in terms of generic facial actions or in terms of emotion categories, and not to attempt to understand the face animation that could be involved to synthetically reproduce them.

Summary of the Most Performing Approaches

- The researcher Yacoob (Yacoob & Davis, 1994; Black & Yacoob, 1997) explored the use of local parameterized models of image motion for recognizing the non-rigid and articulated motion of human faces. These models provide a description of the motion in terms of a small number of parameters that are related intuitively to the motion of some facial features under the influence of expressions.
- Huang and Huang (1997) introduce a system developed in two parts: facial feature extraction (for the

Figure 1. Diagram of the general procedure for facial expression analysis



training-learning of expressions) and facial expression recognition. The system applies a point distribution model and a gray-level model to find the facial features. Then, the position variations are described by 10 action parameters (APs).

- Pantic and Rothkrantz (2000) describe another approach, which is the core of the Integrated System for Facial Expression Recognition (ISFER). The system finds the contour of the features with several methods suited to each feature—snakes, binarization, deformable models, and so forth—making it more efficient under uncontrolled conditions: irregular lighting, glasses, facial hair. A neural network (NN) architecture of fuzzy classifiers is designed to analyze complex mouth movements.
- Many systems base their description of face actions on the Facial Action Coding System (FACS) proposed by Ekman and Friesen (1978). The importance granted to FACS is such that two research teams, one at the University of California, San Diego (UCSD) and the Salk Institute, and another at the University of Pittsburgh and Carnegie Mellon University (CMU), were challenged to develop prototype systems for automatic recognition of spontaneous facial expressions.

  The system developed by the UCSD team, described in Bartlett et al. (2001), analyzes face features after having determined the pose of the individual in front of the camera. Features are studied using Gabor filters and afterwards classified using a previously trained hidden Markov model (HMM). In their study, Bartlett et al. claim AU detection accuracy from 80% for eyebrow motion to around 98% for eye blinks.

  CMU opted for another approach, where face features are modeled in multi-state facial components of analysis. They use neural networks to derive the AUs associated with the motion observed. They have developed the facial models for lips, eyes, brows, cheeks, and furrows. In their article, Tian, Kanade, and Cohn (2001) describe this technique, giving details about the models and the double use of NN, one for the upper part of the face and a different one for the lower part. The average recognition rates achieved are around 95.4% for upper face AUs and 95.6% for lower face AUs.
- Piat and Tsapatsoulis (2000) take the challenge of deducing face expression out of images from another perspective, no longer based on FACS. Their technique finds first the action parameters (MPEG-4 FAPs) related to the expression being analyzed, and then they formulate this expression with high-level semantics. To do so, they have related the intensity of the most used expressions to their associated FAPs.
- Other approaches (Chen & Huang, 2000) complement the image analysis with the study of the human voice to extract more emotional information. These studies are oriented to develop the means to create a human-computer interface (HCI) in a completely bimodal way.

Pantic and Rothkrantz (2000) offer overviews and comparative studies of many techniques, including some of those just discussed, analyzed from an HCI perspective.

Table 1. A summary of the most used image processing techniques

PRE-MOTION ANALYSIS	EXPRESSION ANALYSIS	MOTION INTERPRETATION
Camera calibration—Processing techniques that correct the image distortion due to the camera characteristics (lens distortion, projection, etc.). Illumination analysis—Processing techniques that study the illumination of the analyzed scene to understand its influence on the image of the speaker's face. Head detection and pose determination—Image processing algorithms that aim at giving an accurate location and orientation of the speaker's head in the scene.	Optical flow (OF)—The OF between two images is the field of displacements due to local motion. Principal Component Analysis (PCA)—PCA or *Karhunen-Loeve transform* is a statistical tool that permits vector dimension reduction. It is used to analyze images of facial features by contrasting them against a trained database obtained using PCA over images of that feature under different expressions and lighting. Segmentation—Image processing techniques that aim at separating different objects on an image. Snakes—Active contour models, also called snakes, are geometric curves that approximate the contours of an object on an image by minimizing an energy function.	Face feature modeling—Image data processing techniques that relate the results from analysis facial motion into face animation parameters following specific motion models per feature: eye, mouth, eyebrows, etc. Parameter estimation—Image data processing techniques that relate the results from the analysis of facial motion into face animation parameters following a mathematical correspondence. Among others, we find the following estimators: linear, neural networks, and radial basis functions networks.

OBTAINING PARAMETERS RELATED TO THE SYNTHESIS USED

Some face animation systems need action parameters as input to specify how to open the mouth, the position of the eyelids, the orientation of the eyes, and so forth, in terms of parameter magnitudes associated to physical displacements. The analysis methods studied in this section try to measure displacements and feature magnitudes over the images to derive the actions to be performed over the head models.

Summary of the Most Performing Approaches

- Terzopoulos and Waters (1993) developed one of the first solutions of this nature. Their method tracks linear facial features to estimate corresponding parameters of a three-dimensional, wireframe face model, allowing them to reproduce facial expressions. They utilize anatomical-based muscle actions that animate the 3D face wireframe.

- Based on a similar animation system to that of Water's, Essa, Basun, Darrel, and Pentland (1996) define a suitable set of control parameters using vision-based observations. They call their solution FACS+ because it is an extension of the traditional FAC system. They use optical flow analysis along the time of sequences of frontal view faces to get the velocity vectors on 2D, and then these are mapped to the parameters**.**
- Morishima (2001) has been developing a system that succeeds in animating a generic parametric muscle model after having been customized to take the shape and texture of the person the model represents. By means of optical flow image analysis, complemented with speech processing, motion data is generated. These data are translated into motion parameters after passing through a previously trained neural network.
- Sarris and Strintzis (2001, 2002) developed a system for video-phoning for the hearing impaired. The rigid head motion (pose) is obtained by fitting the projection of a 3D wireframe onto the image being analyzed. Then, non-rigid face movements (expressions) are estimated thanks to a feature-based approach adapted from the Kanade, Lucas, and Tomasi algorithm.
- Ahlberg (2002) also exposes in his work a wireframe fitting technique to obtain the rigid head motion. He uses the new parameterized variant of the face model CANDIDE, named CANDIDE-3, which is MPEG-4 compliant. The image analysis techniques include PCA on eigentextures that permits the analysis of more specific features that control the model deformation parameters.
- The MIRALab research team at the University of Geneva (Switzerland) has developed a complete system to animate avatars in a realistic way, in order to use them for telecommunications. Goto, Kshirsagar, and Magnenat-Thalmann (2001) give a more detailed explanation about the image processing involved. Feature motion models for eyes, eyebrows, and the mouth allow them to extract image parameters in the form of 2D point displacements. These displacements represent the change of the feature from the neutral position to the instant of the analysis and are easily converted into FAPs.
- Also aiming at telecom applications, researchers at the Eurecom Institute have developed a system that takes advantage of robust face feature analysis techniques, as well as of the synthesis of the clone of the individual being analyzed (Andrés del Valle, 2003). They use a Kalman filter to recover the head global position and orientation. The pose data predicted by the filter are used to adapt feature analysis algorithms initially designed to work for a frontal point of view under any other head pose. This solution controls face feature analysis during the change of the speaker's pose.

USING EXPLICIT FACIAL SYNTHESIS DURING THE ANALYSIS

Some face motion analysis techniques use the synthesized image of the head model to control or refine the analysis procedure. In general, the systems that use synthesized feedback in their analysis need a very realistic head model of the speaker, high control of the synthesis, and knowledge of the conditions of the face being recorded.

Summary of the Most Performing Approaches

- Li, Roivainen, and Forchheimer (1993) presented one of the first works to use resynthesized feedback. Using a 3D model, CANDIDE, their approach is characterized by a feedback loop, connecting computer vision and computer graphics.
- Ezzat and Poggio (1996a, 1996b) describe image-based modeling techniques that make possible the creation of photo-realistic computer models of real human faces. To generate the motion for this model, they use an analysis-by-synthesis algorithm, which is capable of extracting a set of high-level parameters from an image sequence involving facial movement using embedded image-based models.
- More recent research is able to develop much more realistic results with three-dimensional models. Eisert and Girod (1998), for instance, present a system that estimates 3D motion from image sequences showing head and shoulder scenes for video telephone and teleconferencing applications. They use a very realistic 3D head model of the person in the video. The model constrains the motion and deformation in the face to a set of FAPs defined by the MPEG-4 standard. Combining the 3D information with the optical flow constraint leads to a linear algorithm that estimates the facial animation parameters.
- Pighin, Szeliski, and Salesin (1999) maximize the previous approach by customizing animation and analysis on a person-by-person basis. They use

new techniques to automatically recover the face position and the facial expression from each frame in a video sequence. Their mesh morphing approach is detailed in Pighin, Hecker, Lischinski, Szeliski, and Salesin (1998). Their face motion and expression analysis system fits the 3D model on each frame using a continuous optimization technique. During the fitting process, the parameters are tuned to achieve the most accurate model shape.

FUTURE TRENDS

There exists a trade-off between the degree of motion detail extracted from the images and the level of semantic understanding desired. Very precise analysis techniques that are able to generate information to accurately animate face models often cannot provide meaningful information about the general facial expression. HCI applications seek a high level of comprehension about the speaker's expression; FA applications simply need data to replicate those expressions. Nowadays, applications are complex, and mix FA and HCI requirements; therefore, current research trends try to satisfy both needs: accurate motion analysis and expression understanding. As a result, the different research perspectives of the scientific communities involved in the field of facial animation (CG, CV, IP for Telecommunications, etc.) are starting to converge.

CONCLUSION

Since the importance granted to facial animation is increasing, analysis and synthesis methods developed to generate face animation are under continuous change to meet new application requirements. Following this trend, the analysis of monocular images to extract facial motion data has appeared as a way to simplify and adapt facial animation to current video media. The effort of this research aims at making facial animation technologies and methods available to the general public, and permitting the study of already stored image data.

KEY TERMS

Computer Graphics (CG): Field of science and technology concerned with methods and techniques for converting data to or from visual presentation using computers.

Computer Vision (CV): A branch of artificial intelligence and image processing concerned with computer processing of images from the real world. Computer vision typically requires a combination of low-level image processing to enhance the image quality (e.g., remove noise, increase contrast), and higher-level pattern recognition and image understanding to recognize features present in the image.

Facial Action Coding System (FACS): A comprehensive system that can distinguish the most possible visually distinguishable facial movements. FACS derives from an analysis of the anatomical basis of facial movement. Using FACS, it is possible to analyze any facial movement into anatomically based minimal action units (AUs).

Facial Animation (FA): The set of CG and CV techniques used to recreate facial motion and expression. We can classify animated characters in two groups: avatars and clones. Avatars are a general, standard representation of a human; a clone is the exact replication of an existing individual.

Facial Animation Parameters (FAP): The standard MPEG-4 defines 68 FAPs. Each one is associated with the movement of specific vertices that compose a head mesh so to generate different a facial expression.

Human-Computer Interaction (HCI): A discipline concerned with the design, evaluation, and implementation of interactive computing systems for human use and with the study of major phenomena surrounding them.

Image Processing (IP): Processing technique algorithms designed to enhance and manipulate an image.

MPEG-4: The latest compression standard developed by the Motion Picture Expert Group. MPEG-4 brings higher levels of interaction with content, controlled by the content developers. It also brings multimedia to new types of networks, including those employing relatively low bit-rates, and mobile ones.

Facial and Body Feature Extraction for Emotionally-Rich HCI

INTRODUCTION

Emotionally-aware Man-Machine Interaction (MMI) systems are presently at the forefront of interest of the computer vision and artificial intelligence communities, since they give the opportunity to less technology-aware people to use computers more efficiently, overcoming fears and preconceptions. Most emotion-related facial and body gestures are considered to be universal, in the sense that they are recognized along different cultures; therefore, the introduction of an "emotional dictionary" that includes descriptions and perceived meanings of facial expressions and body gestures, so as to help infer the likely emotional state of a specific user, can enhance the affective nature of MMI applications (Picard, 2000).

As a general rule, our intuition of what a human expression represents is based on trying to mimic the way the human mind works, while making an effort to recognize such an emotion. This means that even though image or video input is necessary for this task, this process cannot come to robust results without taking into account features like hand gestures or body pose. These features are able to convey messages in a much more expressive and definite manner than mere wording, which can be misleading or ambiguous. Sometimes, a simple hand action, such as placing one's hands over the ears, can pass on the message that you've had enough of what you are hearing more expressively than any spoken phrase.

BACKGROUND

Emotion Representation

Most emotion analysis applications attempt to annotate video information with category labels that relate to emotional states. However, since humans use an overwhelming number of labels to describe emotion, we need to incorporate a higher level and continuous representation that is closer to our conception of how emotions are expressed and perceived.

Activation-emotion space (Cowie, 2001) is a simple representation that is capable of capturing a wide range of significant issues in emotion. It rests on a simplified treatment of two key themes:

- Valence: The clearest common element of emotional states is that the person is influenced by feelings that are "valenced" (i.e., they are centrally concerned with positive or negative evaluations of people, things, or events).
- Activation Level: Research has recognized that emotional states involve dispositions to act in certain ways. Thus, states can be rated in terms of the associated activation level (i.e., the strength of the person's disposition to take some action rather than none).

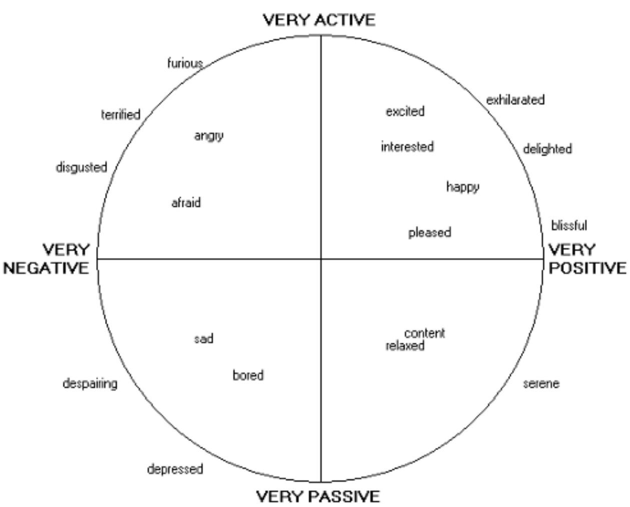
The axes of the activation-evaluation space reflect those themes, with the vertical axis showing activation level, while the horizontal axis represents evaluation. This scheme of describing emotional states is more tractable than using words and still can be translated into and out of verbal descriptions. Translation is possible because emotion-related words can be thought of as positions in activation-emotion space.

A surprising amount of emotional discourse can be captured in terms of activation-emotion space. Perceived full-blown emotions are not evenly distributed in activation-emotion space; instead, they tend to form a roughly circular pattern. In this framework, the center can be thought of as a natural origin, thus making emotional strength at a given point in activation-evaluation space proportional to the distance from the origin. The concept of a full-blown emotion can then be translated roughly as a state where emotional strength has passed a certain limit. An interesting implication is that strong emotions are more sharply distinct from each other than weaker emotions with the same emotional orientation. A related extension is to think of primary or basic emotions as cardinal points on the periphery of an emotion circle. Plutchik (1980) has offered a useful formulation of that idea—the emotion wheel—(see Figure 1).

Facial Expression Analysis

There is a long history of interest in the problem of recognizing emotion from facial expressions (Ekman, 1978), and there have been extensive studies on face perception during the last 20 years (Davis, 1975; Ekman, 1973; Scherer, 1984). The salient issues in emotion recognition from faces are parallel in some respects to the issues associated with voices, but divergent in others. In most cases, these studies attempt to define the facial expression of emotion

Figure 1: The activation-emotion space



in terms of qualitative patterns capable of being displayed in a still image. This usually captures the apex of the expression (i.e., the instant at which the indicators of emotion are most noticeable). More recently, emphasis has switched towards descriptions that emphasize gestures (i.e., significant movements of facial features).

In the context of faces, the task almost always has been to classify examples of the six emotions considered to be universal: joy, sadness, anger, fear, disgust, and surprise (Ekman, 1978). More recently, morphing techniques have been used to probe states that are intermediate between archetypal expressions. They reveal effects that are consistent with a degree of categorical structure in the domain of facial expression, but they are not particularly large, and there may be alternative ways of explaining them—notably by considering how category terms and facial parameters map onto activation-evaluation space (Karpouzis, 2000).

Analysis of the emotional expression of a human face requires a number of pre-processing steps that attempt to detect or track the face; to locate on it characteristic facial regions, such as eyes, mouth, and nose; and to extract and follow the movement of facial features, such as characteristic points in these regions or model facial gestures using anatomic information about the face. Facial features can be viewed (Ekman, 1975) either as static (i.e., skin color), slowly varying (i.e., permanent wrinkles), or rapidly varying (i.e., raising the eyebrows) with respect to time evolution. Detection of the position and shape of the mouth, eyes (particularly eyelids), wrinkles, and extraction of features related to them are the targets of techniques applied to still images of humans. However, in Bassili's (1979) experiments, expressions were recognized at above chance levels when based on image sequences, whereas only happiness and sadness were recognized at above chance levels when based on still images. Techniques that attempt to identify facial gestures for emotional expression characterization face the problems of locating or extracting the facial regions or features, computing the spatio-temporal motion of the face through optical flow estimation, and introducing geometric or physical muscle models describing the facial structure or gestures.

Body Gesture Analysis

The detection and interpretation of hand gestures have become an important part of human computer interaction in recent years (Wu, 2001). To benefit from the use of gestures in MMI, it is necessary to provide the means by which they can be interpreted by computers. The MMI interpretation of gestures requires that dynamic and/or static configurations of the human hand, arm, and other parts of the human body, be measurable by the machine. First attempts to address this problem resulted in mechanical devices that directly measure hand and/or arm joint angles and spatial position. The so-called glove-based devices best represent this solution's group.

Since the processing of visual information provides strong cues in order to infer the states of a moving object through time, vision-based techniques provide at least adequate alternatives to capture and interpret human hand motion. At the same time, applications can benefit from the fact that vision systems can be very cost efficient and do not affect the natural interaction with the user. These facts serve as the motivating forces for research in the modeling, analysis, animation, and recognition of hand gestures. Analyzing hand gestures is a comprehensive task involving motion modeling, motion analysis, pattern recognition, machine learning, and even psycholinguistic studies.

The first phase of the recognition task is choosing a model of the gesture. The mathematical model may consider both the spatial and temporal characteristics of the hand and hand gestures. The approach used for modeling plays a pivotal role in the nature and performance of gesture interpretation. Once the model is decided upon, an analysis stage is used to compute the model parameters from the image features that are extracted from single or multiple video input streams. These parameters constitute some description of the hand pose or trajectory and depend on the modeling approach used. Among the important problems involved in the analysis are those of hand localization, hand tracking, and selection of suitable image features. The computation of model parameters is followed by gesture recognition. Here, the parameters are classified and interpreted in light of the accepted model and perhaps the rules imposed by some grammar. The grammar could reflect not only the internal syntax of gestural commands, but also the possibility of interaction of gestures with other communication modes like speech, gaze, or facial expressions. Evaluation of a particular gesture recognition approach encompasses accuracy, robustness, and speed, as well as the variability in the number of different classes of hand/arm movements it covers.

Gesture Interpretation

Gesture analysis research follows two different approaches that work in parallel. The first approach treats a hand gesture as a two- or three-dimensional signal that is communicated via hand movement on the part of the user; as a result, the whole analysis process merely tries to locate and track that movement, so as to recreate it on an avatar or translate it to specific, predefined input interface (e.g., raising hands to draw attention or indicate presence in a virtual classroom).

The low level results of the approach can be extended, taking into account that hand gestures are a powerful expressive means. The expected result is to understand gestural interaction as a higher-level feature and encapsulate it into an original modal, complementing speech and image analysis in an affective MMI system (Wexelblat, 1995). This transformation of a gesture from a time-varying signal into a symbolic level helps overcome problems such as the proliferation of available gesture representations or failure to notice common features in them. In general, one can classify hand movements with respect to their function as follows (Cadoz, 1994):

- Semiotic: These gestures are used to communicate meaningful information or indications.
- Ergotic: Manipulative gestures that are usually associated with a particular instrument or job.
- Epistemic: Related to specific objects, but also to the reception of tactile feedback.

Semiotic hand gestures are considered to be connected, or even complementary, to speech in order to convey a concept or emotion. Especially two major subcategories—deictic gestures and beats. Gestures that consist of two discrete phases are usually semantically related to the spoken content and used to emphasize or clarify it (McNeill, 1992). This relation provides a positioning of gestures along a continuous space. This space is shown in Figure 2 below.

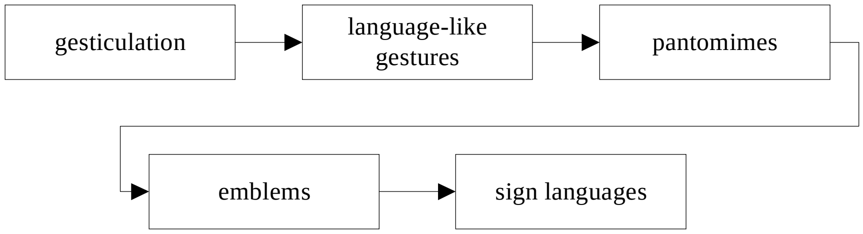
MAIN THRUST OF THE ARTICLE

Facial Feature Extraction

Robust and accurate facial analysis and feature extraction has always been a complex problem that has been dealt with by posing presumptions or restrictions with respect to facial rotation and orientation, occlusion, lighting conditions, and scaling. These restrictions are being eventually revoked in the literature, since authors deal more and more with realistic environments, keeping in mind the pioneering works in the field. A hierarchical, robust scheme coping with large variations in the appearance of diverse subjects, as well as of the same subject in various instances within real video sequences (see Figure 3), has been proposed by Votsis (2003). Soft a priori assumptions are made on the pose of the face or the general location of the features in it. Gradual revelation of information concerning the face is supported under the scope of optimization in each step of the hierarchical scheme, producing a posteriori knowledge about it and leading to a step-by-step visualization of the features in search.

Face detection is performed first through detection of skin segments or blobs, merging of them based on the

Figure 2. Gesture continuum (Cadoz, 1994)



probability of their belonging to a facial area, and identification of the most salient skin color blob or segment. Following this, primary facial features, such as eyes, mouth and nose, are dealt with as major discontinuities on the segmented, arbitrarily rotated face (Figure 4). In the first step of the method, the system performs an optimized segmentation procedure. The initial estimates of the segments, also called seeds, are approximated through min-max analysis and refined through the maximization of a conditional likelihood function. Enhancement is needed so that closed objects will occur, and part of the artifacts will be removed. Seed growing is achieved through expansion, utilizing chromatic and value information of the input image. The enhanced seeds form an object set, which reveals the in-plane facial rotation through the use of active contours applied on all objects of the set, which is restricted to a finer set, where the features and feature points are finally labeled according to an error minimization criterion (Figure 5).

Gesture Tracking and Recognition

The modeling of hand gestures depends primarily on the intended application within the MMI context. For a given application, a very coarse and simple model may be sufficient. However, if the purpose is a natural interaction, a model has to be established that allows many, if not all, natural gestures to be interpreted by the computer.

In general, human hand motion consists of the global hand motion and local finger motion. Hand motion capturing deals with finding the global and local motion of hand movements. Two types of cues are often used in the localization process: color cues (Kjeldsen, 1996) (see Figure 6), and motion cues (Freeman, 1995) (see Figure 7). Alternatively, the fusion of color, motion, and other visual or non-visual cues like speech or gaze are used (Sharma, 1996; Karpouzis, 2004).

To capture articulate hand motion in full degree of freedom, both global hand motion and local finger motion should be determined from video sequences. Different methods have been taken to approach this problem. One possible method is the appearance-based approaches in which 2-D deformable hand shape templates are used to track a moving hand in 2-D (Darrell, 1996). Another possible way is the 3-D model-based approach, which takes the advantages of a priori knowledge built in the 3-D models.

In certain applications, continuous gesture recognition is required; as a result, the temporal aspect of gestures must be investigated. Some temporal gestures are specific or simple and could be captured by low detail dynamic models. However, many high detail activities have to be represented by more complex gesture semantics, so modeling the low-level dynamics is insufficient. The HMM (Hidden Markov Model) technique (Bregler, 1997) and its variations (Darrell, 1996) are often employed in modeling, learning, and recognition of temporal signals. Because many temporal gestures involve motion trajectories and hand postures (see Figure 8), they are more complex than speech signals. Finding a suitable

Figure 3. The original frame from an expressive sequence

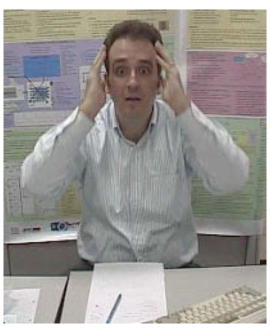


Figure 4. Detected primary facial features

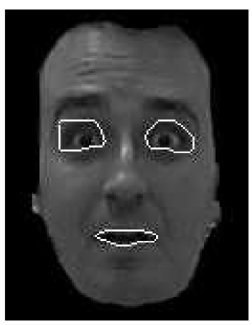

Figure 5. Detected facial features in the apex of an expression

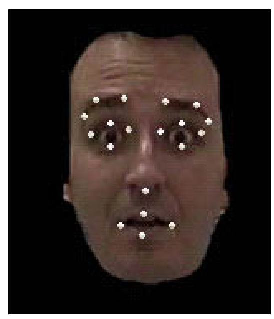

approach to model hand gestures is still an open research problem. Practical large-vocabulary gesture recognition systems by HMM are yet to be developed.

FUTURE TRENDS

General gesture analysis studies consider gestures to be spontaneous, free form movements of the hands during speech (gesticulation), while others, termed emblems, are indicative of a specific emotion or action, such as an insult. An interesting conclusion (McNeill, 1992) is that the alternative use of gestures and speech in order to comprehend the communicated emotion or idea makes the whole concept of body language obsolete. Indeed, the study shows that instead of being "mere embellishments" of spoken content, gestures possess a number of paralinguistic properties. For example, such gestures convey a specific meaning only when considered as a whole, not as mere collections of low-level hand movements. While spoken words are usually unambiguous and can be semantically interpreted only when in a complete sentence or paragraph, gestures are atomic when it comes to conveying an idea, and typically, their actual form depends on the personality and current emotional state of a specific speaker. As a result, gestures cannot be analyzed with the same tools used to process the other modals of human discourse. In the case of gesticulation, we can regard gestures as functions of hand movement over time; the result of this approach is that the quantitative values of this representation (i.e., speed, direction, or repetition) can be associated with emotion-related values such as activation. This essentially means that, in many cases, we do not need to recognize specific gestures to deduce information about the user's emotional state, but merely track the movement of the user's arms through time. This concept can also help us distinguish a specific gesture from a collection of similar hand movements. For example, the "raise hand" gesture in a classroom or discussion and the "go away" or "I've had enough" gestures are similar when it comes to hand movement, since in both cases the hand is raised vertically. The only way to differentiate them is to compare the speed of the upward movement in both cases. In the latter case, the hand is raised in a much more abrupt manner. In our approach, such feedback is invaluable, since we try to analyze the user's emotional state by taking into account a combination of both gesture- and face-related features and not decide based on merely one of the two modals.

CONCLUSION

In this chapter, we presented a holistic approach to emotion modeling and analysis. Beginning from a symbolic representation of human emotions, based on their expression via facial expressions and hand gestures, we described approaches to extracting quantitative and qualitative feature information from video sequences. While these features can be used for simple representation purposes (e.g., animation or task-based interfacing), this methodology is closer to the target of affective computing and can prove useful in providing feedback on users' emotional states. Possible applications include human-like agents that assist everyday chores and react to user emotions, or sensitive artificial listeners that introduce conversation topics and react to specific user cues.

KEY TERMS

Activation-Emotion Space: A 2-D representation of the emotion space, with the two axes representing the magnitude and the hue of a specific emotion.

Affective Computing: A recent theory that recognizes that emotions play an essential role in perception and learning by shaping the mechanisms of rational thinking. In order to enhance the process of interaction, we should design systems with the ability to recognize, to understand, and even to have and express emotions.

Hidden Markov Model: Statistical models of sequential data utilized in many machine learning applications (e.g., speech and gesture recognition).

Model-Based Gesture Analysis: In this framework, gestures are modeled as usually finite states of hand shape or position. This approach captures both the spatial and the temporal nature of the gestures, which is essential for analysis and recognition purposes.

Semiotic Hand Gestures: Gestures used to communicate meaningful information or serving as indications; such gestures convey specific emotions in a more expressive manner than vague hand movement.

Skin Color Estimation: A breakthrough in face detection and segmentation was the representation of skin color with a Gaussian model in a subset of the CrCb space, irrespectively of the actual skin color of the subject.

Universal Emotions: Mainly after the influence of Ekman, these six emotions are considered to be universal, in the sense that they are uniformly recognized across different cultures.

Faculty Perceptions and Participation in Distance Education

INTRODUCTION

Research in the field of distance education has recognized the need for a change and modification of the faculty role in teaching at a distance (Jones, Lindner, Murphy & Dooley, 2002; Kanuka, Collett & Caswell, 2002; Miller & Pilcher, 2001). While technological advancements are an important part of the distance-learning environment, basic changes in teaching methods, technique, and motivation are needed to make distance education more effective (Purdy & Wright, 1992). Many studies cite faculty resistance to instructional technology as a primary barrier to the continued growth of distance education programs (Jones et al., 2002; McNeil, 1990). McNeil (1990) noted that attitudinal issues related to how faculty perceive and interact with technology are a bigger barrier to adoption and diffusion of distance education than is technology infrastructure.

BACKGROUND

This chapter addresses perceptions of faculty with respect to barriers to adoption, roles and responsibilities, competencies, and rewards. Barriers stem from the lack of perceived institutional support (faculty rewards, incentives, training, etc.) for course conversion to distance education formats (O'Quinn & Corry, 2002; Perreault et al., 2002). As distance education programs continue to proliferate globally, colleges and universities must commit to address the needs of faculty (McKenzie, Mims, Bennett & Waugh, 2000). Despite the fact that much of the literature in distance education discusses the importance of faculty, this group has been largely neglected by the research.

Dooley and Murphy (2000) found that faculty members lacked experience in teaching learners at a distance and that they were much more confident in their technical competence than they were in their methodological ability to use modern technologies in their teaching. These authors further found that faculty perceived training and assistance in the use of instructional technologies to be less available than equipment and facilities. Additionally, faculty members who had not participated in distance education perceived the level of support as lower than those who had taught classes at a distance. The ability of an organization to adapt to these changes is influenced by the following: competence, or the knowledge, skills, and abilities of its staff; value, or the amount of importance the staff places on the role of these technologies to accomplish teaching and learning; information technology support, or the availability of high quality facilities, equipment, technical support, and training (Dooley & Murphy, 2000).

Lindner, Murphy, and Dooley (2002) extended these conclusions by looking at how these factors affect faculty adoption of distance education. Research revealed that faculty members lacked confidence in their ability to use technology in their teaching, perceived technology to be a valuable addition to the teaching and learning environment, and believed the overall level of support for the use of technology in teaching to be low. Tenure status and academic rank/position for tenure-track faculty were inversely related to overall distance education scores. Non-tenured assistant professors had the highest overall distance education scores and the highest competency scores.

Students learn from competent instructors who have been trained how to communicate effectively through technology. Thomas Cyrs (1997) identified areas of competence important to a distance education environment: course planning and organization, verbal and nonverbal presentation skills, collaborative teamwork, questioning strategies, subject matter expertise, involving students and coordinating their activities at field sites, knowledge of basic learning theory, knowledge of the distance learning field, design of study guides, graphic design and visual thinking (Cyrs, 1997).

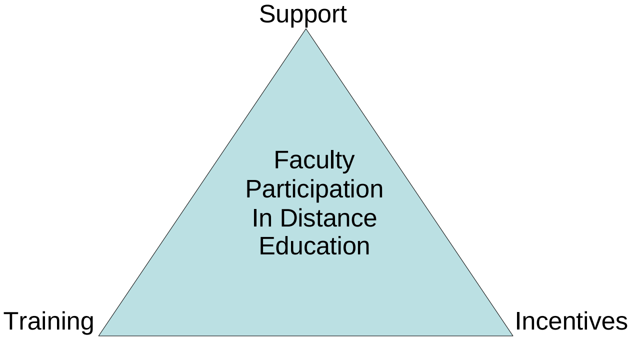
Linda Wolcott (1997) conducted an analysis of the institutional context and dynamics of faculty rewards at research universities. She discovered that 1) distance education occupies a marginal status, 2) distance teaching is neither highly valued nor well rewarded as a scholarly activity, 3) distance teaching is not highly related to promotion and tenure decisions, and 4) rewards for distance teaching are dependent on the academic unit's commitment to distance education.

As indicated by Moore (1997), distance education programs with a commitment to faculty support and training result in higher quality programs. As the complexity continues and the desire to integrate distance education programs expands, attention must be given to faculty training and support.

Enhancing Faculty Participation

Overall, faculty members recognize that distance education technologies are—and will be—an important part of the instructional process. However, they perceive support and training to be less available than equipment. Enhancing faculty participation requires that resources be directed to provide adequate levels of support and training such that these technologies are used for the benefit of students (Howard, Schenk & Discenza, 2004).

Figure 1. Enhancements to increase faculty participation in distance education.



It is the integration of incentives, training, and support that promote the adoption of distance education delivery strategies by university faculty.

While faculty recognize the potential, intervention strategies are necessary to alter how people perceive and react to distance education technologies. It is apparent that steps must be taken to increase faculty training and support. Three major areas require consideration: 1) support, 2) training, and 3) incentives. Support extends beyond "verbal" to providing the support/professional staff to assist faculty. Training should not only include technology exposure, but instructional design, pedagogy/andragogy, and "cook-book" strategies and "how-to" manuals. By providing incentives such as release time, mini-grants, continuing education stipends, and recognition in the promotion and tenure process, faculty will have more than verbal encouragement to continue, or begin, using distance education technologies and will have the reason to do so (Dooley & Murphrey, 2000; Murphrey & Dooley, 2000).

Rockwell et al. (1999) found that the primary incentives for faculty participation were *intrinsic* or personal rewards, including the opportunity to provide innovative instruction and apply new teaching techniques. Other incentives included extending educational opportunities beyond the traditional institutional walls, and release time for faculty preparation.

FUTURE TRENDS AND CONCLUSION

Faculty member participation in distance education requires a competence in using technology, an attitude that distance education is important and valuable, and access to quality infrastructure (Hawkes & Coldeway, 2002). Faculty roles and responsibilities must change to accommodate the use of these technologies and it must be recognized that teaching at a distance requires a different set of competencies (Richards, Dooley & Lindner, 2004). Integration of distance education technologies into the teaching and learning process requires a shift of attitude on the part of the faculty members and the removal of barriers created by the lack of institutional support.

KEY TERMS

Adoption: A decision to make full use of a new idea as a preferred method (Rogers, 2003).

Andragogy: The art and science of teaching adults (Knowles, 1990).

Competence: A measure of perceived level of ability by faculty in the use of electronic technologies often associated with distance education (Jones, Lindner, Murphy & Dooley, 2002).

Distance Education: Any education received by learners that occurs when the instructor and learner are separated by location and/or time.

Incentive: Intrinsic or extrinsic motivational factors that impact faculty decisions to participate in distance education.

Pedagogy: The art and science of teaching children (Knowles, 1990).

Value: A measure of the importance perceived by faculty of the role that technology will have on distance delivery (Jones, Lindner, Murphy & Dooley, 2002).

Fault Tolerance for Distributed and Networked Systems

P. Michael Melliar-Smith
University of California, Santa Barbara, USA

INTRODUCTION

The services provided by computers and communication networks are becoming more critical to our society. Such services increase the need for computers and their applications to operate reliably, even in the presence of faults. Fault tolerance is particularly important for distributed and networked systems (Mullender, 1993), including telecommunication, power distribution, transportation, manufacturing, and financial systems.

Fault-tolerant computing has been oriented towards custom designs and computer hardware (Siewiorek & Swarz, 1998), towards particular kinds of applications (Wensley et al., 1978), and towards operating systems (Borg, 1989). However, as computer and communication systems have become more complex and as hardware has become cheaper, designs have moved towards commercial off-the-shelf hardware and towards fault tolerance middleware located as a software layer between the application and the operating system.

Traditional proprietary designs are now being challenged by industry standards, such as the Fault Tolerant CORBA standard (Object Management Group, 2000) for distributed object applications based on the Common Object Request Broker Architecture (CORBA), and also the Hardware Platform Interface and Application Interface Specification (Service Availability Forum, 2003) for telecommunication and other embedded systems.

Of particular importance in the development of fault-tolerant computing is the distinction between application-aware and application-transparent fault tolerance. In application-aware fault tolerance, the application is aware of, and explicitly exploits, the mechanisms provided by the fault tolerance infrastructure, using application program interfaces (APIs). The application programmer writes code corresponding to the APIs to perform specific operations, such as to checkpoint an application process and to restore the process from the checkpoint, or to send a message across the network to a process on another processor and to receive the message on that other processor.

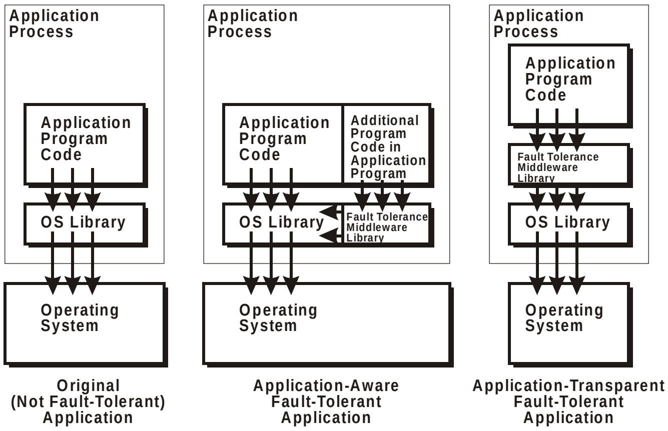
In application-transparent fault tolerance, the application is rendered fault tolerant, without involvement by, or modification to, the application program (Bressoud, 1998; Moser, Melliar-Smith, & Narasimhan, 1998). A fault tolerance middleware library is interposed ahead of the operating system libraries, between the application and the operating system (Narasimhan, Moser, & Melliar-Smith, 2002). When the application invokes standard operating system functions, those invocations are diverted to the fault tolerance middleware library, which modifies the operating system functions to provide additional fault tolerance functionality (Zhao, Moser, & Melliar-Smith, 2004). The application programmer does not need to implement or invoke additional methods for fault tolerance or to include additional fault tolerance code in the application program.

BACKGROUND

The basic terminology of fault-tolerant computing can be found in Laprie (1992). The terms failure, error, and fault were defined originally by Melliar-Smith & Randell (1977) and have become part of the ISO standard.

- A *failure* is the event of a system's generating a result that does not satisfy the system specification, or of the system's not generating a result that is required by the system specification. A failure is defined by the system specification, without reference to any components internal to the system, or to any enclosing system of which the system is a component.
- An *error* is incorrect information, or lack of information, within a system that will, unless detected and corrected, lead to a failure of the system.

Figure 1. The original application is shown at the left. In application-aware fault-tolerance (shown in the middle), the application program includes additional code that invokes the fault tolerance middleware library. In application-transparent fault-tolerance (shown at the right), the fault tolerance middleware library is interposed between the application and the operating system library.



- A *fault* is the original cause of an error, whether hardware or software. Sometimes the cause of the error is strictly objective but sometimes, particularly for software, it is a matter of subjective opinion.

A failure of a system might be a fault within a larger enclosing system. Similarly, a fault might be the failure of one of the components from which the system is constructed.

Faults (Cristian, 1991) are further classified as follows:

- A *crash fault* occurs when a component operates correctly up to some point in time, after which it produces no further results.
- A *timing fault* occurs when a component produces results at the wrong time, either too early or too late.
- An *omission fault* occurs when a component produces some results but not others.
- A *commission fault* occurs when a process or processor generates incorrect results. A *Byzantine* or *malicious fault* is a form of commission fault in which a process or processor generates incorrect results that are intentionally designed to mislead the algorithms or components of the system.

The metrics used in fault-tolerant computing include:

- *Reliability* is a measure of the uptime of a system in the absence of failure, and is given by the Mean Time Between Failure (MTBF).
- *Repairability* is a measure of how quickly a failed component or system can be restored to service, and is given by the Mean Time To Repair (MTTR).
- *Availability* is a measure of the uptime of a system, and is related to MTBF and MTTR by the formula: Availability = MTBF/(MTBF + MTTR). High availability typically means five nines (99.999%) or better, which corresponds to 5.25 minutes of planned and unplanned downtime per year.

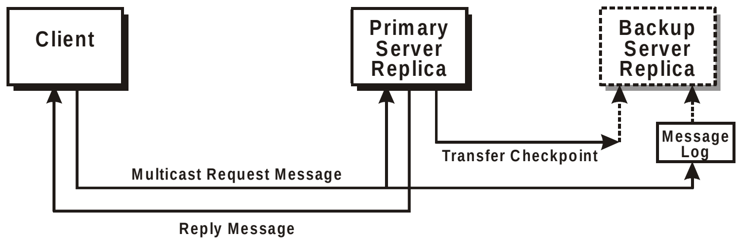
TECHNOLOGY OF FAULT TOLERANCE

Replication

The basic strategy used in fault-tolerant systems to protect an application against faults is *replication*, so that if one replica becomes faulty, another replica is available to provide the service. The unit of replication can be an entire processor, a process, a Java container, a CORBA object or some other component. In this article, we refer to such a unit as a component. The replicas of a component constitute a group of two or more components. To provide fault isolation, the replicas of a component must be independent of each other, with no shared memory or data and with communication controlled by the fault tolerance middleware, so that the failure of one replica does not disable another replica. Several kinds of replication are possible (Powell, 1991).

Passive replication, shown in *Figure 2*, distinguishes one of the server replicas as the primary server replica and the other as the backup server replica. The primary executes methods invoked on the group, and the backup does not execute those methods. In cold passive replica-

Figure 2. Passive replication. A client invokes a method of the replicated server, which is multicast in a request message. The primary server replica executes the method, but the backup server replica does not. A checkpoint containing the state of the primary is transferred to the backup at the end of each method invocation.



tion, the program code is not loaded into memory at the backup. In warm passive replication, the program code is loaded into memory at the backup, and the primary transfers its state periodically to the backup, where it is copied directly into the backup. Warm passive replication results in more rapid recovery from the failure of the primary replica than does cold passive replication.

Active replication, shown in *Figure 3*, regards all of the server replicas as equal and, thus, all of the server replicas execute every method invoked on the group. The replicas execute the methods independently of each other and at approximately, but not necessarily exactly, the same physical time. The first result received from any of the replicas is accepted, and the results from the other replicas are suppressed. Active replication has faster recovery from faults than passive replication because, if one replica fails, the other replicas are already calculating the required results and can supply them without delay.

Active replication with voting is similar to active replication, except that the results from the replicas are subjected to majority voting and the majority value is used.

Semi-active replication is a hybrid of passive and active replication. Both the primary and the backup replicas execute each method invocation. The primary determines the order in which the messages are processed and communicates that order to the backups. A backup follows the directives of the primary, such as the order in which to process messages, and thus lags slightly behind the primary in executing method invocations. Only the primary communicates results and makes further method invocations; the backup does not do so.

Passive replication, active replication, and semi-active replication are used to protect against crash faults. Active replication with voting is used to protect against commission faults.

The most challenging aspect of replication-based fault tolerance is maintaining strong replica consistency, as methods are invoked on the replicas, as the states of the replicas change, and as faults occur. Strong replica consistency simplifies the programming of fault-tolerant applications, particularly for recovery from faults. The basic strategy for maintaining strong replica consistency is to start the replicas in the same state and to ensure that they perform the same operations in the same order. Considerable care is required in implementing the fault tolerance infrastructure to maintain strong replica consistency.

Checkpointing and Restoration from a Checkpoint

To protect an application process against faults, a checkpoint (snapshot) of the process is taken and is trans-

Figure 3. Active replication. All of the server replicas execute every method invoked on the group, and communicate the results of those invocations. Duplicate invocations and duplicate responses are detected and suppressed. A checkpoint is used only to bring up a new active server replica.

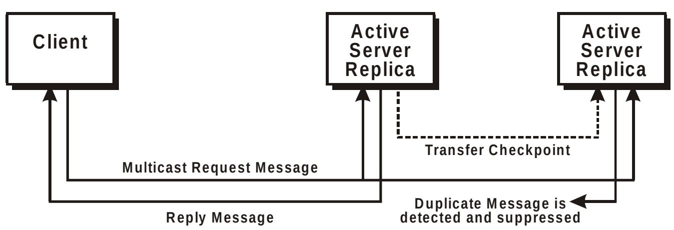


Figure 4. In application-transparent checkpointing, the checkpointing infrastructure captures the state of an application process, either the entire state (full checkpointing), shown at the left, or only the state that has changed since the last checkpoint (incremental checkpointing), shown at the right.

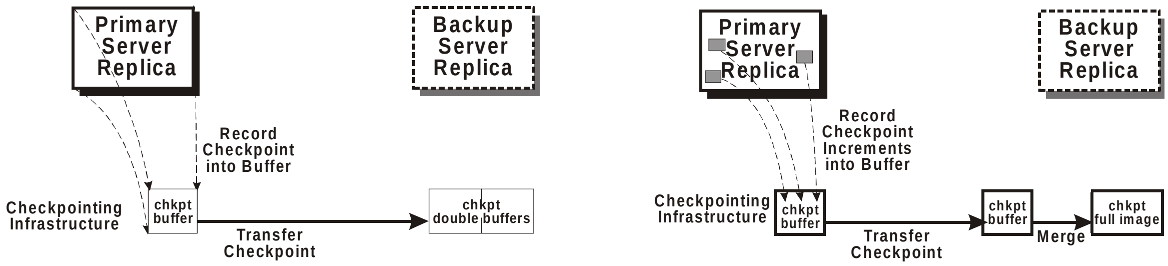


ferred from the primary replica to a backup replica, or from an active replica to a new or recovering active replica, as shown in *Figure 4*.

In application-aware checkpointing, the application programmer implements a getState() method that captures particular parts of the application process state and encodes that state into a byte sequence. The application programmer also implements a corresponding setState() method that decodes the byte sequence and restores the process from the checkpoint. This encoding is called serialization or pickling. The Java Virtual Machine provides serialization for Java objects that are defined to be serializable. For other languages, preprocessor tools can be used to preprocess the source code of a program and synthesize the source code of the required getState() and setState() methods.

In application-transparent checkpointing, the checkpointing infrastructure captures the state of the application process, without the need for the application programmer to implement the getState() and setState() methods.

With full checkpointing, the checkpointing infrastructure captures the entire memory image of the process (including file descriptors, thread stacks, etc.), without knowing about the internal data structures of the application program. It records each checkpoint in a checkpoint buffer and transmits the checkpoint across the network to a designated processor as a background activity. If a fault occurs, the infrastructure restarts the process on the same or a designated processor, using the most recent checkpoint to restore the process to the state it had at the time of the checkpoint.

With incremental checkpointing, the checkpointing infrastructure captures only those pages of the memory image that have changed since the last checkpoint. The infrastructure transmits the incremental checkpoint to the designated processor, where the incremental checkpoint is merged with the most recent full checkpoint.

For applications that involve multiple threads within a process or data structures that contain pointers, it is difficult to implement the getState() and setState() methods of application-aware checkpointing. Thus, application-transparent checkpointing might be preferred. However, application-transparent checkpointing does not produce checkpoints that are portable across hardware architectures, because a checkpoint taken as a binary image contains values of variables that differ for different architectures, such as memory addresses.

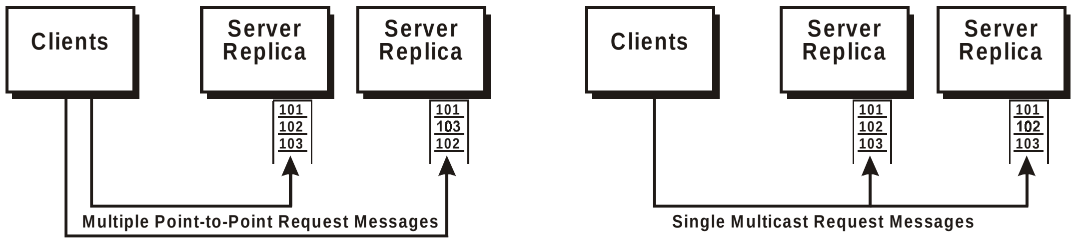
Checkpointing is used by all replication strategies but in different ways. Passive replication uses checkpointing during normal operation. Active replication, active replication with voting, and semi-active replication do not use checkpointing during normal operation, but use it to initialize a new or recovering replica.

Messaging and Multicasting

Fault-tolerant distributed systems typically use multicast protocols to deliver messages to the groups of replicas efficiently, reliably and in the same order, as shown in *Figure 5*. To maintain strong replica consistency, the replicas must receive the messages in the same order, so that they process the invocations and responses in the messages in the same order. For both active and passive replication, the messaging infrastructure must detect duplicate invocations and duplicate responses, and suppress them. Preferably, the duplicates are detected and suppressed at their source, to reduce traffic on the network; otherwise, they must be detected and suppressed at the destinations. For passive replication, the messaging infrastructure logs messages at the backup replica so that, if the primary replica fails, the messages after the checkpoint can be replayed.

Some fault-tolerant systems have exploited multicast group communication protocols that deliver messages reliably and in the same total order (Birman & van Renesse, 1994), which simplifies the maintenance of strong replica consistency. The disadvantage of that approach is that a message cannot be delivered until the total order has been agreed by the processors within the distributed system,

Figure 5. Sending multiple point-to-point request messages to the replicas in a group (shown at the top) is less efficient than sending a single multicast request message to the group (shown at the bottom). Moreover, sending multiple point-to-point request messages to the replicas in a group does not guarantee atomic delivery, with messages from different clients delivered in the same order to all replicas in the group.



with adverse effects on the latency (delay) to message delivery. Moreover, the message order chosen by the multicast protocol might not be appropriate for a real-time application, because it might disregard real-time priorities and deadlines.

Other fault-tolerant systems integrate the multicast protocol more tightly into the replication mechanisms that maintain strong replica consistency. For example, in semi-active replication, messages are delivered to the primary replica when they are received, in whatever order is appropriate, such as that chosen by a real-time scheduler.

Sanitizing Non-Deterministic Operations

Messaging is one source of replica non-determinism in a fault-tolerant distributed system, because messages can be received by the replicas in different orders, due to loss of messages and retransmissions, delays in the network, etc. To maintain strong replica consistency, messages must be delivered to the replicas in the same order.

Another source of replica non-determinism is multi-threading. If two threads within a replica share data, they must claim and release mutexes that protect that shared data. However, the threads in two replicas will most likely run at slightly different speeds. In one replica, one thread might be the first to claim a mutex and, in another replica, a different thread might be the first to claim the mutex. To maintain strong replica consistency, mutexes must be granted to the threads within the replicas in the same order.

Other sources of replica non-determinism include operating system functions that return values local to the processor on which they are executed, such as rand() and gettimeofday(), or inputs for the replicas from different redundant sources, or system exceptions due to, say, lack of memory on one of the processors. These sources of replica non-determinism must be sanitized, so that all of the replicas see the same values of the functions, the same inputs from the redundant sources, and the same system exceptions. Such virtual determinism must be provided for the replicas, regardless of which kind of replication is used.

Fault Detection, Analysis and Notification

Fault detection is essential for reliable operation. Faults can be detected in many different ways and within robust fault-tolerant systems any component can report a fault.

A fault detector (Chandra & Toueg, 1996) monitors the occurrence of faults in a component. Typically, it is based on timeouts and it simply pings a component periodically; failure to respond is regarded as evidence of a fault. A fault detector is unreliable (inaccurate), because it cannot determine whether a component has failed or is merely slow.

A fault notifier allows a component to subscribe for fault reports of particular kinds. It receives fault reports from fault detectors and fault analyzers, and supplies fault reports to the subscribers.

A fault analyzer or filter can be used to reduce the number of fault reports that the fault notifier transmits to a subscriber. It subscribes for fault reports from the fault notifier and aggregates multiple related fault reports into a single fault report.

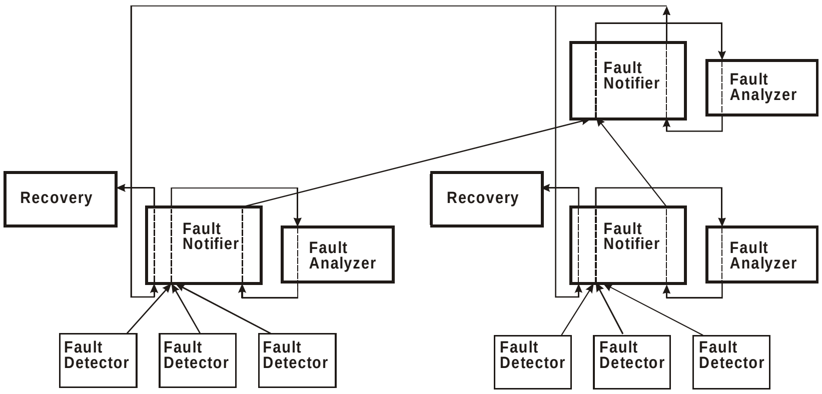
Fault detection, analysis and notification is often arranged hierarchically, as shown in *Figure 6*, so that ping traffic is localized and minimized, and fault reports are disseminated where they are needed quickly.

Recovery and Repair

Recovery ensures that there is a component available that can continue to provide service to the clients. Repair ensures that a faulty component is identified, sometimes

F

Figure 6. Fault detection, analysis and notification are arranged hierarchically to localize and minimize ping traffic, and to disseminate fault reports quickly.



referred to as primary cause analysis, and that steps are taken to test, reinitialize and return to service, or to replace, the faulty component. Repair may take longer than recovery, but is equally essential.

FUTURE TRENDS AND CONCLUSION

Application-aware fault tolerance increases the complexity of the application program, with additional application programming and costs, increased application development and testing timescales, and on-going application maintenance costs.

In contrast, application-transparent fault tolerance incurs little or no increase in the complexity and cost of the application program, but incurs an increase in the complexity of the fault tolerance middleware and in the performance overhead of that middleware.

As applications become more complex, as computer hardware becomes faster and less expensive, and as users demand better quality of service, the costs of application-aware fault tolerance will increase, and the costs of application-transparent fault tolerance will decrease to make application-transparent fault tolerance preferable.

KEY TERMS

Application Aware vs. Application Transparent: In application-aware fault tolerance, the application programmer writes code for fault tolerance methods that perform specific operations. In application-transparent fault tolerance, the fault tolerance middleware performs those operations automatically, using standard operating system functions and the technique of library interpositioning.

Checkpointing (Full, Incremental): In full checkpointing, all of the state of the process is captured. In incremental checkpointing, only that part of the state that has changed since the last checkpoint in captured.

Failure, Error, Fault: A failure is the event of a system's generating a result that does not satisfy the system specification or of the system's not generating a result that is required by the system specification. An error is incorrect information, or lack of information, within the system that will, unless detected and corrected, lead to failure of the system. A fault is the original cause of the error.

Fault (Crash, Timing, Omission, Commission, Byzantine): A crash fault occurs when a component operates correctly up to some point in time, after which it produces no further results. A timing fault occurs when a component produces results at the wrong time. An omission fault occurs when a component produces some results but not others. A commission fault occurs when a component generates incorrect results. A Byzantine or malicious fault is a form of commission fault in which a component generates incorrect results intentionally to mislead the algorithms or components of the system.

Fault Detector, Analyzer, Notifier: A fault detector monitors the occurrence of faults in a component. A fault analyzer subscribes for fault reports from a fault notifier and aggregates multiple related fault reports into a single fault report. A fault notifier receives fault reports from fault detectors and fault analyzers, and supplies fault reports to subscribers for those reports.

Fault Tolerance: The ability to provide continuous service, even in the presence of faults.

Multicast Protocol: Delivers messages reliably and in the same order to all of the replicas within a group.

Recovery and Repair: Recovery is the restoration of the state of a component on the same or a different processor, so that the component can continue to execute operations and provide service. Repair involves identification of the primary cause of the fault and re-initialization or replacement of the faulty component.

Reliability, Repairability, Availability: Reliability is a measure of the uptime of a system in the absence of failure, and is given by the Mean Time Between Failure (MTBF). Reparability is a measure of how quickly a failed system can be restored to service, and is given by the Mean Time To Repair (MTTR). Availability is a measure of the uptime of a system, and is given by: Availability = MTBF/(MTBF + MTTR).

Replication (Passive, Active, Active with Voting, Semi-active): Multiple copies of an application program execute typically as multiple processes on different processors. In passive replication, only one replica, the primary replica, executes the operations, and one or more backups stand ready to perform the operations if the primary fails. In active replication, all of the replicas execute the operations, and communicate their results. In active replication with voting, all of the replicas execute the operations and the result produced by the majority of the replicas is taken as the result of the operation. In semi-active replication, both the primary and the backup replicas execute the operations, but the backups follow the directives of the primary and only the primary outputs the results.

Flexible Job–Shop Scheduling Problems

Imed Kacem
Université de Technologie de Troyes, France

INTRODUCTION

Planning and scheduling problems in various industrial environments are combinatorial and very difficult. Generally, it is extremely hard to solve these types of problems in their general form. Scheduling can be formulated as a problem of determining the best sequence to execute a set of tasks on a set of resources, respecting specific constraints like precedence or disjunctive constraints (Carlier & Chrétienne, 1988). They consist generally in a simultaneous optimization of a set of non-homogeneous and conflicting goals. Therefore, the exact algorithms such as branch and bound, dynamic programming, and linear programming are not suitable for such problems and need a lot of time and memory to converge.

Because of this difficulty, experts prefer to find not necessary the optimal solution, but a good one to solve the problem. To this end, new search techniques such as genetic algorithms (Dasgupta & Michalewicz, 1997; Sarker, Abbas & Newton, 2001), simulated annealing (Kirkpatrick, Gelatt & Vecchi, 1983), and tabu search (Golver, Taillard & De Werra, 1993) are proposed to reach this aim: construct an approximated solution for a large set of hard optimization problems.

In this article, we are interested in the evolutionary techniques and their application to an important branch of scheduling problems. We aim in particular to present an overview of the recent models proposed to solve flexible job shop scheduling problems using genetic algorithms.

FLEXIBLE JOB SHOP SCHEDULING PROBLEM

The Flexible Job Shop Scheduling Problem is an extension of the classical job shop problem. Indeed, it represents two classical combinatorial optimization problems. The first one is a linear assignment since each task can be carried out on a set of resources according to different processing times. The second problem consists of finding the best sequence of the tasks on the resources by respecting all the problem's constraints (interdiction of pre-emptive execution, disjunctive constraints on the resources, precedence constraints) (Dauzère-Pérès, Roux & Lasserre, 1998; Mastrolilli, 2000).

The structure of the flexible job shop scheduling problem can be described as follows. We have a set of jobs and a set of machines. Each job consists of a certain number of ordered operations. The execution of each operation requires one machine selected from the machines existing in the shop. Therefore, we should find the best assignment of the machines before scheduling. The sequencing of operations is fixed for each job (precedence constraints). All machines are initially available and each job has a release date. For a given machine and a given operation, a processing time is defined as the duration necessary to perform the task on the above machine. The pre-emption condition is not allowed, and each machine can perform operations one after the other (disjunctive resource constraints).

MODELLING FLEXIBLE JOB SHOP

The encoding problem is a main step in the genetic algorithm conception. Such a problem has been intensively studied in the literature (Dasgupta & Michalewicz, 1997). In a simple way, solutions can be represented by binary vectors. Such a model is a judicious method for the problems in which solutions can be reduced to a sequence of zeros and ones. Unfortunately, we are not able to use such a representation for solving real-world problems like planning and scheduling problems (Caux, Pierreval & Portmann, 1995). Corrective procedure should be conceived because some illegal configurations can obviously be observed if we use basic genetic operators (crossover or mutation). The literature presents many different encodings for a large set of problems. We can mainly distinguish two types of codings. The first one is the direct representation in which the chromosome represents the solution itself. Such an approach requires conceiving specific genetic operators. The second one is the indirect representation in which the chromosome does not directly represent a solution, and a transition from the chromosome representation to a feasible solution is needed.

Concerning the application of the genetic algorithms to the planning problems, the literature shows a large set of works. Some of them have been successfully applied for solving the flexible job shop scheduling problem. We aim in this article to present most recent of them.

1. PMR (Parallel Machine Representation) (Mesghouni, 1999)
   This coding represents the extension of Kobayashi's representation initially proposed for the classical job shop problem. Therefore, it offers the possibility of considering the assignment property. In fact, each cell is coded by three elements: the operation index (*i*), the corresponding job *j*, and starting time $t_{i,j}$ of operation $O_{i,j}$ on the corresponding machine. This representation can directly describe legal solutions and give all the information to execute the schedule. Unfortunately, it presents some difficulties concerning the generation of some illegal cyclic configurations. To overcome such an inconvenience, Mesghouni has proposed some corrective procedures. Unfortunately, such procedures imply an important cost in terms of computation time and therefore reduce the coding effectiveness.
2. PJsR (Parallel Jobs Representation) (Mesghouni, 1999)
   Such a representation is an extension of the coding presented by Yamada for the classical job shop problem. Its particularity consists of the fact that resources can be reassigned to the different tasks (resource flexibility property). The chromosome consists of a list of jobs. Each job is coded by a row in which each case is represented by a couple of terms. The first term indicates the machine assigned to the operation. The second term is the corresponding starting time at which the above operation will be started.
   This encoding allows us to obtain feasible solutions without illegal configuration by integrating the precedence constraints. Genetic operators are very simple and can easily be implemented. Unfortunately, such a coding has a reduced search capacity by comparing it to other possible encodings. Crossover and mutation operators have been proposed by Mesghouni for the two preceding representations. Despite their simplicity and fastness, they are completely based on the exchange of assignment choices and are not sufficient to take into account the sequencing property.
3. Ternary Permutation Matrix with Assignment Vector (Portmann, 1996)
   This coding was proposed by Portmann initially to consider the precedence constraints for a large range of scheduling problems (Portmann 1996). In fact such a model consists of describing the sequencing property by a matrix *MT* noted "Permutation matrix" such that $MT(i,j)=1$ if *i* precedes *j*, $MT(i,j)=-1$ if *j* precedes *i*, and $MT(i,i)=0$ for every task *i* (see Figure 2). Such a coding allows us to keep the good properties in the generated schedule. In order to make it efficient, Portmann has proposed well-adapted operators that can generate feasible schedules with any corrective procedure (Portmann, 1996). Unfortunately, such a coding is insufficient to deal with the flexible job shop problem because of the assignment property. Nevertheless, Portmann has proposed to associate an assignment vector to the ternary coding. Such a proposition allows us to handle scheduling problems with assignment property but, unfortunately, dissociates their two independent parts.
4. Operations Machines Coding (OMC) (Kacem, Hammadi & Borne, 2003)
   This is a direct representation of the schedule. It allows us to obtain all the information on the assignment choices and the different starting times. In addition, it allows us to integrate the schemata notion (Kacem et al., 2003). By such a coding, a schedule is represented in a table. Each case of the table can have one of two value possibilities: 0 (if the operation is not assigned to the machine considered) or [$t_{i,j}, tf_{i,j}$] (with $t_{i,j}$ and $tf_{i,j}$ respectively the starting time and the completion time of operation $O_{i,j}$ on the chosen machine). An illustrative example is presented in Figure 3(a).
5. List Operations Coding (LOC) (Kacem et al., 2003)
   This consists of representing the schedule in a table with three columns. The first column is reserved for the operations . The second indicates the assigned machine to execute the corresponding operation, and the third column gives the starting time and the completion time. We can notice a great similarity between OMC and LOC. In fact, exploration assignment and sequencing search spaces have the same size. The only difference consists of the representation form. Such a difference gives more simplicity and more exploration possibilities (vertical crossover) for OMC. An illustrative example is presented in Figure 3(b).
6. Jobs Sequencings List Coding (JSLC) (Kacem et al., 2003)
   Although, it is relatively difficult to be designed and difficult to be implemented, this encoding represents an efficient representation. In fact, it presents the same possibilities of the exploration of the assignment space search and offers more possibilities to explore the sequencing of one compared to the two preceding representations. It enables us to consider jointly or separately the assignment and the scheduling problems, and avoid the limited use of the priority rules. This coding is presented in a list of columns. Each column contains the different

Task 1	0	1	-1	1	-1
Task 2	-1	0	-1	1	-1
Task 3	1	1	0	1	1
Task 4	-1	-1	-1	0	-1
Task 5	1	1	-1	1	0

operations having the same index in the jobs. Each cell represents a quadruplet [j, k, ti, j, tfi, j] with j, k, ti, j and tfi, j are, respectively, the job index of the i-th operation, the machine index, the starting time, and the completion time. An illustrative example is presented in Figure 3(c).

7. Others Models and Special Cases Application
Despite the difficulty of the scheduling field, the literature is abundant in the interesting references dealing with such a problem. In particular, for some special cases of FJSP (like classical job shop problem, flow shop or one-machine problem), researchers have proposed many interesting encodings. As illustration, we cite Yamada, Tamaki, and Kobayashi's encodings for the job shop problem. Some encodings like "permutation coding" or "rank coding" seem interesting for the one-machine problem. For the flow shop problem, authors have essentially proposed linear representation. In addition, we note an intensive effort in order to conceive efficient operators. As example, we can cite the excellent work of Lee and Yamakawa (1998), who have proposed new operators preserving precedence properties. Such operators are very interesting to construct feasible solutions for scheduling problems with precedence constraints with any corrective step.

Figure 3. Kacem's encodings

		M1	M2	M3	M4
J 1	O1,1	0,1	0	0	0

3, 2, 0, 4	2, 1, 1,3	$j, k, t_{i,j}, tf_{i,j}$		1, 1, 3, 7
2, 3, 0, 1	3, 4, 4, 6			

(c) JSLC coding

CONCLUSION

As one of most general planning problems, the flexible job shop scheduling one is very hard to solve. Exact methods are limited and are not suitable for such a research field. That is why many researchers have investigated its resolution by using meta-heuristic techniques as genetic algorithms.

The genetic algorithm's literature presents many resolution models based on a direct or an indirect description of possible solutions. Throughout the different encodings presented in this article, we notice the FJSP specificities are very hard to be completely integrated into one model.

In fact, the problem implies two main considerations¾the assignment resource strategy, and how to find the best sequence of tasks on the chosen resources. Nevertheless, the literature shows an intensive and interesting effort to deal with such a problem. Many encodings are proposed and current results are uncourageous and promising.

KEY TERMS

Assignment: A repartition in which we allocate the available resources to achieve the different tasks.

Binary Coding: A basic coding in which a solution of some problems can be represented in a list of zeros and ones.

Coding: A manner in which a solution of a given problem can be represented.

Flexible Job Shop: A shop in which resources are flexible and can execute many types of tasks with variable performances according to the assignment choices.

Genetic Algorithm: A field of algorithms inspired by the evolution of species and applying natural operators like selection, crossover, and mutation.

Scheduling: A research field in which we aim to program the execution of a set of tasks on a set of resources. The schedule obtained should respect some constraints and optimize one or many criteria.

Formal Development of Reactive Agent-Based Systems

INTRODUCTION

Recent advances in both the testing and verification of software based on formal specifications have reached a point where the ideas can be applied in a powerful way in the design of agent-based systems. The software engineering research has highlighted a number of important issues: the importance of the type of modelling technique used; the careful design of the model to enable powerful testing techniques to be used; the automated verification of the behavioural properties of the system; and the need to provide a mechanism for translating the formal models into executable software in a simple and transparent way.

An agent is an encapsulated computer system that is situated in some environment and that is capable of flexible, autonomous action in that environment in order to meet its design objectives (Jennings, 2000). There are two fundamental concepts associated with any dynamic or reactive system (Holcombe & Ipate, 1998): the environment, which could be precisely or ill-specified or even completely unknown and the agent that will be responding to environmental changes by changing its basic parameters and possibly affecting the environment as well. Agents, as highly dynamic systems, are concerned with three essential factors: a set of appropriate environmental stimuli or inputs, a set of internal states of the agent, and a rule that relates the two above and determines what the agent state will change to if a particular input arrives while the agent is in a particular state.

One of the challenges that emerges in intelligent agent engineering is to develop agent models and agent implementations that are "correct." The criteria for "correctness" are (Ipate & Holcombe, 1998): the initial agent model should match the requirements, the agent model should satisfy any necessary properties in order to meet its design objectives, and the implementation should pass all tests constructed using a complete functional test-generation method. All the above criteria are closely related to stages of agent system development, i.e., modelling, validation, verification, and testing.

BACKGROUND: FORMAL METHODS AND AGENT-BASED SYSTEMS

Although agent-oriented software engineering aims to manage the inherent complexity of software systems (Wooldridge & Ciancarini, 2001; Jennings, 2001), there is still no evidence to suggest that any methodology proposed leads toward "correct" systems. In the last few decades, there has been strong debate on whether formal methods can achieve this goal. Software system specification has centred on the use of models of data types, either functional or relational models, such as Z (Spivey, 1989) or VDM (Jones, 1990), or axiomatic ones, such as OBJ (Futatsugi et al., 1985). Although these have led to some considerable advances in software design, they lack the ability to express the dynamics of the system. Also, transforming an implicit formal description into an effective working system is not straightforward. Other formal methods, such as finite state machines (Wulf et al., 1981) or Petri Nets (Reisig, 1985) capture the essential feature, which is "change," but fail to describe the system completely, because there is little or no reference to the internal data and how these data are affected by each operation in the state transition diagram. Other methods, like statecharts (Harel 1987), capture the requirements of dynamic behaviour and modelling of data but are informal with respect to clarity and semantics. So far, little attention has been paid in formal methods that could facilitate all crucial stages of "correct" system development, modelling, verification, and testing.

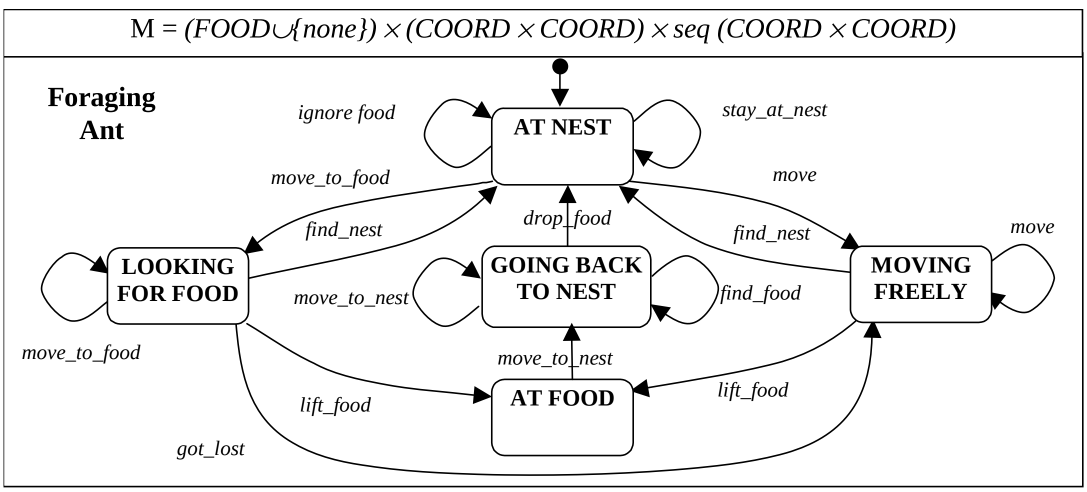
In agent-oriented engineering, there have been several attempts to use formal methods, each one focusing on different aspects of agent systems development. One was to formalise the PRS (procedural reasoning system), a variant of the BDI architecture (Rao & Georgeff, 1995), with the use of Z, in order to understand the architecture in a better way, to be able to move to the implementation through refinement of the specification, and to be able to develop proof theories for the architecture (D'Inverno et al., 1998). Trying to capture the dynamics of an agent system, Rosenschein and Kaebling (1995) viewed an agent as a situated automaton that generates a mapping from inputs to outputs, mediated by its internal state. Brazier et al. (1995) developed the DESIRE framework, which focuses on the specification of the dynamics of the reasoning and acting behaviour of multiagent systems. In an attempt to verify whether properties of agent models are true, work has been done on model checking of multiagent systems with reuse of existing technology and tools (Benerecetti et al., 1999, Rao & Georgeff, 1993). Toward implementation of agent systems, Attoui and Hasbani (1997) focused on program generation of reactive systems through a formal transformation process. A wider approach is taken by Fisher and Wooldridge (1997), who utilised Concurrent METATEM in order to formally specify multiagent systems and then directly execute the specification while verifying important temporal properties of the system. Finally, in a less formal approach, extensions to Unified Modelling Language (UML) to accommodate the distinctive requirements of agents (AUML) were proposed (Odell et al., 2000).

X-MACHINES FOR AGENT-BASED SYSTEM DEVELOPMENT

An X-machine is a general computational machine (Eilenberg, 1974) that resembles a finite state machine but with two significant differences: there is memory attached to the machine, and the transitions are labeled with functions that operate on inputs and memory values. The X-machine formal method forms the basis for a specification language with great potential value to software engineers, because they can facilitate modelling of agents that demand remembering as well as reactiveness. Figure 1 shows the model of an ant-like agent that searches for food but also remembers food positions in order to set up its next goals. Many other biological processes seem to behave like agents, as, for example, a colony of foraging bees, tissue cells, etc. (Kefalas et al., 2003a; Gheorghe et al., 2001; Kefalas et al., 2003b). Formally, the definition of the X-machine requires the complete description of a set of inputs, outputs, and states; a memory tuple with typed elements; a set of functions and transitions; and finally, an initial state and a memory value (Holcombe, 1988).

Having constructed a model of an agent as an X-machine, it is possible to apply existing model-checking techniques to verify its properties. *CTL** is extended with memory quantifier operators: M_x (for all memory instances) and m_x (there exist memory instances) (Eleftherakis & Kefalas, 2001). For example, in the ant-like agent, model checking can verify whether food will eventually be dropped in the nest by the formula: $AG[\neg M_x(m_1 \neq \text{none}) \vee EFM_x(m_1 = \text{none})]$, where m_1 indicates the first element of the memory tuple.

Figure 1. An X-machine that models an ant.



Having ensured that the model is "correct," we need to also ensure that the implementation is "correct," this time with respect to the model. Holcombe and Ipate (1998) presented a testing method that under certain design-for-test conditions can provide a complete test-case set for the implementation. The testing process can be performed automatically by checking whether the output sequences produced by the implementation are identical to the ones expected from the agent model through this test-case set.

A methodology for building complex agent systems by aggregating a set of behaviors of individual agents is available, namely, communicating X-machines. It is demonstrated that they are a powerful extension to the X-machines that also facilitate modelling of multiagent systems (Kefalas et al., 2003a).

FUTURE TRENDS

There are currently three directions to future work. First, there is a need to investigate potential applications. We already identified the area of biology-inspired agent-based systems, such as modelling of biological cells and tissues, as an area that can largely benefit from formal modelling, verification, and testing. Second, current research is underway to extend the testing and verification methods in order to be applicable for communicating asynchronous and possibly nondeterministic systems. Last, there has been an attempt to build tools around the X-machine formal method in order to facilitate the actual agent development process. A markup language, namely X-Machine Definition Language (XMDL), has been defined, and around it, a number of prototype tools, such as a modeller, an automatic translator to Prolog, an animator, and a model checker, have been constructed.

CONCLUSION

Because the X-machine method is fully grounded in the theory of computation, it is fully general and will be applicable to any type of computational task. The paradigm of the X-machine is also convenient when it comes to implementing the models in an imperative programming language. In fact, the translation is more or less automatic. The existence of the powerful testing method described lays the foundation for the method to be used in potentially critical applications. Finally, the model-checking developments will lead to a situation in which one of the key issues in agent software engineering can be solved, namely, how can we guarantee that the agent system constructed will exhibit the desired emergent behavior, or at least substantial progress toward this goal will be achieved.

KEY TERMS

Agent: An agent is an encapsulated computer system that is situated in some environment and that is capable of flexible, autonomous action in that environment in order to meet its design objectives. Agents normally exhibit autonomous, reactive, proactive, and social behaviors.

Communicating X-Machine: A communicating X-machine is a set of stream X-machine components that are able to communicate with each other by exchanging messages.

CTL*: A temporal logic formalism used in model checking. *CTL** employs operators, such as *A* (for all paths), *E* (there exists a path), *X* (next time), *F* (eventually), *G* (always), *U* (until), and *R* (release), that facilitate the construction of temporal logic formulas that correspond to desirable properties of a model.

Formal Methods: Formal methods are rigorous techniques based on mathematical notation that can be used to specify and verify software models.

Model Checking: Model checking is a formal verification technique that determines whether given properties of a system are satisfied by a model. A model checker takes a model and a property as inputs, and outputs either a claim that the property is true or a counterexample falsifying the property.

X-Machine: A deterministic stream X-machine is an 8-tuple ($\boldsymbol{\Sigma}$, Γ, Q, M, Φ, F, q_0, m_0), where $\boldsymbol{\Sigma}$, Γ is the input and output finite alphabet, respectively; Q is the finite set of states; M is the (possibly) infinite set called memory; Φ is the type of the machine, that is, a finite set of partial functions φ that map an input and a memory state to an output and a new memory state, $\varphi: \boldsymbol{\Sigma} \times M \rightarrow \Gamma \times M$; F is the next state partial function that, given a state and a function from the type Φ, denotes the next state—*F* is often described as a state transition diagram, $F: Q \times \Phi \rightarrow Q$; q_0 and m_0 are the initial state and memory, respectively.

Formal Methods in Software Engineering

Ana Funes
Universidad Nacional de San Luis, Argentina

INTRODUCTION

As a general rule, all engineering applications use mathematics or mathematical tools as a basis for their development. However, software engineering is an exception to this rule.

Formal methods (FM) are[1] a collection of methodologies and related tools, geared to the production of software employing a mathematical basis. There are a number of different formal methods each having its own methodology and tools, especially a specification language.

We can say that FM are "mathematically based techniques for the specification, development and verification of software and hardware systems" (retrieved on October 15, 2003, http://foldoc.doc.ic.ac.uk/foldoc).

Most FM are based mainly on specifications – for which they normally have a language to express it. Sometimes, there is also a method to use the language in the software development process.

The aims of FM can vary according to the different methodologies, but they all shared a common goal: the production of software with the utmost quality mainly based on the production of software that is error free. To achieve this, the different FM have developed not only a theory but also different tools to support the formal process.

FM can cover all of the steps of the life cycle of a software system development from requirement specification to deployment and maintenance. However, not all FM have that capacity.

BACKGROUND

Some FM rely on development of a calculus or transformation, where the engineer starts with an expression and then following predefined rules applies them to obtain an equivalent expression. Successive calculations lead to implementation. On the other hand, there are FM that rely on the "invent and verify" technique, where the engineer starts by inventing a new design, which afterwards needs to be verified as correct. From this verified design, implementation follows.

There are several styles of formal specification. Some are mutually compatible while others are not. Table 1 shows a possible classification of the different styles.

Formal languages have formal definitions not only of their syntax but also of their semantics. Table 2 shows a possible classification for the different formal semantic definitions.

Hinchey and Bowen (1995) say that "formal methods allow us to propose properties of the system and to demonstrate that they hold. They make it possible for us to examine system behavior and to convince ourselves that all possibilities have been anticipated. Finally, they enable us to prove the conformance of an implementation with its specification".

In NASA's Langley Research Center site for formal methods, there is a nice definition and also an explanation of different degrees of rigour in FM:

"Traditional engineering disciplines rely heavily on mathematical models and calculation to make judgments

Table 1. Summary of specification language characteristics

Model-oriented. Based on mathematical domains. For example, numbers, functions, sets, etc. Concrete.	**Property-oriented**. Based on axiomatic definitions. Abstract.
Applicative. Does not allow the use of variables.	**Imperative or State-oriented**. Allows the use of variables.
Static. Do not include provisions for handling time.	**Action**. Time can be considered in the specification. There are several ways of doing this: considering time as linear or branching, synchronous, asynchronous, etc.

Table 2. Summary of semantic definitions styles of specification languages

Operational. Concrete, not well suited for proofs.
Denotational. Abstract, well suited for proofs.
Axiomatic. Very abstract, normally only limited to conditional equations.

about designs. For example, aeronautical engineers make extensive use of computational fluid dynamics (CFD) to calculate and predict how particular airframe designs will behave in flight. We use the term 'formal methods' to refer to the variety of mathematical modelling techniques that are applicable to computer system (software and hardware) design. That is, formal methods is the applied mathematics of computer system engineering, and, when properly applied, can serve a role in computer system design analogous to the role CFD serves in aeronautical design.

Formal methods may [be] used to specify and model the behavior of a system and to mathematically verify that the system design and implementation satisfy system functional and safety properties. These specifications, models, and verifications may be done using a variety of techniques and with various degrees of rigour. The following is an imperfect, but useful, taxonomy of the degrees of rigour in formal methods:

Level-1:
Formal specification of all or part of the system.
Level-2:
Formal specification at two or more levels of abstraction and paper and pencil proofs that the detailed specification implies the more abstract specification.
Level-3:
Formal proofs checked by a mechanical theorem prover.

Level 1 represents the use of mathematical logic or a specification language that has a formal semantics to specify the system. This can be done at several levels of abstraction. For example, one level might enumerate the required abstract properties of the system, while another level describes an implementation that is algorithmic in style.

Level 2 formal methods goes beyond Level 1 by developing pencil-and-paper proofs that the more concrete levels logically imply the more abstract-property oriented levels. This is usually done in the manner illustrated below.

Level 3 is the most rigourous application of formal methods. Here one uses a semi-automatic theorem prover to make sure that all of the proofs are valid. The Level 3 process of convincing a mechanical prover is really a process of developing an argument for an ultimate skeptic who must be shown every detail.

Formal methods is not an all-or-nothing approach. The application of formal methods to only the most critical portions of a system is a pragmatic and useful strategy. Although a complete formal verification of a large complex system is impractical at this time, a great increase in confidence in the system can be obtained by the use of formal methods at key locations in the system. (Retrieved October 31, 2003, http://shemesh.larc.nasa.gov/fm/fm-what.html)

NASA as well as other government bodies in the USA, Europe and elsewhere are using FM especially in avionics and systems where the utmost reliability is needed. Some examples from NASA are: Small Aircraft Transportation System (SATS), Formal Analysis of Airborne Information for Lateral Spacing (AILS), also NASA's contractors use FM. For more information on this and other projects, see http://shemesh.larc.nasa.gov/fm/.

As it is stated previously in NASA's definition of the levels of degree of rigour, they are imperfect. Others exist. Most of the FM included in the following text have as an integral part not only a language but also a methodology included, and most of the time this methodology implies different levels of rigour in its use. For example, RAISE – that have its own method – presents three degrees of formality (The RAISE Method Group, 1995):

- *formal specification only*, where formality is only applied to the specification procedure.
- *formal specification and rigourous development*, where formality is applied to the specification procedure as above, and rigour to the development process. This means that the developer starts writing abstract specifications, goes on developing more concrete ones and recording the development relations between them. These relations are then examined, however they are not justified.
- *formal specification and formal development*, it is the extension of the previous degree to do the justification as well.

Here is a not all-inclusive list of FM:

- **ASM** (Abstract State Machines) "methodology for describing simple abstract machines which correspond to algorithms" (Retrieved September 15, 2003, from http://www.eecs.umich.edu/gasm/).
- **B–Method** "B is a formal method for the development of program code from a specification in the Abstract Machine Notation" (Retrieved October 23, 2003, from http://www.afm.lsbu.ac.uk/b/).
- **CSP** (Communicating Sequential Processes) " process algebra originated by C. A. R. Hoare (http://www.afm.lsbu.ac.uk/csp/).

- **Duration Calculus** "modal logic for describing and reasoning about the real-time behavior of dynamic systems" (Retrieved October 20, 2003, from http://www.iist.unu.edu/newrh/II/2/2/page.html).
- **Extended ML** "framework for specification and formal development of Standard ML (SML) programs" (Retrieved October 20, 2003, from http://www.dcs.ed.ac.uk/home/dts/eml).
- **HOL** " automatic theorem proving system based on Higher Order Logic (see http://www.afm.lsbu.ac.uk/hol/).
- **Model Checking** "method for formally verifying finite-state concurrent systems" (Retrieved October 21, 2003, from http://www-2.cs.cmu.edu/~modelcheck/).
- **Petri Nets** "formal, graphical, executable technique for the specification and analysis of concurrent, discrete-event dynamic systems" (Retrieved October 21, 2003, from http://www.petrinets.org/).
- **PVS** (Prototype Verification System) "a specification language integrated with support tools and a theorem prover" (Retrieved October 19, 2003, from http://pvs.csl.sri.com/whatispvs.html).
- **RAISE** (Rigourous Approach to Industrial Software Engineering) "consists of the RAISE development method and RSL, the RAISE Specification Language" (Retrieved November 1, 2003, from http://spd-web.terma.com/Projects/RAISE; See also http://www.iist.unu.edu/raise/).
- **VDM** (Vienna Development Method) "VDM is a notation and set of techniques for modeling computing systems analyzing those models and progressing to detailed design and coding. VDM has its origins in the work of the IBM Vienna Laboratory in the mid-1970s" (Retrieved October 14, 2003, from http://www.csr.ncl.ac.uk/vdm).
- **Z Notation** "is based on Zermelo-Fraenkel set theory and first order predicate logic" (Retrieved October 14, 2003, from http://www.zuser.org/z).

For more information on those and other FM, see http://vl.fmnet.info. This site has links to the sites of many other FM.

Of course, a question to ask oneself is, why are there so many flavors of formal methods? There are undoubtedly several possible answers to the question. One is that since there are many ways to describe a system not everyone agrees on a particular style. Why are there so many different programming languages? The answer to this question could be also the answer to our question. Another answer is that not all of the FM have addressed the same problem. Some of them are geared to system design, others to domain description, some deal with time while others do not included, and so forth.

PROS AND CONS

The issue of whether FM are useful or not was discussed in the literature around ten years ago – see for example, J. Bowen and M. Hinchey´s works (1995) and Luqi and Goguen (1997).

The use of formal specifications has benefits ranging from the possibility of building unambiguous specifications, to the possibility of proving system properties, to automatic code generation. However, they require a high level of expertise in algebra and mathematical logic, and consequently they are more expensive and difficult to use than other traditional methods.

Most opponents give as a main reason the fact that FM make the communication with the end users difficult when requirements must be validated. However, lately there is an ongoing interest in the combined use of semi-formal notations and formal specifications to overcome this problem and the ambiguity and inconsistency inherent in semi-formal notations. This kind of integration is intended to improve understandability – given by graphical notations – and to gain in unambiguity – offered by formal specifications.

According to Pons and Baum (2000), we can carry out integration in four different ways:

1. Supplemental, where the informal notations are enriched with formal concepts.
2. Extension, where the formal notations are extended with concepts from others paradigms, for example, from the object-oriented paradigm.
3. Interface, where formal notations are provided with graphic interfaces to help in the developing of models.
4. Semantics, where the semantics of an accepted semi-formal modelling language is given by a formal language.

There is an important number of theoretical works that deal with the integration of graphical notations and mathematically precise formalisms. Proof of this is the growing interest in providing a more traditional methodology such as UML with formal basis, either through the OCL language or by giving to the UML graphic language a formal semantics – see the works of the 2U consortium (2003) and The precise UML group (2003). The extensive work done on formalizing Java and Java Machine (see Bertelsen, 2003; Hartel & Moreau, 2001). Other good examples can be found in Funes and George (2003), France (1999), DeLoach and Hartrum (2000), Meyer and Souquieres (1999), Goldsack and Kent (1996), Lano (1991), Weber (1996), Kim and Carrington (2000), Amalio et al. (2003), and Reggio and Larosa (1997) among others.

Finally, we should not forget the important role FM have in the development of systems where security and reliability are crucial. Dan Van et al. (2002) cite three factors that were the traditional arguments in favor of FM: first, the growing number of applications with minimal or zero tolerance for errors; second, social, environmental and economic consequences of design errors in hardware and software products, raising social awareness and concern; and third, there are a number of standards and regulatory organizations enforcing quality standards for electronic products.

EXAMPLES

Just so the reader can get the flavor of FM, we present in this section an example of specifications for a stack of natural numbers using the RAISE Specification Language (RSL) (The RAISE Language Group, 1992).

The first specification in Example 1 illustrates the use of the property-oriented style, which is abstract and whose definitions are given by axioms. The second specification given for the stack is model-oriented, based in the use of concrete types (see Example 2). Both specifications use RSL static and applicative style.

The *Stack* type in Example 1 is given by an abstract type since we do not say explicitly how a stack is going to be implemented. The stack is defined by the main operations needed to manage it. To formally specify its behavior, we give the signature of three functions: *pop*, *push* and *top*, the constant *empty* that represents the empty stack, and a set of axioms to express the intended meaning of these operations. The axioms define the es-

Example 1. A stack of natural numbers in RSL (using static applicative property-oriented style)

```
scheme STACK_0 =
class
   type
      Stack
   value
      empty: Stack,
      push: Nat × Stack → Stack,
      pop: Stack ~→ Stack ,
      top: Stack ~→ Nat
   axiom
      e: Nat, s: Stack • pop(push(e, s)) ≡ s,
      e: Nat, s: Stack • top(push(e, s)) ≡ e,
end
```

Example 2. A stack of natural numbers in RSL (using static applicative model-oriented style)

```
scheme STACK_1 =
class
   type
      Stack = Nat *
   value
      empty: Stack,
      push: Nat × Stack → Stack,
      pop: Stack ~→ Stack ,
      top: Stack ~→ Nat
   axiom
      empty ≡ <>,
      e: Nat, s: Stack • push(e, s) ≡ <e> ^ s,
      s: Stack • pop(s) ≡ tl s
                    pre s ≠empty,
      s: Stack • top(s) ≡ hd s
                    pre s ≠empty
end
```

sential properties that must always be true when the operations are applied.

The operations *pop* and *top* are partial functions that are not defined for the empty stack. This fact is reflected by the absence of axioms about *pop(empty)* and *top(empty)*. The operation *push* is a total function.

The first axiom states that pushing an element *e* into a stack *s* and then doing a *pop* returns the former stack *s*. The second axiom states that every time we push an element *e* into a stack, and then we apply *top* to the resulting stack we get the last pushed element *e*.

But, where is the formalism in this specification? We must not forget that as any FM, RSL has defined formally not only its syntax but also its semantic. This allows, for instance, the use of axioms which are truths that must be preserved all along the specification and that in turn can be proved – or not, if the specification has errors or inconsistencies. So the formalism can be found in the fact that using the underlying semantic – in this case, logic and algebra – the specification can be subjected to proof, and therefore, any errors can be found.

In this example, the axioms specify the behavior of the stack; remember that axioms must always be true. If they are not, then there is an error in the specification.

So, besides the abstractness and precision given by a formal specification language, one of the major reasons for expressing specifications in a formal language is the possibility of proving properties of the specifications. Formulating properties and then trying to prove them is a way of ensuring correctness and detecting errors.

The second example – see Example 2 – is a refinement of the first one. Here, we define the *Stack* type not as a sort but as a list of natural numbers – the * besides **Nat** indicates list of **Nat** in RSL.

The axioms that define the operations on the stack are defined using the primitive operations for lists in RSL. The operation *empty* is defined as the empty list. To *push* an element into the stack corresponds to adding the element at the head of the list, returning the resulting augmented stack. To *pop* an element from the stack corresponds to remove the head of the list and return the resulting reduced stack; and to get the *top* of the stack corresponds to get the head of the list and return it. Note that since *pop* and *top* have a pre-condition establishing that they cannot be applied to the empty stack, they are partial functions.

In RAISE – as in many others FM – besides being formal when specifying, we can also be formal in the development process. Software can be developed in a sequence of steps. We can start writing a suitably abstract specification and proceed developing more concrete and detailed ones until the final specification can be automatically translated to a programming language. Each step in the development must conform to the previous and must be proved as a correct development step. For example, we should prove that the specification STACK_1 is a correct development for STACK_0, that is, to prove that STACK_1 implements STACK_0 (i.e., STACK_0 and STACK_1 are in the implementation relation). In RAISE, this means that the specifications have to meet two requirements:

- *property of preservation*: all properties that can be proved about STACK_0 can also be proved for STACK_1.
- *property of substitutivity*: in any specification an instance of STACK_0 can be replaced by an instance of STACK_1, and the resulting specification should implement the former specification.

FUTURE TRENDS

Although traditional methods seem to be the most popular nowadays, the use of FM have grown to occupy more and more a place in software engineering for development of systems where security and reliability are important. However, its use continues being expensive and limited.

Besides its leading role in the development of critical systems, there is also a growing interest in proposing methods and techniques to use formal specifications combined with semi-formal notations to give more rigour to the first phases of the development process.

If formal techniques become, in the future, the foundations of a new generation of CASE tools, it is possible that a bigger portion of software practitioners will adopt them, making formal methods a truly practical tool for all kind of systems.

CONCLUSION

FM are methods based primarily in formal, mathematical notation and principles. They are ideal for defining unambiguously not only the requirements but also every stage in system development including implementation since there are FM that have translators to programming languages.

Because of their profound roots in logic and algebra, they seem harder to understand and learn. However, the FM community aware of this view has been making efforts in producing tools that make their use easier.

KEY TERMS

Action-Oriented Formal Specification Language: Time can be considered in the specification. There are several ways of doing this: considering time as linear or branching, synchronous, asynchronous, and so forth.

Applicative-Oriented Formal Specification Language: Does not allow the use of variables.

Axiomatic Semantics: The meaning is given in terms of conditions, pre and post.

Denotational Semantics: The meaning is given in terms of mathematical functions.

Imperative or State-oriented Formal Specification Language: Allows the use of variables.

Model-Oriented Formal Specification Language: Based on mathematical domains. For example numbers, functions, sets, and so forth. Concrete.

Operational Semantics: The meaning is given in terms of rules that specify how the state of a computer – real or formal – changes while executing a program.

Property-Oriented Formal Specification Language: Based on axiomatic definitions. Abstract.

Semantics: In a language, it is the meaning of a string, as opposed to syntax, which describes how the symbols of the language are combined. Most programming languages have their syntax defined formally (traditionally in BNF), while formal specification languages have also their semantics defined formally.

Specification: A document describing what a system should do, what a problem is or what a domain is all about. In formal methods this document is written in a formal language.

Static-Oriented Formal Specification Language: Do not include provisions for handling time.

Verification: The process of determining whether or not the products of a specification phase fulfill a set of established requirements. Sometimes this is also used to indicate the process of proving that a more concrete specification preserves the properties of a more abstract specification.

ENDNOTE

[1] Some authors use the singular while others employ the plural in referring to FM. We can refer to Ricky W. Butler (2003):
"Some of you are saying, 'Formal Methods is ...? What's wrong with these people, ain't nobody learned them no grammar!' In an age in which few people care about the proper use of language, your concern is commendable; however, in this instance, your concern is also unwarranted."
"In these pages, we are using the term formal methods to refer to a particular collection of knowledge.

Just as the plural-sounding term fluid dynamics is treated as singular, so too may the term formal methods be treated as singular. A legitimate argument can be made as to the acceptability of treating the term as plural, but no legitimate argument can be made as to the necessity of doing so." http://shemesh.larc.nasa.gov/fm/fm-is-vs-are.html; last modified: 10 September 1998 (15:57:28). Universidad Nacional del Centro de la Provincia de Buenos Aires, Argentina

INTRODUCTION

The Unified Modeling Language (UML) has emerged as a modeling language for specifying, visualizing, constructing, and documenting software-intensive systems. It unifies proven software modeling languages that incorporate the object-oriented community's consensus on core modeling concepts. It also includes additional expressiveness to handle problems that previous visual languages did not fully address (Rumbaugh, Jacobson & Booch, 1999).

UML emerged in response to a call for a standard object-oriented design method by the Object Management Group (OMG) in 1997. In mid-2001, OMG started working on a major upgrade to UML, and its evolution will result in version 2.0 (OMG, 2004).

The UML notation includes diagrams that provide multiple perspectives of the system under development. It defines 12 types of diagrams divided into three categories that represent static application structure, aspects of dynamic behavior, and ways for organizing and managing application modules.

The model's elements are defined in terms of their abstract syntax, well-formed rules, and precise text (OMG, 2004). These well-formed rules are expressed in the Object Constraint Language (OCL). Recently, a new version of OCL, version 2.0, has been formally defined and it has been adopted by OMG (Warmer & Kleppe, 2003).

UML is used in many ways and different domains for expressing different types of concepts such as language-independent software specification, high-level architecture, Web site structure, workflow specification, and business modeling. It has been applied successfully to build systems for different types of applications running on any type and combination of hardware, operating system, programming language, and network.

Although UML does not prescribe any particular development process, the OMG presented the Software Process Engineering Metamodel (SPEM) as a standard in November 2001 (OMG, 2004). This metamodel is used to describe a concrete software development process or a family of related software development processes that use the UML notation. SPEM has a four-layered architecture of modeling for describing performing process, process model, process metamodel, and MetaObject Facility (MOF). Several processes fit SPEM. The most popular is Rational Unified Process, developed and marketed by Rational Software (now a division of IBM). RUP is use-driven, architecture-centered, iterative, and risk-driven. Various industry sectors around the world use RUP in different applications: telecommunications, transportation, aerospace, defense, manufacturing, and financial services (Jacobson, Booch & Rumbaugh, 1999; Krutchen, 2000).

The international standardization of UML leads to improvements in CASE tools, methods, and standard modeling libraries. In the market, there are about 100 UML CASE (computer-aided software engineering) tools that vary widely in functionality, usability, performance, and platforms (CASE, 2004).

A recent OMG initiative is the Model-Driven Architecture (MDA), which promotes the creation of abstract models that are developed independently of a particular implementation technology and automatically transformed by tools into models for specific technologies (Kleppe, Warmer & Bast, 2003).

MDA is emerging as a technical framework to improve productivity, portability, interoperability, and maintenance. It defines how models expressed in one language can be transformed into models in other languages. The MDA process is divided into three main steps:

- Construct a model with a high level of abstraction that is called Platform-Independent Model (PIM).
- Transform the PIM into one or more Platform-Specific Models (PSMs), each one suited for different technologies.
- Transform the PSM to code.

The PIM, PSMs and code describe a system in different levels of abstraction. Using MDA, the business is modeled in Platform-Independent Models, which are transformed into Platform-Specific Models. This is carried out in an automatic manner.

The success of MDA depends on the definition of transformation languages and tools that make a significant impact on full forward engineering processes and partial round-trip engineering processes.

BACKGROUND

UML is having a significant impact on the software development industry. So far, there are about 100 UML CASE tools that vary widely in functionality, usability, performance, and platforms (CASE, 2004). Table 1 shows a taxonomy of the UML CASE tools.

The competing tools can be compared and contrasted by the following requirements: easy interface, modeling productivity, implementation productivity, and extensibility. The main stream object-oriented CASE tools can help with the mechanics of drawing and exporting UML diagrams, eliminating syntactic errors and consistency errors between diagrams, and supporting code generation and reverse engineering.

The current techniques available in the commercial tools are not sufficient for MDA-based forward engineering. A source of problems in the code generation process is that, on the one hand, the UML models contain information that cannot be expressed in object-oriented languages while, on the other hand, the object-oriented languages express implementation characteristics that have no counterpart in the UML models. For instance, languages like Java, C++, and Eiffel do not allow explicit associations. These can be simulated by pointers and references, but then the structure of the system is not apparent. This often leads to problems during forward engineering between the specification and code.

Moreover, the existing CASE tools do not exploit all the information contained in the UML models. For instance, cardinality and constraints of associations and preconditions, postconditions, and class invariants in OCL are only translated as annotations. It is the designer's responsibility to make good use of this information, either selecting an appropriate implementation from a limited repertoire or implementing the association by himself.

UML CASE tools provide limited facilities for refactoring source code through an explicit selection made for the designer. However, it will be worth thinking about refactoring at the design level. The advantage of refactoring at the UML level is that the transformations do not have to be tied to the syntax of a programming language. This is relevant since UML is designed to serve as a basis for code generation with the MDA paradigm (Sunyé, Pollet, Le Traon & Jézéquel, 2001).

Many UML CASE tools support reverse engineering. However, they only use more basic notational features with a direct code representation and produce very large diagrams. Reverse engineering processes are facilitated by inserting annotations in the generated code. These annotations are the link between the model elements and the language. As such, they should be kept intact and not be changed. It is the programmer's responsibility to know what he or she can modify and what he or she cannot modify.

Techniques that currently exist in UML CASE tools provide little support for validating models in the design stages. Reasoning about models of systems is well supported by automated theorem provers and model checkers, however these tools are not integrated into CASE tools environments. Another problem is that as soon as the requirements specifications are handed down, the system architecture begins to deviate from specifications (Kollmann & Gogolla, 2002).

To solve these problems a lot of work has been carried out dealing with the semantics for UML models, advanced metamodeling techniques, and rigorous processes that fit MDA.

The Precise UML Group, pUML, was created in 1997 with the goal of giving precision to UML (Evans, France, Lano & Rumpe, 1998). It is difficult to compare the existing formalizations and to see how to integrate them in order to define a standard semantics since they specify different UML subsets and they are based on different formalisms (Ahrendt et al., 2002; McUmber & Cheng, 2001;

Table 1. UML CASE tools

Main Stream Object-Oriented CASE Tools	Rational Rose, Argo/UML, Poseidon, Together, GDPro, Stp/UML, MagicDraw
Real-Time/Embedded Tools	Tau UML Rhapsody Rational Rose Real Time
Basic Drawing Tools	Visio

Kuske, Gogolla, Kollmann & Kreowski, 2002; Laleau & Polack, 2002; Ziemann & Gogolla, 2003; Favre & Clerici, 2001; Favre, 2003).

Other works describe advanced metamodeling techniques that allow the enhancement of UML. Gogolla and Henderson-Sellers (2002) analyze the UML metamodel part dealing with stereotypes, and make various suggestions for improving the definition and use of stereotypes. Barbier, Henderson-Sellers, Le Parc-Lacayrelle, and Bruel (2003) introduce a formal definition for the semantics of the whole-part relation that can be incorporated into version 2.0 of UML.

UML CASE tools could be enhanced with functionality for formal specification and deductive verification; however, only research tools provide support for advanced analysis. For example, the main task of the USE tool (Ziemann & Gogolla, 2003) is to validate and verify specifications consisting of UML/OCL class diagrams. Key (Ahrendt et al., 2002) is a tool based on Together (CASE, 2004) enhanced with functionality for formal specification and deductive verification.

To date, few tools provide support for the MDA paradigm, for example, AndroMDA, AMEOS, CodagenArchitect, OptimalJ, and ArcStyler (CASE, 2004). The tool market around MDA is still in flux. References to MDA-based tools can be found at the OMG Web site (MDA, 2004).

MAIN THRUST OF FORWARD ENGINEERING AND UML

Formal and semi-formal techniques can play complementary roles in software development processes. This integration is beneficial for both graphical and formal specification techniques. On the one hand, semi-formal techniques have the ability to visualize language constructs, allowing a great difference in the productivity of the specification process, especially when the graphical view is supported by means of good tools. On the other hand, formal specifications allow us to produce a precise and analyzable software specification before implementation and to define semi-automatic forward engineering processes.

Favre, Martinez, and Pereira (2003) propose a rigorous process to forward engineer UML static models. The emphasis is given to the last steps in the road from UML to code. The bases of this approach are the *GSBL^{oo}* algebraic language and the *SpReIm* model for defining structured collections of reusable components.

The GSBL^{oo} language was defined taking into account the structuring mechanisms of UML. This language is relation-centric, which means that it expresses different kinds of UML relations (dependency, association, aggregation, and composition) as primitives to develop specifications. GSBL^{oo} allows us to keep a trace of the structure of UML models in the specification structure that will make it easier to maintain consistency between the various levels when the system evolves.

The *SpReIm* model allows us to define structured collections of reusable components that integrate algebraic specifications and object-oriented code. It takes advantage of the algebraic formalism power to describe behavior in an abstract way, while integrating it with concrete implementations. A component is defined in three levels of abstraction that integrate incomplete algebraic specifications, complete algebraic specifications, and object-oriented code.

A specific reusable component is Association. It describes a taxonomy of associations classified according to kind, degree, navigability, and multiplicity. The first level describes a hierarchy of incomplete specifications of associations using GSBL^{oo} and OCL. Every leaf in this level corresponds to sub-components at the second level. A realization sub-component is a tree of algebraic specifications: the root is the most abstract definition, the internal nodes correspond to different realizations of the root. For example, for a “binary, bi-directional, and many-to-many” association, different realizations through hashing, sequences, or trees could be associated. These sub-components specify realizations starting from algebraic specifications of Eiffel libraries.

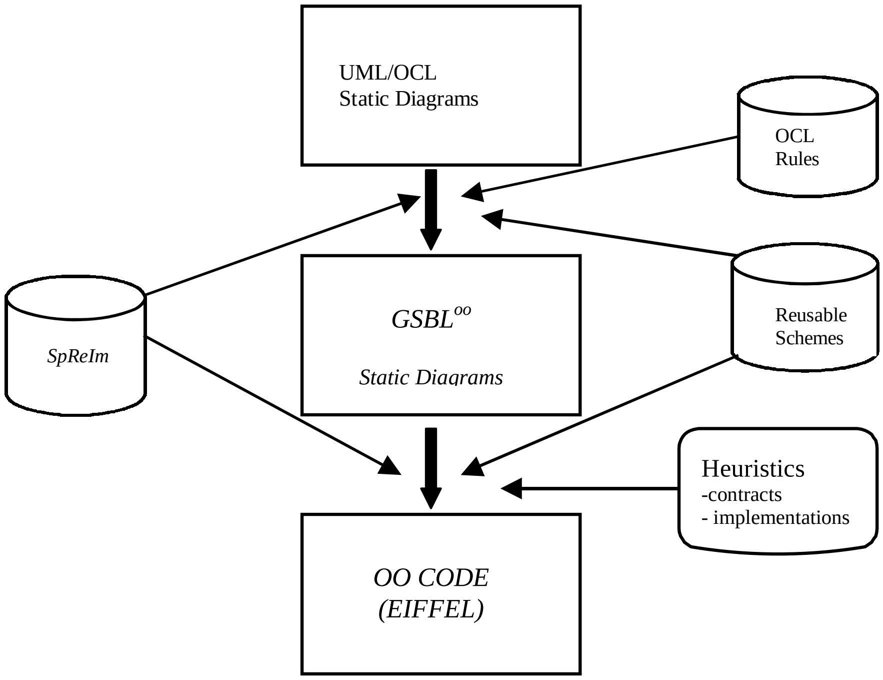
The implementation level associates each leaf of the realization level with different implementations in Eiffel. Implementation sub-components express how to implement associations and aggregations. For example, a bi-directional binary association with multiplicity “one-to-one” will be implemented as an attribute in each associated class containing a reference to the related object. On the contrary, if the association is “many-to-many,” the best approach is to implement the association as a different class in which each instance represents one link and its attributes.

The component reuse is based on the application of reuse operators: *Rename*, *Hide*, *Extend*, and *Combine*. These operators were defined on the three levels of components.

Figure 1 shows the main steps of the transformational process. Starting from UML class diagrams, an incomplete algebraic specification can be built by instantiating reusable schemes and components, which already exist in the GSBL^{oo} predefined library. Analyzing OCL specifications, it is possible to derive axioms that will be included in the GSBL^{oo} specification.

Preconditions written in OCL are used to generate preconditions in GSBL^{oo}. Postconditions and invariants

Figure 1. From UML static models to Eiffel



allow us to generate axioms in GSBL^{oo} (Favre, 2001). Thus, an incomplete specification can be built semi-automatically. The refinement of the GSBL^{oo} specification into a complete algebraic specification and code is based on a library of *SpReIm* components.

Then GSBL^{oo} specifications need to be transformed into object-oriented code. The Eiffel code is constructed gradually. First, associations and operation signature are translated. From OCL and GSBL^{oo} it is possible to construct contracts on Eiffel and/or feature implementation by applying heuristics. Associations are transformed by instantiating schemes that exist in the Association component.

The proposed transformations preserve the integrity between specifications and code. Software developers could perform maintenance and evolution on system specification, but not on the implementations. Modifications at specification levels must be applied again to produce a new and efficient implementation. Most of the transformations can be undone, which provides great flexibility in software development. All of the proposed transformations could be automated; they allow traceability and could be integrated into iterative and incremental software development processes supported by current UML CASE tools.

A detailed description of the forward engineering process may be found in Favre, Martinez, and Pereira (2003).

FUTURE TRENDS

UML is evolving as a result of insights gained through their use, both in industry and academia. The evolution of UML requires a large effort that is guided by user community.

The current UML 1.5 metamodel is insufficient to maintain the consistency between restructured design models, various design views, and implementations. This situation might be changed in the future since UML evolves to version 2.0.

Currently, OMG is promoting a transition from code-oriented to MDA-based software development techniques. Many tools claim to be compliant with MDA. The existing MDA-based tools do not provide sophisticated transformation from PIM to PSM and from PSM to code. To date, they might be able to support forward engineering and partial round-trip engineering between PIM and code. However, it will probably take several years before a full round-trip engineering based on standards occurs (many authors are skeptical about this).

Techniques that currently exist in UML CASE tools provide little support for generating business models. In light of the advances of the MDA paradigm, new types of UML tools that do a more intelligent job might emerge. It is probable that the next generation of tools will be able to describe the behavior of software systems in terms of business models and translate it into executable programs on distributed environment.

CONCLUSION

There is a great number of UML CASE tools in existence that facilitates code generation. Unfortunately, the current techniques available in these tools provide little automation for round-trip engineering. The formalization of UML can help to overcome these problems. In this direction, a rigorous process to transform UML static models into code was defined. It is based on the integration of semiformal notations with algebraic specifications.

Transformations are supported by a library of reusable schemes and by a system of transformation rules that allow translating UML constructs to algebraic specifications and Eiffel step-by-step. All the UML model information (classes, associations, and OCL constraints) are overturned in specifications having implementations implications. In particular, the transformation of different kinds of UML associations to Eiffel have been analyzed.

This research is still evolving, and additional issues will have to be tackled in order to fit new versions of UML and the MDA paradigm.

KEY TERMS

Class Diagram: A diagram that shows a set of classes and their relationships (association, dependency, generalization/specialization, realization); class diagrams address the static design view of a system.

Computer-Aided Software Engineering (CASE): A tool to aid in the analysis and design of software systems.

Forward Engineering: The process of transforming a model into code through a mapping to a specific implementation language.

Model-Driven Architecture: A framework based on UML and other industry standards for visualizing, storing, and exchanging software design and models.

OCL (Object Constraint Language): A language used to express side effect-free constraints.

Refactoring: A change to a system that leaves its behavior unchanged, but enhances some nonfunctional quality factors such as simplicity, flexibility, understanding, and performance.

Reverse Engineering: The process of transforming code into a model through a mapping from a specific implementation language.

Unified Modeling Language (UML): A language for visualizing, specifying, constructing, and documenting the artifacts of a software-intensive system.

INTRODUCTION

Franchising is "a business opportunity by which the owner (producer or distributor) of a service or a trademarked product grants exclusive rights to an individual for the local distribution and/or sale of the service or product, and in return receives a payment or royalty and conformance to quality standards. The individual or business granting the business rights is called the *franchisor*, and the individual or business granted the right to operate in accordance with the chosen method to produce or sell the product or service is called the *franchisee*." (Justis & Judd, 2002)

In his best seller, *Business @ the Speed of Thought,* Bill Gates (1999) wrote: "Information Technology and business are becoming inextricably interwoven. I don't think anybody can talk meaningfully about one without talking about the other." Thus, to see how information technology (IT) is used in franchising, one needs to know how franchising really works.

BACKGROUND

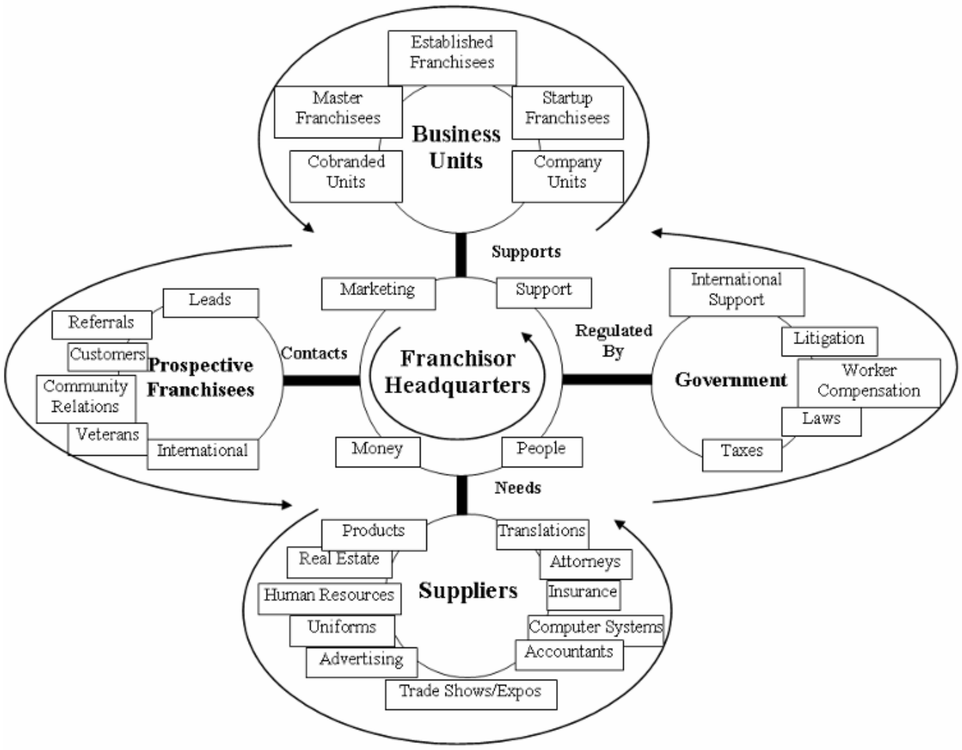
Understanding the Franchisor

The activities of the franchisor can be described using Figure 1 with five categories, having many sub-activities (represented by rectangles) in each of them:

- Franchisor Headquarters, including: (1) Support, helping business units; (2) Marketing, selling to prospective franchisees; (3) People, performing support and development; and (4) Money, dealing with financial/accounting issues. It also supports the following four different categories of activities.
- Business units, including company units, startup franchisees, established franchisees, master franchisees, and cobranded units. Among these five the franchisor should do the best to support startup franchisees, since good beginning is half done. Established and master franchisees are the ones the franchisor needs to provide incentives (e.g., cobranded units) to encourage expansion. Company units are typically used as role models for the franchisees.
- Prospective franchisees, contacted through several ways: (1) leads from marketing channels; (2) referrals from, for example, happy customers; (3) customers who love the products/services so much and would like to own the business themselves; (4) community and media relationships, helping deal with issues such as children's education; (5) public services like recruiting veterans; and (6) international contacts generated from master franchisees.
- Suppliers, including products and goods distributors and business service providers such as real estate agents, human resources providers, uniform vendors, marketing and advertising agents, trade shows/expos organizers, accountants, information systems vendors, insurance providers, attorneys, language translators, and many others.
- Government, including (1) federal, state, and international taxes; (2) local, region, and global laws; (3) insurances such as worker compensation; (4) possibilities of litigations from government, customers, and franchisees; and (5) supports for international expansions.

As we can see from Figure 1, the franchisor has to deal with many issues to grow the system. The learning process of the franchisor is incrementally developed through the following five stages (Justis & Judd, 2002): (1) Beginner – learning how to do it; (2) Novice – practicing doing it; (3) Advanced – doing it; (4) Master – teaching others to do it; and (5) Professional – becoming the best that you can be. At a higher stage of the development, most of the problems in the previous stages have been dealt with.

Figure 1. Understanding how the franchisor works



However, more complicated and challenging questions will arise as the franchise continues the expansion. This is especially true when the system reaches the stage of professional, when many unforeseen and difficult problems could happen all of a sudden. Bud Hadfield (1995), the founder of Kwik Kopy franchise and the International Center of Entrepreneurial Development, said it the best: “The more the company grows, the more it will be tested.” To capture the learning process in Figure 1, a counter-clockwise round arrow is used in each of the five categories. It depicts the increasing intensity of learning in every area of the sub-activities (represented by rectangles) as the franchise continues surviving and thriving. For example, as the system expands, the real estate sub-activity becomes much more complicated since the issue of territory encroachment becomes more significant and harder to deal with.

Understanding the Franchisee

The activities of the franchisee can be described using Figure 2 with five categories, having many sub-activities (represented by rectangles) in each of them:

- Franchisee outlet, consisting of making sales to customers, marketing and advertising, dealing with financial/accounting issues, and managing people who make sales.
- Customers, including five types: potential, infrequent, frequent, online, and cobranded.
- Franchisor headquarters, providing supports to the franchisee, demonstrations from field representatives, training and continued education from the management group, discussion forums, and distance learning.
- Suppliers, similar to the list shown in Figure 1.
- Government, similar to the list shown in Figure 1.

The franchisee also goes through previously mentioned five-stage learning process (i.e., beginner, novice, advanced, master, and professional) represented by a counter-clockwise round arrow used in each of the five categories in Figure 2. Once again, the arrow depicts the increasing intensity of learning as the franchisee continues growing the business and many unforseen problems/issues may rise up to challenge the practices.

Understanding the Franchisor/ Franchisee Relationship

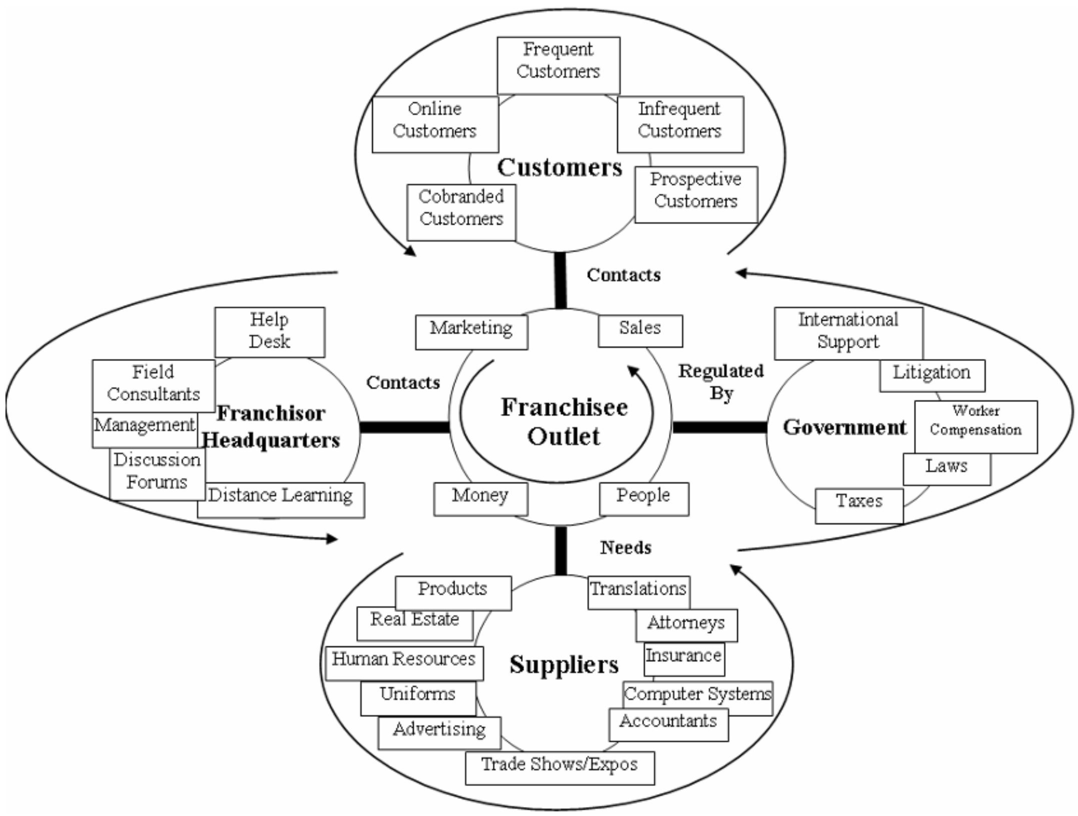
Developing a good “family” relationship between the franchisor and the franchisee is believed to be the most important factor for the success of a franchise (Justis & Judd, 2002). To understand how the relationship is developed, one needs to know the franchisee life cycle (Schreuder, Krige & Parker, 2000):

- The Courting Phase: Both the franchisee and the franchisor are excited with the relationship. This corresponds typically to the beginner stage of the franchisee.
- The "We" Phase: The relationship starts to deteriorate, but the franchisee still values the relationship. This corresponds typically to the novice stage of the franchisee.
- The "Me" Phase: The franchisee starts to question the reasons for payments-related issues with the attitude that the success so far is purely of his/her own work. This corresponds typically to the advanced stage of the franchisee.
- The Rebel Phase: The franchisee starts to challenge the restrictions being placed upon him or her. This corresponds typically to the master stage of the franchisee, since the rebel ones tend to be those who know the system very well and are capable of influencing others to follow them.
- The Renewal Phase: The franchisee realizes the "win-win" solution is to continue teaming up with the franchisor to grow the system. This corresponds typically to the professional stage of the franchisee.

The major challenge for the franchisor is to turn a "rebel" franchisee into the "renewal" one by providing a learning and innovative environment where the franchisee can continue contributing to the growth of the system. Successful collaborative learning and innovations will provide a strong incentive for the professional franchisees to continue their renewal relationship with the firm, which in turn will have positive impact on maintaining the good relationship with other franchisees and recruiting new ones. On the other hand, constant failures in this stage will intensify the rebel franchisees to desert the firm, which in some cases leads to the demise of the franchise. Lying behind the successful collaboration is the working knowledge of the franchise firm. Knowledge is defended as "a justified personal belief that increases an individual's capacity to take effective action" (Alavi & Leidner, 1999). Knowledge becomes "working" when the action produces results. When knowledge produces results, the personal belief becomes much more strengthened, intensified, and justified. As such, the individual's capacity is much more increased and better results are obtained.

This spiral-up cycle of working knowledge development is very important in the context of franchising. Figure

Figure 2. Understanding how the frachisee works



3 shows that the development process is incrementally developed through the five stages of the spiral-up cycle defined earlier: beginner, novice, advanced, master, and professional. The foundation of the learning cycle is the capability of sharing and coaching the working knowledge throughout the franchise system. The process of influencing others for knowledge dissemination consists of five steps (Justis & Vincent, 2001): (1) Knowledge, proven abilities to solve problems in the franchise environment; (2) Attitude, constructive ways of presenting and sharing the working knowledge; (3) Motivation, incentives for learning or teaching the working knowledge; (4) Individual Behavior, the strengths of the participants to learn and enhance the working knowledge; and (5) Group Behavior, collaborative ways to create, dissimilate, and manage the hard-earned working knowledge. The franchisor/franchisee "family" relationship building in Figure 3 is also surrounded with a dashed line, meaning the relationship is enlarged and expanded without limits as the franchisee incrementally learns the working knowledge through the influencing of the franchisor and the fellow franchisees. By going through the processes of learning and influencing, both the franchisor and franchisee gain the working knowledge progressively and mange the franchisee life cycle effectively.

FUTURE TRENDS

An Attention-Based IT Infrastructure in Franchising

In an information-rich world, Herbert Simon (Nobel laureate in Economics in 1978) wrote: "a wealth of information creates a poverty of attention" (Simon, 1971). As such, the "proper aim of a management information system is not to bring the manager all the information he needs, but to

Figure 3. Understanding the franchisor/franchisee family relationship

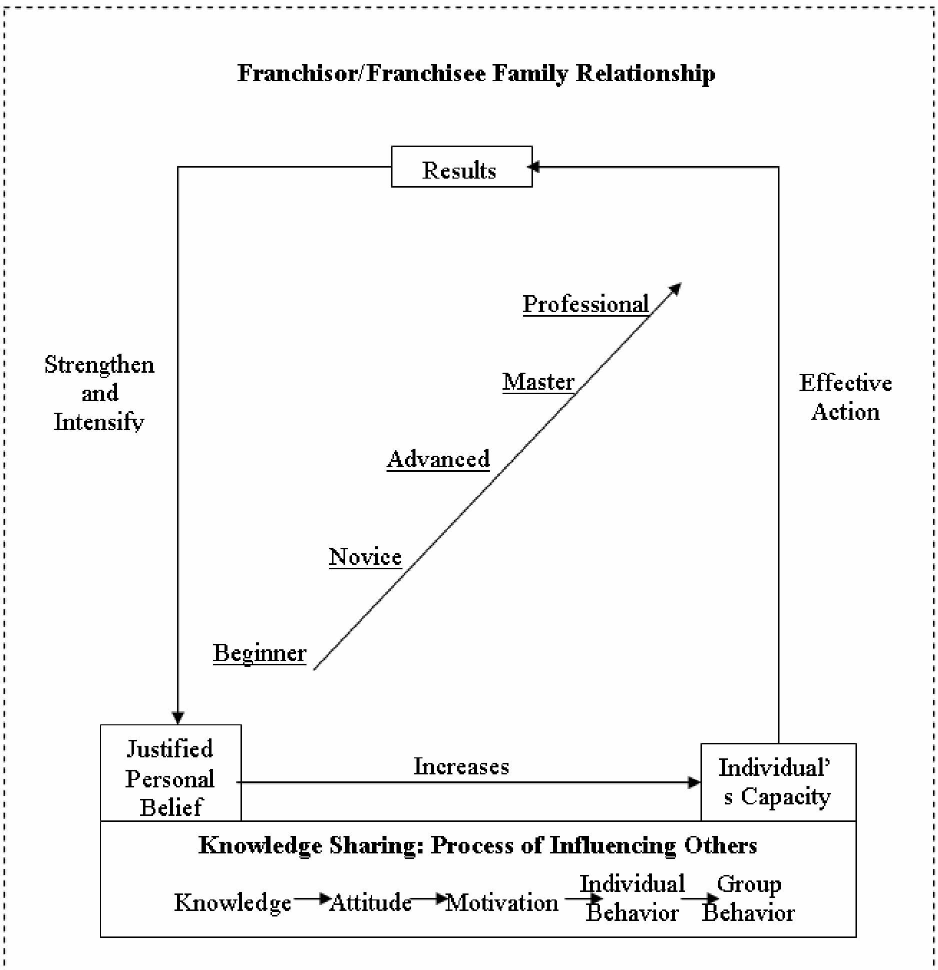


Figure 4. An attention-based IT infrastructure in franchising

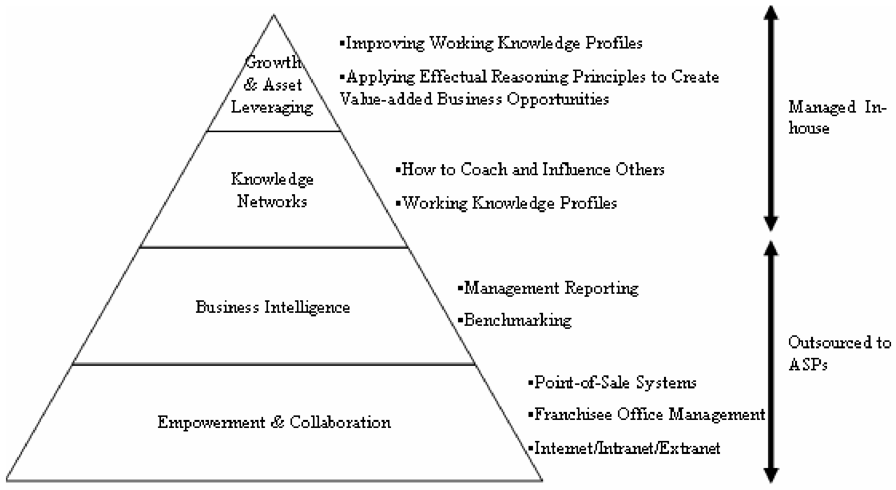


recognize the manager's environment of information so as to reduce the amount of time he must devote to receiving it" (Simon, 1971). From the discussions in the last section, it is obvious that an attention-based IT infrastructure in franchising shall be one devoted to enabling the building of a good "family" relationship between the franchisor and the franchisee. In Figure 4, we propose such an IT architecture for franchise organizations to manage the massive information produced by the firms. The architecture, adapted from Gates' Digital Nervous Systems (1999), consists of the following four layers:

- Empowerment and Collaboration: Point-of-sale and office management systems are used to empower the franchisees (Chen, Justis & Chong, 2002). Internets, extranets, and intranets networking the franchisor, the franchisees, customers and suppliers are deployed to improve collaboration (Chen, Chong & Justis, 2002).
- Business Intelligence: Data warehousing and data mining techniques are used to transform volumes of data into reports and benchmarks for management to glean business intelligence (Chen, Justis & Chong, 2004; Chen, Justis & Watson, 2002; Zhang, Chen & Pawlowski, 2003).
- Knowledge Networks: Intranet-based systems consisting of the skills of coaching/influencing others and working knowledge profiles (Chen, Hammerstein & Justis, 2002) are implemented for knowledge sharing and learning within the franchise business. A distance-learning curriculum (Chen, Chong & Justis, 2000) of working knowledge modules can also be deployed.
- Growth and Asset Leveraging: Value networks are developed with the goal of improving working knowledge profiles and applying effectual reasoning principles to create value-added business opportunities (Chen, Justis & Yang, 2004).

To demonstrate how the attention-based IT infrastructure is related to the activities of the franchisor and the franchisee (shown in Figures 1 and 2) and the "family" relationship building (shown in Figure 3), we show in Figure 5 the character of the business process and the information flow in the franchise business and explain why the attention-based IT infrastructure is needed. The foundation of the architecture, adapted from Inmon (1996), consists of four levels: (1) data collected from the empowerment and collaboration activities of the franchisor (Figure 1) and the franchisee (Figure 2); e-business strategy shall be one empowering the franchisor and the franchisees to do their activities (Chen, Chong & Justis, 2002); (2) reconciled data in the franchise data warehouse (Chen, Justis & Watson, 2002); (3) derived data residing in data marts based on various franchisee-centered segmentations such as franchise development and support; and (4) business intelligence reports generated from analytical data analysis; for example, management reporting and benchmarking could be produced by online analytical processing (OLAP) periodically, which may lead to more proactive analysis of top/low performer attributes using the data mining techniques (Chen, Justis & Chong, 2004).

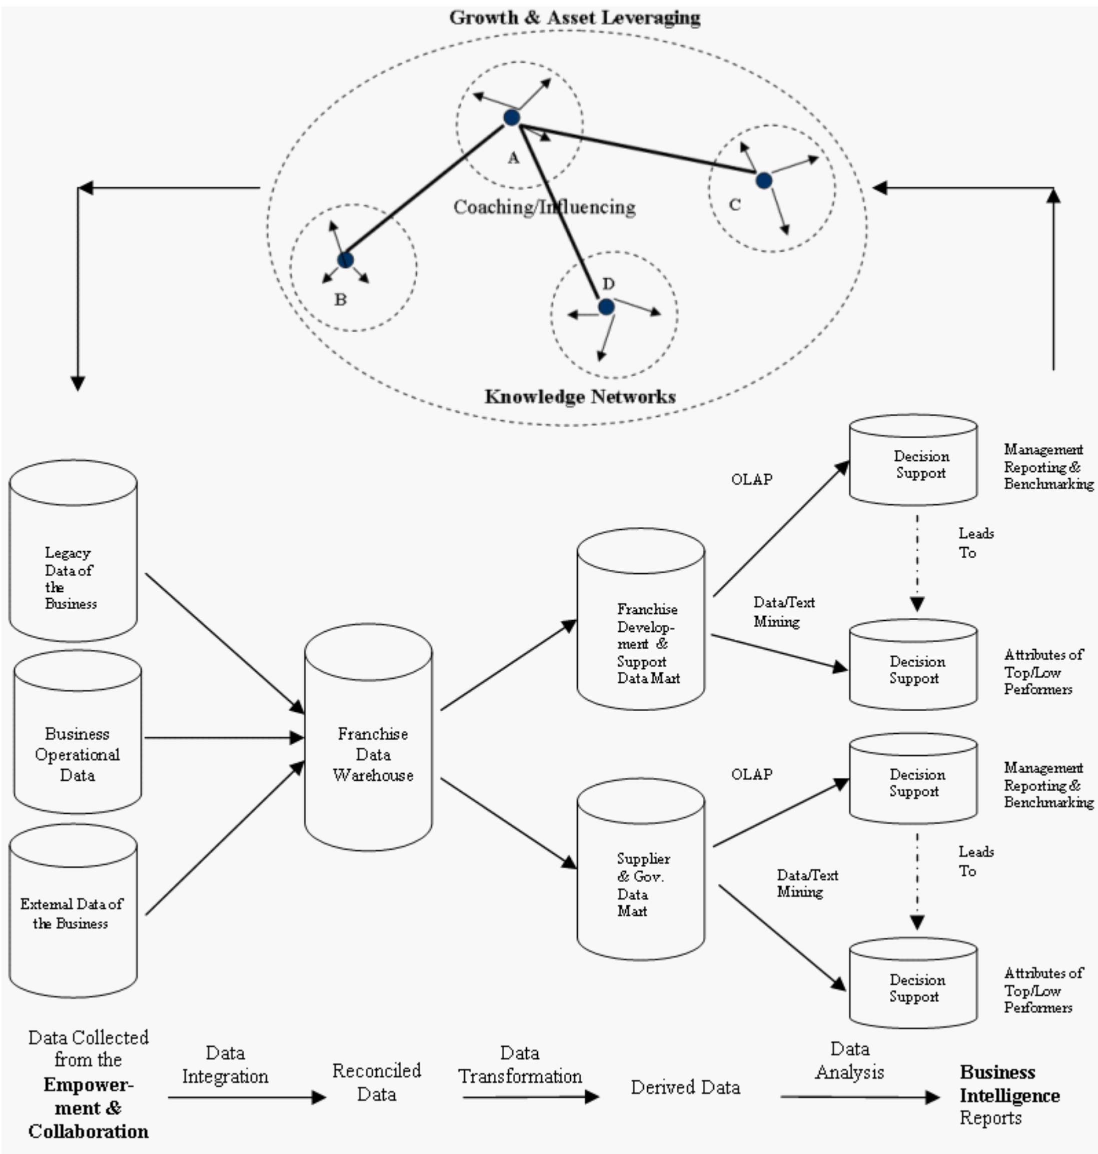
The business intelligence reports will help the franchise system to identify key top performers and their success attributes. With their involvement, working knowledge profiles can be developed and dissimilated throughout the knowledge networks of the business using coaching/influencing techniques (Chen, Hammerstein & Justis, 2002). The top of Figure 5 depicts such a knowledge sharing and dissemination idea described in Figure 3 in detail. There are four franchisees (A - D) in the figure. Each franchisee (a dot) has his/her personal knowledge network (arrows pointing out of the dot). The knowledge network may include the customers' likes and dislikes, the kind of employees to hire, the competitors' and suppliers' pricing strategies, and the social needs in the local community. Each franchisee is surrounded with a circle with dashed lines, meaning there is no limit to the personal knowledge network. Suppose franchisee A is the top performer and is charged and rewarded with coaching/influencing other franchisees to survive and thrive. Thus, clusters (connected dots) of knowledge network are formed and surrounded with a circle with dashed lines, meaning there is no limit for improving and leveraging the assets of the business (Chen, Justis & Yang, 2004).

Using the attention-based IT architecture as a guide, we recommend franchise organizations to outsource IT in the first two layers to application service providers (ASPs) (Chen, Ford, Justis & Chong, 2001). The concept of subscribing IT services through ASPs has special appeal in the franchising industry because an ASP can duplicate success for other similar franchises quickly and inexpensively (Yao, Wohl, Watson & Chen, 2004).

CONCLUSION

Franchising has been popular as a growth strategy for small businesses; it is even more so in today's global and

Figure 5. Implementing the attention-based IT infrastructure in franchising



e-commerce world. Although IT is quite important in franchising, IT researchers have largely ignored this arena. One major reason is that few IT researchers are vested in the knowledge of how franchising functions, and without this intimate knowledge it is difficult to implement effective IT systems. Based on years of academic and consulting experiences in franchising and IT, the authors propose a framework of IT in franchising. At the heart of the framework is to manage working knowledge and use IT to build up the "family" relationship between the franchisor and the franchisee.

KEY TERMS

Attention-Based IT Infrastructure: An IT infrastructure that is able to sort through volumes of data and produce the right information at the right time for the right persons to consume.

Franchisee: The individual or business that receives the business rights and pays the royalties for using the rights.

Franchisee Life Cycle: The stages a franchisee goes through in the franchise system: Courting, "We," "Me," Rebel, Renewal.

Franchising: A business opportunity based on granting the business rights and collecting royalties in return.

Franchisor: The individual or business that grants the business rights.

Franchisor/Franchisee Learning Process: The stages of learning, including beginner, novice, advanced, master, and professional.

Franchisor/Franchisee Relationship Management: The vital factor for the success of a franchise, including: Knowledge, Attitude, Motivation, Individual Behavior, and Group Behavior.

From Digital Divide to Digital Dividend

INTRODUCTION

Despite rapidly falling costs of hardware, software, and telecommunications services, a wide gap persists between rich and poor nations in terms of their capabilities of accessing, delivering, and exchanging information in digital forms (Carter & Grieco, 2000). Developing countries, comprising over 81% of the world population, account for a tiny fraction of global e-commerce. An estimate suggests that 99.9% of business-to-consumer e-commerce in 2003 took place in the developed regions of North America, Europe, and Asia Pacific (Computer Economics, 2000).

Whereas high-income countries have income 63 times that of low-income countries, the respective ratios are 97 for PCs (personal computers), 133 for mobile phones, and over 2,100 for Internet hosts (Dholakia & Kshetri, 2003). While reliable data on e-commerce transactions are not available, the ratio is likely to be even higher for e-commerce transactions since e-commerce is virtually nonexistent in many developing countries. The pattern indicates that the gap between developed and developing countries is wider for more recent technologies such as PCs, mobile phone, and the Internet than for technologies that were introduced earlier.

In the absence of appropriate policy measures, it is likely that the "global digital divide" will become wider (Dholakia & Kshetri, 2003; Economist.com, 2000). Policy measures directed at making appropriate networks available to the digitally excluded populations at reasonable costs could bridge the gap or at least decrease the rate at which it widens.

This article provides an assessment of two computer networks that redefine the conventional definition of market value by allowing developing nations and communities (Brooks, 2001) to reap the benefits of modern ICTs (information and communications technologies): Global Trade Point Network (GTPNet) and Little Intelligent Communities (LINCOS).

BACKGROUND

The global digital divide is the result of the complex interactions among ICTs and various economic, political, and social factors in the environment. First, a large majority of potential users in developing countries are unable to afford a telephone line, a PC, and the telephone and Internet services provider (ISP) access charges. Whereas the cost of a PC is 5% of the per capita GDP (gross domestic product) in high-income countries, it is as high as 289% in low-income countries (ITU, 2001). Furthermore, monthly Internet access charge as a proportion of per capita GDP in the world varies from 1.2% in the US to 614% in Madagascar (UNDP, 2001).

Second, for some consumers in developing countries that are willing to pay for the connection of a telephone line, there is a big gap between demand and supply. For instance, in 2001, 33 million people in the developing world were on the registered waiting lists for telephone connections, the average waiting periods being over 10 years in some countries.

A third problem is related to the lack of skills. A majority of potential users in developing countries lack English language and computer skills, prerequisites for the use of the Internet. For instance, in 1998 about 85% of the text on the Internet was in English (Nunberg, 2000). This proportion decreased to 80% in 1999 and 50% by 2003. Although a shift of Internet content to non-English languages is under way, some knowledge of English is still necessary to use the Internet as the bulk of software used in the Internet is in English (Hedley, 1999) and most of the human-computer interfaces favor English-language users (Goodman, Press, Ruth, & Ruthowski, 1994).

A fourth problem is related to the lack of relevant content. Although there are over 17 billion Web pages[1] in existence, the content remains largely geared to the needs of advanced nations. Edejer (2000) observes the difficulty of finding reliable health-related information relevant to developing countries online:

Few reports of health research from developing countries are published in journals indexed by Western services such as Medline. *Western indexing services cover some 3,000 journals, of which 98% are from the developed world. The whole of Latin America accounted for 0.39% of the total number of articles referenced by Medline in 1996.... Because only a small number of journals from developing countries are indexed by Medline, research from these countries is almost invisible.*

CREATIVE WAYS TO BRIDGE THE DIGITAL DIVIDE: SOME EXAMPLES

The effectiveness of a network in bridging the global digital divide is thus a function of (a) the network's ability to identify priorities of digitally excluded populations and (b) the network's ability to attack the major barriers to Internet and e-commerce adoption. In the following section, we examine two networks designed to enable e-business systems for the global poor: GTPNet (Figure 1) and LINCOS (Figure 2).

Global Trade Point Network of the World Trade Point Federation (http://www.wtpfed.org/)

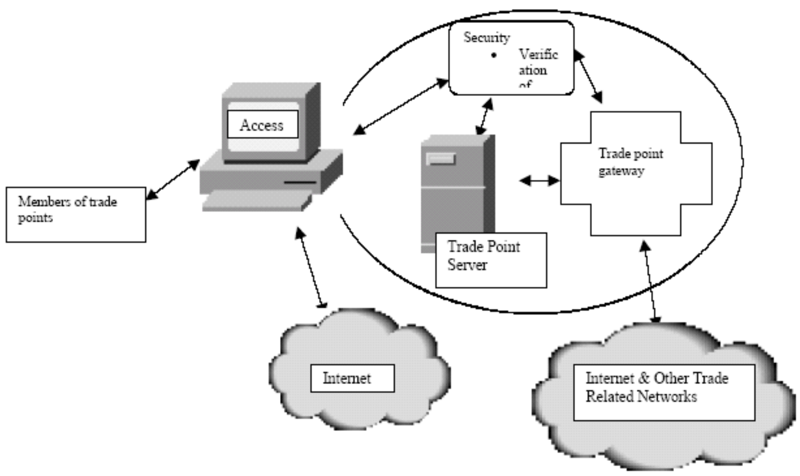
The United Nations Conference on Trade and Development (UNCTAD) launched the Global Trade Point Program in 1992 to facilitate the access to international markets for SMEs. The program was taken over by the World Trade Point Federation in November 2002. In mid-2003, GTPNet had a human network of 121 trade points in over 80 countries on five continents[2].

In a trade point, participants in foreign trade transactions (e.g., customs authorities, foreign trade institutes, banks, chambers of commerce, freight forwarders, transport and insurance companies) are grouped together under a single physical or virtual roof to provide all required services at a reasonable cost. It is a source of trade-related information providing actual and potential traders with data about business and market opportunities, potential clients and suppliers, trade regulations and requirements, and so forth. A survey found that 85.7% of trade-point customers are SMEs and microenterprises (UNCTAD, 1997).

The ETO (electronic trading opportunity) system is probably one of the most important aspects of the GTPNet. It was started by the UN Trade Point Development Center (UNTPDC) in June 1993 and is the world's largest Internet-based business opportunities system. ETOs are offers and demands for products, services, and investment and are distributed point to point and company to company. They are forwarded to the GTPNet system by trade points and third-party information providers. A random survey of ETO users conducted in 1998 revealed that 48% of the ETO users received 1 to 10 responses per posted ETO, an additional 14% receive 10 to 30 responses, and about 7% receive over 100 reactions. About a third of respondents made business deals on the basis of ETOs.

Developing countries also have a much higher share in the ETOs than in overall global e-commerce. A UNTPDC analysis of ETOs posted on the GTPNet during March 1 to July 15, 1998, indicated that 20% of them were posted by US-based companies, followed by companies in China (19%), South Korea (11%), and India (7%; UNCTAD, 1998). It is interesting to note that the US accounted for 74% of the global Internet commerce market in 1998 (Wang, 1999).

Figure 1. UNCTAD GTPN



Password-restricted areas have been added to the GTPNet site, which uses state-of-the-art tools for uploading, downloading, automatic updating, and searching for information. Only trade points and members of trade points can send ETOs and see hot ETOs[3]. Java is used to control access, certify trading partners, and handle payments. The Java-based secure infrastructure ensures integrity and confidentiality of all trade information. Certification is the first step in secure trading. Prospective traders download the UNTPDC's 100%-pure Java-based applet and use it to provide the UN with reference data about their banking, trading, and services. After the UN certifies it, the company uses the Java applet residing in their standard Internet browser to access the network. Similarly, the smart-card project of the UNCTAD is facilitating the payment flow in international trade. As discussed in the next section, the first- and second-level smart cards allow secure ETO, confidentiality, payment information integrity, authentication, and so forth.

The Secure Electronic Authentication Link (SEAL) project and concept were developed by the United Nations Trade Point Development Center. Its smart-card project facilitates payment flows in international trade. The first-level smart card allows users to automatically authenticate their user profile to the SEAL and secure ETO on the GTPNet. The second-level smart card allows confidentiality of information, payment information integrity, cardholder account authentication, merchant authentication, and interoperability with the ETO system on the Internet and the GTPNet.

Most of the trade points are, however, located in big cities, and many least developed countries are still deprived of the services of trade points. GTPNet sites are also vast and not well organized (Lehrer, 2003). A recent international forum on ways to improve the trade point programs for SMEs came up with many suggestions[4] including the necessity of encouraging and assisting nonexporting companies, possibly by even creating special e-commerce programs open to new exporters only; providing guidance for the management; providing translation services so that import-export business can be conducted in multiple languages; and providing convenient online payment mechanisms.

LINCOS: Little Intelligent Communities (http://www.lincos.net/)

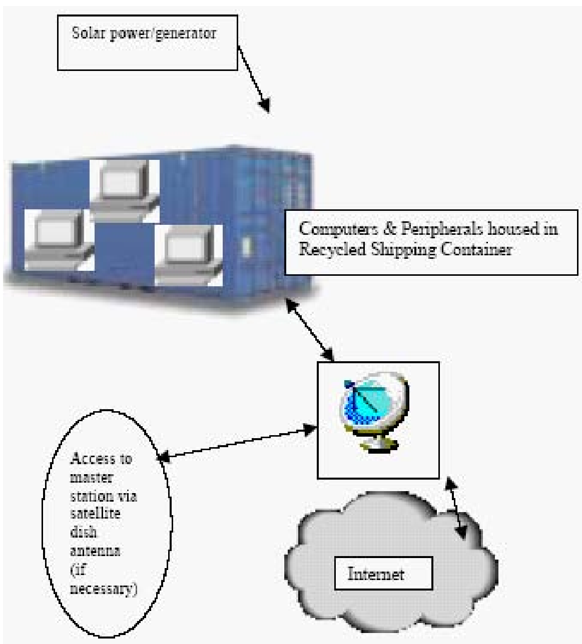
The LINCOS initiative was developed jointly by the Fundación Costa Rica para el Desarrollo Sostenible, the Media Lab at MIT, and the Instituto Tecnológico de Costa Rica in 1998 (Saxe et al., 2000). LINCOS selected Hewlett Packard's E-inclusion as the model. It has alliances with over 10 academic institutions and at least 10 technology companies (United Nations, 2000). Initially, LINCOS used recycled shipping containers to house computers, peripherals, and generators. Each unit comprised of five computers and other facilities to provide a broad range of services including Internet access; health, education, banking, and government services; electronic trading; technical support for SMEs; telecom and information centers; video conferencing and entertainment; forest, soil, and water analysis; and so forth. The ultimate goal of the project is to achieve sustainability by allowing each community within the network to make decisions related to the technologies and advance them independently[5].

Each unit is satellite operated and solar-power enabled, and can operate independently of traditional infrastructures. The satellite dish antennae link them to any telecom network or master station as needed. Eggers and Siefken (2000) comment on LINCOS' performance:

LINCOS units can be taken anywhere—mountain, jungle or village—and make web-browsing, telephony and e-mail available even in the most remote spot. Equipped with their own generators, these units need neither external energy nor communication cables; they connect directly via satellite.

The units are installed in a container equipped with five computers. Additional LINCOS units are to be provided if more computers need to be added. The investment for each unit was as high as $85,000 in the Dominican Republic and $50,000 in San Marcos de Terazu, Costa Rica (Proenza, 2001), but is expected to decrease with the

Figure 2. LINCOS network



increase in production (United Nations, 2000). In 2000, LINCOS won ALCATEL's first place prize for technological innovation in Latin America. Over 30 projects in Latin America participated in the competition[6].

The prototype LINCOS sites, which have already been deployed in Costa Rica, are providing several benefits. For instance, coffee growers use LINCOS sites to find the best prices in the world as well as next week's weather. Thanks to LINCOS' assistance, Costa Rican coffee farmers have also created Web pages and learned how to request budgets for buying equipment and register their trademarks (Amighetti & Reader, 2003).

While a container has had obvious advantages for carrying the equipment to remote communities, the "container concept" was later abandoned because it created the concept of "temporariness"; the target users did not regard it as "rooted in the community" and tended to develop the feeling that the project was brought to the community in a "top-down" manner as a wrapped-up "development package"[7]. A second drawback of LINCOS is that it has attracted relatively rich people instead of helping the poor (Amighetti & Reader, 2003). According to the World Bank's Charles Kenny, LINCOS have had mixed results because of the lack of sufficient interest of the target audience. He argues: "Poor people don't seem to think that the Internet is the answer to all their problems" (Rich, 2003, p. 93).

POLICY IMPLICATIONS: LOCAL, NATIONAL, AND GLOBAL

Rapidly dropping costs of ICTs, developments of user-friendly software and interfaces, and the versatility of the Internet offer the potential for leapfrogging many of the development obstacles. Civil society, governments, and entrepreneurs of developing countries can take actions to bridge the digital divide by targeting highly excluded communities by designing an appropriate combination of new and old technologies, and by setting projects in the context of a longer term plan to extend the benefits more widely.

Although the networks discussed in this article are helping to bridge the digital divide between the developing and developed countries to some extent, most of them are not yet able to reach really excluded populations in developing countries. For instance, mainly rich people are benefiting from LINCOS. Similarly, there are no trade point programs in small villages of developing countries.

There is a huge untapped market for modern ICTs in developing countries if the services are *affordable* and *appropriate* to the target population, and e-business companies need not provide their services in philanthropic ways. Lyle Hurst, director of HP's E-inclusion, a partner of LINCOS, said in 2002 that the mobile digital community centers will be a significant market opportunity for all involved. To exploit the potential, comprehensive research on the needs of the digitally excluded population, and on the most appropriate networks to satisfy such needs by using locally available expertise and resources is needed.

The experiences of LINCOS and GTPNet indicate that lack of awareness and interest with the target audience are the major drawbacks of the networks discussed in this article. National governments, international agencies, and technology marketers are required to work together to educate the target users about the potential benefits of such networks.

Equally important, perhaps, is what Rossman (2004) refers to as the "fluency divide"—the disparity between privileged and unprivileged groups in terms of their capability of finding and applying information to achieve their goals. While it is important to bridge the digital divide of unequal access to devices, equipment, and contents, policy makers are also required to work on bridging the fluency divide between those passively consuming information and those that have the motivation and skills to find and apply information to achieve their goals.

KEY TERMS

Digital Divide: The fact that people in developing countries use modern ICTs less than those in developed countries.

Gross Domestic Product (GDP): The sum of the total value of consumption expenditure, total value of investment expenditure, and government purchases of goods and services.

High-Income Countries: Have a per capita income of $9,266 or more (in 2001).

Information and Communications Technologies (ICTs): Technologies that facilitate the capturing, processing, storage, and transfer of information.

Internet: The "global information system that (i) is logically linked together by a globally unique address space based on the Internet Protocol (IP) or its subsequent extensions/follow-ons; (ii) is able to support communications using the Transmission Control Protocol/Internet Protocol (TCP/IP) suite or its subsequent extensions/follow-ons, and/or other IP-compatible protocols; and (iii) provides, uses or makes accessible, either publicly or privately, high level services layered on the communications and related infrastructure described herein" (The Federal Networking Council definition).

Low-Income Countries: Have a per capita income of less than $875 (in 2001).

PPP (Purchasing Power Parity): A rate of exchange that accounts for price differences across countries, allowing international comparisons of real output and incomes.

Functional Dependency and Other Related Dependencies

Robert A. Schultz
Woodbury University, USA

INTRODUCTION

The invention and rise of the relational database starting in the 1960s was accompanied by the remarkable development of canonical design techniques, making it possible to avoid many database designs with unintended bad consequences (Codd, 1970, 1971). These techniques, called "normal forms," prevent the occurrence of what are called "anomalies." If a database design contains an anomaly, the implemented database will behave in unintended ways. If there is a deletion anomaly, data will unexpectedly disappear; an insertion anomaly will produce difficulties in adding data; and a modification anomaly will result in extra and unexpected operations in the course of changing data in the database (Kroenke, 2002).

In a relational database, data is organized into tables; tables are composed of records; and records are made up of fields (or data items or attributes). One or more fields or data items, called keys, are used to locate records and the remaining data items in them. A primary key uniquely identifies each record. If more than one field is needed to guarantee unique identification, the primary key is called a concatenated key or composite key. When more than one combination of data items or fields could serve as a primary key, the keys not actively used are called candidate keys.

The following (partial) table contains potential examples of all three anomalies:

- *Deletion anomaly*: If all the instructors who teach a given course are deleted, we will lose information about the course name.
- *Insertion anomaly*: We cannot input information about a course or register a student for the course unless we have an instructor for the course.
- *Modification anomaly*: In order to change the name of a course, we have to go through the records of all the instructors in the table and change the name there.

Intuitively, it is somewhat obvious that Instructor is the wrong field to choose as a key for finding information about classes. The advantage of the normal forms is that they provide a standard procedure for finding a database design that avoids the anomalies.

BACKGROUND

The normal forms are almost all defined in terms of the concept of dependency, and, in particular, the concept of functional dependency. Dependency in almost all cases is between data items (equivalently, fields or attributes); intuitively, one attribute A is functionally dependent on another attribute B if one needs to know the value of B in order to determine the value of A.

These are the most commonly found normal forms:

- **First Normal Form (1NF):** The table designs must have no repeating groups. That is, there are no fields with more than one distinct value within the same record. This normal form is automatically satisfied if a relational database is used, because data must be entered in a table with single values for each field. Primary Key 2 is an example if we were allowed to enter multiple values in a field.

To put this table into First Normal Form, we have to create a second table containing the repeating group and the original key. The two tables are as follows (with primary key underlined):

Course(<u>CourseID</u>,CourseName,Instructor,Rank) and
Course Student<u>(CourseID,StudentID,</u>StudentName,Grade)

(Primary Key 1)

Instructor	InstructorRank	CourseNumber	CourseName	StudentName	Grade
Dr. Wilson	Assistant Prof.	CI 110	Computer Apps	Rod Hudson	C
Mrs. Day	Associate Prof	EN 111	Freshman Comp	Alice Adams	B

(Primary Key 2)

CourseID	**CourseName**	**Instructor**	**Rank**	**Student ID**	**StudentName**	**Grade**
CI110.F03.sec1	Computer Apps	Dr. Wilson	Asst Prof	555-44-3323 430-22-1123 554-55-6689 5454-92-5587	Rod Hudson, Joan Crawford, Andy Bierce, Luigi Nono	A B A C
EN111.S04.sec 3	Freshman Comp	Mrs. Day	Full Prof	490-40-2221 554-55-6689	Alice Adams, Andy Bierce	D B

- **Second Normal Form (2NF):** The table designs are in 1NF, and there are no partial functional dependencies, that is, functional dependencies on part of a primary key.

In the example above, **StudentName** in the second table Course-Student is functionally dependent only on **StudentID**. So, it is a violation of Second Normal Form. We convert this table to 2NF by creating a new table with the partially dependent fields and the key they were partially dependent on. Now we have the following:

Course(CourseID,CourseName,Instructor,Rank)
Course-Student(CourseID,StudentID,Grade)
Student(StudentID,StudentName)

- **Third Normal Form (3NF):** The table designs are in 2NF, and there are no nonkey functional dependencies, that is, no functional dependencies on data items that are not keys.

Continuing the example, in the Course table, **Rank** is functionally dependent on **Instructor**, which is not a key. To produce 3NF, we remove the functionally dependent field(s) to another table and include the original nonkey field as a key. So, we get the following:

Instructor(Instructor,Rank)
Course(CourseID,CourseName,Instructor)
Course-Student(CourseID,StudentID,Grade)
Student(StudentID,StudentName)

- **Boyce–Codd Normal Form (BCNF):** The definition of BCNF is that the table designs are in 3NF and continue to remain so for all candidate keys.

Examples grow more complex for the remaining normal forms. It is not too hard to construct an example of BCNF. If we add fields to the Student table, say, which could also serve as primary keys such as **DriversLicense** or **CreditCardInfo,** then if one of these fields were made key, the Student table would no longer be in 3NF, because **StudentName** would now be dependent on a nonkey field. Basically, the result would be to once again remove **StudentName** to a separate table dependent only on **StudentID**, and to leave all the candidate keys by themselves in a separate table.

- **Fourth Normal Form (4NF):** The table designs are in BCNF, and there are no multivalued dependencies.

- **Fifth Normal Form (5NF):** The table designs are in 4NF, and there are no join dependencies.

- **Domain Key/Normal Form (DK/NF):** All constraints on values can be derived from domain and key dependencies.

As you will note, Second and Third Normal Forms explicitly mention functional dependencies, and the Boyce–Codd Normal Form extends the application of the Third Normal Form to other choices of primary key. Fourth Normal Form uses a more complex kind of dependency defined in terms of functional dependency. The remaining two, Fifth Normal Form and Domain Key Normal Form, introduce somewhat different kinds of dependencies. The last two Normal Forms are not often met with in practice. Near the end, I will comment on the different forms of dependency these Normal Forms employ. For the commonly employed Normal Forms, functional dependency is the key concept.

UNDERSTANDING FUNCTIONAL DEPENDENCY

There are two different ways of defining functional dependency: an intuitive intensional way and a precise extensional way. Intensional definitions use psychological or meaning elements involving dependencies in knowledge—for example, we need to know customer name in order to know customer address. Extensional definitions are based solely on differences in the way data appear in the table—notably, patterns of repetition of field values (Lewis & Langford, 1959).

Thus, intension has to do with the meanings of the terms involved, and extension with what objects are denoted by or referred to by the terms. In general, if two terms have the same intension or meaning, they have the same extension, but two terms can have the same extension but different meanings or intensions (Frege, 1892; Geach & Black, 1952). Intensions are difficult to use in mathematical or scientific or technical contexts, because we do not have clear criteria for the identity of intensions. But, in fact, functional dependency (and the normal forms using it) can be defined extensionally (Martin, 1983):

Data item B of record R is functionally dependent on data item A of record R if, at every instant of time, each value in A has no more than one value of B associated with it in record R.

All one needs to do is examine the pattern of repetitions in the record. If there are multiple values of *B* for one value of *A* in a record at any time, then, according to Martin's definition, *B* is not functionally dependent on *A*.

Many authors use intentional elements in their definitions. For example, Kroenke (2002), in his *Database Processing,* explicitly defines functional dependency using intensional terms:

…attribute Y is functionally dependent on attribute X if the value of X determines the value of Y. Stated differently, if we know the value of X, we can obtain the value of Y.

However, intensional elements may be almost indispensable shortcuts. If we actually had available all the data elements in a database, there would be no question about using extensional methods. But when the full (extensional) database is not available, we may need to turn to intensional elements to determine functional dependency and, hence, database design (Schultz, 2002).

OTHER DEPENDENCIES

Finally, there remain the "higher" normal forms, that is, Boyce–Codd Normal Form, 4th Normal Form, 5th Normal Form, and Domain Key Normal Form.

For Boyce–Codd Normal Form, we need to check whether every field on which other fields are functionally dependent is potentially a key (that is, has unique values for each record) and then check functional dependencies on these candidate keys. There are no new implications about dependency or functional dependency.

Fourth Normal Form adds the concept of multivalued dependency. One definition is as follows:

In a table R with columns A, B, and C, B is multivalued dependent on A if there is more than one value of B for a single value of A.

If *C* is also multivalued dependent on *A*, anomalies arise (mainly update anomalies). A set of tables is in Fourth Normal Form if there are no multivalued dependencies present. Thus, multivalued dependency is also clearly an extensional matter, having to do with whether or not there are certain repetitions of values in a table. So even though multivalued dependency is different from functional dependency, it can be treated in a similar way (Kroenke, 2002).

Typically, one encounters multivalued dependency when two independent attributes depend on the same attribute in the same table. Please see the table below.

This situation produces a modification anomaly. If Joan Crawford switches her major to Theater, we need to update at least three rows to reflect her activities. If she becomes a double English and Theater major, we need to add three rows. This cannot be done automatically by the database—special efforts or programming would be required.

A better solution would be to put the table into 4NF by splitting the two independent attributes into two tables, each with the original key:

Student-Major(<u>StudentName</u>,Major)
Student-AthleticActivity(<u>StudentName,</u> AthlActiv)

StudentName	Major	AthlActiv
Rod Hudson	IT	Weight room
Joan Crawford	English	Weight room
Joan Crawford	English	Tennis
Joan Crawford	English	Swimming

Fifth Normal Form uses the concept of join dependency rather than functional dependency. Join dependency states that any decomposition of tables must be able to be rejoined to recover the original table. Tables in 5NF are join dependent. Failure to achieve 5NF is normally uncovered when data are added to the decomposed tables. Then it is discovered that the rejoined tables contain spurious data. It seems more likely that intensional considerations will help with 5NF than the other normal forms, because join dependency cannot be determined by simply looking at the data. It is not clear whether anything other than an iterative trial and error procedure is possible for detecting join dependency. These considerations are extensional, because they depend only upon patterns of field values in joined and unjoined tables. But that does not make the process of determining Fifth Normal Form any easier (Kroenke, 2002).

There is some question whether 5NF is actually desirable in all circumstances. Examples are also a bit more complex than for the preceding normal forms, so I will refer the interested reader to C. J. Date's treatment (1994).

Domain key normal form (DK/NF) is different. If a database is in DK/NF, it is provable that no anomalies can occur. Whereas the other normal forms (First, Second, Third, Boyce–Codd, Fourth, and Fifth) were designed to avoid certain anomalies, and there is no guarantee that some further anomaly may pop up that is not prevented by these normal forms. Unfortunately, there is no effective procedure for putting a set of tables into DK/NF (Fagin, 1981; Quine, 1966). As David Kroenke (2002) put it, "Finding, or designing, DK/NF relations is more of an art than a science." Although the theoretical claims for DK/NF are probably unassailable, the practical difficulties in achieving DK/NF can probably not be ameliorated (Schultz, 2003).

Again, the complexity of DK/NF examples requires us to refer the interested reader to the sources mentioned in the last paragraph.

CONCLUSION

Database normalization is an accepted part of database design and will continue to be, through whatever enhancements are brought about by integration of more traditional design methods into object-oriented technology and other new technologies. Because functional dependency is a critical part of database normalization, it will continue to be necessary for system designers to be familiar with the concept.

KEY TERMS

Anomalies: These are unwanted consequences of inadequate database design. Data can be unintentionally lost or be more difficult to add or modify than the designer intended.

Dependencies: These are relations between data items or fields, or, occasionally, tables. Detecting dependencies is the key to putting tables in the various normal forms and, hence, is the key to avoiding anomalies.

Domain Key/Normal Form (DK/NF): Rather than functional dependencies, DK/NF is based on domain dependencies and key dependencies only. Although it is provable that a set of tables in DK/NF avoids all anomalies, it is also provable that there is no procedure for producing this normal form.

Functional Dependencies: Intuitively, one attribute is functionally dependent on a second attribute when you need to know the value of the second in order to find out the value of the first. More precisely, each value of the second attribute has no more than one value of the first associated with it.

Join Dependency: Any decomposition of tables must be able to be rejoined to recover the original table. Tables in 5NF are join dependent.

Key: This is a data item or field used to locate records in a table. A *primary key* uniquely identifies each record. If more than one field is needed to guarantee unique identification, the primary key is called a *concatenated key* or *composite key*. When more than one combination of data items or fields could serve as a primary key, the keys not actively used are called *candidate keys*.

Multivalued Dependencies: These are relations between three attributes. In a table *R* with columns *A*, *B*, and *C*, *B* is multivalued dependent on *A* if there is more than one value of *B* for a single value of *A*. Multivalued dependences must be eliminated to produce Fourth Normal Form.

Normal Forms: These are canonical patterns for table design that enable designers to avoid anomalies. Occasionally, tables are "denormalized" to improve database performance.

Relational Database: Database management system (DBMS) type in which relations between tables are implemented only by means of connections in the data, rather than hard-coded in the database. Its main advantages are flexibility and maintainability. Current popular examples include Oracle and SQL Server. Increased system performance made it the preferred DBMS starting in the 1990s.

Relational Database Structure: Information is organized into *tables*; tables are composed of *records*; and records are made up of *fields* (also known as *data items* or *attributes*).

Functional Integration of Decision Making Support

Guisseppi A. Forgionne
University of Maryland Baltimore County, USA

INTRODUCTION

Because of the importance to individual, group, and organizational success, information systems research has examined ways to improve support for decision making for the last three decades. The research has generated a variety of information systems to provide the necessary support. In the process, there has been an evolution from simple data access and reporting to complex analytical, creative, and artificially intelligent support for decision making (Holsapple & Whinston, 1996).

Various information systems have evolved to support the decision-making process. By studying the systems' characteristics, advantages, and disadvantages, researchers and practitioners can better design, develop, and implement robust decision-making support systems (Forgionne & Kohli, 1995; Kumar, 1999). This article facilitates such study by presenting and illustrating the underlying information system architectures for robust decision-making support.

BACKGROUND

Several frameworks have been developed to describe the human decision-making process. The most popular is Simon's three-phase paradigm of intelligence, design, and choice (Simon, 1960). This paradigm seems to be the most general, implying virtually all other proposed frameworks, and the Simon paradigm appears to have best withstood empirical testing (Borenstein, 1998; Martinsons, Davison & Tse, 1999). Such scrutiny, however, has suggested the expansion of the basic formulation to conclude with an implementation phase.

During the intelligence phase, the decision maker observes reality, gains a fundamental understanding of existing problems or new opportunities, and acquires the general quantitative and qualitative information needed to address the problems or opportunities. In the design phase, the decision maker develops a specific and precise model that can be used to systematically examine the discovered problem or opportunity. This model will consist of decision alternatives, uncontrollable events, criteria, and the symbolic or numerical relationships between these variables. Using the explicit models to logically evaluate the specified alternatives and to generate recommended actions constitutes the ensuing choice phase. During the subsequent implementation phase, the decision maker ponders the analyses and recommendations, weighs the consequences, gains sufficient confidence in the decision, develops an implementation plan, secures needed financial, human, and material resources, and puts the plan into action.

A variety of individual information systems have been offered to support during the phases and steps of the decision-making process (Mirchandi & Pakath, 1999; Sauter, 1997). Much can be learned about this support by examining the support offered by the individual systems.

ISSUES, CONTROVERSIES, AND PROBLEMS

Decision-making support has evolved over time and across disciplines (Mirchandani & Pakath, 1999). Initial support was offered by a decision support system (DSS). In the typical DSS, the decision maker utilizes computer technology to: (a) organize the data into problem parameters, (b) attach the parameters to a model, (c) use the model to simulate (experiment with) alternatives and events, and/or (d) find the best solution to the problem. Results are reported as parameter conditions (status reports), experimental forecasts, and/or recommended actions. Feedback from the user-controlled processing guides the decision maker to a problem solution, and created information and knowledge are stored as additional inputs for future or further processing.

The DSS concept presumes that the problem pertinent data and models have been created and made available to the system prior to user processing (Hooghiemstra, Kroon, Odijk, Salomon & Zwaneveld, 1999). It also assumes that the user can utilize the computer technology to perform the technical processing operations and computations required by the system (Lawrence & Sim, 1999). In fact, DSS users rarely have the technical skill to recognize, capture, and process pertinent data and models or to interpret the results of the models' processing within the problem context (Raghunathan, 1999). In short, the DSS concept offers little direct support for the intelligence, early design, and implementation phases of decision making.

To be useful for decision making, problem pertinent data must be identified, located, captured, stored, accessed, and interpreted (Seely & Targett, 1999). Data warehousing can be used to facilitate access and reporting, while data mining can help with the interpretation function. An executive information system (EIS) can deliver these data access, reporting, and interpretation functions to the decision maker in an intuitive and appealing manner.

In a typical EIS, the decision maker utilizes computer technology to: (a) organize the data into specified broad categories, (b) view (slice and dice) the data from interesting perspectives, (c) generate "warnings" for the decision maker by scanning current trends, and (d) mine the data for less obvious relationships. Results are reported as category summaries (status reports), sliced and diced details (drill down reports), and/or suggested problem parameters (events). Feedback from the user-controlled processing guides the decision maker to a general problem understanding, and the created parameters are stored as additional inputs for future or further processing.

The user should exit EIS processing with a general understanding of the problem or opportunity and with relevant problem information (such as general objectives, range of decision alternatives, and range of pertinent events). Additional decision analysis beyond EIS processing will be required to explicitly formulate the problem and complete the decision-making process. Put another way, an EIS directly supports only the intelligence phase of decision making.

Technical and domain expertise will be needed to recognize, formulate, and solve most complex and significant decision problems or opportunities. Although such expertise will be available within, and outside, an organization, the expertise may be difficult, costly, and time-consuming to locate, access, and utilize. The corresponding knowledge, however, can be acquired and embedded within a Knowledge Based System (KBS), and the system can be used to capture, store, and deliver the expertise to the decision maker (Ayyub, 2001). A typical KBS captures and stores as inputs problem pertinent knowledge, either from experts, cases, or other sources, and the models (inference engine or reasoning mechanisms) needed to draw problem solution inferences from the knowledge. In other words, a KBS directly supports some of the design and most of the choice phases of decision making. Specifically, a KBS facilitates problem structuring and the evaluation and selection of alternatives.

Since decision making is a sequential and continuous process, learning will be essential to the successful completion of the process. Users will learn from their interactions with a KBS (or other individual decision-making support system) and, in the process, gain skills that can be applied to future decision-making tasks. Applying learning to the solution of the current problem, however, often will require system support (Steiger, 1998). Machine learning systems (MLS) can provide such support by mimicking the learning processes of physical systems. In a typical MLS, the decision maker utilizes computer technology to: (a) organize the problem data, (b) structure (operationalize) the learning model, and (c) simulate learning. Results are reported as problem conditions (status reports), forecasted problem outcomes, and/or and an explanation of the learning logic.

Besides learning, creativity often is needed to successfully complete the decision-making process (Keys, 2000). While the previous systems free decision makers to

Table 1. Individual decision-making support systems

System	Type	Support
Decision Support System (DSS)	Individual	Specifying relationships between criteria, alternatives, and events; choice
Executive Information System (EIS)	Individual	Intelligence; developing decision criteria; identifying relevant uncontrollable events
Knowledge-Based System (KBS)	Individual	Develop decision alternatives; choice
Machine Learning System (MLS)	Individual	Logically evaluate decision alternatives
Creativity Enhancing System (CES)	Individual	Design; develop an implementation plan; put implementation plan into action

Table 2. Integrated decision-making support systems

System	Type	Support
Intelligent Decision Support System (IDSS)	Integrates the functions of DSS and KBS (and/or MLS)	Developing decision alternatives; specifying relationships between criteria, alternatives, and events; choice
Executive Support System (ESS)	Integrates the functions of DSS and EIS	Intelligence; developing decision criteria; identifying relevant uncontrollable events; specifying relationships between criteria, alternatives, and events; choice
Whole-Brained Decision Support System (WDSS) and Group Decision Support System (GDSS)	Integrate the functions of DSS and CES	Gain problem/opportunity understanding; design; choice
Management Support System (MSS)	Integrates the functions of DSS, EIS, and KBS (and/or MLS)	Intelligence; design; choice

concentrate on the creative aspects of decision making, they do not provide direct support for the creative process (Savransky, 2001). Since decision makers may not be inherently creative, support for creativity can considerably enhance their decision-making process. A creativity enhancing system (CES) offers such support (Forgionne, Clements & Newman, 1995). In a typical CES, the decision maker utilizes computer technology to: (a) organize (chiefly categorize and classify) the problem ideas and concepts, (b) structure ideas and concepts into problem elements and relationships, and (c) simulate conceptual problem solutions. Results are reported as problem elements (status reports), the problem's conceptual structure (criteria, alternatives, events, and relationships), and/or forecasted outcomes from the conceptual analyses.

The major individual systems, and their primary and direct support, are summarized in Table 1. An examination of this table shows that none of the individual systems offer complete and integrated support for all phases and steps of the decision-making process.

SOLUTIONS AND RECOMMENDATIONS

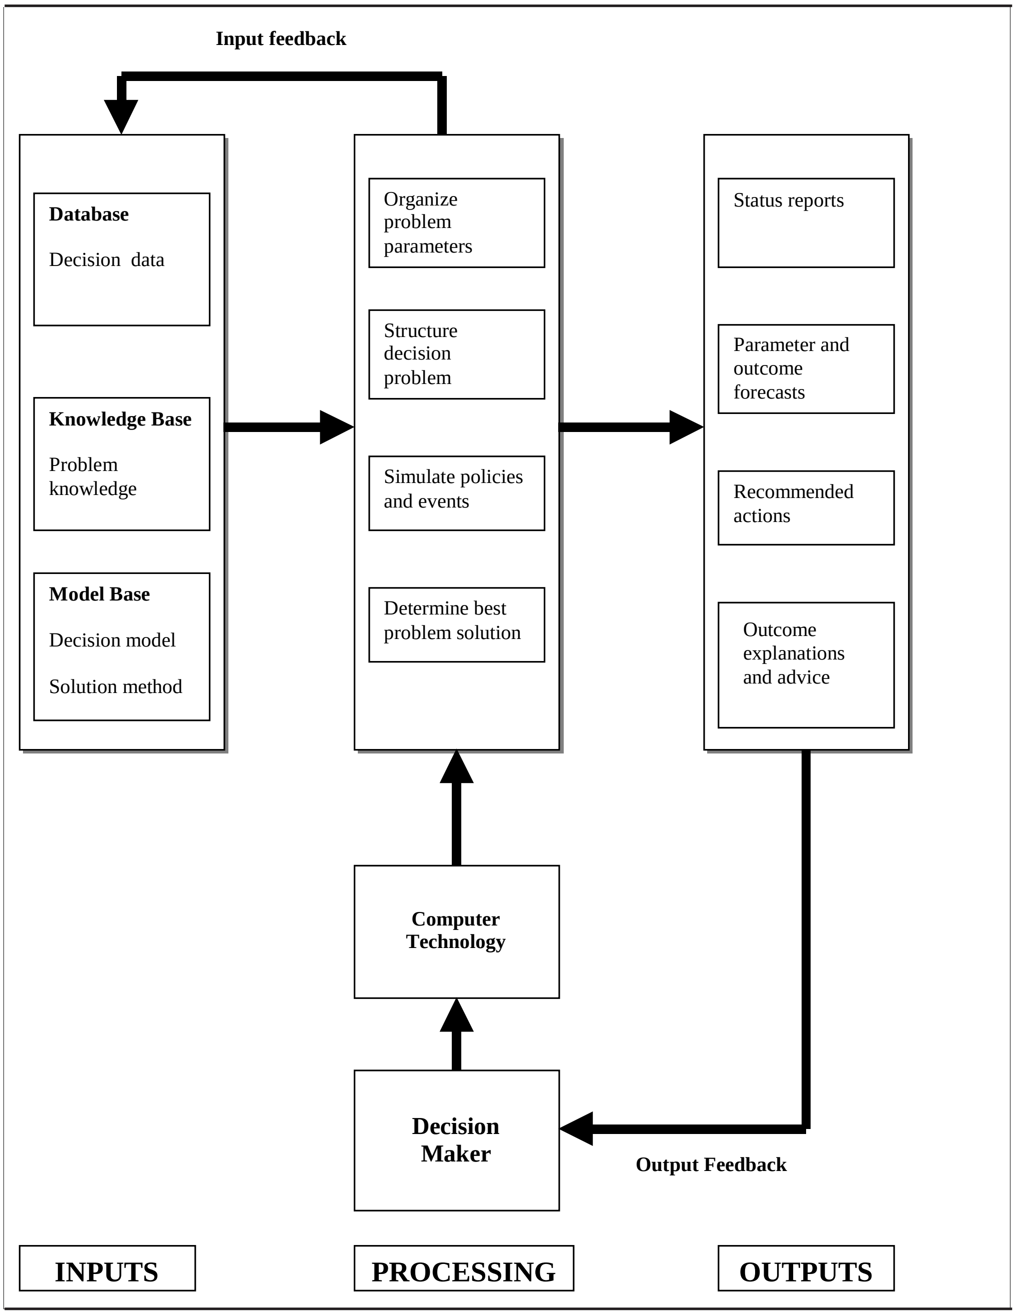
The need for complete and integrated decision-making support has encouraged researchers to seek the synergistic effects that can be achieved by combining the functionalities of the individual systems. The result has been the development of the various integrated systems for decision-making support summarized in Table 2.

As Table 2 indicates, each integrated system, such as an ESS or MSS, integrates the functionality of particular individual systems to provide decision-making support. While the integrated functionality has created more complete and unified decision-making support, the suggested synergies still leave significant gaps in decision-making support. For example, an IDSS still leaves gaps in design support, while an MSS does not provide creativity support. With even more system choices available than previously, the decision maker, and/or staff, are forced to match the relevant functionality with his/her/their decision-making support needs. Decision makers, and/or staff, may be ill equipped to make these selections and design, build, and implement the desired system.

An alternative strategy is to create one decision-making support system that synthesizes the main features and functions for the various decision-making support systems. The decision technology system (DTS), which is presented in Figure 1, has been proposed to support this alternative strategy. As Figure 1 illustrates, a DTS has a database, knowledge base, and model base. The database contains the data directly relevant to the decision problem, including the values for the uncontrollable events, decision alternatives, and decision criteria. The knowledge base holds problem knowledge, such as formulas for converting available data into the problem's parameters, guidance for selecting decision alternatives and problem relationships, or advice in interpreting possible outcomes. The model base is a repository for the formal (tabular, graphic, conceptual, or mathematical) models of the decision problem and the methodology for developing results (simulations and solutions) from the formal models.

Decision makers utilize computer technology (hardware and software) to process the inputs into problem-relevant outputs. Processing will involve:

Figure 1. Decision technology system (DTS)



(a) organizing problem parameters – accessing the database, extracting the decision data, and organizing the information in the form needed by the solution model and methodology;

(b) structuring the decision problem – accessing the model base, retrieving the appropriate decision model, and operationalizing (attaching organized parameters to) the decision model;

(c) simulating policies and events – using the operationalized decision model to perform the computations needed to simulate outcomes from user-specified alternatives and then identifying the alternative (or alternatives) that best meets the decision criterion (or criteria) among those tested;

(d) finding the best problem solution – accessing the model base, retrieving the appropriate solution method, and using the retrieved method to systematically determine the alternative (or alternatives), among all possible alternatives, that best meets the decision criterion (or criteria).

The DTS can use problem ideas, concepts, and knowledge drawn from the knowledge base to assist users in performing these processing tasks.

Processing will generate status reports, forecasts, recommendations, and explanations. The status reports will identify relevant uncontrollable events, decision alternatives, and decision criteria and show the current values for these problem elements. Forecasts will report the events and alternatives specified in the simulations and the resulting projected values of the decision criteria. The recommendations will suggest the values for the decision alternatives that best meet the decision criteria, and the corresponding criteria values, under current and forecasted values for the uncontrollable events. Explanations will justify the recommendations and offer advice on further processing. Such advice may include suggestions on interpreting the output and guidance for examining additional scenarios.

Input feedback from the processing provides additional data, knowledge, and models that may be useful for future decision making. Output feedback (which can include outcomes, cognitive information, task models, and what-if, goal-seeking, and other types of sensitivity analyses) is used to extend or modify the original analyses and evaluations (Sengupta & Abdel-Hamid, 1993).

Figure 1's general DTS architecture can support all phases of the decision-making process in a complete, integrated, and continuous manner. Critical problem data can be captured in a DTS database, and the system can be used to organize this captured information, generate timely focused reports, and project trends. Such processing helps the decision maker to quickly monitor the decision environment, set objectives, and evaluate the processed information for opportunities or problems, thereby supporting the intelligence phase of decision making.

The DTS, augmented by the managers' (or perhaps staff's) insights and judgments, can be used to process captured constructions and frameworks into criteria, events, and alternatives needed to formulate a model of the decision problem. Additional processing with the captured statistical methodologies can estimate the parameters required to operationalize the formulated decision problem model, thereby supporting the design phase of decision making. The formulated models, again augmented by the managers' insights and judgments, are used to evaluate alternatives in a systematic and analytic fashion and to recommend alternatives, thereby supporting the choice phase of decision making.

Decision technology systems (DTS) can provide the analyses in vivid detail with tables, graphs, and other supporting material. Such supporting material will increase the decision maker's confidence in the recommendations, improve the decision maker's perception of support system effectiveness, and enable the decision maker to better explain, justify, and communicate the decisions during implementation, thereby supporting the implementation phase of decision making.

Along with the original analyses and evaluations, DTS feedback loops increase the users' confidence in the recommendations and enable the decision maker to better explain, justify, and communicate the decisions during implementation. The loops also support decision making in a continuous and dynamic manner (Forgionne, 1999, 2000).

FUTURE TRENDS

Realizing the DTS promise presents significant technical and management challenges. Problem pertinent data, models, and knowledge must be identified, located, retrieved, and captured (Balasubramanian, Nochur, Henderson & Kwan, 1999). Intelligent data warehousing and mining can support the data retrieval tasks, and it may be possible to adapt these methodologies for model and knowledge retrieval support. Differences in data, knowledge, and model structures, however, may necessitate the development of new methodologies for knowledge and model retrieval tasks.

Also, it will be challenging to collect and deliver the tools and to manage the design, development, and implementation effort. Agents and object-oriented methods can be used to capture the tools and make them available for system operation (Siskos & Spyridakos, (1999). The resulting system, however, will profoundly challenge the nature of the decision maker's work as well as altering the structure of the organization. By providing complete and integrated decision-making support, a DTS will enable the decision maker to perform technical tasks previously outsourced to specialists. The result may be an organization with fewer hierarchical levels and smaller staff.

CONCLUSION

Over the years, support for decision making has taken a variety of forms. As the forms have evolved, decision-making support has become more comprehensive and integrated. Today, there are many system choices available, and matching the appropriate system to the particular problem or opportunity has created a new task for management.

The evolution has illustrated the synergistic value that can be achieved through higher levels of functional integration. This article has presented a concept, the DTS, which can offer a mechanism to consolidate the advances and promote a revolution in management. The proposed system has also created significant research opportunities – determining the best integration strategy, identifying the best design and development tools to achieve the strategy, and examining the impact of integrated decision support on management, decision making, and organizational structure, among others. It also clarifies the needs to: (a) have effective and efficient information reporting and communication systems in place and (b) to integrate the decision-making support systems with information reporting and communication systems.

KEY TERMS

Artificially Intelligent Systems: Information systems that help users manage data and models by delivering virtual expertise and other forms of artificial intelligence in support of these tasks.

Creativity Enhancing System: Information systems that are designed to offer creative tools that help users formulate problems and perform other creative tasks in decision making.

Decision Making Process: The process of developing a general problem understanding, formulating the problem explicitly, evaluating alternatives systematically, and implementing the choice.

Decision Support Systems: Information systems that interactively support the user's ability to evaluate decision alternatives and develop a recommended decision.

Decision Technology System: An information system that is designed to support all phases of the decision-making process in a complete and integrated manner.

Executive Information Systems: Information systems that access, report, and help users interpret problem pertinent information.

Integrated Decision-Making Support Systems: Information systems that integrate the functions of one or more individual (stand alone) decision-making support systems.

Knowledge-Based Systems: Information systems that capture and deliver problem pertinent knowledge to users.

Machine Learning System: Information systems that mimic the human learning process and deliver the knowledge to users.

F

Functionalities and Position of Manufacturing Execution Systems

Vladimír Modrák
Technical University of Košice, Slovakia

Introduction

Efforts to separate unequivocally substantial signs of versatile tools of manufacturing management are usually marked by a narrowed view of the field of their use. Similarly, it is so also in the case of specifying the functionality and position of MES (Manufacturing Execution Systems) in the hierarchy of information systems. Presentations generalising MES in this field do not always correspond with models that have a generic character. For that reason it appears useful to investigate the mentioned MES characteristics from a number of angles, and particularly in relation with the basic types of manufacturing systems.

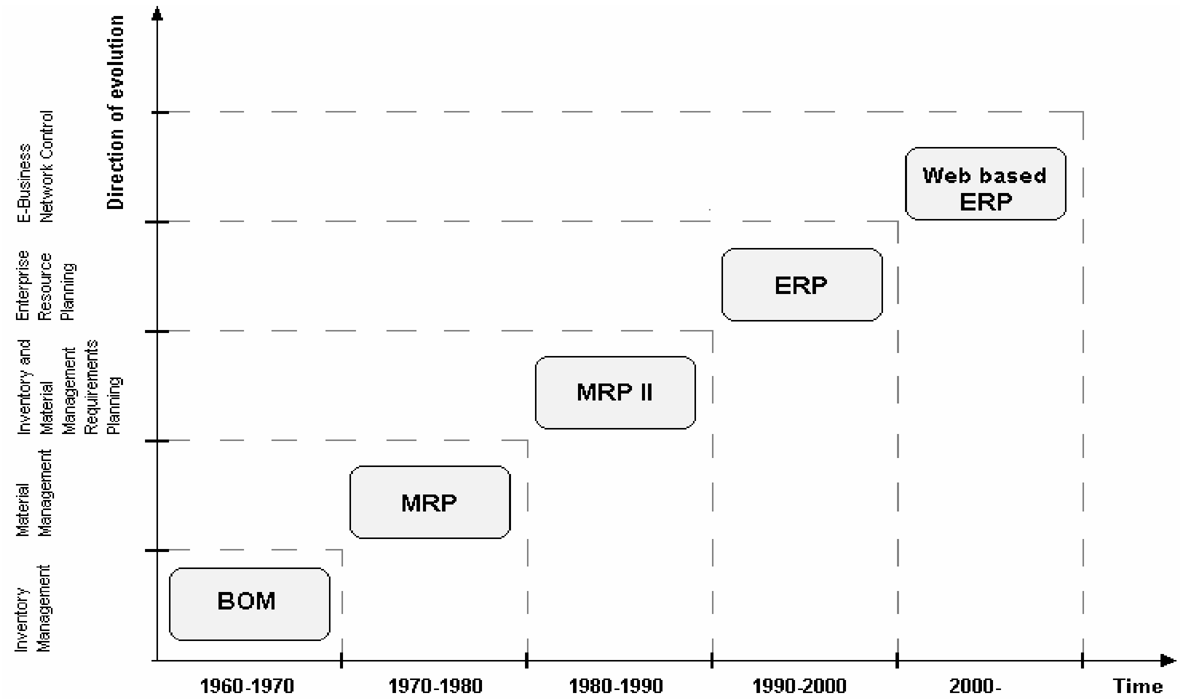
BACKGROUND OF MES EVOLUTION

From a historical point of view, the infiltration of information technology into manufacturing technology was conditioned by the development and advancement of host mainframe computing in the 1950s and '60s. It gave manufacturers the ability to capture, manipulate, and share information and automate calculation and analysis in order to support design of increasingly complex and capable products. Simultaneously in the framework of manufacturing management, an inventory control took on great importance and most of the software in the 1960s was developed for this purpose. Typically, tools called BOM (bill of materials) processors, which were used as a means to represent process plans, handled inventory control. The focus shifted in the 1970s to Material Requirement Planning (MRP) as the complexity of manufacturing operations increased. This managerial instrument enabled financial managers to both view and control their business processes much more closely. The tools to automate business processes were enhanced by adding further functionalities to meet the increased requirements. Subsequently in the 1980s, the term Manufacturing Resources Planning (MRP II) became popular. An MRP II presented extension of MRP functions to integrate all aspects of the planning and control of the personnel, materials and machines (Kimble & McLoughlin, 1995). Following, solutions that are marked by the acronym ERP (Enterprise Resource planning) were performed in the early 1990s. An ERP system can be defined as an integrated information processing system supporting various business processes such as finance, distribution, human resources and manufacturing (Choi & Kim, 2002). The newest version of ERP II has been much publicized by the Gartner Group. Fundamentally, ERP II signals a shift in traditional ERP applications from focusing on internal data gathering and management process information to partners, vendors and customers externally via the Web (Farver, 2002). The overall view on evolution of ERP systems is shown in Figure 1. Initially this concept attained a huge popularity among manufacturers, but as the scope of managed systems increased, the ERP system was not suitable for controlling activities on the shop floor level. For this purpose, new tool of manufacturing management called "Manufacturing Execution Systems" was evolved and utilized during the 1990s. There are more interpretations of MES depending on different manufacturing conditions, but the common characteristic to all is that an MES aims to provide an interface between an ERP system and shop floor controllers by supporting various "execution" activities such as scheduling, order release, quality control, and data acquisition (MESA 6, 1997).

VIEW ON MES FUNCTIONALITIES

A concept of Manufacturing Execution Systems is one of several major information systems types aimed at manufacturing companies. MES can be in simple way also defined as a "tool for manufacturing management". The functions of an MES range from operation scheduling to production genealogy, labor and maintenance management, performance analysis, and to other functions in between. There are several general models of typical MES functions that are principally divided into core and support functions. The core functions deal primarily with actual management of the work orders and the manufacturing resources. Other functional capabilities of MES may be required to cover support aspects of the manufacturing operations. According to McClellan (1997), the function parts pertaining to first group of functions include:

Figure 1: Functionality evolutions of ERP systems



- Planning system interface
- Work order Management
- Workstation management
- Material movement management
- Data collection
- Exception management
- Inventory/materials.

The same author describes support functions as open systems and simultaneously gives a picture of which other functions the MES should include:

- Maintenance management
- Time and attendance
- Statistical Process Control
- Quality assurance
- Process data/performance analysis
- Documentation/product data management
- Genealogy/product trace-ability
- Supplier management

Alike quantity of core and support functions along with some identical components are identified in other concepts (Kisiel, 2001) that are depicted in Figure 2.

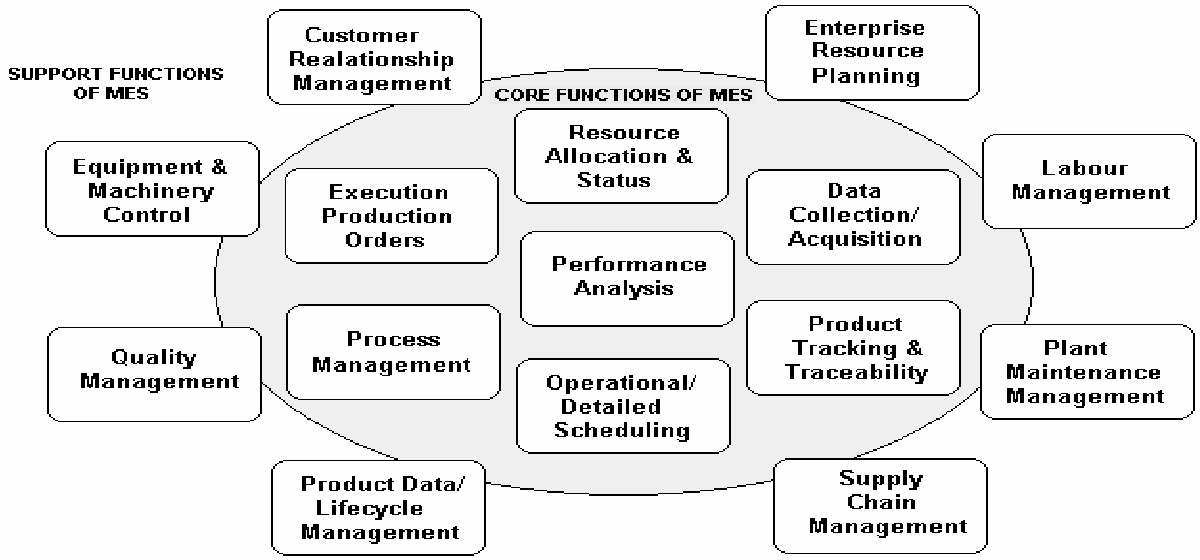
MESA International presents another attitude to MES functionalities that is more-or-less based on the assumption of profitability to begin to deal with wider model of basic elements to ensure incorporating all-important functions into MES (MESA 2,1997). Accordingly, MES would include functionalities such as:

1. Resource Allocation and Status
2. Operations/Details Scheduling
3. Dispatching production Units
4. Document Control
5. Data Collection/Acquisition
6. Labor management
7. Quality Management
8. Process Management
9. Maintenance Management
10. Product Tracking and Genealogy
11. Performance Analysis

A point of debate about MES functionalities also is connected with different types of manufacturing. Commonly, manufacturing can be divided into three types (Grover, 1987):

- Job Shop Production. The manufacturing lot sizes are small, often one of a kind.
- Batch Production. This category involves the manufacture of medium-sized lots of the same item of product. This type is called also discrete manufacturing.
- Mass Production. This is the continuous specialized manufacture of identical products.

Figure 2. A MES functionality model



Understandably, from an automation point of view a discrete manufacturing presents a much more complicated concept comprising of various technologies that are used to integrate manufacturing system to one another. One of specific models of MES functions is aimed to a typical FMS (flexible manufacturing system) consisting of numerical controlled machining centers, automated handling systems for jobs and tools, automated storage/retrieval systems, auxiliary processing facilities, and set-up stations. Choi and Kim (2002) propose a two-tier MES architecture suitable for bridging the gap between an FMS controller and ERP system. The two-tier MES consists of a main-MES in charge of main shop-floor operations and an FMS-MES in charge of FMS operations. The main MES is connected to the ERP system, and the FMS-MES is connected to the FMS controller. Then on the basis of IDEFO (Information Definition for Data Modeling), the overall structure of shop floor operations required for main-MES is grouped into the following functions:

- Customer Inquire Handling
- Received Order Handling
- Load/Process Control
- Engineering Change Orders Handling

and structure of FMS operations pertaining to FMS-MES functions include:

- Retrieve detailed machining-process plans for the jobs
- Generate FMS machining schedule and send out NC-file transfer instructions and tool preparation instructions
- Download NC files and send out set-up instructions
- Tool presetting and installation
- Perform machining operations while collecting data

Outlined structures of shop floor operations and FMS operations, present methodical approaches to specifying MES functionalities. In this connection, functional requirements of MES may be identified without functional redundancy. Obviously, the scope of operations or functions depends on number of subsystems, but the key functions remain unchanging in their essence. Because, there are no reference MES models that can be used for general manufacturing environments, overcoming of this aspect leads through the presentations of sample solutions by types of environment and other criterions. For example, modeling three different management systems for maintenance, quality and production (Brandl, 2002) based on the new S95 standard of ISA (ISA, 2000).

AGGREGATIVE ROLE OF MES

MES has been developed and used as the interface between ERP and automation systems, since it was generally recognized that ERP systems weren't scalable.Because batch production presents the most intricate manufacturing concept and constitutes a significant portion of total manufacturing activities, then discrete manufacturing may be considered to be a substantive area of MES applications. The mentioned and other ISA standards, significantly help in the implementation of integrated manufacturing systems. It aims to model integration of business systems like ERP with control systems like DCS and SCADA. The standard S88.01 (ISA, 1995) has been developed to support batch control level optimization. It provides standard models and terminology for the design and operation of batch control systems. At the control level, the key attribute is the integration of all process information into one place. Ordinarily used for this purpose, are both a programmable logic controllers and SCADA software (Supervisory Control and Data Acquisition) that is positioned on the top of hardware to which it is interfaced, in general via PLCs or other hardware modules (SCADA).

An Important function of MES is to provide a feedback to ERP with aim to adjust their scheduling data and algorithms in more realistic manner. In this connection there is necessary to take in consideration of certain aspects of incompatibility. Originally, ERP systems have been developed more for financial managers then manufacturing managers. Moreover, the data flow frequency in ERP system is lower then at the MES level. By analogy, it would not make sense to feed a quantity of output data available at shop floor level into ERP system and a reversal. An effort to do so often involved large amount of manual data entry. Therefore, one important role of optimization by MES may be seen in reduction of manual data entry on the boundaries of information system layers. Basically, it's relevant in this case when enterprise information and control systems are designed as one complex. Then expected reductions of manual activities may be achieved by the integration of system layers that are specified in the concepts of the reference model of Open System Interconnection (OSI). Management functions by this model usually include activities, which are common for several layers, but they are not supported by the services provided by a specific layer. For modeling layer-to-layer interactions, with aim to integrate the bordering layers, it is also appropriate to analyze of manufacturing systems from the viewpoint its three main categories. These are:

- The physical plant
- The formal control/information system
- Human beings working in the system

The first two are deterministic and mechanistic. They are designed to be controllable and predictable. Human beings working in the systems exhibits humanistic traits that are quite different from the technical systems they interact with. This manufacturing system classification helps to create object-oriented models on the highest modeling level that are enabling to utilize advanced technologies as object-oriented data management and others.

Supplementary integration between MES and ERP is seldom uncomplicated. One manner to get around presumable complications is by execution business process modeling. The sense of this kind of modeling is to make such new organization of work more feasible than in the past. That is why process modeling and improvement becomes a key issue of successful implementation of any MES strategy. Business process improvement especially is the fundamental way to stay competitive in the market. Of particular importance in business process improvement, is the way of the collected measurements are analyzed. Both operational and structural measurements are needed to properly benchmark business processes.

FUTURE TRENDS

In general, the research of MES is still in its beginning stages. The expected role of the next research can be seen in the development of fully integrated systems of manufacturing management. It also includes information integration of manufacturing activities with external entities, what will lead to web-based solutions of MES. From this perspective, the future trend clearly calls for overall information control systems convergence.

Many other research initiatives with diverse objectives can be identified in specific areas of MES development. One of them lies in development of so-called *component-based application framework* (Füricht et al. 2002; Boyle, 2000), which might more easily compose MES application. This direction of improvement is oriented on the development of high-level modeling methods respecting requirements for functional openness of the framework approach.

CONCLUSION

In reality, majority enterprise information and control systems on different levels are developed and operated on incompatible technologies and based on heterogeneous architectures. Additionally, they are ordinarily in different stages of their own lifecycles and have varied levels of openness. A supplementary integration of separate information systems is rather complicated when taking into consideration the lack of standard interfaces. A plant–wide system, built according to the requirements of each facility, is needed in the situation of an absence of enterprise information and control systems. In this sense, a frequent interest of manufacturers concerns a balanced scale of MES functionalities. As mentioned earlier, it depends on more factors. For instance, when an existing ERP system contains factory floor control functionality, then the functionality model of MES has only supplement character. In this sense, one of expected direction of MES evolution that could help to overcome outlined topical issues is "fusion" of MES and ERP systems. Hopefully it will reduce implementation difficulties of information system integration, but it probably will not mean the elimination of MES level.

KEY TERMS

Distributed Control System (DCS): A supervisory control system typically controls and monitors set points to sub-controllers distributed geographically throughout a factory (Falco, Stouffer, Wavering & Proctor, 2004).

Enterprise Resources Planning: consists of those systems that provide financial, order management, production and materials planning, and related functions. The modern ERP systems focus on global planning, business processes and execution across the whole enterprise (intra-enterprise systems), with an accrued recent importance of aspects like supply chain planning and the whole supply chain management aspects and extending to include the whole inter-enterprise supply chain (OMG, 1997).

Manufacturing Execution System: A collection of hardware/software components that enables the management and optimization of production activities from order launch to finished goods. While maintaining current and accurate data, an MES guides, initiates, responds to and reports on plant activities as they occur. An MES provides mission-critical information about production activities to decision support processes across the enterprise (Wallace, Barkmyer, Denno, Feng, and Jones,1999).

Manufacturing Resources Planning II: is a suite of sophisticated programs that attempt to integrate all aspects of the planning and control of the personnel, materials and machines required to manufacture a range of products in one comprehensive computer based system (Kimble & McLoughlin, 1995).

Programmable Logic Controller (PLC): A small industrial computer used in factories originally designed to replace relay logic of a process control system and has evolved into a controller having the functionality of a process controller. (Falco, Stouffer, Wavering & Proctor, 2004).

Scalability: is understood as the possibility to extend the SCADA based control system by adding more process variables, more specialized servers (e.g. for alarm handling) or more clients. The products achieve scalability by having multiple data servers connected to multiple controllers (Daneels & Salter,1999).

Supervisory Control and Data Acquisition System (SCADA): It is a part of control system, but rather focused on the supervisory level. As such , it is a purely software package that is positioned on top of hardware to which it is interfaced, in general via Programmable logic Controllers (PLCs) or other commercial hardware modules (Daneels & Salter,1999).

Fundamentals of Multirate Systems

Gordana Jovanovic-Dolecek
National Institute for Astrophysics, Optics and Electronics, Puebla, Mexico

INTRODUCTION

Digital signal processing (DSP) is an area of science and engineering that has been rapidly developed over the past years. This rapid development is a result of significant advances in digital computers technology and integrated circuits fabrication (Elali, 2003; Grover & Deller, 1999; Mitra, 2001; Oppenheim & Schafer, 1999; Smith, 2002; Stein, 2000; White, 2000).

Classical digital signal processing structures belong to the class of single-rate systems since the sampling rates at all points of the system are the same.

The process of converting a signal from a given rate to a different rate is called sampling rate conversion. Systems that employ multiple sampling rates in the processing of digital signals are called multirate digital signal processing systems. Sample rate conversion is one of the main operations in a multirate system (Stearns, 2002).

BACKGROUND

Decimation

The reduction of a sampling rate is called decimation, because the original sample set is reduced (decimated). Decimation consists of two stages: filtering and downsampling, as shown in Figure 1. The discrete input signal is *u*(*n*) and the signal after filtering is *x(n)*. Both signals have the same input sampling rate f_i.

Downsampling reduces the input sampling rate f_i by an integer factor *M*, which is known as a downsampling factor. Thus, the output discrete signal *y(m)* has the sampling rate f_i/M. It is customary to use a box with a down-pointing arrow, followed by a downsampling factor as a symbol to represent downsampling, as shown in Figure 2.

The output signal *y(m)* is called a downsampled signal and is obtained by taking only every *M*-th sample of the input signal and discarding all others,

$$y(m) = x(mM) \tag{1}$$

The operation of downsampling is not invertible because it requires setting some of the samples to zero. In other words, we can not recover *x(n*) from *y(m)* exactly, but can only compute an approximate value.

In spectral domain downsampling introduces the repeated replicas of the original spectrum at every $2\pi/M$. If the original signal is not bandlimited to $2\pi/M$, the replicas will overlap. This overlapping effect is called aliasing. In order to avoid aliasing, it is necessary to limit the spectrum of the signal before downsampling to below $2\pi/M$. This is why a lowpass digital filter (from Figure 1) precedes the downsampler. This filter is called a decimation or antialiasing filter.

Three useful identities summarize the important properties associated with downsampling (Dabrowski, 1997; Jovanovic-Dolecek, 2002). The first identity states that the sum of the scaled, individually downsampled signals is the same as the downsampled sum of these signals. This property follows directly from the principle of the superposition (linearity of operation). The second identity establishes that a delay of *M* samples before the downsampler is equivalent to a delay of one sample after the downsampler, where *M* is the downsampling factor. The third identity states that the filtering by the expanded filter followed by downsampling, is equivalent to having downsampling first, followed by the filtering with the original filter, where the expanded filter is obtained by replacing each delay of the original filter with *M* delays. In the time domain, this is equivalent to inserting *M*-1 zeros between the consecutive samples of the impulse response.

Figure 1. Decimation

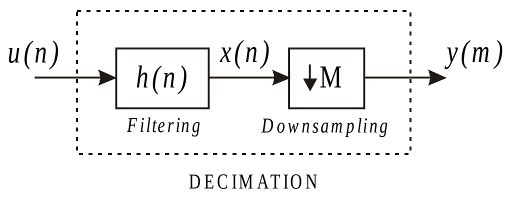

Figure 2. Downsampling

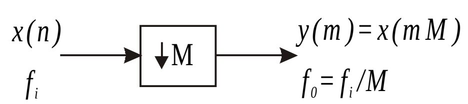

The polyphase decimation, which utilizes polyphase components of a decimation filter, is a preferred structure for decimation, because it enables filtering to be performed at a lower sampling rate (Crochiere & Rabiner, 1996; Diniz, da Silva & Netto, 2002).

Interpolorization

The procedure of increasing the sampling rate is called interpolation, and it consists of two stages: upsampling and filtering (shown in Figure 3).

The upsampler increases the sampling rate by an integer factor L, by inserting L-1 equally spaced zeros between each pair of samples of the input signal *x(n)* as shown by,

$$y(n) = \begin{cases} x(n/L) & for \;\; n = mL \\ 0 & otherwise \end{cases} \tag{2}$$

where L is called interpolation factor.

As Figure 4 illustrates, the symbol for this operation is a box with an upward-pointing arrow, followed by the interpolation factor. We can notice that the input sampling rate f_i is increased L times.

The process of upsampling does not change the content of the input signal, and it only introduces the scaling of the time axis by a factor L. Consequently, the operation of upsampling (unlike downsampling) is invertible, or, in other words, it is possible to recover the input signal *x(m)* from samples of *y(n)* exactly.

The process of upsampling introduces the replicas of the main spectra at every $2\pi/L$. This is called imaging, since there are L-1 replicas (images) in 2π. In order to remove the unwanted image spectra, a lowpass filter must be placed immediately after upsampling (Figure 3). This filter is called an anti-imaging filter. In the time domain, the effect is that the zero-valued samples introduced by upsampler are filled with "interpolated" values. Because of this property, the filter is also called an interpolation filter.

We have already seen three useful identities of the downsampled signals, and now we will state the identities associated with upsampling. The fourth identity asserts that the output signal obtained by upsampling followed by scaling of the input signal will give the same result as if the signal is first scaled and then upsampled. The fifth identity states that a delay of one sample before upsampling is equivalent to the delay of L samples after upsampling. The sixth identity, which is a more general version of the fifth identity, states that filtering followed by upsampling is equivalent to having upsampling first followed by expanded filtering (Dabrowski, 1997; Diniz, da Silva & Netto, 2002; Jovanovic-Dolecek, 2002).

Cascade of Sampling Convertors

An interchange of cascaded sampling converters can often lead to a computationally more efficient realization (Fliedge, 2000; Vaidyanathan, 1993). If upsampling precedes downsampling, where both operations have the same factor, the signal is not changed. However, if downsampling is performed before upsampling, and both operations have the same factor, the resulting signal will be different from the input signal. Rational sampling conversion, that is, changing the sampling rate by a ratio of two integers, L/M can be efficiently performed as a cascade of upsampling and downsampling, where the interpolation and decimation filters are combined into one filter.

FUTURE TRENDS

Applications

Multirate systems have applications in digital radio, speech processing, telecommunications, wavelet transform, digital filtering, A/D converters, spectrum estimation, and so forth.

There are many applications where the signal of a given sampling rate needs to be converted into an equivalent signal with a different sampling rate. For example, in digital radio, three different sampling rates are used: 32 kHz in broadcasting, 44.1 kHz in digital compact disc (CD), and 48 kHz in digital audio tape (DAT) (Fliedge, 2000; Mitra, 2001). Conversion of the sampling rate of audio signals between these three different rates is often necessary. For example, if we wish to play CD music which has a rate of 44.1 kHz in a studio which operates at a 48 kHz rate,

Figure 3. Interpolation

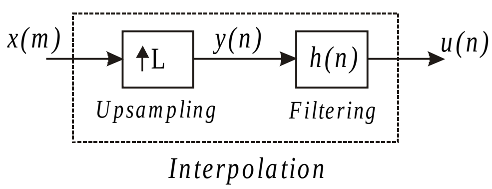

Figure 4. Interpolation

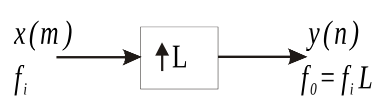

then the CD data rate must be increased to 48 kHz using a multirate technique.

In speech processing, multirate techniques are used to reduce the storage space or the transmission rate of speech data (Ifeachor & Jervis, 2001). In the past years, multirate speech and audio signal processing has been a research topic that has produced several efficient algorithms for echo and noise cancellation, active noise cancellation, speech enhancement, and so forth (Diniz, da Silva & Netto, 2002; Jovanovic-Dolecek, 2002; Smith, 2001).

An example of an application of multirate signal processing in telecommunications is the translation between two multiplexing formats, time division multiplexing (TDM) and frequency division multiplexing (FDM) (Fliedge, 2000; Harris, 2004; Smith, 2001). The filter banks are used to separate a signal into two or more signals (analysis filter bank) or to compose two or more signals into a single signal (synthesis filter bank). Multirate systems and filter banks have found many applications in source and channel coding, thereby providing a bridge between communication system design/analysis and signal processing tools (Vaidyanathan, 1993).

One of the most fascinating developments in the field of multirate signal processing has been the establishment of its link to the discrete wavelet transform (Diniz, da Silva, & Netto, 2002; Rao, 2002; Suter, 1998). This link has been responsible for the rapid application of wavelets in fields such as image compression.

Multirate processing has found important application in the efficient implementation of DSP functions (Ifeachor & Jervis, 2001). The multirate approach increases the computational speed, decreases the overall filter order, reduces word-length effects, decreases power consumption, making it vital for efficient filtering. Basic multirate techniques used to satisfy the filter requirements are the polyphase decomposition, multistage filtering and frequency masking approach.

The need for inexpensive, high resolution analog/digital (A/D) converters has led to the use of oversampling techniques in the design of such converters, that is, to sample the analog signal at a rate much higher than the Nyquist rate, one uses a fast low-resolution A/D converter, and then decimates the digital output of the converter to the Nyquist rate. Such A/D converter relaxes the sharp cutoff requirements of the analog anti-aliasing filter, resulting in a more efficient structure, (Jovanovic-Dolecek, 2002; Mitra, 2001).

Another application of multirate signal processing is in the area of spectrum estimation. The computational requirements for narrowband spectrum estimation based on discrete Fourier transform can be significantly reduced by using the sampling rate conversion (Vaidyanathan, 1993).

It is expected that in future the applications of multirate systems will play a very important role for resolving problems in communications, control, wavelet analysis, analog/digital converters and so forth. From the other side, the different applications will give an impulse to develop a new algorithms and design methods for multirate systems.

CONCLUSION

There are many applications where the signal of a given sampling rate needs to be converted into an equivalent signal with a different sampling rate. The main reasons could be to increase efficiency or simply to match digital signals that have different rates. During the past several years, the multirate processing of digital signals has been attracted by many researchers and "the utilization of multirate techniques is becoming an indispensable tool of the electrical engineering profession" (Suter, 1998).

Changing the sampling rate can reduce the computation necessary to complete some DSP operations, and thus reduce the overall system cost. Consequently, the main advantage of multirate systems lies in their high computational efficiency.

KEY TERMS

Analysis Filter Bank: Decomposes the input signal into a set of subband signals with each subband signal occupying a portion of the original frequency band.

Continuous-Time Signals: Defined along a continuum of time t and thus are represented by continuous independent variables, for example $x_c(t)$. Continuous-time signals are often referred to as analog signals.

Decimation: The process of decreasing the sampling rate. It consists of filtering and downsampling.

Decimation Filter: The filter used in decimation to avoid aliasing caused by downsampling.

Digital Filter: The filter is a discrete-time system, which changes the characteristics of the input discrete signal in a desired manner to obtain the discrete output signal.

Digital Filter Bank: Set of digital bandpass filters with the common input or a common output.

Discrete-Time Signals: Defined at discrete time values and thus the independent variable has discrete values n, as for example x(n).

Interpolation: The process of increasing the sampling rate. It consists of upsampling and filtering.

Interpolation Filter: The filter used in interpolation to remove the unwanted images in the spectra of the upsampled signal.

Multirate System: Discrete–time systems with unequal sampling rates at various parts of the system.

Sampling: The generation of a discrete-time signal x(n) from a continuous signal $x_c(t)$ is called sampling, where $x(n)= x_c(nT)$. T is called the sampling period and its inverse $1/T$ is the sampling frequency or the sampling rate.

Subband Coding (SBC) Filter Bank: Consists of an analysis filter bank followed by synthesis filter bank. This type of filter bank is used for partitioning signals into subbands for coding purposes, and vice versa.

Synthesis Filter Bank: Combines subband signals into one signal.

Transmultiplexer Filter Bank (TMUX): Consists of a synthesis filter bank followed by an analysis filter bank. This type of filter bank is used for converting time-multiplexed signals (TDM) into frequency-multiplexed signals (FDM), and vice versa.

Future of Small Business E-Commerce

Simpson Poon
IVE, Hong Kong and Charles Sturt University, Australia

INTRODUCTION

The use of the Internet for business purposes among small businesses started quite early in the e-commerce evolution. In the beginning, innovative and entrepreneurial owners of small businesses attempted to use rudimentary Internet tools such as electronic mail (e-mail) and file transfer protocol (FTP) to exchange messages and documents. While primitive, it fulfilled much of the business needs at the time. Even to date, e-mail and document exchange, according to some of the latest research findings, are still the most commonly used tools despite the fact that tools themselves have become more sophisticated.

There has been a plethora of research on small-business use of the Internet and e-commerce in general. Some of the earlier research can be traced back to the mid-1990s, when small-business e-commerce was in its infancy (e.g., Abell & Lim, 1996; Cronin, Overfelt, Fouchereaux, Manzvanzvike, Cha, & Sona, 1994; Fuller & Jenkins, 1995; Poon & Swatman, 1995), and when this chapter was written, articles were still being published in this area around the world. While the findings are many and varied, there are a number of highlights. Essentially, four groups of factors had been commonly found to influence the adoption of e-commerce among small businesses (see Figure 1).

(1) Organizational factors: Demographic factors such as size and the industry sector had been found to have an influence on the level of adoption (Poon & Swatman, 1999; Thong, 1999). The information intensity of products was also found to be a determining factor influencing adoption (Hui & Chau, 2002). While there was evidence that the nature of a product did not necessarily determine e-commerce success (Poon, 2000), anecdotal evidence suggested that small businesses offering digital products or products with high information intensity seem to benefit more from e-commerce.

(2) Technological factors: The level of IT adoption within an organization as well as along the supply chain of an organization was suggested to be good predictors of success in small-business c-commerce adoption (Mehrtens, Cragg, & Mills, 2001). Research has shown that the technical competence of key personnel within a small firm also related to the perceived success when adopting IT (Thong, 1999).

(3) Management factors: Studies into IT and e-commerce adoption have repeatedly identified the importance of management's involvement in facilitating adoption. Findings generally point out that the proactive attitude and actions of management, as well as the innovativeness of their strategy toward e-commerce, had led to success (Poon & Swatman, 1998; Thong, 1999). In the case of a small business, the dominant role of the owner or director means management is often the determining factor of e-commerce success.

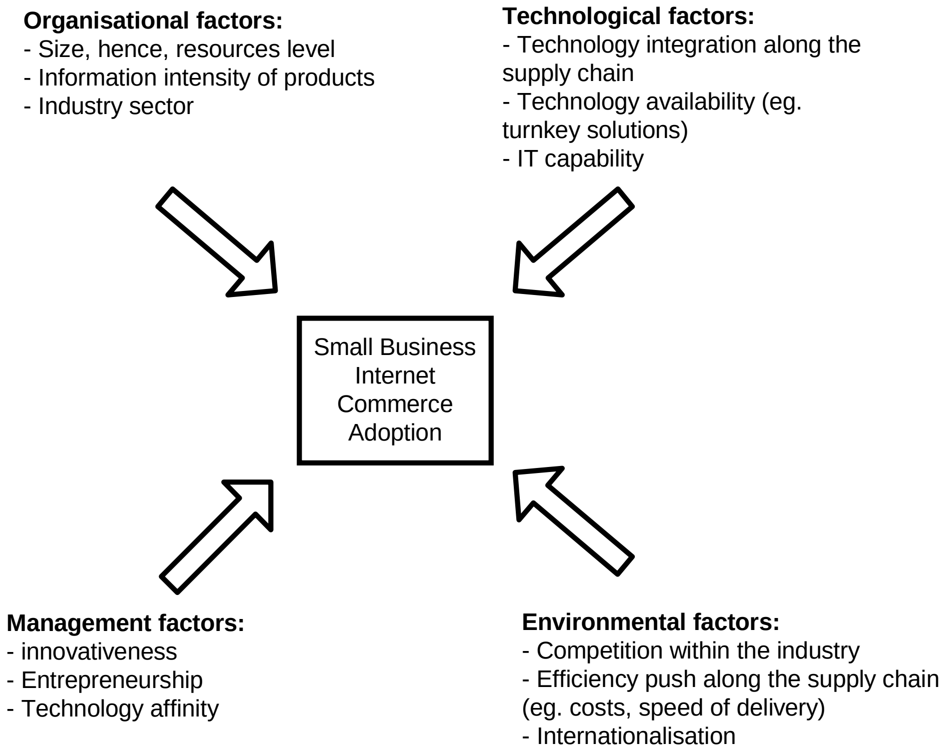
(4) Business-sector factors: The level of IT adoption and the expectation to use IT for interfirm activities within the industry sector a small business is in also seem to influence the level and extent of e-commerce adoption (Premkumar & Roberts, 1999; Raymond & Blili, 2001). If there is a lesson from electronic-data-interchange (EDI) adoption to be learned, it is that small businesses were often under the influence of more powerful business partners along the supply chain to adopt interorganizational technologies such as EDI. Similar patterns have been observed in c-commerce adoption cases.

BACKGROUND

Besides the well-mentioned business-to-consumer (B2C) and business-to-business (B2B) e-commerce setup, the Internet also enables small businesses to form business networks known as e-clusters. Compared to the traditional "hub-and-spokes" topology of networked organizations, involving a large organization and a number of small businesses during EDI adoption, the Internet sees the formation of e-clusters. Small businesses are known to form business clusters: a group of firms working closely together for business advantages. This phenomenon has been observed both in the East (Akizawa & Kijima, 1997), the West (Brown & Lockett, 2001), and around the world (UNIDO, 2001).

Brown and Lockett (2001) highlighted how small businesses empower such clusters using e-commerce technologies. The e-clusters formed can leverage both the synergy of the group and the technological advantages

Figure 1. Four groups of factors commonly found to influence Internet adoption among small businesses



to further enhance the agility of the whole cluster. Governments are also keen to investigate how industries, particularly those whose key products are of digital nature, can benefit from e-clustering (Sakai, 2002). E-clusters will be a key economic drive for nations that have a high percentage of small and medium-sized enterprises (SMEs). The productivity and operational efficiency among SMEs within such clusters can be enhanced through the economy of information exchange.

FUTURE TRENDS

From Competitive Advantage to Necessity

As more small businesses are using the Internet to support business activities, it is no longer an option but a key to competitiveness. For small businesses that have suppliers and/or customers who have adopted e-commerce, not being able to interact using Internet technologies is a competitive disadvantage. As such, small businesses are expecting to be e-commerce ready or risk losing out in the future. As e-commerce software and services are maturing and becoming affordable, widespread adoption is expected.

From Fragments to Clusters

For a few years, e-commerce adoption has been a fragmented process, meaning individual small businesses tried to establish a Web presence or install e-commerce software onto their systems. As efforts such as application service providers, B2B marketplaces, and industry-wide platforms are maturing, small businesses are becoming part of a supply web, a member of a B2B marketplace, or are tightly integrated into a large organization's extranet. The result is that small businesses will become part of one or more e-clusters, reflecting the nature and flows of business activities.

From Paper Based to Paperless

While clichés about a paperless office have been around for over a decade, it becomes closer to such a reality when B2C, B2B, and B2G (business to government [or public establishments]) activities are increasingly popular. In some countries, submission of information such as taxation assessments is now carried out as part of an e-government setup. Small businesses are under pressure to carry out business transactions not only with other businesses, but also with government and public organizations over the Internet.

From Driven to Driving

Many small businesses in the 1990s were driven to adopt e-commerce, sometimes unwillingly. This might be due to the lack of knowledge and human resources to address related technical and business issues. As technologies are becoming more user friendly and affordable, together with readily available technical specialists, adoption of some kind of e-commerce applications and/or systems has risen dramatically. The complexity of e-commerce systems from a user's perspective is not that much different from office software. Most importantly, the e-commerce strategy should not be someone else's agenda, but the driving solution of the small firm.

CONCLUSION

The percentage of small businesses adopting and using e-commerce is increasing every year. Small businesses that used to be slow to adopt IT are now either already pursuing or actively using e-commerce for their business activities. There are many reasons for this, but the availability of easy-to-use and affordable solutions, lower entry barriers, and driving forces from business partners are the key influencing factors. Small businesses are now left with few options except to adopt e-commerce to streamline their operations and stay competitive. As business activities and transactions are increasingly carried out over the Internet, small businesses that have scant resources will find e-commerce is now part of their solution rather than part of the problem as in the early days of the dot-com era.

KEY TERMS

E-Cluster: An e-cluster is a group of firms; in this article they are small businesses, which engage in various kinds of business relationships and are using e-commerce to support such business relationships.

E-Commerce: E-commerce in this article means using the Internet and related technologies and software to support business activities in general. It ranges from simple setup such as e-mail and file transfer to complex systems such as supply chain management and enterprise resources-planning systems.

Electronic Data Interchange (EDI): EDI in this article means a set of document-exchange standards used to implement interorganizational systems exchanges to achieve automated computer-to-computer document exchange regardless of the communication technologies used.

Industry-Wide Platform: In this article it refers to using a mixture of information and communications technologies set up over the Internet to set up a multipurpose platform that enables firms within a sector, along a supply chain, or as part of a consortium to exchange business information and transact.

Small Business: The commonly adopted definition of a small business is that the firm size should be less than 500 employees. However, there are other interpretations of how small a business should be to be considered a small business including firm sizes of less than 100 (the Netherlands), 50 (Ireland), or even 20 (Australia). Business turnover, management and organizational structure, as well as other supplementary criteria, are also used by some authors.

Supply Web: An elaborated web of supply chains intersecting each other. A small business can be on one or more of the supply chains within this web. Supply chains within this web may or may not be in the same industry.

Gender and Computer Anxiety

Frank E. Ritter
The Pennsylvania State University, USA

INTRODUCTION

Because of their ability to enhance productivity, computers have become ubiquitous in the workplace. By the early 1990s the use of computers in the workplace reached a per capita penetration that the telephone took 75 years to achieve (Webster & Martocchio, 1992). During the past several decades, there has been both speculation and hard research related to the psychological effects of computer technology. More recently the role of attitudes towards computers in influencing the acceptance and use of computer-based management information systems (MIS) has been highlighted by a growing number of MIS researchers. Generally, these studies focus on the negative attitudes towards computers and concerns about the impact of MIS on individual performance in the workplace.

Computer anxiety has been reported to be associated with negative attitudes towards computers. As computers play a pervasive role in MIS and decision support systems, these findings emphasize the need for additional empirical research on the determinants of computer anxiety and attitudes towards computers. Furthermore, with the increasing participation of women in information technology professions, important questions are whether men and women differ with regard to computer anxiety and attitudes towards computers, and what factors explain such differences where they exist, and how to ameliorate anxiety where it occurs.

The Concept and Correlates of Computer Anxiety

Much has been speculated about computer anxiety, both what it is and what to do about it. Computer anxiety is context specific and covers a wide variety of situations in which people interact with computers. Context-specific anxiety tests ask the question: "How do you feel when a specific type of situation occurs?" Commonly, the relationship between a measure of computer anxiety and other variables is examined. For example, the relationship of computer anxiety to computer-related experience has historically been a hotly contested question in MIS research, human-computer interaction (HCI), and educational psychology. Demographic variables posited or found to be related to computer anxiety include gender, age, organizational level, and academic major (Dambrot, Watkins-Malek, Silling, Marshall & Garver, 1985; Gutek & Bikson, 1985; Zmud, 1979). Personality variables examined as potential determinants of computer anxiety include trait anxiety, math anxiety, cognitive style, and locus of control (Howard & Smith, 1986; Igbaria & Parasuraman, 1989; Morrow, Prell & McElroy, 1986). Additionally, several studies have examined the relationship between computer anxiety and academic achievement. For example, Hayek and Stephens (1989) and Marcoulides (1988) reported significantly lower computer anxiety being associated with higher academic achievement.

BACKGROUND

Initially, computer anxiety became of interest during the technological revolution. In 1963 a social psychologist at IBM completed a nationwide study to examine popular beliefs and attitudes about one of the prime symbols of our rapidly changing technology—the electronic computer. Lee's (1970) findings concluded that the American public viewed computers on two independent dimensions. The first dimension, the "Beneficial Tool of Mankind Perspective," described a positively toned set of beliefs that computers are beneficial in science, industry, and business. The second dimension, the "Awesome Thinking Machine Perspective," connoted fear of an incomprehensibly complex machine with capabilities far exceeding those of a human. This perspective, which reflects ignorance about the capabilities and limitations of computers, is one of the generic origins of computer anxiety.

Later, during the 1980s, much of the writing about computer anxiety and attitudes towards computers was concentrated in trade and business publications (e.g., Howard, 1986; Igbaria & Parasuraman, 1989). During this time period uncertainty was often considered the primary predictor of computer anxiety. This uncertainty referred to an individual's ability to learn to use the computer or to the potential the machine had to rearrange traditional office functions and power structures. Sabotage and hostility were sometimes responses to these uncertainties, especially when they were accompanied by fear of replacement by the machine. This particular concern was often voiced by middle managers who viewed their jobs as information conduits or as a mosaic of clerical tasks, all of which could be performed more efficiently by a computer. Managers with longer tenure with a company and those who felt they were currently utilizing their time quite effectively were likely to resist computer adoption and use. Additionally, computer usage required typing skills. Those persons who did not know how to type or considered typing a low-status skill were reluctant to adapt to the new technology.

Collectively two groups displayed the most susceptibility to computer anxiety: individuals without computer experience overestimated the difficulties involved in learning and interacting with computers; and individuals whose jobs appeared threatened resisted adaptation to technological improvements (Gilroy & Desai, 1986). It has been well documented that among individuals demonstrating computer anxiety are significant numbers of women, as examined in the next section.

The Role of Gender in Computer Anxiety

According to feminist technology studies, computers are widely perceived as belonging to the "male domain" of mathematics, science, electronics, and machinery (Beyer, 1999; Cockburn & Ormrod, 1993; Faulkner, 2001). This, coupled with reports of greater prevalence of math anxiety among women than men (e.g., Brown & Josephs, 1999; Chipman, Krantz & Silver, 1992), suggests that women are likely to have a more negative view of computer use than men. It is not surprising that men have been found to display lower computer anxiety, higher computer aptitude, and more positive attitudes towards computers in general than women (Chua, Chen & Wong, 1999; Coffin & Machintyre, 2000; Colley, Gale & Harris, 1994; Whitely, 1997).

The limited empirical research on gender differences in computer anxiety, attitudes towards computers, and computer experiences among working adults reveals conflicting results, however. By the early 1990s, only 25 studies presented sufficient statistical information that could be converted to correlations, and an additional 13 qualitative research reports supported only slight differences between men and women in computer anxiety (Rosen & Maguire, 1990). In contrast, other studies reported no gender differences associated with computer use in the workplace.

More specific studies found stronger correlations and gender differences. One of the most frequently cited studies on computer anxiety is by Rosen, Sears, and Weil (1987). They examined the relationship between computer anxiety and gender role as measured by the Bem Sex Role Inventory (Bem, 1974). This instrument identified individuals as belonging to one of four identity groups: masculine, feminine, androgynous, or undifferentiated. They found that feminine-identity individuals had more computer anxiety and more negative computer attitudes than did masculine-identity individuals, regardless of gender. Another influential instrument employed extensively in early studies on microcomputer anxiety in management is the Computer Anxiety Rating Scale (CARS) developed by Raub (1981). Raub investigated math anxiety, gender, age, trait anxiety, and knowledge of computers as possible correlates of computer anxiety. She suspected a gender effect based on the negative socialization of women toward mathematics, science, and technology and on the resulting production of anxieties. Raub found the relationship between computer anxiety and gender so strong that she ran separate regressions for males and females.

CARS has been used in more recent research as well. Anderson (1996) utilized CARS to determine whether or not perceived knowledge of software, computer experience, overall knowledge of computers, programming experience, and gender were predictors of computer anxiety. Table 1 displays the CARS portion of the Anderson questionnaire. Collaborating Raub's results, Anderson's study showed higher computer anxiety is accompanied by less experience and less perceived knowledge of computers, and that at higher levels of computer anxiety, women are over-represented.

Indirectly, the use of CARS led to the introduction of statistical modeling as a more formal investigation of the psychological mechanisms that trigger computer anxiety and the remedies for it. For example, the work of Howard (1986) is distinctive during the 1980s in its similarity to more recent research on computer anxiety. Howard developed a sequence of models addressing the predictors of computer anxiety and the use of computers in management. In schematic form, Figure 1 shows the possible relationships between psychological variables and the attitudes of managers toward the usefulness of microcomputers as management tools. Howard's study confirmed that computer anxiety is a significant inverse correlate of managers' positive attitudes toward microcomputers.

Similar to Raub, Howard speculated that gender may correlate with math anxiety and possibly with computer anxiety. Gender as a math anxiety correlate reflects psychological differences between men and women with

Table 1. The Computer Anxiety Rating Scale (CARS) is based on research by Raub (1981)

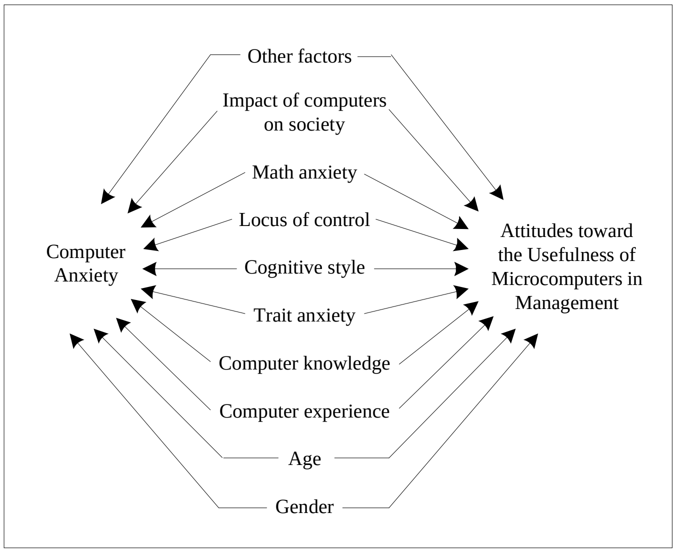
The responses are scaled as follows:

1 = Strongly Agree
2 = Agree
3 = Unsure
4 = Disagree
5 = Strongly Disagree

Items 2 through 10 are reverse scored so that high scores indicate high levels of computer anxiety.

1. I am confident that I could learn computer skills.
2. I am unsure of my ability to learn a computer programming language.
3. I will be able to keep up with the important technological advances of computers.
4. I feel apprehensive about using the computer.
5. If given the opportunity to use a computer, I'm afraid that I might damage it in some way.
6. I have avoided computers because they are unfamiliar to me.
7. I hesitate to use the computer for fear of making mistakes that I cannot correct.
8. I am unsure of my ability to interpret a computer printout.
9. I have difficulty understanding most technological matters.
10. Computer terminology sounds like confusing jargon to me.

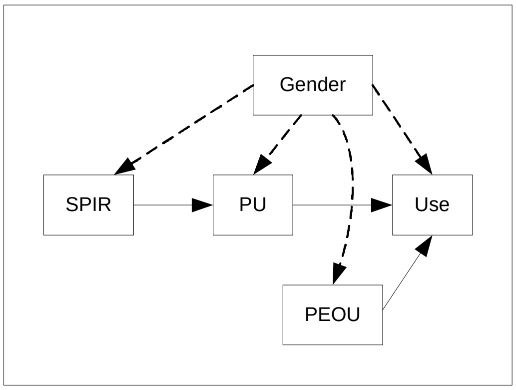
Figure 1. Computer anxiety and other possible correlates of managers' attitudes towards microcomputers adapted from Howard (1986)



regard to mathematics that may result from early socialization of females away from scientific and technical endeavors. If math anxiety and computer anxiety are similar phenomena, then they are likely to have common psychological roots. Thus, for both Raub and Howard, the prime psychological root of computer anxiety appeared to be that certain people simply did not see themselves as technological types. Math anxious types see mathematics and computers and all the paraphernalia of technology as for someone else and when required to use it experience stress.

A current perspective of Howard's usefulness of microcomputers research is several recent studies examining the diffusion of information technology (IT) in the workplace. Many of these studies have demonstrated a strong link between self-efficacy and individual reactions

Figure 2. Gender effects on TAM variables (Gefen & Straub, 1997)



to computing technology, both in terms of adoption and use of computers, and in terms of learning to use computer systems and applications. Beliefs about our capabilities to use technology successfully are related to our decisions about whether and how much to use technology, and the degree to which we are able to learn from training (Compeau, Higgins & Huff, 1999). While inconsistencies in group differences exist, overall findings of IT diffusion research suggest that women and men exhibit different perceptual tendencies and usage patterns in computer-related circumstances (Chou, 2001; Gefen & Straub, 1997; Hackbarth, Grover & Yi, 2003; Venkatesh, Morris & Ackerman, 2000).

Gefen and Straub (1997), and Venkatesh, Morris, and Ackerman (2000) are two prevalent examples of IT diffusion research predicated on influential theories evaluating information technology perception and use: the Technology Acceptance Model (TAM) and the Theory of Planned Behavior (TPB). Gefen and Straub (1997) modeled IT diffusion by extending TAM and the Social Presence/Information Richness (SPIR) factor addendum to include gender in the context of e-mail system usage. Figure 2 shows the effects of gender on TAM and cultural extensions, specifically the perceived attributes of SPIR, perceived ease of use (PEOU), and perceived usefulness (PU). Gefen and Straub sampled 392 female and male knowledge workers using e-mail systems in the airline industry in North America, Asia, and Europe. Study findings indicated that women's perceptions of e-mail are different from male co-workers. Covariates gender and culture accounted for 37% of the variance in SPIR, 53% of the variance in PEOU, and 59% of the variance in SPIR, culture, and PU combined. In this study gender definitely had an impact on the IT diffusion process.

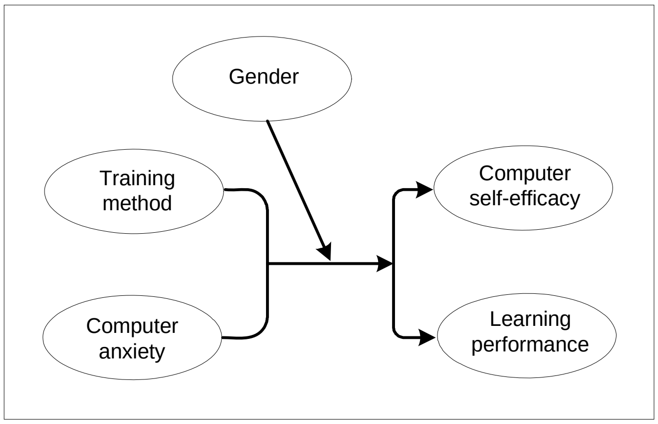
Using TPB as a framework, Venkatesh, Morris, and Ackerman (2000) investigated gender differences in the context of adoption and sustained usage of technology in the workplace. User reactions and technology usage behavior were studied over a five-month period among 355 workers being introduced to a new software application. Men's attitude toward using the new technology was strongly motivated by achievement needs and task-oriented or instrumental behavior. In contrast, women's attitude toward using the new technology was more strongly influenced by subjective norm and perceived behavioral control. Sustained technology usage behavior in both men and women was driven by early usage behavior, emphasizing the importance of gender-based early evaluations of a new technology.

The above studies suggest several implications: when marketing IT and considering its effects, the gender of the users should be considered; and when training users on particular information technology such as e-mail systems, groups composed primarily of women should be addressed in a different manner than mixed or mainly masculine groups. When training mostly female groups, user friendliness and the ability of the system to convey the presence of the communicator should be emphasized.

Computer training has been widely researched and considered an essential contributor to the success of organizational computing. Computer anxiety and attitudes toward computers have often been identified as the critical factors influencing computer learning performance and training methodology. From the late 1980s up to today, the relationship of training techniques and personal characteristics has played a key role in training end users of information systems.

Characteristic of such training studies, Chou (2001) developed a conceptual model to evaluate how training method, an individual's gender, and computer anxiety level affect learning performance and computer self-efficacy. Chou used two types of training methods: an instruction-based method and a behavior-modeling method. The instruction-based method is a traditional approach that teaches primarily by lecture and follows a deductive way to learning, where learners proceed from general rules to specific examples (Davis & Davis, 1990; Simon, Grover, Teng & Witcomb, 1996). On the other hand, the behavior-modeling approach is a task-focused method involving a visual observation of the behaviors of a user performing a task. Learners then imitate and extend the demonstrated behavior in practice and experimentation to master the task. The behavior-modeling method employs an inductive approach that teaches by hands-on demonstrations first, followed by complimentary lectures (Compeau & Higgins, 1995; Gist, Schwoerer & Rosen, 1989). Figure 3 shows Chou's research model. In this model, gender was

Figure 3. Moderating effects of gender on computer self-efficacy and learning performance (Chou, 2001)



proposed as a moderating variable that moderates the effects of training method and computer anxiety on both learning performance and computer self-efficacy. When the training methods were tested on students, gender effects in general were found to be significant: male subjects performed better then female subjects. Male students had better learning performance, higher computer self-efficacy, and lower computer anxiety. Female students had significantly lower self-efficacy and a lower self-image about their computer learning capabilities. The behavior-modeling method appeared to enhance the computer self-efficacy of male students, whereas the instruction-based method benefited female students, suggesting that instruction technique preference varies with gender.

Studies on the relationships between computer anxiety, learning performance, and gender contribute solid knowledge about end-user training potential. This knowledge aids educators and trainers in the development of more personalized and therefore effective training programs for groups and individuals (Bostrom, 1998; Chou, 2001; Davis & Davis, 1990; Santhanam & Sein, 1994).

FUTURE TRENDS

In the developing research area of profiling Internet users, extrapolation of the computer anxiety literature offers parallels between gender differences in Internet use and differences in expertise and attitudes towards computers. It is widely assumed that women's participation in the Internet is hampered by their attitudes towards computers, which in turn is reflective of their attitudes towards new technology (Durndell & Haag, 2002; Gackenback, 1998; Jackson, Ervin, Gardner & Schmitt, 2001; Kraut et al., 1998; Schumacher & Morahan-Martin, 2001; Weiser, 2000).

Supporting this claim, Durndell and Haag (2002) utilized a Computer Self-Efficacy Scale, a Computer Anxiety Scale, and an Attitude to the Internet Scale in obtaining information from 74 female and 76 male university students on their Internet usage. Durndell and Haag found significant gender effects throughout, with males tending to report greater computer self-efficacy, lower computer anxiety, more positive attitudes towards the Internet, and longer use of the Internet than females. Similarly, Schumacher and Morahan-Martin (2001) reported males feeling more comfortable and competent with computers and the Internet. One explanation is that males, from childhood on, have more experience with computers than females, especially with games and programming that enhance technological sophistication and increase overall levels of competence and comfort with computers. Sussman and Tyson (2000) suggested the nature of communication on the Internet may vary by gender, and Balka and Smith (2000) proposed gender differences in Web navigation strategies.

Employing psychological methodology, DeYoung and Spence (2004) designed an instrument, the Technology Profile Inventory (TPI), to profile information technology users for dynamic personalization of software interfaces. Their approach was to generate a broad range of items for assessing responses to information technology, to examine their factor structure in a normal population, and to investigate potential associations between the emergent factors and variables that have, in the past, been associated with responses to computers, including gender, age, experience with information technology, and use of information technology. In application, a Web page could conform itself to suit the technology profile of each user who encounters it, for instance, a program could display all of its options for someone high in "computer interest" while displaying only the most functional options for someone who just wants to accomplish a task as simply as possible.

CONCLUSION

Computers are a vital asset in today's business and education world. The emergence of computers and information systems has been perhaps the single largest factor influencing organizations during the past three decades. Despite the increasing dispersal of computers, there is significant evidence that individual computer usage is affected by the computer anxiety or fear of computers that is widespread, and negative attitudes towards computers in general. This suggests that the potential benefits of computers as aids to professionals may not be fully realized, and the success of using a computer is dependent on the user's acceptance and commitment. The presence of computer anxious individuals in the workplace can lead to performance problems, decline in motivation, work quality, and moral, and can increase errors, absenteeism, interpersonal conflicts, and turnover (Brosnan, 1998; Mikkelsen, Ogaard, Lindoe & Olsen, 2002).

Historically, a commonly held stereotype of computer anxiety is that of a frightened female secretary, struggling to learn the new word processor that her (male) boss is making her use as a replacement for her old, trusty IBM Selectric typewriter. The majority of gender and computer anxiety research does not support this description—both the secretary and the boss in this story may be anxious, but for different reasons and with different implications. In this particular case role has a greater effect than gender. However, the confusing continuum of disagreement characterizing the role of gender as it relates to attitudes toward computers, and by extension, IT diffusion and learning performance in the workplace, carries on today. While men may still represent a majority of the IT workforce, the number of women in technology-oriented areas continues to rise. As a result, the implementation of new technology requires an understanding of the factors that are likely to lead to user acceptance and sustained usage across gender and experience levels.

Does gender matter when examining attitudes and anxiety toward computers? The only valid conclusion that can be drawn from the existing body of literature is: it is important, but we do not fully understand gender as a moderating variable in the context of computer anxiety. One standard recommendation is to do more research and bring to the forefront the need to be cognizant of sex differences. The hypothesis that some users will have less overall experience with computers and are therefore more likely to have negative attitudes towards computers should be kept in mind when creating, adopting, and using information technology systems. Also, if cognitive style is distributed differently across genders, which it currently appears to be, it too may be a relevant factor in IT diffusion. One way to ameliorate these differences is for new technology introductions to be accompanied by user involvement, training, and active practical use. Special attention should be paid to the user's sex and their experience level. Because of the ramifications in society, education, and the workplace, educators and managers need to know how to recognize computer anxiety and the strategies to help alleviate or eliminate it. It is important that future research has focus and direction, and answers larger questions, such as: understanding how high levels of computer anxiety develop; what role such anxiety plays in career choices; and constructing methods to reduce computer anxiety within technological environments.

KEY TERMS

Cognitive Style: Information processing habits that represent an individual's typical modes of perceiving, thinking, remembering, and problem solving. Various cognitive styles have been identified, measured, and shown to affect the manner in which individuals perceive their environments. As just one example, two such styles are field-independence and field-dependence. Field-independent individuals perceive objects as separate from the field, impose personal structures on the environment, set self-defined goals, work alone, choose to deal with abstract subject matter, are socially detached and rely on their own values, and are self-reinforcing. In contrast, field-dependent individuals tend to rely on the environment for clues about an object, prefer a structure provided by the environment, experience the environment more globally, are interested in people, use externally defined goals, receive reinforcement from others, focus on socially oriented subject matter, and prefer to work with others (Riding & Rayner, 1998; Witkin, Moore, Goodenough & Cox, 1977).

Computer Anxiety: The tendency of a particular individual to experience a level of uneasiness over his or her impending use of a computer, which is disproportionate to the actual threat presented by the computer. Computer anxiety, defined by Raub (1981), is "the complex emotional reactions that are evoked in individuals who interpret computers as personally threatening."

Computer Anxiety Rating Scale (CARS): A self-report inventory consisting of 10 statements designed to measure computer anxiety. The scale comprises a mix of anxiety-specific statements (e.g., "I feel apprehensive about using the computer") and positive statements (e.g., "I am confident that I could learn computer skills") (Raub, 1981).

Computer Self-Efficacy: Computer self-confidence or perceptions of ability. Beliefs about one's ability to perform a specific behavior or task on a computer.

Locus of Control: Individuals' perceptions of whether they themselves influence events and outcomes in their lives (internal control), or that events and outcomes are influenced by factors such as luck, fate, chance, or powerful others (external control). Locus of control is considered a trait characteristic that is unlikely to change significantly in an individual's lifetime.

Math Anxiety: The psychological fear or anxiety associated with engaging in mathematical activity. Characteristics of math anxiety are an above-average number of negative attitudes (e.g., nervousness, solitude, uneasiness, and low confidence) and/or intense emotional reactions to math based on past experiences. Math anxiety and test anxiety are generally significant correlates and somewhat resemble computer anxiety as a situational manifestation of a general anxiety construct.

Perceived Ease of Use (PEOU): The degree to which an individual believes that using a particular information technology system would be free of effort. An application perceived to be easier to use than another is more likely to be accepted by users (Davis, 1989).

Perceived Usefulness (PU): The degree to which an individual believes that using a particular information technology system would enhance his or her job performance. A system high in perceived usefulness is one that a user believes has a positive usage to performance relationship (Davis, 1989).

Social Presence/Information Richness Factor (SPIR): A factor appended to TAM derived from Hofstede's (1980) work on dimensions of cultural differences among countries that include a disposition toward masculine attitudes and other behavioral indexes. The extension combines perceived social presence and the sense of human contact embodied in a medium with the information richness of the medium (Straub**,** 1994).

Technology Acceptance Model (TAM): A causal model hypothesizing that actual information technology system use is affected by behavioral intentions that themselves are affected by attitudes toward use. Beliefs about the system, perceived usefulness, and perceived ease of use in TAM directly affect attitudes toward use (Davis, 1989).

Technology Profile Inventory (TPI): A psychological instrument that generates technology profiles to predict how individuals are likely to respond to various aspects of information technology. The ability to profile information technology users facilitates the design of software capable of dynamic personalization (DeYoung & Spence, 2004).

Theory of Planned Behavior (TPB): Defines relationships among beliefs, attitude toward a behavior, subjective norm, perceived behavioral control, behavioral intention, and behavior. The theory has been widely applied across a range of disciplines such as marketing, consumer and leisure behavior, medicine, and information technology. When applied in technology adoption and usage contexts, TPB explains an individual's adoption of new technologies (Ajzen**,** 1991).

Trait Anxiety: Traits are properties of individuals that dispose them to react in certain ways in given classes of situations. Trait anxiety is a chronic predisposition to be anxious and nervous that may be based on feelings of inadequacy, usually due to poor past performances, low-self image, or low-self esteem.

Generic Framework for Defining Domain-Specific Models

Arnor Solberg
SINTEF ICT, Norway

Jon Oldevik
SINTEF ICT, Norway

Audun Jensvoll
EDB Telesciences, Norway

INTRODUCTION

As a result of the widespread popularity of the Unified Modeling Language (UML) (OMG, 2003-1), many companies have invested in introducing a UML-based methodology. There are many general purpose UML-based methodologies on the market today; among the most popular are UP (Jacobson, Booch & Rumbaugh, 1999), RUP (Kruchten, 2000), Catalysis (D'Souza & Wills, 1998), Select Perspective (Allen & Frost, 1998), and KOBRA (Atkinson et al., 2001). Typically, these general purpose software system development methodologies do not immediately fulfill a company's need. Aiming to provide methodologies that may be applied in many domains and for many purposes, these general purpose methodologies typically become extensive and are perceived as overwhelming. At the same time they typically lack support for the more exclusive needs that the companies and domains encounter. Thereby, introducing a general purpose methodology in an organization commonly implies two particular challenges that at first sight seems to be contradictory. On one hand there is a problem that the general purpose methodology provides/prescribes far too much and encounters too many situations. On the other hand the general purpose methodology does not support specific modeling concepts, mechanisms, and techniques wanted by the particular company or development group. Thus, in that respect the general purpose methodology actually covers too little. This state of affairs is why lots of consultants, researchers, and others are in the business of helping companies to introduce these methodologies, as well as customizing general purpose methodologies to be appropriate for the actual company and purpose. The customization is typically tuned based on different criteria such as domain, kind of customers, quality demands, size of the company, and size of the software development teams. A common way of customizing a general purpose methodology is by removing, adding, and/or merging prescribed tasks, phases, roles, and models/artifacts of the methodology. However, even if introduction of a general purpose methodology almost always requires a customization effort, there does not seem to be any standard and formalized way of doing it.

BACKGROUND

Our research group has for quite some time worked with customizing methodologies to satisfy specific needs. Our customization has been accomplished by taking a set of different general purpose methodologies (e.g., RUP, UP, OOram (Reenskaug & Wold, 1996)), methodology expertise, and experience as input into a collaborative process together with architects and super-users. By massaging this input through an iterative and incremental process in which we have analyzed the company's need and existing methodology (or practice) in use within the company, company culture, particularities of the domain, customers, market, and so forth. The output has been a tailored methodology.

Some results of this work have been the COMBINE methodology (COMBINE, 2003, 2000), the DAIM methodology (Hallsteinsen, Solberg, Fægri, Oldevik & Syrstad, 2003; DAIM, 2001), TeMOD (Solberg & Oldevik, 2001) and the Configurable LIght-Weight Method (CLIMB) (Solberg, Oldevik & Jensvoll, 2002a). What we have discovered during our work was that even if we gained substantial benefits from tailoring general purpose methodologies to the needs of the company, the company itself is quite diverse. Thereby, a need was expressed of even more tailoring to fit the purpose of different domains and product families within the company. For instance when developing TeMOD for Telenor[1] and later CLIMB for EDB Telesciences[2], a main request was to deliver a methodology that was tailored to capture and utilize existing domain knowledge. However, one of the goals of making

TeMOD and CLIMB was to provide a common methodology to be used throughout the company, in order to achieve a common way of developing and specifying systems. Thus, we were not supposed to end up with a set of proprietary special purpose methodologies, one for each domain and system development group. Our challenge became to keep TeMOD and CLIMB as the common methodologies for the respective company, enforcing standardized processes and specifications, and at the same time get the methodology to support specific needs of different domains and utilize the existing domain knowledge possessed within the company.

The most popular general purpose UML-based software engineering methodologies have both diversities and commonalties. One frequent commonality is that they are model driven. A model-driven methodology signifies that the methodology prescribes a set of models as the artifacts to be produced during the system development process. Model-driven methodologies have gained increasing popularity, even more so after the Model-Driven Architecture (MDA) (OMG, 2001; Frankel, 2003) initiative was launched. Our approach to the above described challenge was to exploit this model-driven aspect to develop a generic framework that provides utilities for tailoring model-driven methodologies in a formal and standardized way. Using the framework, the tailoring will only affect the expression of the models prescribed by the general purpose methodology.

FRAMEWORK DESCRIPTION

By applying the tailoring framework, a domain-specific reference model is produced. The reference model describes the extensions of the actual general purpose methodology made for a specific domain. It consists of UML-profiles, existing (reusable) models, and patterns.

The set of UML-profiles, existing models, and patterns defined in a reference model are developed, structured, and aligned according to the chosen general purpose software engineering methodology. UML-profiles are used for defining domain concepts and reference architectures. Existing models are prepared for reuse, and patterns describe standard solutions of recurring problems within the domain. Thus, tailoring a software engineering methodology using the framework constitutes a leveraging of the methodology in an environment of domain concepts, defined reference architectures, existing models, and patterns.

Figure 1. Example of framework usage

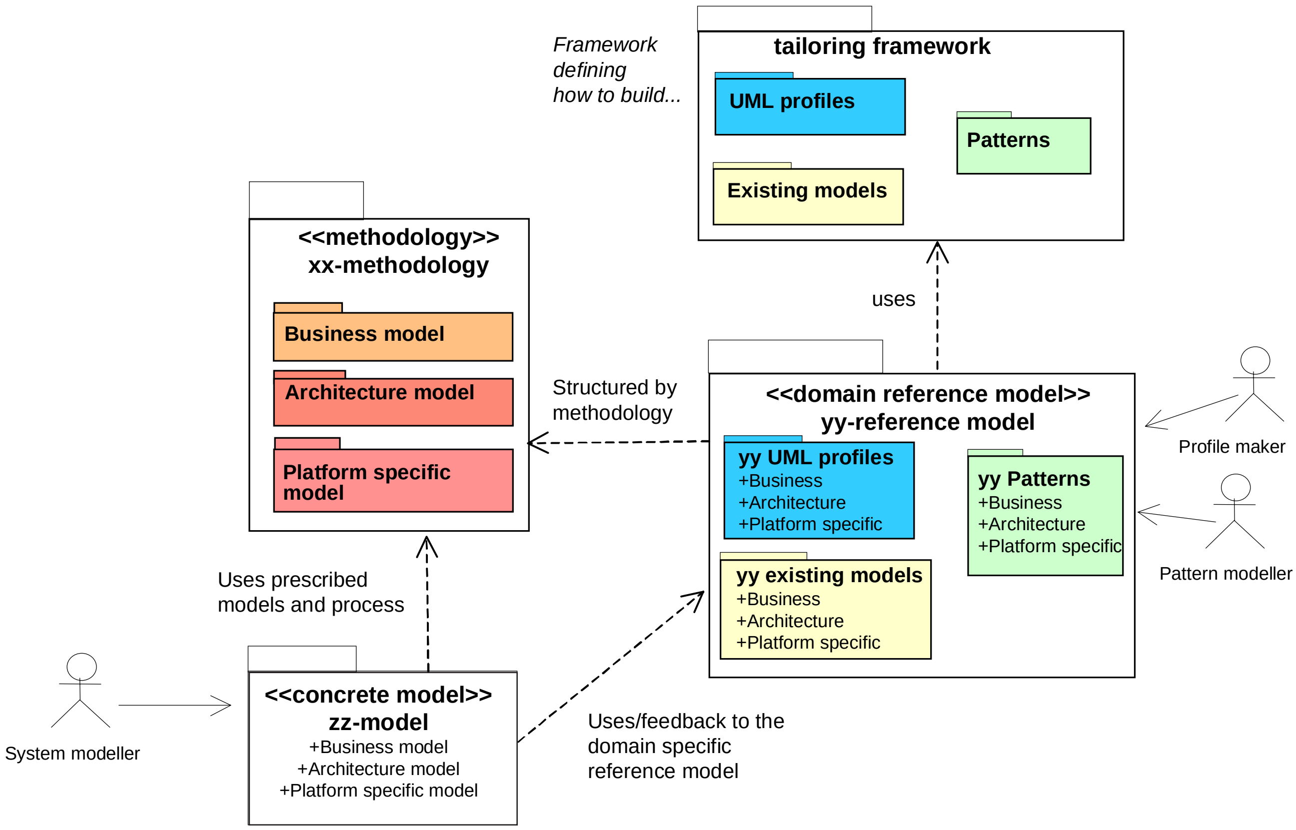

Figure 1 shows the structure of use of the framework. The tailoring framework defines how to build appropriate UML-profiles, patterns, and existing models, and it defines how to use the reference-model in correspondence with the chosen general purpose methodology. The domain-specific reference model is built using the tailoring framework and is structured according to the chosen methodology. The profile maker and pattern modeler have the main responsibilities of building the domain-specific reference model. The system modeler uses the chosen methodology's prescribed models and process, as well as the reference model for the actual domain, to build concrete models. The system modeler might also feed back reusable models to be part of the reference model. Those models will then be categorized according to the chosen methodology, and become an existing model of the domain-specific reference-model.

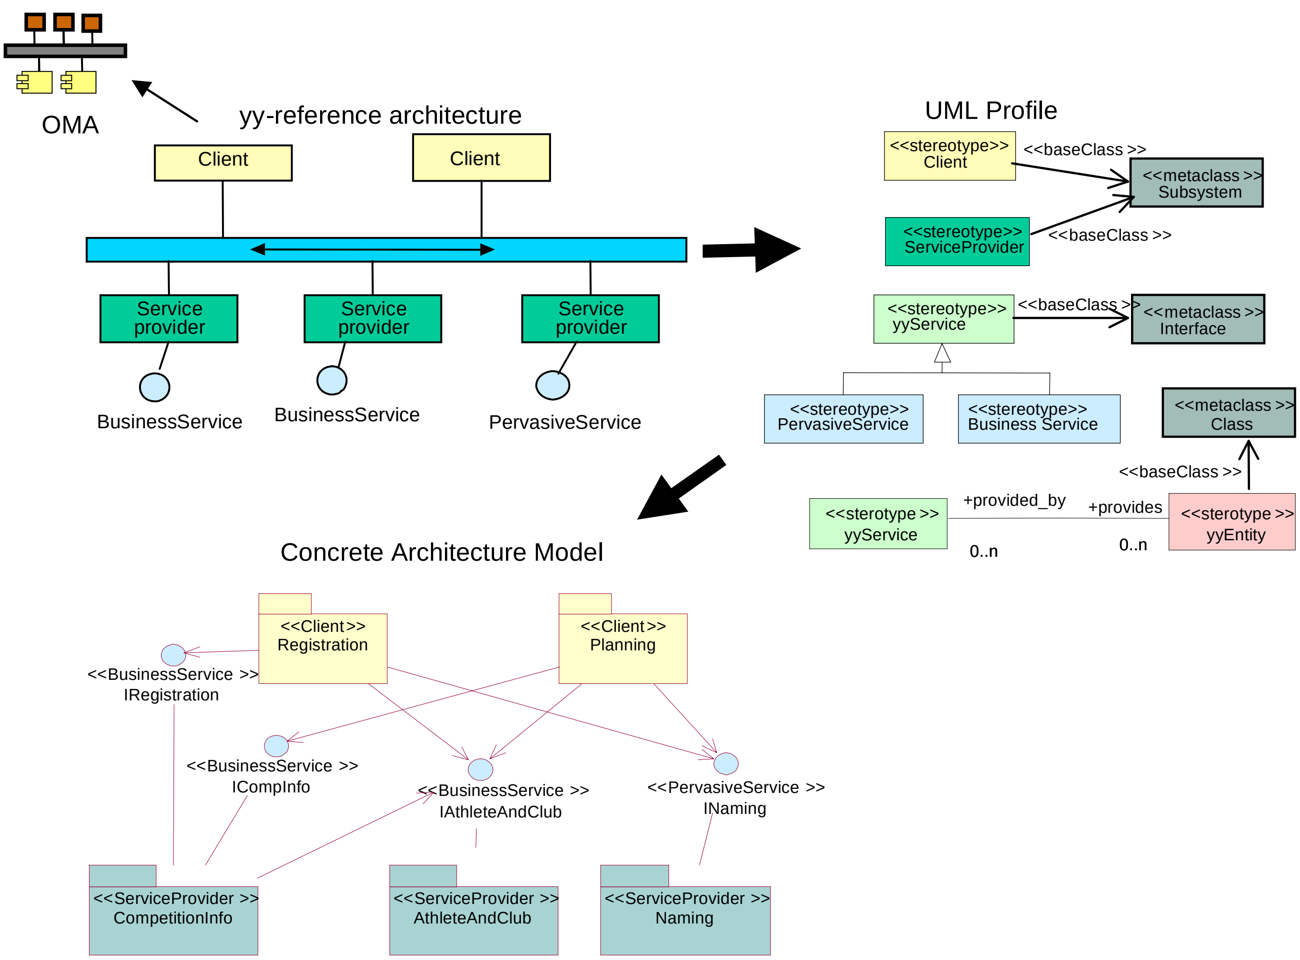
Figure 1 indicates use of a general purpose methodology, xx-methodology, which specifies three main models as outcomes of the development process: a business model, an architecture model, and a platform-specific model. The yy-reference-model (supporting the yy-domain or yy-product-family) is structured according to the xx-methodology and specifies a set of UML-profiles, patterns, and existing models in accordance with the model architecture of the xx-methodology (business, architecture, and platform-specific). The concrete zz-model consists of a business model, an architecture model, and a platform-specific model produced according to the xx-methodology and the yy-reference-model.

In the example of Figure 1, the domain reference model includes UML-profiles, patterns, and existing models at all model levels (business, architecture, and platform-specific). This is not required. However, the tailoring framework requires that the constituents of the domain reference model should be structured according to the model architecture of the chosen general purpose methodology. This will ensure commonality and standardization across domain-specific reference models.

The tailoring framework is generic and might be used to customize all UML-based, model-driven methodolo-

Figure 2. Reference architecture, UML-profile, and usage example



gies (including UP, RUP, TeMOD, and CLIMB). In principle, an infinite set of domain reference models supporting a specific domain or product family might be developed as customizations of a particular methodology (thus, a one-to-many relationship between methodology and reference model). There are also one-to-many relationships between methodology and concrete model, as well as between domain reference model and concrete model.

It is also plausible to use the tailoring framework to extend or specialize a specific domain reference model, for instance to support a sub-domain. In the following we describe how the three constituents of the reference model are applied. A more thorough example can found in Solberg, Oldevik, and Jensvoll (2002b).

UML-Profiles

The framework prescribes the common techniques for defining UML-profiles, using the UML extension mechanisms, stereotypes and tagged values, both of which extend the concepts we can work with in the UML world.

The UML-profiles of the framework describe the essential concepts from the domain in question. These profiles - that is, the concepts defined in these profiles (the stereotypes) - can be used as first-class modeling concepts when defining concrete models. Thus, customizing for an organization or a development group, the wanted domain modeling concepts are defined using UML profiles.

The framework recommends always developing a profile defining the reference-architecture used within the domain or product family. Such a profile will give essential support when modeling concrete system architectures. Figure 2 shows an example of defining the reference architecture for the yy-domain by a UML-profile. The architecture model prescribed by the general purpose methodology is then customized to support the reference architecture of the domain or product family. The figure shows the yy-reference-architecture for the yy-domain or the yy-product-family. The figure also indicates that the yy-reference-architecture is related to a standard bus architecture like the OMA.[3] The UML-profile extends the UML with the appropriate architectural concepts, which then become employed as first-class modeling concepts in the concrete architecture model.

Detailing of the UML-profile might be done in a tabular form as shown below (for the yyService and the yyEntity).

Similarly, UML-profiles might be made for all the model levels defined by the chosen methodology. For example, for the xx-methodology indicated in Figure 1, we might have domain profiles for the business, architecture, and platform-specific level defining the vocabulary to be used for modeling each of these levels respectively. An example of a platform-specific UML profile can be found in JSR (2001).

Patterns

Patterns represent special kinds of existing models that describe a recurring problem and suggest a general solution to that problem. The tailoring framework is used to define patterns and categorize them according the actual model architecture of the chosen methodology. For the xx-methodology in Figure 1, there might be business model patterns, architecture model patterns, and platform-specific model patterns. A pattern is employed by instantiating it (as a template) into a concrete model; the concrete model defines who/what is fulfilling the responsibilities defined by the roles in the pattern.

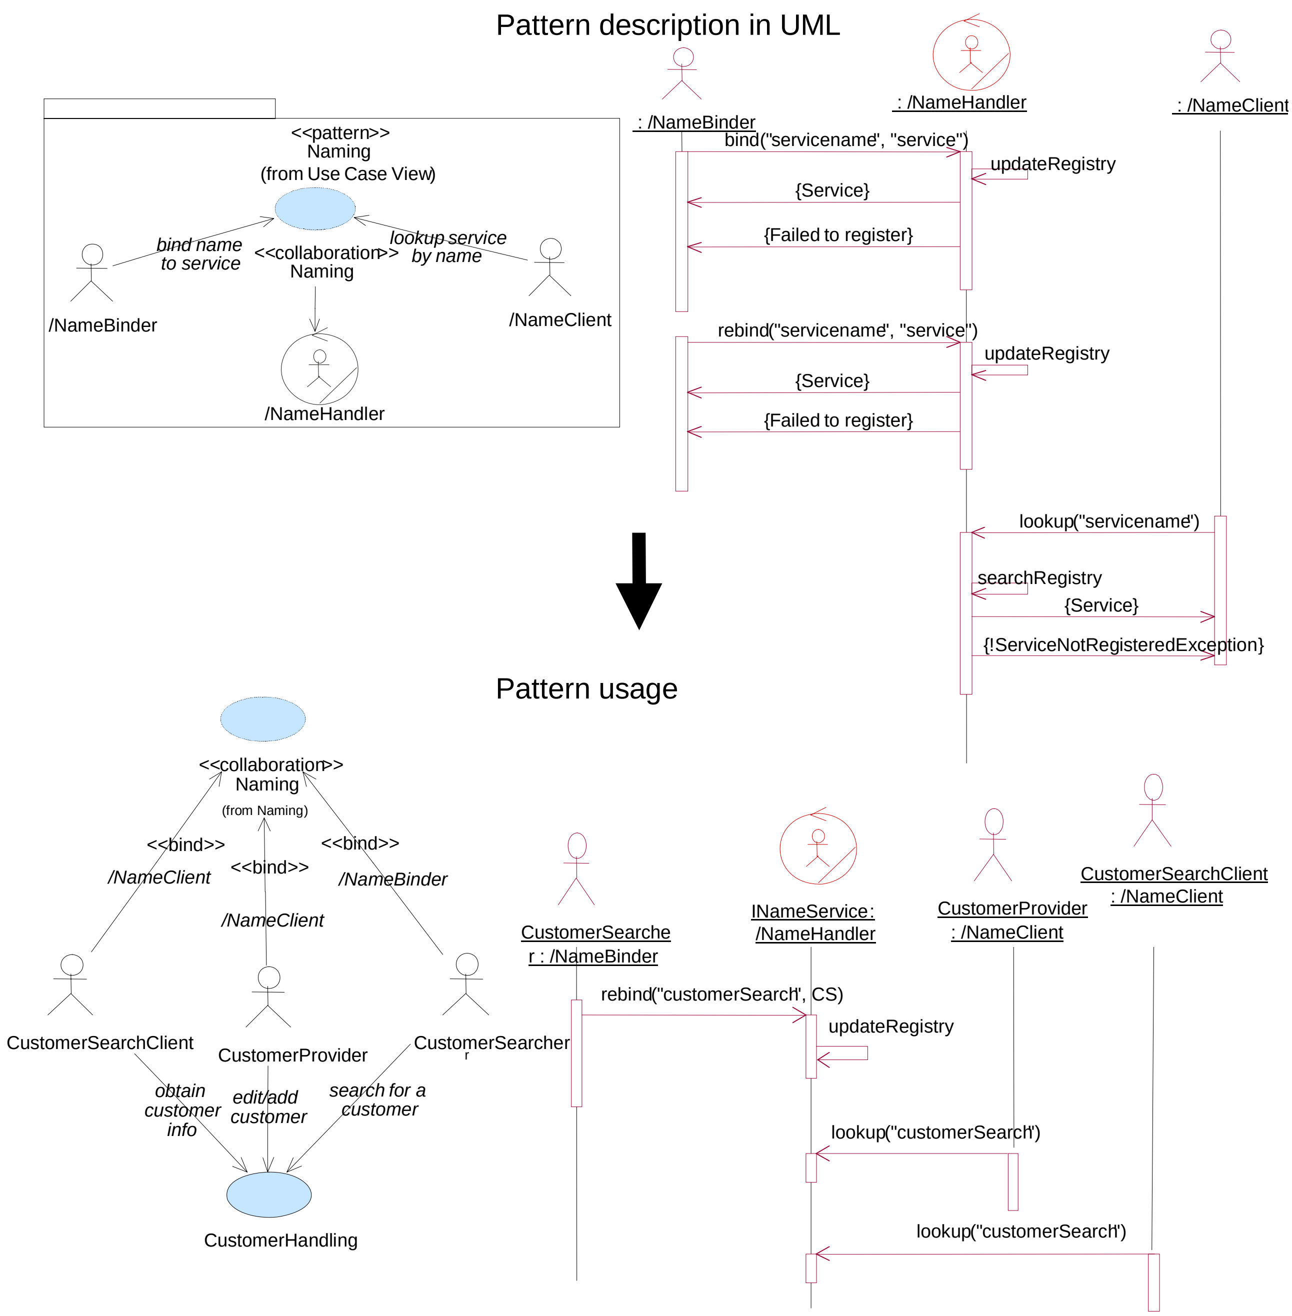
The tailoring framework includes a framework for pattern definition and use. This pattern framework includes both some special notation (defined in a UML-profile) and a template for pattern description.

The pattern structure technique of UML collaboration is used as the basis to define the pattern. The pattern structure technique is used for viewing the collaboration as a single entity from the outside. The collaboration details are further defined using UML activity diagram or UML sequence diagram. A simple example describing a pattern for a naming service and the usage of the pattern is shown in Figure 3.

UML has defined a naming convention denoting roles which allows a simple way of indicating a role. The general syntax is:

Stereotype	**Metamodel base**	**TaggedValues**	**Description**	**Constraints**
yyService	Interface	Transactional network-accessible	A service access interface, corresponds to a yyservice from the architecture profile.	self.allOppositeAssociationEnds -> forAll (a | a.type.oclIsTypeOf (yyService) or a.type.oclIsTypeOf (yyEntity))
yyEntity	Class	Persistent	Represents information provided through an yyservice.	self.allOppositeAssociationEnds -> forAll(a | a.type.oclIsTypeOf(yyEntity))

Figure 3. Pattern description and usage



ObjectName '/' ClassifierRoleName ':' ClassifierName [',' ClassifierName]*

The top left of Figure 3 shows the pattern structure in terms of roles collaborating to fulfill a mission defined by the unified responsibilities of the roles in the collaboration. The naming pattern defined includes three roles: NameBinder, NameClient, and NameHandler.

A collaboration is modeled as a use case stereotyped with <<collaboration>>. The roles are modeled as UML actors with role-names. These roles can either be external or internal to the pattern. It is the external roles that are parameterized when the pattern is used. The worker stereotype is used to denote internal actors. The NameHandler is an internal role in the example. The semantics of the collaboration 'use-case' is the same as a UML collaboration pattern structure (a use-case realization).

- The sequence diagram of the top right defines the behavior of the pattern by specifying interactions between roles.

In order to use a pattern, the desired external roles of the pattern must be instantiated. This is done by using a specialized '*binding*' relationship from the pattern collaboration source to the roles that instantiate the designated roles of the pattern. The role parameters are bound by the role-name specified on the binding relation, for example, '/NameClient'. The lower left of Figure 3 shows how a pattern can be instantiated by binding the roles from the pattern. There are no limits as to how many roles can be bound to another role or actor.

The sequence diagram at the lower right shows an example of synthesizing the pattern onto a specific architecture.

Existing Models

Existing models represent already defined concrete models that can be reused by package import and referencing. In the same way as for the UML-profiles and patterns, the tailoring framework prescribes that the existing models should be categorized and structured according to the model architecture of the chosen general purpose methodology. Typical usage of an existing model is to reuse, for example, an existing interface by inheritance or reference. Thus, the existing model part of the framework is to provide support for reuse also at the model level.

An existing model is reused in terms of package import, where the namespace defined by the package becomes available. All public artifacts (use-cases, actors, interfaces, classes, etc.) become available to the importing package. Alternatively, elements from an existing model can be used simply by scoped naming (UML pathnames), that is,

nnCore::PervasiveServices::NamingService::INaming,

which refers to the INaming interface contained in the package structure implied.

The general mechanism for reuse of a model, being it a pattern or a standard model, is by import of the package that defines the model. This makes the model elements defined in that package available (by model elements, meaning interfaces, classes, etc.). In principle, we can then reference interfaces from that package.

Package import is straightforward in UML, done with the <<import>> dependency stereotype between packages.

FUTURE TRENDS

A future trend will still be to configure model-driven, general purpose methodologies by means of selecting those parts of the general purpose methodology which seem relevant - for example, the set of roles, tasks, models, and process steps. This is basically how Rational Unified Process is configured to fit the actual purpose (Kroll & Kruchten, 2003). However getting better tool support for this configuration activity will be more in focus in the future. The RUP platform already provides some tool support for configuration (see *www-306.ibm.com/software/rational/*). Also, preconfigured methodologies for different domains and purposes will be provided, such as the dX process (Martin, 2004), which more or less is RUP made agile. However, these are still at a general purpose level and will typically need to be further customized to be appropriate for a specific company or development group.

Another trend in this regard is the development of domain languages in the context of the actual methodology and to utilize these in an MDA-based system development. The idea is to have your modeling concept formally defined and categorized in alignment with the set of main models you develop (e.g., Business Model, Architecture Model, and Platform-Specific Model), and to perform model transformation and code generation. This is typically accomplished by means of UML's extension mechanisms and the MOF (OMG, 2003b). There exists already many domain languages in the form of UML profiles; some are also standardized (e.g., JSR, 2001; OMG 2002). Defining your metamodel and syntax more or less from scratch, like in MetaCase *(www.metacase.com)* is another possible future trend in this respect.

The scoping for your language and your methodology is notified to be important as to get efficient methodologies providing efficient modeling concepts. This is for instance an important aspect of the System Family approach (Atkinson et al., 2001; Families, 2003), where the right level of scoping is said to be the System Family typically covering a set of tidy, related products where the commonality are substantial.

Also, formalizing and combining some of these ideas, like selecting parts of general purpose methodologies, appropriate scoping and making extensions of your modeling language to fit your domain or system family, and providing utilities for supporting reuse we believe will be a future trend. Our framework is one potential approach.

CONCLUSION

In this article, we have described a generic framework for customizing general purpose methodologies for the purpose of providing better support to specific needs within a domain or product family. An important aspect of this has been to ensure utilization of the existing knowledge possessed within the actual domain.

The tailoring framework introduces the need for new roles responsible for developing and maintaining reference models. The developers must also learn to use the actual reference model appropriately. Thus, successful introduction of the tailoring framework requires a well-defined process and careful consideration of the relevant risks.

The framework has already been used within the Telenor group and the EDB Telesciences, and we have seen several benefits from its application. It assists in:

- Establishing and maintaining models representing knowledge possessed within the domain.
- Model reuse: The reference-model advocates model-level reuse, leveraging existing models and patterns describing best practice for solving recurring problems within the domain. Current tool support is rather immature, so there is still potential for gaining substantial improvement of the efficiency of the model development with sufficient tool support.
- Reuse at the right level: It has been proven that efficient reuse is easier to gain within a product family community or a fairly small-scoped domain, as opposed to general purpose reuse in widely scoped domains. It is then easier to build a reusable asset library within the reach of the users.
- Ensuring consistency of a set of models: Customizing a general purpose methodology with stereotypes, common domain models, or common patterns will help make the models more consistent.
- Standardization: The reference model functions as the "standard" for the specific domain, without contradicting the prescriptions of the general purpose methodology which function as the standard for a set of domains (e.g., the enterprise as a whole).
- Adding more semantics to the models: The use of stereotypes and the description of patterns can help make the models more powerful and expressive for the readers and the modelers.
- Preparing for code generation: Code generation can be made more powerful when defining reference models, and can utilize the defined UML-profiles, patterns, and existing models.

KEY TERMS

Framework: The underlying structure supporting or containing something.

General Purpose Methodology: Methodology that attempts to be applicable across domains and for different kinds of systems and purposes.

Model-Driven Architecture (MDA): An approach under construction within the OMG trying to define and standardize model-driven software system development.

Model-Driven System Development: A software system development approach where the output of the development activities is a set of models. The code itself is seen as a model that is specified using programming language. The process is driven by the development of the set of prescribed models.

Pattern: Describes a recurring problem and suggest a general solution to that problem.

Software System Development Methodology: Defines techniques and mechanisms, as well as the process steps to go about developing software systems.

UML Profile: An extension of the UML metamodel typically used to define further concepts, e.g., domain-specific concepts. A set of UML profiles is standardized within the OMG (e.g., JSR, 2001; OMG, 2002). A UML profile is developed using the UML's extension mechanisms: stereotypes, tagged values, and constraints.

Unified Modeling Language (UML): A graphical specification language, standardized by Object Management Group (OMG).

Geographic Information Systems as Decision Tools

Martin D. Crossland
Oklahoma State University, USA

INTRODUCTION

Geographic information systems (GISs) as a technology have been studied and reported extensively and, not unexpectedly, in the field of geography. The various ways of capturing spatial data, arranging attribute data into appropriate database structures, and making the resulting large data sets efficient to store and query have been extensively researched and reported (Densham, 1991). However, the geographic research community has only recently noted the need to study how GISs are used as decision tools, especially with regard to how such decision making might be related to a decision maker's cognitive style (Mennecke, Crossland, et al., 2000). As an example, the University Consortium for Geographic Information Science called for research examining how geographic knowledge is acquired through different media and by users with different levels of experience and training (University Consortium for Geographic Information Science, 1996).

Researchers in the fields of decision sciences and information systems have more recently begun to make contributions in the area of decision making with GISs. When a GIS is employed as a decision support system, in these studies the resultant system is often referred to as a *spatial decision support system*, or *SDSS* (see Crossland, 1992; Crossland, Perkins, et al., 1995; Mennecke et al., 2000).

A *geographic information system* in its simplest form is a marriage of accurately scaled digital maps with a database. The digital maps comprise spatially referenced details such as natural elements (lakes, rivers, topographic elevation contours, etc.), manmade objects (buildings, roads, pipelines, etc.), and political boundaries (city limits, state and county lines, international boundaries, etc.). These natural elements are typically referenced, with varying degrees of precision, to latitude/longitude coordinates on the earth's surface. It must be noted here that the degree of precision and, more importantly, differences in degrees of precision for the various elements are the subjects of much research and user consternation in applications of GISs to solving problems. The database, in turn, catalogs information about the various spatial elements (e.g., the names of rivers, names of buildings, building owner, operator of a pipeline, etc.). These descriptive entries in the database are often referred to as *attributes* of the various spatial elements.

A GIS may be paired with the *global positioning system* (*GPS*), from which real-time, satellite-derived location information may be derived, as provided by an appropriate GPS receiver.

BACKGROUND

With regard to the effectiveness of decision making when using information tools, there is a relatively long history of researchers emphasizing that tools which provide graphical presentations and graphical representations of information are deserving of special note and study. For example, Ives (1982) discussed at great length the role of graphics in business information systems. He even went so far as to state, "The map, perhaps more than any other chart form, gains the most from the availability of computer graphics" (p. 16).

Several more recent studies have drawn from Image theory (Bertin, 1983) to help explain why decision makers using GISs may experience greater effectiveness in decision making. Image theory states that one graphical representation of information may be considered more efficient than another for a particular question, if that question can be answered in the mind of the decision maker in a lesser amount of time. In his *Semiology of Graphics*, Bertin defined image theory and put forth the constructs of images and figurations. An *image* is a meaningful visual form, perceptible in a minimum instant of vision. A *figuration* is a more complex construction comprising multiple images. Figurations are inherently less efficient than images, according to image theory. This is because the viewer is able to grasp the full informational content of an image in a brief moment of viewing it. Figurations, on the other hand, comprise multiple images which must be mentally extracted, processed, and related in the viewer's perception. Although the informational content may be richer in a figuration, it is inherently less efficient for quick extraction of specific information.

The more recent studies propose that one role of GISs is to collapse more complex figurations into simpler figurations or even to simple images. This has the net effect of increasing a decision maker's efficiency in extracting relevant information for the purpose of evaluating and making a decision. For examples the reader is encouraged to review Crossland (1992), Crossland, Herschel, et al. (2000), Crossland et al. (1995), and Mennecke et al. (2000).

Although there seems to be a common assumption that GISs improve decision making (Morrison, 1994), only a few studies to date have performed controlled experiments to actually test this assumption. Those that have been accomplished typically used dependent variables of decision time and decision accuracy to measure decision-making effectiveness. These include Crossland (1992), Dennis and Carte (1998), Mennecke et al. (2000), Smelcer and Carmel (1997), and Swink and Speier (1999). All of these studies found that the addition of a GIS to a spatially referenced decision-making task had a positive effect on decision outcomes.

THE ROLE OF COGNITIVE STYLE IN DECISION MAKING WITH GISS

With respect to decision making, the term *cognitive style* has been used to refer to enduring patterns of an individual's cognitive functioning that remain stable across varied situations. Various elements of cognitive style have been speculated upon and studied in various disciplines. With respect to decision making using GISs, two elements have been studied in some depth, *field dependence* and *need for cognition*.

Field dependence (FD) measures a person's ability to separate an item from an organized field or to overcome an embedded context (Witkin, Lewis, et al., 1954). Zmud and Moffie (1983) proposed that people with lower field dependence tend to outperform those with higher field dependence in structured decision tasks and that they tend to make more effective use of transformed information (e.g., aggregated values and graphical formats, such as are typically found in a GIS). FD can be measured using commercially available testing instruments. Because making decisions using a GIS, by its nature, involves mentally extracting relevant information from a potentially complex field of information, studies have hypothesized that low field dependence should predict better decision making with a GIS or other spatially referenced tool. In particular, field dependence is seen as an inverse proxy for an individual's level of spatial cognition—the ability of an individual to grasp and analyze information within a spatial context.

Need for cognition (NFC) was proposed by Caccioppo and Petty (1982) as a measure of a person's internal motivation to pursue and enjoy cognitive tasks and activities. They developed a questionnaire which can be used to measure this cognitive-style attribute. People who score high on the need for cognition scale tend to enjoy the engagement of thought activity in a task as much or more than even the result of a task. The studies named below hypothesized that this tendency to engage more fully in a task should lead to more effective decision making, as measured by the dependent variables of decision time and decision accuracy.

Studies that looked at FD, NFC, or both as independent variables of decision-making performance using GISs include Crossland (1992), Crossland et al. (1995), and Mennecke et al. (2000). In general, the findings may be summarized as follows:

- Field dependence exhibits an inverse main effect on decision time, but not on decision accuracy. That is, subjects with lower field dependence tend to solve spatially referenced problems more quickly, but not more accurately. It may be that the efficiency predicted by image theory does contribute to faster decision making, but not to more accurate decisions.
- Need for cognition exhibits a positive main effect on decision accuracy, but not on decision time. That is, higher-NFC subjects tend to solve spatially referenced problems more accurately, but not more quickly. This last finding was noted as unexpected by Crossland (1992). He speculated that perhaps an individual with a high NFC might tend to spend longer in thinking about the problem and its solution, thereby extending the decision time. It would seem, however, that this extra thinking effort may have contributed to a more accurate solution.

FUTURE TRENDS

Some questions and issues in this area of research that remain to be addressed include:

- How do other important measures of cognitive style affect a decision maker's ability to solve spatially referenced problems accurately and quickly?
- How does problem complexity factor in or even interact with the decision maker's task? Several studies also examined problem complexity as an independent variable (Crossland, 1992; Crossland et al., 1995; Mennecke et al., 2000). Crossland et al. (1995) reported an observed interaction of field dependence with problem complexity that would be interesting to explore further.
- To what extent are SDSSs/GISs effective in collapsing figurations (as defined by image theory) into

images or into simpler figurations? Are there certain levels of complexity beyond which it becomes impractical or ineffective to combine or collapse displays into simpler decision tools? How does the cognitive style of the decision maker factor into this consideration?

- Are SDSSs/GISs even necessary for certain types of problems? Perhaps a series of static, hard-copy outputs are sufficient for some decisions by some decision makers, and the combined or flattened displays are not necessary. The cognitive style of the decision maker may be an important factor in this.
- Studies in this area may be useful in understanding more generally how technology is useful in supporting decision makers in other contexts. For example, Vessey (1991) and Vessey and Galletta (1991) suggested that three variables would influence the mental representation that the decision maker develops: (1) the problem representation, (2) the problem-solving task, and (3) the decision maker's problem-solving skills.
- It may be useful to apply cognitive fit theory to these types of problem-solving tasks, as proposed by Mennecke et al. (2000), to better understand the factors that appear to be important in influencing a user's formation of a mental representation of spatial tasks.

CONCLUSION

The roles of components of cognitive style of a decision maker are important factors in how well he can solve problems and carry out spatially referenced tasks when using a GIS. Although current research has shown that simply using a GIS can enhance decision-making effectiveness, the cognitive style of the subject is a less well understood element of the process. More research is needed in this area to better define and understand it.

KEY TERMS

Attributes: are the pieces of information contained in a GIS database that describe or detail a spatially referenced element.

Cognitive Style: refers to enduring patterns of an individual's cognitive functioning that remain stable across varied situations.

Digital Map: any form of geographic boundaries or spatially referenced drawings that have been captured, or "digitized," into an electronic form. Each element of the map is or may be linked to various descriptive or identifying types of information in a database.

Field Dependence (FD): measures a person's ability to separate an item from an organized field or to overcome an embedded context.

Figuration: as defined in image theory, is a complex construction comprising multiple images. Figurations are inherently less efficient for extracting information than images, according to image theory.

Geographic Information System (GIS): a marriage of accurately scaled digital maps with a database. The digital maps comprise spatially referenced details such as natural elements (lakes, rivers, topographic elevation contours, etc.), manmade objects (buildings, roads, pipelines, etc.), and political boundaries (city limits, state and county lines, international boundaries, etc.). These natural elements are typically referenced, with varying degrees of precision, to latitude/longitude coordinates on the earth's surface.

Global Positioning System (GPS): provides real-time, satellite-derived location information based on information received by an appropriate GPS receiver. GPS is funded by and controlled by the U.S. Department of Defense (DOD). While there are many thousands of civil users of GPS worldwide, the system was designed for and is operated by the U.S. military. A GPS may be employed in the original construction of the digital map information to be stored in a GIS. Or, if the GIS is already constructed, the GPS may be employed to accurately render the position of new elements to be added to the GIS or the current position of a mobile element to be referenced against the information stored in the GIS. A good example might be a freight truck moving on a highway. The GPS receiver on the truck can derive its current latitude and longitude and then send that information to the GIS system in the truck cab, to a GIS in a central control center via radio, or to both for subsequent reporting and analysis.

Image: as defined in image theory, is a meaningful visual form, perceptible in a minimum instant of vision.

Need for Cognition (NFC): a measure of a person's internal motivation to pursue and enjoy cognitive tasks and activities.

Spatial Decision Support System (SDSS): typically, a geographic information system (GIS) that has been extended to provide knowledge workers with decision-making tools and support data.

Spatially Referenced Data: entities, typically recorded as records in a database, which have some notion of a definite location in space.

Geospatial Information Systems and Enterprise Collaboration

Donald R. Morris-Jones
SRA, USA

Dedric A. Carter
Nova Southeastern University, USA

INTRODUCTION

Organizations and teams are becoming increasingly more distributed as groups work to expand their global presence while rationalizing team members across skill sets and areas of expertise instead of geographies. With this expansion comes the need for a robust and comprehensive language for pinpointing locations of globally distributed information systems and knowledge workers. Geospatial information systems (GISs) provide a common framework for jointly visualizing the world. This shared understanding of the world provides a powerful mechanism for collaborative dialogue in describing an environment, its assets, and procedures. The collaborative framework that GIS provides can help facilitate productive dialogue while constraining impulses of extreme positions. Collaboration and GIS intersections take many forms. Under a collaborative work-flow model, individuals use GIS to perform their job and post data back to the central database (e.g., engineering designs and as-built construction).

This article addresses the increasing role of GIS in emerging architectures and information systems in a number of applications (e.g., land planning, military command and control, homeland security, utility-facilities management, etc.). Real-time applications, mobile access to data, GPS (global positioning satellite) tracking of assets, and other recent developments all play a role in extending the scope and utility of the GIS-enabled enterprise. The impact of new GIS Web services standards and open geospatial-data archives are also addressed as areas of increased potential for remote GIS collaboration in global organizations. The expansion of enterprise GIS within organizations increases the opportunity and necessity of using GIS collaboratively to improve business processes and efficiency, make better decisions, respond more quickly to customers and events, and so forth.

BACKGROUND

The term *geospatial* is increasingly used to describe digital data about the earth in GIS, image, or GPS formats. The related technologies of GIS, remote sensing image-processing systems, and GPS data collection are all components of geospatial information systems. Geospatial-technologies use continues to expand in a great variety of applications ranging from land planning to utility-engineering design and military command and control. Those applications, which were once relegated to discrete groups of specialists, have now begun to take a more prominent role in the enterprise. Duffy (2002) describes the transition of GIS from a specialist technology to a more mainstream environment in the industry information-systems department from the end of the last decade into 2002.

The essence of collaboration is people and organizations working together to accomplish a common goal. Information–technology- (IT) enabled collaboration has improved business processes in many organizations and contributed to more functional and profitable operations. Collaboration technologies are characterized by three major generic attributes: communication, information sharing, and coordination (Munkvold, 2003). These characteristics can be further refined into available channels such as synchronous or asynchronous, the medium of sharing information through repositories or real-time interaction, and work-flow management to coordinate steps in a decision process or protocol. Geospatial technologies and systems extend collaboration in unique ways for problems that are related to location.

GIS provides a geographic dimension to enterprise collaboration, which helps solve a variety of problems that are difficult to address by any other means. For example, vehicle-routing and dispatching applications make it possible for Sears to deliver goods to customers more efficiently within tighter time windows. As a result, Sears is more profitable and customers are more satisfied.

This example of distributed-network optimization using efficient queuing mechanisms based on location information is a simple illustration of the impact that GIS data may have on existing business processes. In fact, most aspects of business-process automation initiatives at present require some element of collaboration either between networked systems or dispersed individuals.

Collaboration utilizing GIS and geospatial frameworks continues to be a focus of research both in the United States and abroad (Boettcher, 2000; Songnian, 2004; Stasik, 2000).

EMERGING GEOSPATIAL INFORMATION-SYSTEMS ARCHITECTURES AND COLLABORATIVE ENTERPRISE APPLICATIONS

As organizations become more dispersed in an effort to rationalize across areas of expertise in lieu of geographies, complex infrastructures for location analysis and coordination may emerge (Munkvold, 2003). In recent years, GIS software companies have developed an expanding and increasingly capable enterprise suite of tools. Early generations of GIS were used by GIS specialists only; these systems were available in stand-alone or project-systems configurations. GIS product options have improved and now provide a sound basis for supporting casual users as well as specialists with desktop, distributed client-server, and Internet solutions.

Geospatial data standards and interoperability have greatly improved the ease of using data in different formats or geographic projections. Geospatial Web-services standards provide Internet access to geospatial data stored in geospatial-data archives. Federal-government initiatives (e.g., Geospatial One Stop, the National Map, Homeland Infrastructure Foundation Level Database, etc.) will increase data standardization and access, and reduce expensive, redundant data collection.

GIS-enabled collaboration can now involve a broad range of different types of users within and outside of a particular organization. These users can be expert or casual as well as stationary or mobile. Medeiros, de Souza, Strauch, and Pinto (2001) present an analysis of aspects of coordination in a collaborative system for spatial group-decision support that resulted in a prototype system for a distributed GIS.

Geospatial Information-Systems Products and Architectures

GIS-product vendors continue to innovate and expand the solution set available to the user (Atkinson & Martin, 2000).

Enterprise suites of GIS include the following different types of products.

- Desktop GIS with varying levels of functionality
- Spatial analysis extensions
- Internet GIS with limited functionality or full functionality
- Mobile GIS
- Geospatial-data middleware
- Software to embed geospatial functionality in business applications
- 3D GIS
- Geospatial-data visualization software
- GPS tracking software
- Remote sensing image-processing software
- Geospatial Web-services software
- Location services

GIS products are available to support stand-alone users, and distributed client-server and centralized Internet architectures. GPS tracking units and mobile GIS on Personal Digital Assistants (PDAs) and pocket PCs extend the range of the technology into the field. Wireless communication of data is improved through the use of data compression and area-of-interest extraction techniques.

Geospatial-data management functionality is improving but is less capable than business-data management functionality. While Oracle states that their products now provide equivalent data-management functionality for spatial and business data, experience is limited for enterprise replication of geospatial data. ESRI, the GIS-software market leader, promises to add geospatial-data replication to its ArcSDE product with the release of ArcSDE 9.1, which is projected for 2005. The large size of geospatial-data files means that substantial bandwidth is needed to move data through a communications network.

Location services refer to mobile geospatial services that will primarily be delivered to location-aware smart phones. The E-911 legislation mandates that cell phones must become location aware so emergency vehicles can locate 911 callers who use cell phones. Cell-phone operators and partners are and will offer an increasing array of location services to provide users with directions for driving, the nearest services of different types, and the location of buddies (i.e., those who have authorized sharing this information, etc.). An example system is presented in the location-based tourist-guide application of Simcock, Hillenbrand, and Thomas (2003). This tool combines a mobile PDA device and GPS technology to provide the user with location tours that are self-guided.

Collaborative Land-Use Planning

Geospatial data provides a common view or abstraction of an area. GIS has been used extensively in land-use planning. While GIS initially served and continues to serve as a tool for planners, it is increasingly used to facilitate collaboration with the public. The ability to show land and its characteristics to groups of people with divergent views provides a common frame of reference, which can make it easier to develop consensus or agreement on difficult issues. The common GIS data framework serves to constrain more extreme positions, which are more likely to be presented without geospatial data. The implementation of the collaborative system in Medeiros et al. (2001) described earlier was targeted as a land-use and planning application for a distributed GIS.

The Urban and Regional Information Systems Association (URISA) is in the third year of hosting an annual conference on the topic of public participation in GIS (URISA, 2004b; Voss et. al., in press). A discussion of presentations at the second conference in the series mentioned that Internet GIS technology was used to present and solicit public comment regarding alternative proposed designs for the World Trade Center buildings and parks (URISA, 2004a). From the number of questions and issues that were identified in the conference, it is clear that there is not yet a commonly accepted model for how GIS should be used to facilitate public participation in planning. As the role and power of planners, politicians, GIS specialists, developers, and the public could potentially shift with more publicly available geospatial data and analytic capabilities, there is no simple answer to the question of how collaboration between government and the public should be enhanced using GIS. Clearly, the technology increases options for public participation in land planning.

The Orton Family Foundation, a Vermont-based non-profit organization dedicated to better decision making by communities, has developed 2D and 3D GIS software to help people develop, visualize, and analyze the implications of alternative approaches to land- and growth-management planning (Orton Family Foundation, 2004). Their CommunityViz GIS software has been used extensively by smaller communities to help involve the public in land planning. In Eureka Township, Minnesota, GIS was used to help the Eureka Township Envisioning Project understand the impacts of alternative growth-management scenarios on septic-system placement and water quality (Orton Family Foundation).

Utilities-Engineering Design and Construction

Utilities use geospatial-information systems to plan and manage their assets and design new components of their outside plant infrastructure (e.g., poles, wires, transformers, pipes, etc.). While most of the collaboration occurs within the utility, collaboration occurs to some degree with developers and government officials. For example, a developer will submit their design for a new subdivision, usually in CAD (computer-aided design) format. Field surveys are often conducted at the site and these surveys are increasingly conducted using GPS technology. The utility designer will import this CAD into either a CAD or GIS tool, which will be used to design the utility infrastructure that is needed to support the proposed development. Typically, the proposed design is analyzed as if it were connected to the network, so a proposed version of the design is developed. Alternative designs may be developed and costs of the alternatives may be determined so that the most cost-effective option can be chosen. Designs may be reviewed by other designers or a design supervisor to select the preferred option, which may also be with the developer and government officials. When approved for construction, the design will be attached to a work order and assigned to a crew which will be dispatched to the construction site. The design may be modified in the field if logistical difficulties are encountered. Construction crews will record as-built conditions for the project, and this data will be reviewed and posted to the database, which represents the utility assets that are constructed.

This utility design and construction process occurs over an extended period of time, which makes it a long transaction. Engineers will typically extract a version of the database to use to develop their designs. Usually, a utility will use optimistic logic and not formally lock the portion of the database that is included in the versioned database. Conflicts between alternative designs in the same general area are flagged for resolution by an engineering supervisor.

This CAD- and GIS-based process represents a major increase in productivity in design and maintenance of utility maps and records. Utility GIS practitioners often network through an organization called the Geospatial Information & Technology Association (GITA, 2004).

C4ISR and Defense Geospatial Applications

Command, control, communications, computers, intelligence, surveillance, and reconnaissance (C4ISR) is a military application that makes extensive use of geospatial technologies. The National Geospatial-Intelligence Agency, the National Reconnaissance Office, and other agencies collect imagery and produce different types of geospatial data for military and intelligence purposes. For example, cruise missiles use topographic data as a model of the terrain. The terrain is sensed by the cruise missile and pattern-matching techniques are used to follow the landscape to reach a target. High-resolution imagery is interpreted to help select targets.

C4ISR provides the military forces with geospatially enabled command and control capabilities. Trends are to make C4ISR more widely available to help cut through the fog of war and provide a better coordinated understanding of the battle space. The Geo-Intel 2003 conference included discussions of the importance of geospatial data and technologies and the role played by them in the rapid and successful movement of U.S. troops in the Iraqi War.

In the future, geospatial intelligence and C4ISR will be more ubiquitous. Currently, the military is still in the process of adopting geospatial data for battle-space operations. The Commercial Joint Mapping Toolkit initiative could place GIS-enabled C4ISR in the hands of up to one million U.S. military forces.

Homeland-Security Command Centers

Homeland–security command centers are making effective use of GIS to provide planning and response capabilities. The emphasis on situational awareness and command and control is similar to DOD C4ISR applications. 3D GIS applications developed by IT Spatial are playing a major role in command centers in Washington, DC, and elsewhere. Plume modeling software combined with demographic data, 3D GIS data, and real-time weather data provide a capability to predict terrorist acts, like a dirty nuclear explosion, and their consequences. There is no shortage of investigation of 3D GIS technologies (Manoharan, Taylor, & Gardiner, 2002). The better the consequences are understood, the more effective the response can be from emergency first-responder forces. First responders in the field can access data and also feed back information regarding emergencies and events to provide command and control personnel and other responders with better understanding. This impact of geospatial information in emergency situations has been the subject of research by several in the wake of the attacks of September 11, 2001 (Kevany, 2003; Kwan & Lee, in press; Rauschert, Agrawal, Sharma, Fuhrmann, Brewer, & MacEachren, 2002), in addition to some early research examining this area prior to the attacks (Kumar, Bugacov, Coutinho, & Neches, 1999). GPS tracking can be used to understand the location of police cars, ambulances, and other emergency vehicles. Integration of GIS with live video data feeds also provides a useful real-time picture of ground conditions and events. There are some, however, that continue to point out the numerous impediments to effectively using GIS in disaster-control decision situations (Zerger & Smith, 2003).

GIS additionally continues to play an important role in the containment of medical outbreaks and the analysis of systems mapped to locations, such as in the work of Cockings, Dunn, Bhopal, and Walker (2004).

Presence Awareness in Instant Messaging and RFID-Based Asset Tracking

In an effort to better display the impact of emerging technologies such as radio-frequency identification (RFID), Web services on GIS, and collaboration for real-time presence management, AMS, through its Center for Advanced Technologies, customized the BuddySpace instant messaging (IM) product to allow IM users the ability to display the location of other users. This information was automatically captured through the implementation of a GIS Web service and an RFID network (Del Vecchio & Carter, 2004). This location or presence awareness adds an additional useful dimension to dialogue between IM users. There are alternative methods of collecting the location data and these options include

- entering and geocoding addresses,
- GPS data collection, and
- RFID-tag readings.

The RFID-tag approach is interesting due to future expectations for expansion in the use of this technology. RFID tags must be read by a stationary reading device, and the location of this reader can be determined by address geocoding or GPS. RFID tags that are read can be related to their location, and this could prove useful for supply chain applications. This experiment builds on the assertions of Mitchell (2003), which state that Web services will further propel GIS into the spotlight.

FUTURE TRENDS

Geospatial technologies have begun to play mission-critical roles on a large scale in a variety of different types of organizations. Early adopters of geospatial technologies included many organizations that traditionally have maintained maps and records to manage their assets and operations. Geospatial functionality will increasingly be embedded in various business applications (e.g., SAP ERP) that might support almost any organization with simple geospatial data visualization, queries, and analysis. In addition, spatial extensions to commercial RDBMS products will permit organizations to visualize the geospatial dimensions of their business data without a major investment.

The ability to deliver data in real time to mobile users extends GIS to the field. The number of mobile GIS users and the wireless communication of data to and from these mobile users will continue to expand. Location services will deliver focused geospatial-information services (e.g., directions, nearest services, etc.) to cell-phone users willing to pay for these supplemental options. According to Nellis (2004), these innovations are "…now at the heart of a vast array of real-time interactive mobile computing, geo-location applications and asset management, along with wireless geographic services that are revolutionizing the role of geography and geospatial information analysis in meeting the needs of everyday society."

The high cost of geospatial data has been a major impediment to its adoption. As geospatial data are increasingly available from geospatial Web-services-compliant sites, costs to access data will decline and users will be able to develop and use applications more rapidly. There will continue to be some significant policy concerns and debate with regard to the privacy implications of GIS technology as outlined in Balough (2001).

CONCLUSION

Geospatial information systems provide unique capabilities for geospatial-data visualization and analysis. While the large data sizes associated with this technology make real-time and mobile uses more challenging, it is now possible, and increasingly practical and necessary, to use GIS across an enterprise for real-time, mobile geospatial applications. Military and homeland-security markets are currently driving the market for collaborative GIS enterprise applications. Other markets have also emerged and more will surely follow as the advantages of location awareness and geospatial analysis are better appreciated.

KEY TERMS

C4ISR: Command, control, communications, computers, intelligence, surveillance, and reconnaissance, a military application framework that makes extensive use of GIS technologies.

CAD: Computer-aided design.

Enterprise Collaboration: Application of systems and communications technologies at the enterprise level to foster the collaboration of people and organizations to overcome varying levels of dispersion to accomplish a common goal. This term, when applied to the use of technologies, is also known as e-collaboration or distributed collaboration.

Geospatial Information Systems (GISs): Systems that provide a common framework for jointly visualizing the world.

Global Positioning Satellite (GPS): A format of presenting geospatial data for tracking purposes used often in location-based services.

RFID: Radio-frequency identification. This technology uses the electromagnetic spectrum radio signals to transmit information from a transponder (tag) to a receiver for purposes of identifying items. This technology has been in development for a standard to replace the Universal Product Code (UPC) symbol with the Electronic Product Code (ePC) symbol through the Auto ID Center, formerly of MIT.

GIS-Based Accessibility Measures and Application

Fahui Wang
Northern Illinois University, USA

Wei Luo
Northern Illinois University, USA

INTRODUCTION

Accessibility refers to the relative ease by which the locations of activities, such as work, shopping and healthcare, can be reached from a given location. Access varies across space because of uneven distributions of supply and demand (*spatial factors*), and also varies among population groups because of their different socioeconomic and demographic characteristics (*nonspatial factors*). Taking healthcare access for example, spatial access emphasizes the importance of geographic barrier (distance or time) between consumer and provider, whereas nonspatial access stresses non-geographic barriers or facilitators such as social class, income, ethnicity, age, sex, and so forth. Since the 1960s, health policymakers in the United States have attempted to improve health care for the citizenry by considering aspects of both spatial and nonspatial factors. Such efforts are exemplified in designations of Health Professional Shortage Areas (HPSA) and Medically Underserved Areas or Populations (MUA/P) by the U.S. Department of Health and Human Services (DHHS), for the purpose of determining eligibility for certain federal health care resources. The DHHS is considering consolidating the HPSA and MUA/P designations into one system because of their overlapping criteria (U.S. DHHS, 1998). See guidelines at http://bphc.hrsa.gov/dsd (last accessed April 1, 2004).

BACKGROUND

Measuring Spatial Accessibility

According to Joseph and Phillips (1984), measures of spatial accessibility include *regional availability* and *regional accessibility*. The former is expressed as a demand (population) to supply (i.e., practitioner in the case of healthcare access) ratio within a region, and it is simple and easy to implement. The latter considers complex interaction between supply and demand in different regions based on a gravity kernel, and it is less intuitive and requires more computation.

The regional availability approach has two problems: interaction across regional boundaries is generally not adequately accounted for and spatial variability within a region is not revealed (Wing & Reynolds, 1988). Several methods have been developed to mitigate the problems. For example, Luo (2004) uses a *floating catchment area (FCA) method* for assessing physician accessibility. Assuming a threshold travel distance of 15 miles for primary health care, a 15-mile circle is drawn around a residential tract as its catchment area. The circle with the same radius (i.e., catchment area) "floats" from the centroid of one tract to another, and the physician-to-population ratio within each catchment defines the accessibility there. The underlying assumption is that services that fall within the circle are fully available to any residents within that catchment. However, not all physicians within the catchment are reachable within the threshold distance by every resident in the catchment, and physicians on the periphery of the catchment may also serve nearby residents outside the catchment and thus may not be fully available to residents within the catchment.

A method developed by Radke and Mu (2000) overcomes the above fallacies. It repeats the process of "floating catchment" twice (cone on physician locations and cone on population locations), and can be easily implemented in a geographic information system (GIS) (Wang & Luo, 2004).

First, for each physician location j, search all population locations (k) that are within a threshold travel time (d_0) from location j (i.e., catchment area j), and compute the physician to population ratio R_j within the catchment area:

$$R_j = \frac{S_j}{\sum_{k \in \{d_{kj} \le d_0\}} P_k}, \qquad (1)$$

where P_k is the population of tract k whose centroid falls within the catchment (i.e., $d_{kj} \le d_0$), S_j is the number of physicians at location j, and d_{kj} is the travel time between k and j.

Next, for each population location i, search all physician locations (j) that are within the threshold travel time

(d_0) from location i (i.e., catchment area i), and sum up the physician to population ratios R_j at these locations:

$$A_i^F = \sum_{j \in \{d_{ij} \le d_0\}} R_j = \sum_{j \in \{d_{ij} \le d_0\}} \left(\frac{S_j}{\sum_{k \in \{d_{kj} \le d_0\}} P_k} \right), \qquad (2)$$

where A_i^F represents the accessibility at resident location i based on this two-step FCA method, R_j is the physician to population ratio at physician location j whose centroid falls within the catchment centered at i (i.e., $d_{ij} \le d_0$), and d_{ij} is the travel time between i and j.

One may notice that it draws an artificial line (say, 30 minutes) between an accessible and inaccessible physician. Physicians within that range are counted equally regardless of the actual travel time. *A gravity model* such as the one in Joseph and Bantock (1982) can be used to weight a nearby physician higher than a remote one. The gravity-based accessibility A_i^G at location i can be written as:

$$A_i^G = \sum_{j=1}^{n} \frac{S_j d_{ij}^{-\beta}}{V_j}, \text{ where } V_j = \sum_{k=1}^{m} P_k \, d_{kj}^{-\beta}, \qquad (3)$$

where n and m indicate the total numbers of physician and population locations, respectively, and all other variables are the same as in Equation (2).

Luo and Wang (2003, p.874) have proven that the two measures A_i^F and A_i^G are equivalent. The only difference is except that travel time impedance is dichotomous in Equation (2) but continuous in Equation (3). The measure A_i^F by the two-step FCA method may be a more favorable choice for practical uses. First, it is simple and can be easily adopted by state health departments. Secondly, it is intuitive as it compares supply vs. demand and does not need to define the travel friction coefficient b in the gravity model. Defining bð is particularly troublesome since its value varies from place to place and also over time. Finally, the FCA method is particularly suitable for identifying areas with low accessibility, as the gravity-based method tends to conceal local pockets of poor accessibility (Luo & Wang, 2003, p.876).

Analyzing Nonspatial Factors

Population subgroups differ in terms of needs and accessibility according to their age, sex, social class, ethnicity, and other nonspatial characteristics. For example, Field (2000) compiled a list of factors affecting healthcare access, standardized all indicators according to a normal distribution, and then combined them to produce a final composite index of relative advantage.

Possible nonspatial factors for healthcare access include:

(1) Demographic variables (such as age and sex). For example, populations with high needs include seniors with ages above 65, children with ages 0-4 and women with ages 15-44.
(2) Socioeconomic status. Low socioeconomic status may incur important barriers to health access and lead to ill health. Variables may include population in poverty, female-headed households, home ownership and median income.
(3) Environment. Overcrowding or poor living conditions may contribute to higher levels of ill health (e.g., Field, 2000, p.315). Variables may include households with an average of more than one person per room and housing units lack of basic amenities (lacking complete plumbing or kitchen facilities).
(4) Linguistic barrier and service awareness. Minorities or lower educational attainment may be associated with lower service awareness (e.g., Field, 2000, p.317), and linguistic isolation may create an important barrier to healthcare access (e.g., U.S. DHHS, 1998). Variables may include non-white minorities, population without a high-school diploma and households linguistically isolated.
(5) Transportation mobility. People dependent solely on public transit may have less mobility and their accessibility to physicians is diminished to a great degree (e.g., Field, 2000). Variables may include households without vehicles.

As these variables are often correlated, a simple aggregation of the indicators may not be appropriate. Wang and Luo (2004) use the factor analysis to consolidate nonspatial factors, and identify three major factors (i.e., socioeconomic disadvantages, socio-cultural barriers, and high healthcare needs).

FUTURE TRENDS

The spatial accessibility measure and nonspatial factors need to be integrated together for assessing accessibility. In evaluating healthcare access, one may assign larger weights to population subgroups with high healthcare needs and directly incorporate this factor into the spatial accessibility measure such as Equation (2). The spatial accessibility measure can be used to identify the first type of physician shortage areas (i.e., *geographic areas* as in the official HPSA designation guidelines). Nonspatial factors (e.g., the "socioeconomic disadvantages" and "socio-cultural barriers" factors) can be used to identify the second type of physician shortage areas (i.e., *popu-*

lation groups as in the official HPSA designation guidelines). Figure 1 shows the result of an integrated approach to defining physician shortage areas in Illinois, U.S., based on the data in 2000.

CONCLUSION

Both spatial and nonspatial factors need to be considered in evaluating accessibility. Spatial access emphasizes the importance of geographic barrier between supply and demand, and nonspatial factors include non-geographic barriers or facilitators such as age, sex, ethnicity, income, social class, education and language ability. A GIS-supported two-step floating catchment area method has proven to be appropriate in measuring spatial accessibility. Nonspatial variables can be consolidated by factor analysis into a few independent factors. Applying the methodology in assessing healthcare access, spatial and nonspatial factors can be integrated together to identify two types of physician shortage areas (i.e., geographic areas and population groups).

KEY TERMS

Accessibility: The relative ease by which the locations of activities, such as work, school, shopping and healthcare, can be reached from a given location.

Floating Catchment Area Method: A geographic information systems (GIS) supported method for assessing the scarcity of supply versus demand. For example, assuming a threshold travel distance of 15 miles for primary health care, a 15-mile circle is drawn around a residential location as its catchment area. The circle "floats" from one location to another throughout a study area, and the physician-to-population ratio within each catchment indicates whether an area is medically underserved.

Gravity Models: Models that measure the interaction between social/economic objects, similar to the gravity model in physics. In the models, the intensity of interaction (e.g., trips, migration or communication) is positively related to the sizes of objects (e.g., population) but inversely related to the distance or travel time between them.

Health Professional Shortage Area (HPSA): Geographic areas or population groups designated by the U.S. Department of Health and Human Services (DHHS) that are underserved in healthcare.

Nonspatial Accessibility: Non-geographic barriers or facilitators such as social class, income, ethnicity, age, sex, and so forth, that affect one's accessibility to a service.

Spatial Accessibility: Consumers' ability to overcome geographic barriers (distance or time) in order to gain access to service providers.

Global Implications of E-Commerce Tool and Artefact Creation

Deborah Bunker
SISTM, University of New South Wales, Australia

INTRODUCTION

It is argued that Electronic Commerce (EC) platforms can be seen as artefacts—tools that are made, used, inherited and studied within a cultural context. This context encompasses economic, historical, technical, and social values and assumptions that are focused on particular ideas and definitions (relating to the example of B2C activities and processes contained within Electronic Grocery Systems (EGS)). The issue we should face as makers, users, inheritors, and scholars of these tools, however, is that the tool context and inherent in-built values on which this context is based, particularly relating to matters of effective use of EC tools in a B2C marketplace, may not be in evidence across all cultures. This would make the successful use of EC, in a global sense, a difficult and complex undertaking.

BACKGROUND

Understanding the process and role of tool creation and use in relation to the information technology and systems (ITS) discipline/paradigm (and EC in particular) is fundamental to understanding the cultural bias inherent in the process. The definitions used in this chapter are those generally used by the research community in the area of technology transfer (TT) (Robinson, 1988). These definitions are loaded with such terms as "artefacts," "technology," and "tools." If we accept that ITS is a tool-focused discipline, then we must look at the context of the creation of those tools in order to better understand how they can be used more appropriately and effectively in different cultural contexts.

Bunker and Dean (1996) discuss Kuhn's (1970) theory that suggests that the underlying structure of a discipline arises from a set of assumptions generally accepted by practitioners, teachers, and disciplinary constituents. Techniques and tools defined by the discipline are created from a common understanding. They may be part of an evolutionary creation process or equally be created through a "paradigm shift"; however, they do become indicative of the generally held underlying assumptions of the discipline. Schein (1984) suggests a three-stage ascent from basic assumptions to the artefacts and creations that drive the evolution of paradigms. If we look at the tools in current use by a discipline, generally accepted underlying assumptions may be deduced.

The model of a discipline is in four parts (see Figure 1). By extending the idea of tools as the visible sign of paradigmatic assumptions that underpin a discipline, we find that four entities play a role: the tool Maker, the tool User, the Scholar, and the Inheritor of the discipline. The tools that reflect the ITS discipline are created and used in a multitude of contexts. What are the implications for the discipline and the diffusion and use of these tools?

ITS Tools in Context

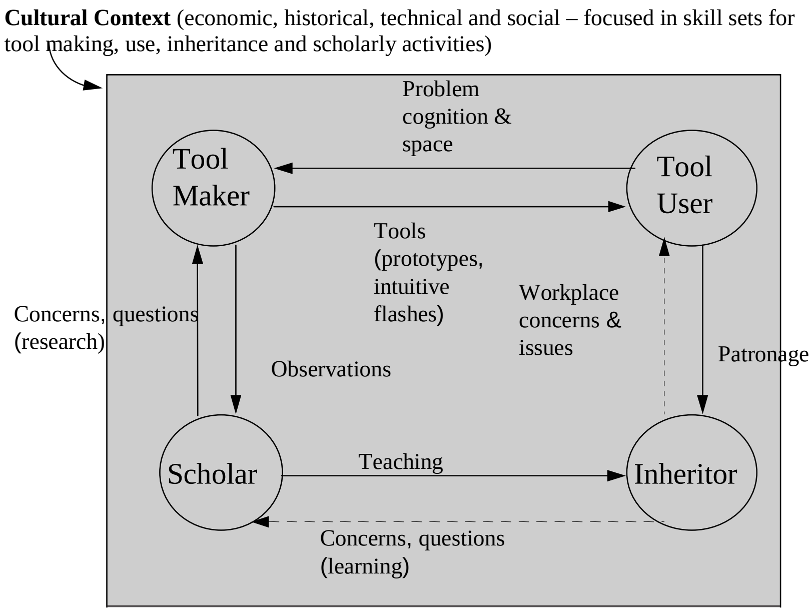
Young (1971) in his *An Introduction to the Study of Man* defines tools in the following ways: tool making assumes skills and ways of life that are transmitted by interpersonal communication and tradition rather than genetics; tool making involves foresight as to the use of the tool; tools are made by a technique that is learned from others and involves symbolic communication (language); tools are made according to an evolutionary convention (gradual) and are made and used in a cultural context. For example, the ITS literature is full of stories about ITS failure (Sauer, 1993). Are these really stories about the lack of contextual acceptance of these tools within organisations or target cultures?

Techniques and tools are created from a common understanding or cultural context. They become an expression of generally held underlying assumptions (Schein, 1984). The cultural context underpinning tool creation and use is created and evolves over time. The assumptions, which in turn underpin cultural context, are deep-seated, taken-for-granted, invisible, and preconscious, and are patterned into what Schein (1984) terms cultural "paradigms."

Cultural paradigms can be expressed in a number of ways. Research conducted by Kluckhorn and Strodtbeck (1961) and Hofstede (1980) are typical examples of the different assumptions upon which various cultures are based. Schein (1984) expresses the assumptions of cultural paradigms as the: organisation's relationship to its environment; the nature of reality and truth; the nature of human nature; the nature of human activity; and the nature of human relationships.

If we accept that there are vast differences in cultural paradigms around the world, and that ITS tool creation

Figure 1. Disciplinary model (Bunker & Dean, 1996)



and use is underpinned by these cultural paradigms, what then, are the implications for the development and use of an ITS tool in one culture for diffusion and use in another? In this fast-paced, highly volatile and mobile global society, many organisations find themselves in a situation where the transfer, diffusion, and use of ITS is pushed at an extraordinary rate. Cardwell (1994) argues the importance of ITS as being a strategic technology of which the applications and scope exceeds all others. Richard Baskerville (1995) explains that the use and management of ITS are an expression of an organisation's structure and culture, and that as we computerise the symbolic universe of the organisation, we can view the system and its information as artefacts.

This has far reaching implications for organisations, nations, and the global economy. Robinson (1988) has likened the process of developing technology in one society and implanting it in another without adaptation as an organ transplant from one body to another without any testing for compatibility.

Electronic Commerce (EC) Tools in Context: Electronic Grocery Systems (EGS)

The Internet has played a key role in the establishment of EC activities (especially in B2C relationships), and EGS systems have been dependent on the development of Internet technologies and their uptake speed and scale by potential consumers. Consumers in the West have begun to demand increases in the quality of service being offered by their grocery provider. Shoppers want a product selection adapted to their needs and the ability to shop at their convenience at any time (Choudrie et al., 1998).

The introduction of the Internet and the development of EGS systems have allowed consumers to shop at their convenience rather than being bound to retail opening trading times. The subsequent growth of the Internet and the increasing demand for value-added grocery shopping has created demand-pull for EGS services. Consumer demand for EGS services, combined with supplier demands for shopper profile information, has created a large uptake of EGS systems from a business and consumer perspective (Deutsch et al., 2000).

As discussed earlier, however, we have also seen the need for contextual value or cultural compatibility between the creator and the recipient of a technology in order for the technology to be transferred and utilised successfully. A certain level of cultural homogeneity is necessary in order for the tools and artefacts of one culture to be successfully utilised within another (Bunker, 1998). Electronic grocery shopping (EGS) systems utilise the tools and artefacts of ITS that have been created from a predominantly Western and particularly North American cultural viewpoint (Simon & Doran, 1998). This viewpoint assumes that the shopping culture of the consumer accepts multiple distribution channels for consumer items, but it neglects resources and skills required by the consumer to best utilise these multiple channels, as well as any essential social activity associated with the shopping task and associated processes. These types of systems may be acceptable in a culture that has had a history and experience (and thus development of suitable associated technology and skills) of multiple purchase and distribution channels in B2C transactions such as the retail, catalogue, and home shopping B2C channels of North America. We can see that EGS systems, in their current form, generally assume:

- Computer ownership or access
- Internet access (Internet service providers, as well as reliable and secure telecommunications infrastructure)
- Basic computing skills
- Product and outlet brand awareness (knowing exactly what you want and who you want it from)
- Product quality awareness (where it is manufactured and which company manufactures it)
- Basic purchasing strategies (little opportunity for special savings)
- Particular lifestyle benefits to consumers in terms of time savings, convenience, and prestige of using EGS systems
- Acceptance of additional distribution costs to the purchase decision
- Population density for overall cost effectiveness of storage and distribution for the e-business
- A limited range of goods
- A "type" of customer behaviour (pattern buying, rational purchase decision, and utility)
- A trust in the security and reliability of the system

(Brandtweiner, 1998; Heikkila et al., 1998; Pereira, 1998, Strader & Hendrickson, 1998)

A certain lifestyle, skill set, and access to resources is assumed, and the more social element of the shopping experience is missing. Diverse cultural dimensions are not expressed within the definition of the tool.

FUTURE TRENDS

In viewing EGS systems as tools or artefacts that have been created with in-built values and assumptions, we find that the cultural context of the user of an EGS system is important in understanding how these systems might be best implemented and utilised (Simon & Doran, 1998). Johnson (1997) discusses four types of value meanings in technology: moral/metaphysical (past intended use of the technology); support (present intended use of the technology); material (in-built characteristics which influence the use of the technology); and expressive values (motivation for use of the technology). All of these contribute to the assumed skill sets required to utilise the technology. It is these expressive values that encapsulate the more diverse elements of the shopping experience within many non-Western cultural contexts. Value meanings link back to the definitions of tools as outlined by Young (1971). Tool making is not only technical in nature, but is bound by cultural values and an understanding of how the tool has been created for use in an acceptable manner. This understanding reflects a certain level and mixture of skills. Ayres (1978), in discussing his ideas on the theory of economic progress of civilisation, states that "…absolute mutual contingency of skills and tools is of supreme importance for an understanding of technology as a function of human behaviour" (Ayres, 1978, p. 108).

Skills and technology are bound together as technology is created and used as a result of an assumed skill set that is heavily influenced by core assumptions and values (culture). It is evident that EGS systems (in their current state) assume limited technical and purchase decision skills within a culture and the B2C experience, while totally neglecting social skills and their important skills.

EGS systems are engendered with the cultural attributes of Western society (Pargman, 1998). For non-Western cultures that may have different resource availability and different social marketplaces, these systems may not be as effective as more traditional means of transacting business. Many non-Western cultures, for instance, are considered developing economies, a value-laden term, to be sure, which is generally used to describe a local village-based economic structure. These economies are reliant on intricate social interactions and customs to ensure effective B2C trading relationships and the maintenance of a robust local economy. If you have ever visited a local marketplace in China, Egypt, or suburban Australia, you are able to see these relationships in action and their effect in a B2C transaction. The utility and logistical benefits associated with EGS systems may be of limited benefit to the types of economic structures where personal interaction is important, as they are a product of a different cultural context and, therefore, may be better suited to a Western mass market style of B2C transaction.

There are distinctly different philosophical positions in particular extremes of culture. The skills required to design, make, understand, and use tools, as well as the languages we use to define and represent them, would be significantly different from one type of culture to another. An EGS system that lacks consideration and design for a diverse resource base and social attributes of a shopping experience may not necessarily fit within the shopping experience of other cultures and contexts.

For instance, in many cultures in a B2C transaction, the process of bargaining over a particular price for a product is an important ceremonial and symbolic act that reflects on a vendor and a customer's perception of intent within the B2C transaction process. This affects the understanding by the customer of the product quality, integrity of the vendor, product range, and so forth, and also affects the vendor's understanding of his or her potential customers, the marketing strategies, and the range of services or products to offer. In this context, the nature of information gathering and the transaction process takes on a significantly richer meaning, which may not be facilitated or captured by an EGS system.

CONCLUSION

If Global Technology Transfer (GTT) is to be fully understood, then further research is necessary. If we better understand the cultural context in which ITS is created, as well as the cultural context of the recipient, we may have to admit that some ITS may not be appropriate for transfer under certain circumstances, it may have to be radically redeveloped to accommodate differences in context, or the culture of the recipient may have to change in order to accommodate the technology. We may need to consider the development of information technology and systems as artefacts that should be designed to be adaptive as a matter of priority. Within this design, there is a real need to consider the stakeholders' expectations and the resultant "evaluative dispositions" that are derived from their values (Lyytinen & Hirschheim, 1987 in Lycett et al., 1997).

These values are cultural paradigms and, as such, are not generally articulated (Claver et al., 2001). Lycett et al. (1997) discuss the stakeholder's "intentionality" or the representation of values in structures, practices, and conventions of an organisation. Schein (1984) articulates much the same argument when he speaks of the artefacts and creations of an organisation such as documents and charters. ITS are also artefacts or tools which are a direct expression of the cultural paradigm of their creators.

In researching within our discipline, this question needs to be considered: Can an ITS only be reflective of the basic assumptions and values (cultural paradigms) of its creators and immediate user population? Is the temporal "snapshot" that Lycett et al. (1997) discuss that provides "the picture of reality" of the system all that we can ever hope to have, or can we assume that we can (and should) develop ITS tools (physical tools) and techniques and methods (conceptual tools) that can be adapted and changed to suit contextual differences?

The new age of globalisation in which information is shared and ITS has had a significant impact in the world marketplace, would appear to be only taking place where there is a similar cultural, historical, and economic context of development (Bunker & MacGregor, 2002). It is the development context that facilitates the building of these ITS tools, as well as their transfer and use within other contexts. The context of ITS tool creation, use, inheritance, and knowledge may, therefore, be a limiting factor in its potential usefulness and applicability on a global scale.

KEY TERMS

Context: "The client as the receiver of the technology, must create the context (technology, transfer, context, talent, modification, management, resource and contribution) and verify its capacity to receive and apply the technology and information in the new environment" (Lien, 1994).

Electronic Commerce: "(1) Transactions conducted over the Internet, either by consumers purchasing goods and services or directly between businesses. (2) Conducting business online" (Davis & Benamati, 2003).

Electronic Grocery Shopping: "By extension of this concept (Electronic Commerce) Electronic Grocery Shopping (EGS) involves the specific purchase of grocery items which is facilitated via computer networks" (Deutsch et al., 2001).

Technology: "Technology is broadly defined as the documented or licensed technology, the embodying artefacts (equipment, software tooling), and the wherewithal to know how to successfully deploy the technology" (Robinson, 1988).

Technology Transfer: "The conveyance or shift of tools, techniques, procedures and/or the legal titles thereto used to accomplish some human purpose" (Reisman & Zhao, 1991).

Globalization of Consumer E–Commerce

Daniel Brandon, Jr.
Christian Brothers University, USA

INTRODUCTION

This article reviews globalization aspects of "business to consumer" (B2C) electronic commerce. According to *Computerworld*, "Globalization is the marketing and selling of a product outside a company's home country. To successfully do that on the Internet, a company needs to *localize* – make its Web site linguistically, culturally, and in all other ways accessible to customers outside its home territory" (Brandon, 2001). This overview describes the key issues in the globalization of electronic commerce; for more detail, see the full book chapter (Brandon, 2002).

BACKGROUND

"Ever since the end of the Cold War, the world has been rushing toward ever-higher levels of national convergence, with capital markets, business regulation, trade policies, and the like becoming similar" (Moschella, 2000). The value of cross-border mergers grew six-fold from 1991 to 1998 from U.S. $85 billion to $558 billion. The world has not witnessed such a dramatic change in business since the Industrial Revolution (Korper & Ellis, 2000). More than 95% of the world population lives outside of the U.S., and for most countries, the majority of their potential market for goods and services is outside of their borders. Over 60% of the world's *online* population resides outside of the United States (IW, 2000).

Today, the majority of Fortune's 100's Web sites are available only in English (Betts, 2000). In our rush to get on the WWW, we sometimes forget that WW is for "World Wide" (Giebel, 1999). Today's average Web site gets 30% of its traffic from foreign visitors, yet only 1% of small and mid-size American businesses export overseas (Grossman, 2000b).

KEY ISSUES

"Localization" (shortened to L12N in Internet terms) considers five global dimensions: geographic, functional, regulatory, cultural, and economic (Bean, 2000). We shall overview each of these somewhat overlapping and interrelated issues in these groupings: language, cultural, legal, payment/currency, dates/units, and logistics.

Language

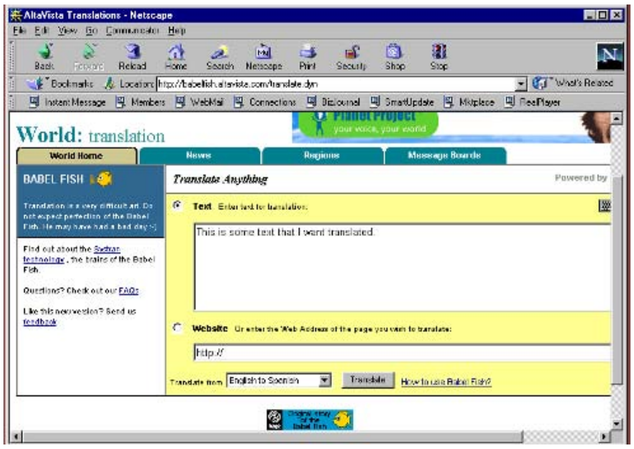
According to IDC, by 2005, more than 70% of the one billion Web users around the world will be non-English speakers (Wonnacott, 2001). For the immediate future, most of the Internet community will still understand English, but overall English is the native language to only 8% of the world. Most users in foreign countries prefer content in their own language; for example, 75% of users in China and Korea have such a preference (Ferranti, 1999). It was found that visitors spend twice as long, and are three times more likely to buy from a site presented in their native language (Schwartz, 2000). We also have to take into account differing dialects that are used across various countries speaking a specific language. The combination of language and dialect is called a "locale".

One can convert Web pages by hiring a translator or using a computer-based translation product or service. Hiring a translator will provide the best localization but is more costly than the automatic methods. Translators can easily be found in the Aquarius directory (http://aquarius.net) or Glen's Guide (www.gleensguide.com). It is best to use a translator that "lives" in the local region; if a translator has not lived in a region for a decade, he has missed 10 years of the local culture. There are also many companies that provide translation services such as: Aradco, VSI, eTranslate, Idiom, iLanguage, WorldPoint, and others. The cost of these services is about 25 cents per word per language (Brandon, 2002). Automatic translation software is another option, but it is still in its infancy (Reed, 2000). Some popular software products for translation are: www.e-ling.com, www.lhs.com, and www.systransoft.com. The automatically-translated text typically does not convey the meaning of the original text.

There are several Web sites which provide free translation services such as: http://babelfish.altavista.com, *http://translator.go.com*, and www.freetranslation.com. For example, Figure 1 shows the "BabelFish" Web site where we are requesting a translation of an English sentence into Spanish. Figure 2 shows the translation results.

Another alternative, although certainly not optimal, is to provide a link on your English Web page for these free services so that visitors can translate your content themselves. Figure 3 shows a portion of the CBU School of Business English version Web site.

Figure 1



The automatic Spanish translated version (using BabelFish) is shown in Figure 4. Note that automatic version, while syntactically and grammatically correct, does not convey the exact intended meaning to most of the titles and phrases.

Figure 5 is the version converted by a translator manually, and even though you may not speak Spanish, you can see the extent of the differences (Brandon, 2000). Shown in Figure 6 is the home page for FedEx (www.fedex.com). One can select from over 200 countries for specific language and content.

Cultural

Creating an effective foreign Web site involves much more than just a good language translation. Not only do languages differ in other countries but semantics (the meaning of words and phrases) and cultural persuasions in a number of key areas are different. "Sensitivity to culture and national distinction will separate success from failure" (Sawhney & Mandai, 2000). To be effective, a Web site has not only to be understandable and efficient, but has to be culturally pleasing and inoffensive. To accomplish that, it may be necessary that not only language be localized, but that content, layout, navigation, color, graphics, text/symbol size, and style may be different. Many companies have put forth global Web sites simply by translating the English into the targeted language, but then had to pull back and redesign the localized site due to cultural offenses.

A country's humor, symbols, idioms, and marketing concepts may not send the same messages to other countries in the world. Some areas of global disagreement to avoid are: equality of the sexes or races, body parts and sexuality, abortion, child labor and majority age, animal rights, nudity, guns, work hours and ethic, capital punishment, scientific theories, and religious particulars (Brandon, 2002).

Colors have symbolic and special meaning in most locals. Purple is a problem in many places; it symbolizes death in catholic Europe and prostitution in the Middle East. Euro Disney had to rework its European sites after the first version used too much purple. Overall blue is the most culturally accepted color (Brandon, 2001). It is also very important to respect other cultures "symbols" (heroes, icons, etc.) both positive and negative (swastika). One guide site is *Merriam Webster's Guide to International Business* (*www.bspage.com/address.html*).

Legal

Recently French court's ruling that Yahoo must make auctions of Nazi memorabilia unavailable in France indicates how uncertain and risky international e-business can be. "The troubling aspect of this case is that different countries can say that content not even targeted at their population breaks the law" (Perrotta, 2000). With the Internet, it is not possible to know for sure where a user is logged in due to "IP tunneling" possibilities.

"Freedom" laws (such as the U.S. First Amendment) are not universal, and saying/printing some things can be illegal in some parts of the world. In the U.S., you can say what you like about "public figures" but not so in most of the rest of the world. Another legal issue concerns the privacy of personal data collected online. Many parts of the world have stricter laws than does the U.S., and U.S. companies have had judgments rendered against them in foreign courts. There are other areas that could cause legal problems, too. One is foreign advertising restrictions; for example, in Germany, one cannot directly compare your product with that of a competitor. In some other countries this comparison may not be illegal but may leave a bad taste.

Figure 2

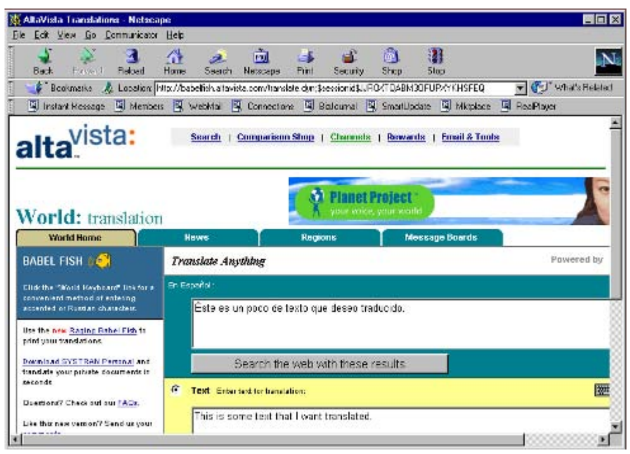


Figure 3

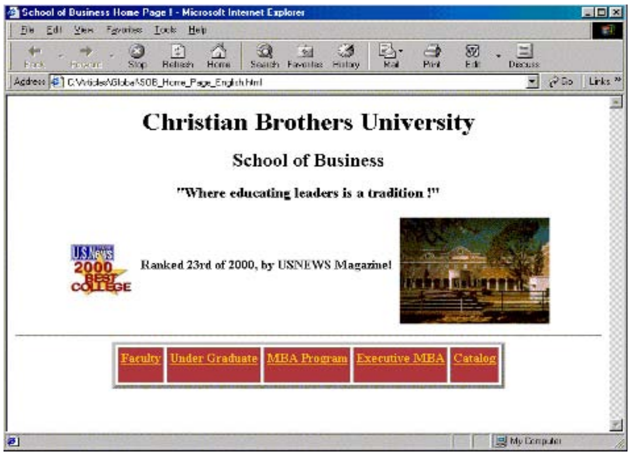

Payment and Currency

Nearly half of the U.S. Web sites refuse international orders because they are unable to process them (Grossman, 2000a). Foreign exchange rates vary daily so indicating that your prices are in your country's funds (exclusive of local taxes and custom duties) and using credit cards (so the credit card company does the conversion) is one way to deal with that issue. One can also link to a converter site (www.xe.net/ucc, www.oanda.com) or place a calculator on your page (www.xe.net/currency) as a utility for your customers or do your own conversions (see Figure 8, later).

However, credit cards are rare in Japan as is the use of checks. There, postal workers collect cash on delivery (CODs), and some companies send goods to brick and mortar places for consumers to pick up. In Germany, only 5% of Web users (second to U.S. in overall net usage) use credit cards. Eighty-eight percent of European merchants use invoice billing (with a long net payment due time). So while credit cards are a convenient and popular mechanism in the U.S., it is not so in the rest of the world. To complicate matters even further, there are many (and always changing) international sales taxes, value added taxes (VAT) in Europe, with different exempt items in each country. One approach to avoid all these problems is to use an escrow service such as Paymentech (www.paymentech.com) which now handles about three billion transactions a year.

Time-Date and Units of Measure

Dates are very important in e-commerce when being used for events such as: delivery dates, credit card expiration dates, product expire dates, etc. There is an international standard on dates (ISO 8601 Date Format), and even though you may not use it internally in your programs (for database operations and calculations), your Web display should be in the localized format. For example, the common U.S. format of 10/6/2000 is not uniformly understood; instead use Oct-6-2000. Major databases (i.e., Oracle) allow you to switch date formats per session or connection so the way a date is input (inserted into a table) or output (selected from a table) is automatically converted to the internal table representation of the date.

In the U.S., a 12-hour clock is common, except in U.S. military establishments. The rest of the world uses mostly a 24-hour clock, so it is best to display time in the 24-hour format. Of course, time zones will be different, so include your time zone along with the phone numbers for personal customer support. It is best to spell out the time zone in the native language. You could instead give your support time in GMT (Greenwich 2000 Standard) and use or link to www.timeanddate.com for a customizable world clock and calendar. In addition to dates and times, other units of measure will be different also. Only the U.S. and Canada still use the "English System"; the rest of the world is on the metric system now, even Britain.

"Addressing" a customer may be more involved; some foreign addresses may have longer and more address fields. There is a universal standard of sorts here called the "UPU" (universal address formats). Generally, it is of good advice including a country code (for validation of remaining fields), at least three address lines (40 characters each), city field (30 characters), a "state/province/region" field (20 characters), a postal code/zip field (10 characters), and a contact phone number (20 characters). Figure 7 shows an order form using these specifications.

Logistics

Logistics involve both getting your products to the customer, as well as allowing the customer to return un-

Figure 4

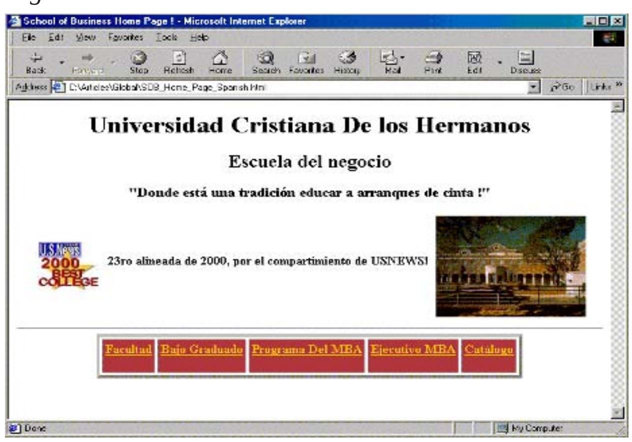

Figure 5

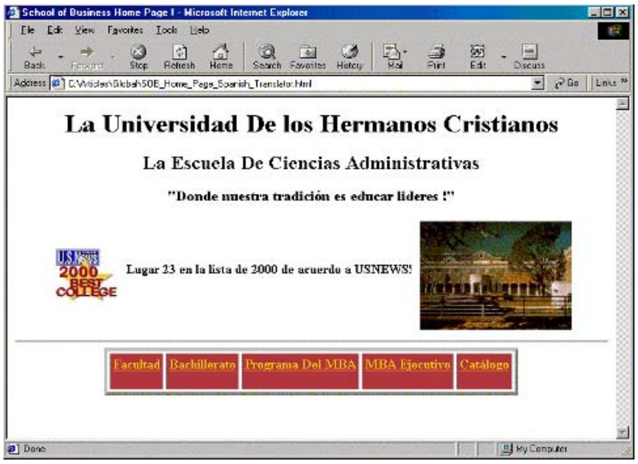


wanted goods. Some parts of the world have relatively primitive transportation networks. In China, villages do not have postal service. Also, each locale typically has a set of customs and tariffs that you may need to add to the price of your goods. This "landed cost" of an order is the sum of the price of goods, shipping charges, insurance, duties/customs, VAT, and any import or export fees. You may need a "Shippers Export Declaration" depending on value and mode of transportation (www.census.gov/foreign-trade/www/correct.way.html) or other documents depending on countries and goods. As well as normal shipping insurances, you may need to consider export insurance (www.exim.gov). Of course, the language as well as logistic terminology varies; however, there is a standard set of international logistic acronyms ("incoterms" - *www.schenkerusa.com/incoterms.html*).

Many countries have *foreign import restrictions* and/or quotas. In addition, many countries have certain *export restrictions*. Japan has more than 200 trade laws and 17,000 regulations on imports (Pfenning, 2001). Today, 85% of U.S. companies do not ship to customers seeking delivery abroad, and the 15% that do ship ignore these compliance issues and push the responsibility of customs, restrictions, and payment onto their customers (Shen, 2000).

There are several ways to handle all these logistics issues. One is to use shipping companies that handle all these problems for you (at a nominal charge) such as FedEx (www.fedex.com) or UPS (www.ups.com). Another alternative is to use software or services that handle all these payment, custom, and restrictions issues by preparing the paperwork and calculating "landed costs"; one example can be found at www.mycustoms.com.

Still another alternative is to use a centralized distribution center in foreign regions to reduce shipping costs and eliminate some import taxes and tariffs (Tapper, 2000), either directly or with a partner. There are also total fulfillment providers such as: National Fulfillment Services, DupliSoft, Fill It, SubmitOrder, Equire, FedexLogistics, and so forth. These organizations not only handle delivery but also inventory, returns, customer service, and in some cases, Web ordering and payment.

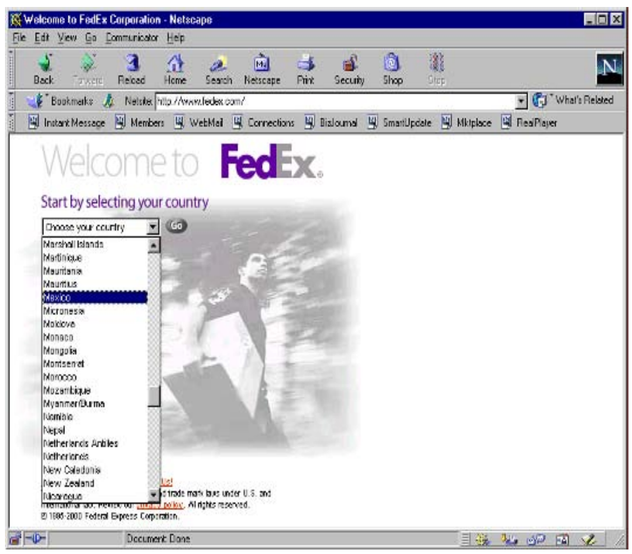
FUTURE TRENDS

In the not too distant future, the Web will be everywhere, and by "everywhere", we mean not only in all of our electronic devices but everywhere in the world. Future trends in B2C e-commerce will involve this convergence of Web connectivity both in geographics, demographics, and electronics. For example in the future, automobiles are likely to have satellite and wi-fi Internet connections not just for navigation and information, but for marketing and sales also (in several languages). As one drives down a street, they will be able to receive live commercial messages from businesses as they physically approach the retail outlets, and these retail outlets could be outlets for international products as well.

CONCLUSION

Is globalization right for an organization? It can be very costly to build and maintain a foreign presence. We have identified and briefly discussed the key issues in this article. But there are many other issues that may affect your global e-commerce. "Building a global e-business calls for hosts of strategies that include partnering with or acquiring foreign companies, assembling sales and

Figure 6



support operations, understanding new laws, languages, cultures, and implementing technology that can sustain a global endeavor" (Bacheldor, 2000). Many organizations are successful by using foreign partners such as: E-Steel, GlobalFoodExchange, and Office Depot. It has been said that the "Net brutally punishes latecomers" (Sawhney & Mandai, 2000), so it is essential to start planning the internationalization and localization of e-commerce now. Also remember the Web is a two-way street; foreign corporations will be coming after your customers soon!

KEY TERMS

Character Set: The set of symbols used to represent a language (alphabet, numerals, special symbols).

Encoding: The bit pattern to use for each symbol in a character set.

Export Restrictions: Restrictions on the type, quantity, or destination of goods that can be exported out of a country.

Globalization: The marketing and selling of a product outside a company's home country.

Import Restrictions: Restrictions on the type, quantity, or origin of goods that can be imported into a country.

Incoterms: A standard set of international logistic acronyms.

Landed Cost: The cost of an order including the price of goods, shipping charges, insurance, duties/customs, value added tax (VAT), and any import or export fees.

Locale: The combination of language and dialect.

Localize: Make a Web site linguistically, culturally, and in all other ways accessible to customers outside ones home territory.

Shippers Export Declaration: Documentation necessary to export goods outside one's home country.

UPU: Universal address formats.

VAT: Value added tax.

G

Governance in IT Outsourcing Partnerships

Erik Beulen
Atos Origin / Tilburg University, The Netherlands

INTRODUCTION

The literature first devoted attention to IT outsourcing partnerships in 1990 (Gantz, 1990; Rochester & Douglas, 1990). An IT outsourcing partnership consists of a service recipient and one or more external service providers and the relationship between them. The service recipient hands over the responsibility for the execution of the IT services to the service provider but remains the responsibility for managing the IT outsourcing partnership. The relationship between the service recipient and the service provider is defined in contracts describing the mutual obligations. The contract value of IT outsourcing partnerships is substantial, meaning over 10 million US$ or Euros. These contracts are also long-term contracts. The average duration of contracts is over 36 months (Cox, 2002). This description is based on the work of Lacity and Hirschheim (1993), Willcocks, Fitzgerald and Feeny (1995), and Currie and Willcocks (1998). The IT services outsourcing market is still growing every year, approximately 10% (Cox, 2002). Therefore, it is essential that sufficient attention be devoted to the governance of IT outsourcing partnerships.

BACKGROUND

Yet, not all organizations that have outsourced their IT services are satisfied. The reasons why outsourcing does not always result in success are legion. On the basis of both the literature, as well as actual practice, three important factors that influence the success of an IT outsourcing partnership have been identified: maturity of the service recipient, the degree of flexibility inherent in the contracts and the ability of the service providers to integrate the IT services taken over into their own organization.

Maturity

Service recipients with prior outsourcing experience are better able to implement the governance structure required for IT outsourcing partnerships (McFarland & Nolan, 1995). However, most organizations have limited experience with outsourcing (Willcocks & Fitzgerald, 1994), particularly outsourcing relationships that involve the management of multiple IT outsourcing suppliers (Currie & Willcocks, 1998).

Flexibility

Most outsourcing contracts are of long duration, however, and are not structured to allow changes in information needs to be easily operationalized (Klepper, 1995). This requires procedures for dealing with changes that lead to situations that are not covered by the contract: the Liaison Model (Burnett, 1998). This procedure is used as a basis for formulating agreements between both parties that complement the signed IT outsourcing contract: the concept of ex-post negotiations (Hart, 1995).

Integration

The service providers must integrate the IT services, including the IT professionals taken over, into their own organization. Objectives can only be realized through integration (Lacity & Willcocks, 2001). Many service providers have difficulty with this integration, however. In addition to management attention, initial investments constitute an important issue related to integration and result in an increase in costs (Beulen & Ribbers, 2002).

FRAMEWORK

In line with the definition of IT outsourcing partnerships, the descriptive framework for the governance of IT outsourcing partnerships contains three dimensions. The framework includes governance factors for the service recipient, the relationship between the service recipient and the service providers, and the service providers.

Table 1 contains a summary of the governance factors. These are further explained in the next three sections. The governance factors are based on the case studies analyzed – see Table 2 – the interviews with the experts, professional judgment and a study of the literature.

GOVERNANCE FACTORS RELATED TO THE SERVICE RECIPIENT

There are four management factors related to the service recipient: attention to IT within business units, a clear IT strategy, information management as the link between business functions and service providers and a properly

Table 1. Governance factors by dimension

Dimensions	Governance Factors
The service recipient	1.1 Attention to IT within business units=
	1.2 A clear IT strategy
	1.3 Information management as the link between business units and service providers
	1.4 A properly functioning Chief Information Officer
The relationship between the service recipient and the service providers	2.1 Mutual trust between the service recipient and the service provider
	2.2 Experience in establishing and maintaining IT outsourcing relationships
	2.3 Efficient and effective IT outsourcing contracts
	2.4 An audit & benchmark process in place
The service providers	3.1 Adequate contract and account management
	3.2 Adequate service delivery processes
	3.3 The availability of human resources to service providers

Table 2. IT outsourcing partnerships analyzed

Firm	Sector	# of Employees	Region(s)	Total Contract Value in US $	Contract Start Date	Contract Duration (Years)
1	Discrete Manufacturing	6,2	Europe	30 million	1992 (already renewed)	5
2	Utilities	1,8	Europe	23 million	1996	5
3	Discrete Manufacturing	200	Asia	21 million	1998	5
4	Services	200	Europe	40 million	1997	5
5	Process Industry	68	Europe/Asia/ North	Yearly revenues 90 million (750 employees)	1999 onwards	Purchase of internal IT division
6	Process Industry	68	Asia	0.4 million	1999	3
7	Tele-communications	100	Europe/Middle East/Asia	Confidential (> 20 million)	1997	5
8	Media	8	Europe	4 million	1995 (already renewed)	5
9	Discrete Manufacturing	2	Asia	1 million	2000	2
10	Utilities	2	Europe	100 million	2000	5
11	Discrete Manufacturing	200	Europe/Asia/ Americas	Yearly revenues 550 million (initially 1,500 employees)	1990 onwards	Purchase of internal IT division (various contracts)

functioning chief information officer (CIO). These factors are further explained in this section.

Attention to IT within Business Units

The outsourcing objectives of service recipients are often focused on cost savings (Outsourcingproject, 2002). This is not necessarily in line with the information needs of the business units of the service recipient. Building on this, business units should no longer judge IT on the basis of costs, but on the basis of its added value. A shift must take place from the minimization of costs to the maximization of business impact (Kotwica and Field,1999). When business management pays proper attention to IT, the organization is able to anticipate needs in a timely fashion. In view of the ever decreasing time-to-market, it is not an excessive luxury to involve IT proactively in the development of new products and services.

A Clear IT Strategy

IT strategy is defined as the strategy of the service recipient in relation to its information technology and IT services, and the role these play, or will play, within the service recipient (King, 1978). The development and implementation of the IT strategy is the responsibility of the CIO. An IT strategy is essential because organizations are able to implement new technologies within their organization on the basis of this strategy, and will subsequently be able to derive strategic benefits from this (Earl, 1987). From a governance perspective, it is also important to create alignment between the business and IT. The IT strategy can be a facilitating factor in accomplishing this (Henderson & Venkatraman, 1993).

Information Management as the Link between Business Units and Service providers

The information manager is responsible for the alignment of the demand for IT services by the service recipient's business units with the services provided by the service providers (Quinn, Doorley, & Paquette, 1990). The information manager is furthermore responsible for the IT outsourcing partnership and supports the CIO in the implementation of the IT strategy (McFarland & Nolan, 1995). The cost of the effort expended by the information management function is between 2% and 10% of the contract value. In order to be able to properly carry out these tasks, information managers require knowledge of the business operations, as well as IT (Willcocks & Fitzgerald, 1994).

A Properly Functioning Chief Information Officer

The CIO is responsible for the development and implementation of the IT strategy and carries final responsibility for the IT outsourcing partnership relationships (Lacity & Willcocks, 2001). A CIO could also play an important role in the alignment of business operations with IT. Many organizations set up an IT board for this purpose (Dreyfuss, 2002). This is an organization-wide steering committee in which all business units and information management is represented and which is chaired by the CIO. The IT board is able to explore the political field of influence and decisions concerning the IT services to be provided can be prepared and discussed here.

GOVERNANCE FACTORS FOR THE RELATIONSHIP

There are four factors that govern the relationship: mutual trust between the service recipient and the service provider; experience in establishing and maintaining IT outsourcing relationships; efficient and effective outsourcing contracts; and an audit & benchmark process in place. These governance factors are described in further detail in this section.

Mutual Trust between the Service recipient and the Service provider

Trust is a particularly important criterion for the selection process used by service recipients (Apte, 1990; Lacity & Hirschheim, 1993). But trust is also necessary for maintaining a relationship. This is not easy in actual practice. There does not always exist equality, a true partnership, between the service recipient and the service provider. This issue is not specific to the IT services industry. Kraljic (1983) has been pleading for the creation of partnerships since the eighties: "Purchasing must become Supplier Management". The culture factor is furthermore also important for creating trust (Hofstede, 1980). Grönroos (1990) states that the culture of a service provider is focused on creating service-oriented attitudes and proactive behaviors.

Experience Establishing and Maintaining IT Outsourcing Relationships

Experience is an important selection criterion for choosing a service provider (McFarland & Nolan, 1995). In addition, mature service providers use a standard methodology for setting up and managing IT outsourcing partnerships. Aside from the experiences of the service provider, it is also important for the service recipient to build up experience in outsourcing. Lacity and Hirschheim (1993) state that the lack of experience with outsourcing is an important argument for deciding not to outsource: "customers' inexperience with IS outsourcing".

Efficient and Effective Outsourcing Contracts

Many authors, such as Lacity and Hirschheim (1993), and Kern and Willcocks emphasize the importance of a contract "…the centrality of the contract" (Kern and Willcocks, 2002). Aside from a precise description of the IT services to be provided and the agreed upon service levels, it is important for contracts to be flexible (Klepper, 1995). One way of achieving flexibility is to manage IT as a portfolio and to enter into contract with multiple service providers.

An audit & Benchmark Process in Place

It is important for the service recipient to formulate agreements about the conduct of audits (Allen, 1975; Willcocks & Fitzgerald, 1994): a verification of the service provider's processes. In addition, agreements must be made about establishing regular benchmarks [Lac'98]: Is the price/ quality ratio of the IT services provided in conformance with the marketplace? Service providers that deliver their services in a process-oriented manner, for example, through means of ISO certification, the implementation of ITIL or CMM, are generally in a better position to provide the services contracted for.

GOVERNANCE FACTORS FOR SERVICE PROVIDERS

There are three governance factors related to the service provider: adequate contract and account management, adequate service delivery processes and the availability of human resources. These factors are explained in further detail in the following subsections.

Adequate Contract and Account Management

Contract and account management make up the front office of the service provider and are denoted as the "customer outsourcing interface" by MacFarland and Nolan (1995). It is important in this regard to make a clear distinction between contract management and account management (Beulen, 2000). Contract management is responsible for the operational management and therefore the direction of the service delivery processes. Contract management is therefore focused on the effectiveness and efficiency of the agreed upon contractual commitments. Account management is responsible for maintaining the relationship with the service recipient and is focused on obtaining an extension of existing contracts and on expanding the services provided through means of new contracts.

Adequate Service Delivery Processes

The existence of adequate service delivery processes are considered to be a "core capability" by Feeny, Earl and Edwards (1997): "delivery of IS services" and using Mintzberg's (1979) terminology, the "operating core". When the service delivery processes are set up, it is essential to make a distinction between the service provider's service delivery units and competence centers. Service delivery units are involved in the delivery of the IT services that have been contractually agreed upon with the service provider's customers. The service delivery units must be assessed in terms of their degree of effectiveness and efficiency and are directly controlled by the contract managers. Competence centers are involved in researching the potential of new technological developments and which are responsible for building up knowledge about these new technologies (Cash, McFarlan & McKenney, 1988).

The Availability of Human Resources to Service providers

From the mid-nineties to the year 2000, the shortage of IT professionals was seen as a factor that would limit the growth of the IT services industry. Due to economic developments, there has been a decrease in this shortage in the labor market (Hirschheim & Lacity, 2000). In spite of this, service providers must continue to pay attention to the availability of IT professionals for delivering their IT services.

FUTURE TRENDS

Four trends related to IT outsourcing partnerships can be identified: business process outsourcing (BPO), multiple sourcing, offshore outsourcing and insourcing. Except for insourcing, these trends complicate the governance of IT outsourcing partnerships both for the service recipients and the service providers.

Business Process Outsourcing

In addition to outsourcing the IT services for their supporting processes, an increasing number of organizations are also deciding to outsource complete business processes. Therefore, BPO requires different skills from the IT professionals. IT professionals must have greater knowledge of the business processes, and they must possess business knowledge. On top of that, the service providers have to also employ non-IT staff in order to handle the administrative activities related to the offered services.

Table 3. Trends in IT outsourcing partnerships

Business Process Outsourcing
Multiple Sourcing
Offshore Outsourcing
Insourcing

Multiple Sourcing

Many organizations outsource their IT services to more than one service provider: multiple sourcing. This heavily impacts the required service recipient's management attention. Also the complexity of the contracts increases by multiple sourcing. Not only the responsibilities between the service recipient and the service provider but also the responsibilities between service providers have to be detailed in the contracts.

Offshore Outsourcing

In offshore outsourcing, the service providers execute the services out of a low cost country to their customer, the service recipient, which is located in a high cost country. Due to time difference, language barriers, and cultural differences, managing offshore outsourcing partnerships requires extra management attention from both the service recipient and the service provider. In the contractual part of the partnership, jurisdiction and settlement need to be addressed properly.

Insourcing

Insourcing means that not all of the IT services are performed by one or more service providers and that a portion of the IT services are provided by the internal IT division. This implies that some aspects will continue to be looked after by the internal IT division itself. The internal IT division also requires attention. Some service recipients will choose the insourcing option to avoid outsourcing debacles and to ensure business continuity. This remains the question if the internal IT division is capable in executing the services properly.

CONCLUSION

Achieving governance in IT outsourcing partnerships is not easy. It requires a lot of management attention from both the service recipient and the service provider. Also, implementing governance factors for the relationship between the service recipient and the service provider is key. However, time does not stand still. Business process outsourcing is expected to become increasingly dominant and increasing numbers of multiple outsourcing relationships will come into being. Also, offshore outsourcing is emerging. In addition, service recipients will also selectively repatriate certain components of their IT services: insourcing. This will have an impact and will lead to an increase of complexity in managing IT outsourcing partnerships.

KEY TERMS

Business Process Outsourcing: Service recipients handover the responsibility for the execution of complete business processes to service providers. Most of the business processes in business process outsourcing are IT related processes.

Insourcing: The internal IT division of service recipients executes the IT services to the departments of the service recipient.

IT Outsourcing Partnership: The relationship between the service recipient and the service provider is defined in contracts describing the mutual obligations. The contract value of IT outsourcing partnerships is substantial, meaning over 10 million US$ or Euros. These contracts are also long-term contracts. The average duration of contracts is over 36 months.

Multiple Sourcing: Service recipients that have outsourced the responsibility to execute the services to more than one service provider.

Offshore Outsourcing: Service providers execute the IT services out of a low cost country to their customer, the service recipient, which is located in a high cost country.

Outsourcing Contracts: Describe long-term mutual obligations between the service provider(s) and the service recipient. The contract value is substantial, meaning over 10 million US$ or Euros. The average duration of outsourcing contracts is over 36 months.

Service Provider: Responsible for the execution of the IT services to the service recipient in IT outsourcing relationships.

Service Recipient: Hands over the responsibility for the execution of the IT services to one or more service providers but remains the responsibility for managing the IT outsourcing partnership.

Governance Structures for IT in the Health Care Industry

Reima Suomi
Turku School of Economics and Business Administration, Finland

INTRODUCTION

The pressures for the health care industry are well known and very similar in all developed countries (i.e., altering population, shortage of resources for staff and from taxpayers, higher sensitivity of the population for health issues, new and emerging diseases, etc.). Underdeveloped countries experience different problems, but they have the advantage of learning from the lessons and actions that developed countries underwent perhaps decades ago. On the other hand, many solutions also exist, but they all make the environment even more difficult to manage (i.e., possibilities of networking, booming medical and health-related research and knowledge produced by it, alternative caretaking solutions, new and expensive treatments and medicines, promises of biotechnology, etc.).

From the public authorities' points of view, the solution might be easy—outsource as much as you can out of this mess. Usually, the first services to go are marginal operational activities, such as laundry, cleaning, and catering services. It is easy to add information systems to this list, but we believe this is often done without a careful enough consideration. Outsourcing is often seen as a trendy, obvious, and easy solution, which has been supported by financial facts on the short run. Many examples show that even in the case of operational information systems, outsourcing can become a costly option, not to mention lost possibilities for organizational learning and competitive positioning through mastering of information technology.

BACKGROUND

We have found the following reasons for the late adoption of modern information technology in the health care sector (Suomi, 2000):

- Fragmented industry structure
- Considerable national differences in processes
- Strong professional culture of medical care personnel
- One-sided education
- Handcrafting traditions
- Weak customers
- Hierarchical organization structures

ICT and governance structures meet in two ways. On one side, ICT enables new governance structures for the health care industry. On the other, it is an object in need of governing. As both sectors offer a multitude of new possibilities, innovations are called for in the industry (Christensen, Bohmer, & Kenagy, 2000).

IT governance thinking matures in organizations as any other discipline. Van Grembergen, De Haes, and Guldentops (2003) have defined the following stages in their IT Governance Maturity Model:

- Non-existent
- Initial/ad-hoc
- Repeatable but intuitive
- Defined process
- Managed and measurable
- Optimized

Needless to say, in the health care industry, IT Governance thinking is non-existent or initial/ad hoc in the best situation.

THE MEANING OF ICT GOVERNANCE STRUCTURE IN HEALTH CARE

IT is an old acronym for information technology. Nowadays, it is replaced often with the term ICT, referring to information and communication technology. This emphasizes the communication services that are developing very quickly, such as the Internet and mobile services. The letter *C* is often upgraded to the second dimension: alongside communication it can refer to contents. IT or ICT governance is defined (IT Governance Institute, 2001) as follows:

IT governance is the responsibility of the board of directors and executive management. It is an integral *part of enterprise governance and consists of the leadership and organizational structures and processes that ensure that the organization's IT sustains and extends the organization's strategies and objectives.*

For many, there is a temptation to understand governance as just a synonym for management. This is an oversimplification. Management is a goal-oriented activity, whereas governance is often given from the outside, and organizations just have to live with it. This is not to say that all governance structures would be beyond management control; management can influence most governance structures, at least in the long run. The long run is a key term in many aspects. We talk about structures that are semi-permanent and not changed very frequently. Structure is a term closer to architecture than to infrastructure; governance structures are architectural terms and are then implemented into infrastructures through different organizational forms. The terms *organization form* and *governance structure* are not synonyms. Organizational forms are more formal and touch upon one organization, whereas governance structures are found in a richer selection of forms and organize themselves over a number of organizations. Table 1 summarizes our discussion.

Governance structures are present in almost any human decision-making situation. In Table 2, we have a collection of key aspects of governance structure issues in health care.

FUTURE TRENDS

One of the biggest changes in the industry is that information related to health, sickness and medicines is not scarce. Internet is a rich source of such information, at different levels of expertise and at different languages. The gap between what information is available and what a health-care professional should know is growing very fast (Weaver 2002). This will shift the power balance between health professionals and patients: increasingly often the patients are the best experts on their disease. Different electronic forums or Virtual Communities (Rheingold 1993) related to health are born on the Internet. They have different services and values to offer to the healthy ones and to the chronic and acute sick (Utbult, 2000). Similarly, the interaction between the patients and health care professionals is going to change: electronic means are going to take share from face-to-face meetings (Cain, Sarasohn-Kahn & Wayne 2000; Gibson 2003).

For organizing patient flows through the health care system modern ICT offers many possibilities. Should patient data be all the time available anywhere though electronic means, would the Healthcare Supply Chains be much more effective (More & McGrath 2001). Effectiveness means that patients are taken care of in the best and most effective places, be they public or private, and of right level of expertise. As patient data can be electronically cumulated into huge databases, these databases can be used for different statistical, research and other purposes. This calls for care and proper legislation giving the principles.

Managing and building governance structures for ICT in health care organizations is not that much different from other organizations. Even in health care organizations, the scope and status of information resource management has to be decided. Issues such as sourcing decisions, charging arrangements, data privacy, and security issues all deserve their attention. There are certain problems that need to be solved in this area:

Table 1. *Comparison of terms management, organizational form, and governance structure*

	Management	Organizational Form	Governance Structure
Time perspective	Short	Medium	Long
Focus	Action	Internal organization	Inter-organizational structures
Management Control	In action	Easy	Difficult
Metaphor	Communication channels	Infrastructure	Architecture
Character	Concrete	Formal	Abstract

***Table 2.** ICT governance structure issues in health care*

ICT as an enabler
• Health-related information on the web
• Private-public sector co-operation
• Allocation of patients to different levels of care
• Customer contacts distribution between electronic and classical means
• Ownership, structure and allocation of patient, population-level and other critical data
• Electronic forums for patients to interact
• Electronic prescription systems
ICT as an object to be governed
• New legislation needs because of the new data processing possibilities
• Data privacy and security
• Structure and status of the information resource management in health care units
• ICT-general management partnership
• Sourcing decisions of ICT
• Charging arrangements on ICT-services

- Data privacy and security needs are extremely important and might sometimes conflict with optimal care.
- As the area is new, legislation is often lagging behind.
- The field is a meeting place for two strong professional cultures—medical doctors and ICT-professionals—that might bring along difficulties.

CONCLUSION

Health is undoubtedly among the most important issues for all of us. In a modern society, the threats towards health are changing all the time, but at the same time, the possibilities to maintain health and cure illnesses grow exponentially. The task is to make needs and solutions meet in an effective way. This is about information and communication technologies and governance structures.

Modern ICT allows health care organizations to structure themselves in new, innovative ways, and simultaneously to empower the customers to interact with the organizations, with fellow patients, and with information sources in revolutionary new ways. In this environment, health care professionals also have to adjust their roles.

KEY TERMS

Electronic Patient Record: All health-related information related to a patient in electronic form, assembled as a single entity.

Electronic Prescription: Prescriptions created and handled in electronic form in an integrated information system.

Healthcare Supply Chain: A managed set of activities related to the health care activity of a patient, organized so that all necessary information is available all the time and the participants in the chain have a complete picture of the total process.

Sourcing Decision: Decision whether to buy goods/services from the market or to make them self. Sourcing decision can be made as an independent decision unit or as a part of a bigger group.

Virtual Community: A social aggregation on the Internet when people interact long enough to form personal relationships.

Graph Encoding and Recursion Computation

Yangjun Chen
University of Winnipeg, Canada

INTRODUCTION

It is a general opinion that relational database systems are inadequate for manipulating composite objects that arise in novel applications such as Web and document databases (Abiteboul, Cluet, Christophides, Milo, Moerkotte & Simon, 1997; Chen & Aberer, 1998, 1999; Mendelzon, Mihaila & Milo, 1997; Zhang, Naughton, Dewitt, Luo & Lohman, 2001), CAD/ CAM, CASE, office systems and software management. Especially, when recursive relationships are involved, it is cumbersome to handle them in relational databases, which sets current relational systems far behind the navigational ones (Kuno & Rundensteiner, 1998; Lee & Lee, 1998). To overcome this problem, a lot of interesting graph encoding methods have been developed to mitigate the difficulty to some extent. In this article, we give a brief description of some important methods, including analysis and comparison of their space and time complexities.

BACKGROUND

A composite object can be generally represented as a directed graph (digraph). For example, in a CAD database, a composite object corresponds to a complex design, which is composed of several subdesigns. Often, subdesigns are shared by more than one higher-level design, and a set of design hierarchies thus forms a directed acyclic graph (DAG). As another example, the citation index of scientific literature, recording reference relationships between authors, constructs a directed cyclic graph. As a third example, we consider the traditional organization of a company, with a variable number of manager-subordinate levels, which can be represented as a tree hierarchy.

In a relational system, composite objects must be fragmented across many relations, requiring joins to gather all the parts. A typical approach to improving join efficiency is to equip relations with hidden pointer fields for coupling the tuples to be joined. The so-called *join index* is another auxiliary access path to mitigate this difficulty. Also, several advanced join algorithms have been suggested, based on hashing and a large main memory. In addition, a different kind of attempt to attain a compromise solution is to extend relational databases with new features, such as *clustering* of composite objects, by which the concatenated foreign keys of ancestor paths are stored in a primary key. Another extension to relational system is *nested relations* (or NF^2 relations). Although it can be used to represent composite objects without sacrificing the relational theory, it suffers from the problem that subrelations cannot be shared. Moreover, recursive relationships cannot be represented by simple nesting because the depth is not fixed. Finally, *deductive databases* and *object-relational databases* can be considered as two quite different extensions to handle this problem (Chen, 2003; Ramakrishnan & Ullman, 1995).

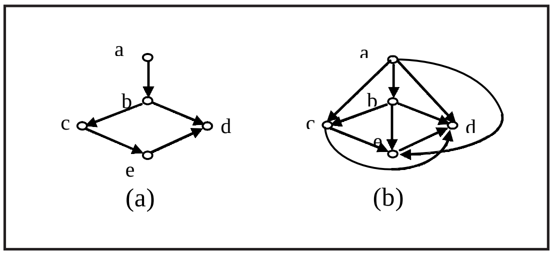
In the past decade, a quite different kind of research has also been done to avoid *join* operations based on *graph encoding*. In this article, we provide an overview on most important techniques in this area and discuss a new encoding approach to pack "ancestor paths" in a relational environment. It needs only $O(e \cdot b)$ time and $O(n \cdot b)$ space, where b is the breadth of the graph, defined to be the least number of disjoined paths that cover all the nodes of a graph. This computational complexity is better than any existing method for this problem, including the graph-based algorithms (Schmitz, 1983), the graph encoding (Abdeddaim, 1997; Bommel & Beck; Zibin & Gil, 2001) and the matrix-based algorithms (La Poutre & Leeuwen, 1988).

RECURSION COMPUTATION IN RELATIONAL DATABASES

We consider composite objects represented by a digraph, where nodes stand for objects and edges for parent-child relationships, stored in a binary relation. In many applications, the transitive closure of a digraph needs to be computed, which is defined to be all ancestor-descendant pairs. For instance, the transitive closure of the graph in Figure 1(a) is shown in Figure 1(b).

In this article, we mainly overview the graph encoding in a relational environment. The following is a typical structure to accommodate part-subpart relationships (Cattell & Skeen, 1992):

Figure 1. A graph and its transitive closure



- Part(Part-id, ...)
- Connection(Parent-id, Child-id, ...)

where Parent-id and Child-id are both foreign keys, referring to Part-id. In order to speed up the recursion evaluation, we will associate each node with a pair of integers, which helps to recognize ancestor-descendant relationships.

In the rest of the article, the following three types of digraphs will be discussed.

(i) Tree hierarchy, in which the parent-child relationship is of one-to-many type; that is, each node has at most one parent.
(ii) Directed acyclic graph (DAG), which occurs when the relationship is of many-to-many type, with the restriction that a part cannot be sub/superpart of itself (directly or indirectly).
(iii) Directed cyclic graph, which contains cycles.

Later we will use the term *graph* to refer to the *directed graph*, since we do not discuss non-directed ones at all.

RECURSION WITH RESPECT TO TREES

Perhaps the most elegant algorithm for encoding is *relative numbering* (Schmitz, 1983), which guarantees both optimal encoding length of log*n* bits and constant time recursion tests for trees. Consider a tree *T*. By traversing *T* in *postorder*, each node *v* will obtain a number (it can be integer or a real number) *post*(*v*) to record the order in which the nodes of the tree are visited. A basic property of postorder traversal is

$$post(v) = \max\{\, post(u) \mid u \in \text{descendant}(v)\}.$$

Let $l(v)$ be defined by

$$l(v) = \min\{\, post(u) \mid u \in \text{descendant}(v)\}.$$

Then, a node u is a descendant of v if $l(v) \leq post(u) \leq post(v)$.

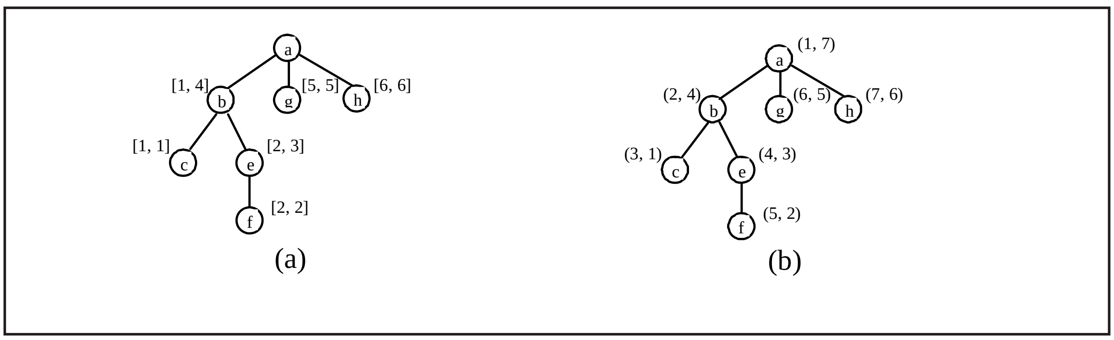
In terms of this relationship, each node v can be encoded by an interval $[l(v), post(v)]$ as exemplified by Figure 2(a).

Another interesting graph encoding method is discussed in Knuth (2003), by which each node is associated with a pair $(pre(v), post(v))$, where $pre(v)$ represents the preorder number of v and can be obtained by traversing *T* in a preorder. The pair can be used to characterize the ancestor-descendant relationship as follows.

Proposition 1 - Let v and v' be two nodes of a tree *T*. Then, v' is a descendant of v if $pre(v') > pre(v)$ and $post(v') < post(v)$.

Proof. See Exercise 2.3.2-20 in Knuth (1969).

Figure 2. Labeling a tree



If *v*' is a descendant of *v*, then we know that *pre*(*v*') > *pre*(*v*) according to the preorder search. Now we assume that *post*(*v*') > *post*(*v*). Then, according to the postorder search, either *v*' is in some subtree on the right side of *v*, or *v* is in the subtree rooted at *v*', which contradicts the fact that *v*' is a descendant of *v*. Therefore, *post*(*v*') must be less than *post*(*v*).

Figure 2(b) helps for illustration. The first element of each pair is the preorder number of the corresponding node and the second is its postorder number. With such labels, the ancestor-descendant relationships can be easily checked. For instance, by checking the label associated with b against the label for f, we see that b is an ancestor of f in terms of Proposition 1. Note that b's label is (2, 4) and f's label is (5, 2), and we have 2 < 5 and 4 > 2. We also see that since the pairs associated with g and c do not satisfy the condition given in Proposition 1, g must not be an ancestor of c and vice versa.

Definition 1 - (*label pair subsumption*) Let (p, q) and (p', q') be two pairs associated with nodes *u* and *v*. We say that (p, q) is subsumed by (p', q'), denoted $(p, q) \prec (p', q')$, if $p > p'$ and $q < q'$. Then, *u* is a descendant of *v* if (p, q) is subsumed by (p', q').

According to the tree labeling discussed previously, the relational schema to handle recursion can consist of only one relation of the following form:

Node(Node_id, *label_pair*, ...),

where label_pair is used to accommodate the preorder and the postorder numbers of the nodes of a graph, denoted label_pair.*preorder* and label_pair.*postorder*, respectively. Then, to retrieve the descendants of node *x*, we issue two queries as below.

```
Q1: SELECT  label_pair
    FROM    Node
    WHERE   Node_id = x
```

Let the label pair obtained by evaluating Q_1 be *y*. Then, the second query is of the following form:

```
Q2: SELECT  *
    FROM    Node
    WHERE   label_pair.preorder > y.preorder
    and     label_pair.postorder < y.postorder
```

From this, we can see that with the tree labeling, the recursion w.r.t. a tree can be handled conveniently in a relational environment. If a tree is stored in a preorder, we can control the search so that it stops when the first pair that is not subsumed by *y* is encountered.

RECURSION WITH RESPECT TO DGAS

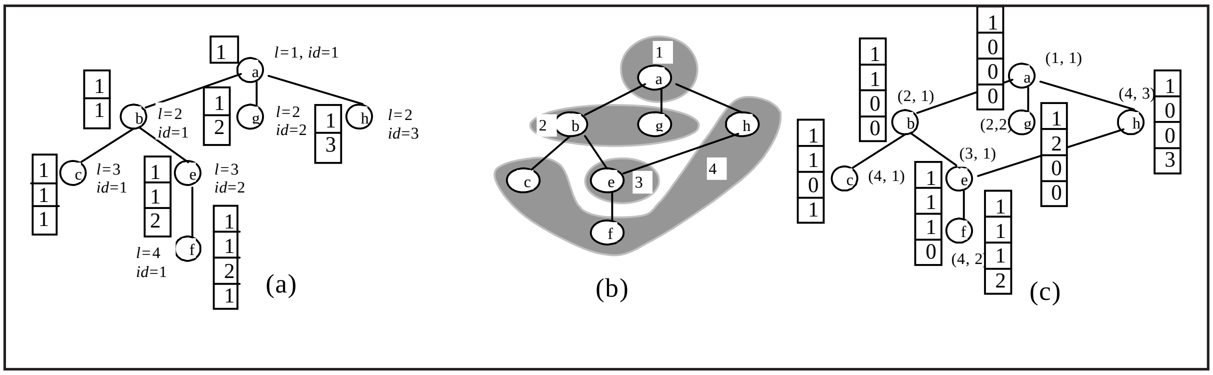
In this section, we consider the recursion computation w.r.t. DAGs.

- *Range-compression*
  The relative numbering was extended to handle DAGs by (Agrawal, Borgida & Jagadish, 1989). Their method is called *range-compression* encoding. It encodes each node *v* in a DAG as an integer *id*(*v*), obtained by scanning a certain spanning forest of the DAG in postorder. In addition, each node *v* is associated with an array *A* of length k ($1 \le k \le n$), in which the *i*th entry is an interval $[l_i, r_i]$ with the property that a node *u* is a descendant of *v* if there exists an integer *j* such that $l_i \le id(u) \le r_j$. Since an array contains *n* entries in the worst case, this encoding method needs $O(n^2)$ space and time.
- *Cohen's encoding and EP encoding*
  In the language research, the graph encoding is also extensively explored for type-subtype checking that is in essence a recursion computation. Thus, the methods proposed in that area can be employed in a relational environment. Perhaps the most interesting method is Cohen's encoding for tree structures (Cohen, 1991). It was generalized to DAGs by Krall, Vitek and Horspool (1997) into what is called *packed encoding* (PE).

Cohen' encoding stores with each node *v* its level l_v, its unique identifier id_v, as well as an array A_v such that for each node $u \in$ ancestor(*v*), $A_v[l_u] = id_u$. The test $v \in$ descendant(*u*) is then carried out by checking whether both $l_v \ge l_u$ and $A_v[l_u] = id_u$ hold. An example of the actual encoding is given in Figure 3(a).

EP encoding partitions a DAG into a number of slices: $S_1, ..., S_k$ for some *k* such that no two ancestors of a node can be on the same slice. In addition, each node *v* is assigned a unique identifier id_v within its slice *S*. Thus, *v* is identified by the pair (s_v, id_v), where s_v is the number for *S*. Furthermore, each node *v* is associated with an array A_v such that for all $u \in$ ancestor(*v*), $A_v[s_u] = id_v$. The DAG shown in Figure 3(b) is partitioned into four slices numbered 1, 2, 3 and 4, respectively. Accordingly, the DAG can be encoded as shown in Figure 3(c). We note that in EP encoding slices play a role similar to that of levels in Cohen's encoding. In fact, Cohen's algorithm partitions

Figure 3. Cohen's encoding and EP encoding



a tree into levels while EP encoding partitions a DAG into slices. According to Fall (1995), it is NP-hard to find a minimal partition of slices. Moreover, if the sizes of slices is bounded by a constant, the array associated with a node is of length O(n) at average. So the space and time overhead of EP encoding is on the order of O(n^2).

- *Pre-postorder encoding*
  Now we discuss a new encoding method, which needs only O($e \cdot b$) time and O($n \cdot b$) space, where b is the breadth of the graph, defined to be the least number of disjoined paths that cover all the nodes of a graph.

What we want is to apply the pre-postorder encoding discussed previously to a DAG. To this end, we establish a *branching* of the DAG as follows (Tarjan, 1977).

Definition 2 - (*branching*) A subgraph $B = (V, E')$ of a digraph $G = (V, E)$ is called a branching if it is cycle-free and $d_{indegree}(v) \le 1$ for every $v \in V$.

Clearly, if for only one node r, $d_{indegree}(r) = 0$, and for all the rest of the nodes, v, $d_{indegree}(v) = 1$, then the branching is a directed tree with root r. Normally, a branching is a set of directed trees. Now, we assign every edge e a same cost (e.g., let cost $c(e) = 1$ for every edge e). We will find a branching for which the sum of the edge costs, $\sum_{e \in E} c(e)$, is maximum.

For example, the trees shown in Figure 4(b) are a maximal branching of the graph shown in Figure 4(a) if each edge has the same cost.

Assume that the maximal branching for $G = (V, E)$ is a set of trees T_i with root r_i (i = 1, ..., m). We introduce a *virtual root* r for the branching and an edge $r \rightarrow r_i$ for each T_i, obtaining a tree G_r, called the representation of G. For instance, the tree shown in Figure 4(c) is the representation of the graph shown in Figure 2(a). Using Tarjan's algorithm for finding optimum branchings (Tarjan, 1977), we can always find a maximal branching for a directed graph in O($|E|$) time if the cost for every edge is equal to each other. Therefore, the representative tree for a DAG can be constructed in linear time.

Figure 4. A DAG and its branching

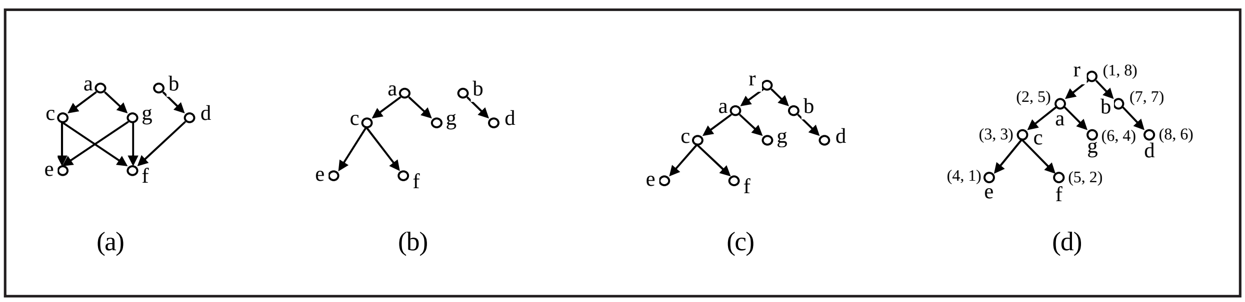


Figure 5. Linked lists associated with nodes in G

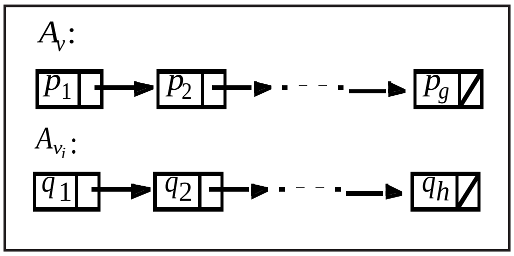


We can label G_r in the same way as shown in the previous subsection. See Figure 4(d).

In a G_r (for some G), a node v can be considered as a representation of the subtree rooted at v, denoted $T_{sub}(v)$; and the pair (*pre*, *post*) associated with v can be considered as a pointer to v, and thus to $T_{sub}(v)$. (In practice, we can associate a pointer with such a pair to point to the corresponding node in G_r.) In the following, what we want is to construct a pair sequence: $(pre_1, post_1)$, ..., $(pre_k, post_k)$ for each node v in G, representing the union of the subtrees (in G_r) rooted respectively at $(pre_j, post_j)$ (j = 1, ..., k), which contains all the descendants of v. In this way, the space overhead for storing the descendants of a node is dramatically reduced. Later we will show that a pair sequence contains at most O(b) pairs, where b is the breadth of G. (The breadth of a digraph is defined to be the least number of the disjoint paths that cover all the nodes of the graph.)

The question is how to construct such a pair sequence for each node v so that it corresponds to a union of some subtrees in G_r, which contains all the descendants of v in G. For this purpose, we sort the nodes of G topologically; that is, $(v_i, v_j) \in E$ implies that v_j appears before v_i in the sequence of the nodes. The pairs to be generated for a node v are simply stored in a linked list A_v. Initially, each A_v contains only one pair produced by labeling G_r.

We scan the topological sequence of the nodes from the beginning to the end and at each step we do the following:

Let v be the node being considered. Let v_1, ..., v_k be the children of v. Merge A_v with each for the child node v_l (l = 1, ..., k) as follows. Assume $A_v = p_1 \rightarrow p_2 \rightarrow \ldots p_g$ and $A_{v_i} = q_1 \rightarrow q_2 \rightarrow \ldots\ q_h$, as shown in Figure 5. Assume that both A_v and A_{v_i} are increasingly ordered. (We say a pair p is larger than another pair p', denoted $p > p'$ if $p.pre > p'.pre$ and $p.post > p'.post$.)

We step through both A_v and A_{v_i} from left to right. Let p_i and q_j be the pairs encountered. We will make the following checkings.

Algorithm *pair-sequence-merge*$(A_i, A_{v_i}$ **);**

(1) If $p_i.pre > q_j.pre$ and $p_i.post > q_j.post$, insert q_j into A_v after p_{i-1} and before p_i and move to q_{j+1}.

(2) If $p_i.pre > q_j.pre$ and $p_i.post < q_j.post$, remove p_i from A_v and move to p_{i+1}. (*p_i is subsumed by q_j.*)

(3) If $p_i.pre < q_j.pre$ and $p_i.post > q_j.post$, ignore q_j and move to q_{j+1}. (*q_j is subsumed by p_i; but it should not be removed from A_{v_i} .*)

(4) If $p_i.pre < q_j.pre$ and $p_i.post < q_j.post$, ignore p_i and move to p_{i+1}.

(5) If $p_i = p_j'$ and $q_i = q_j'$, ignore both (p_i, q_i) and (p_j', q_j'), and move to (p_{i+1}, q_{i+1}) and (p_{j+1}', q_{j+1}'), respectively.

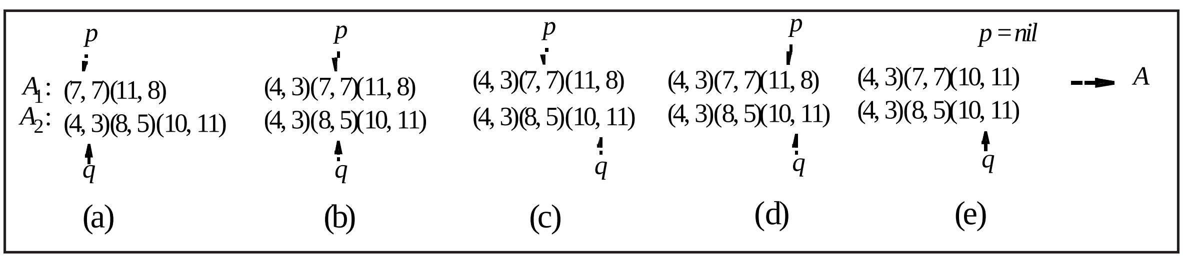
(6) If $p_i = nil$ and $q_j \neq nil$, attach the rest of A_{v_i} to the end of A_v.

The following example helps for illustration.

Example 1 - Assume that A_1 = (7, 7)(11, 8) and A_2 = (4, 3)(8, 5)(10, 11). Then, the result of merging A_1 and A_2 is (4, 3)(7, 7)(10, 11). Figure 6 shows the entire merging process.

In each step, the A_1-pair pointed to by p and the A_2-pair pointed to by q are compared. In the first step, (7, 7) in A_1 will be checked against (4, 3) in A_2 (see Figure 6(a)). Since (4, 3) is smaller than (7, 7), it will be inserted into A_1 before (7, 7) (see Figure 6(b)). In the second step, (7, 7) in A_1 will be checked against (8, 5) in A_2. Since (8, 5) is subsumed by (7, 7), we move to (10, 11) in A_2 (see Figure 6(c)). In the third

Figure 6. An entire merging process



step, (7, 7) is smaller than (10, 11) and we move to (11, 8) in A_1 (see Figure 6(d)). In the fourth step, (11, 8) in A_1 is checked against (10, 11) in A_2. Since (11, 8) is subsumed by (10, 11), it will be removed from A_1 and p becomes *nil* (see Figure 6(e)). In this case, (10, 11) will be attached to A_1, forming the result $A = (4, 3)(7, 7)(10, 11)$ (see Figure 6(e)).

We can store physically the label pair for each node, as well as its label pair. Concretely, the relational schema to handle recursion w.r.t., a DAG can be established in the following form:

Node(Node_id, *label*, *label_sequence*, ...),

where *label* and *label_sequence* are used to accommodate the label pairs and the label pair sequences associated with the nodes of a graph, respectively. Then, to retrieve the descendants of node *x*, we issue two queries. The first query is similar to Q_1:

Q_3: SELECT label_sequence
FROM Node
WHERE Node_id = *x*

Let the label sequence obtained by evaluating Q_3 be *y*. Then, the second query will be of the following form:

•Q_4: SELECT *
FROM Node
WHERE ϕ(label, *y*)

where $\phi(p, s)$ is a boolean function with the input: *p* and *s*, where *p* is a pair and *s* a pair sequence. If there exists a pair *p*' in *s* such that $p \prec p'$ (i.e., $p.pre > p'.pre$ and $p.post < p'.post$), then $\phi(p, s)$ returns *true;* otherwise *false*.

Based on the method discussed in the previous subsection, we can easily develop an algorithm to compute recursion for cyclic graphs. First, we use Tarjan's algorithm for identifying *strongly connected components* (*SCCs*) to find the cycles of a cyclic graph (Tarjan, 1972) (which needs only $O(n + e)$ time). Then, we take each SCC as a single node (i.e., condense each SCC to a node) and transform a cyclic graph into a DAG. Next, we handle the DAG as discussed earlier. In this way, however, all nodes in an SCC will be assigned the same pair (and the same pair sequence). For this reason, the method for computing the recursion at some node *x* should be slightly changed.

FUTURE TRENDS

The computation of transitive closures and recursive relationships is a classic problem in the graph theory and has a variety of applications in data engineering, such as CAD/CAM, office systems, databases, programming languages and so on. For all these applications, the problems can be represented as a directed graph with the edges being not labelled, and can be solved using the techniques described in this article. In practice, however, there exists another kind of problem, which can be represented only by using the so-called weighted directed graphs. For them, the edges are associated with labels or distances and the shortest (or longest) paths between two given nodes are often asked. Obviously, these techniques are not able to solve such problems. They have to be extended to encode path information in the data structure to speed up query evaluation. For this, an interesting issue is how to maintain minimum information but get high efficiency, which is more challenging than transitive closures and provides an important research topic in the near future.

CONCLUSION

In this article, we provide an overview on the recursion computation in a relational environment and present a new encoding method to label a digraph, which is compared with a variety of traditional strategies as well as the methods proposed in the database community. Our method is based on a tree labeling method and the concept of branchings that are used in graph theory for finding the shortest connection networks. A branching is a subgraph of a given digraph that is in fact a forest, but covers all the nodes of the graph. On the one hand, the proposed encoding scheme achieves the smallest space requirements among all previously published strategies for recognizing recursive relationships. On the other hand, it leads to a new algorithm for computing transitive closures for DAGs in $O(e \cdot b)$ time and $O(n \cdot b)$ space, where *n* represents the number of the nodes of a DAG, *e* the numbers of the edges, and *b* the DAG's breadth. In addition, this method can be extended to cyclic digraphs and is especially suitable for a relational environment.

KEY TERMS

Branching: A branching is a subgraph of a directed graph, in which there are no cycles and the indegree of each node is 1 or 0.

Cyclic Graph: A cyclic graph is a directed graph that contains at least one cycle.

DAG: A DAG is a directed graph that does not contain a cycle.

Graph Encoding: Graph encoding is a method to assign the nodes of a directed graph a number or a bit string, which reflects some properties of that graph and can be used to facilitate computation.

Strongly Connected Component (SCC): An SCC is a subgraph of a directed graph, in which between each pair of nodes there exists a path.

Transitive Closure: The transitive closure of a directed graph G is a graph G^*, in which there is an edge from node a to node b if there exists a path from a to b in G.

Tree: A tree is a graph with a root, in which the indegree of each node is equal to 1.

Harmonizing IT and Business Strategies

Kevin Johnston
University of Cape Town, South Africa

INTRODUCTION

The alignment of business strategy with IT strategy has been a concern of chief information officers (CIOs) (Berkman, 2000; Croteau & Bergeron, 2001; Crowley, 2001), chief executive officers (CEOs) (Armstrong, Chamberlain, Moore & Hart, 2002; Mesoy, 1999), academic researchers (Henderson & Venkatraman, 1999; Reich & Benbasat, 2000; Tallon & Kraemer, 2000), and research companies (Broadbent, 2000; Croteau & Bergeron, 2001; Meta Group, 2001) since the age of vacuum tubes. In surveys (Mesoy, 1999) of CIO concerns, alignment has consistently been rated as a major issue. A Cutter study reported that business-IT alignment was "the number one problem facing IT" (Crowley, 2001).

Many authors (Burgleman, Maidique & Wheelwright, 2001; Croteau & Bergeron, 2001; Hartman, Sifonis, & Kador, 2000; Reich & Benbasat, 2000) agree that it is important to align IT strategy with the organization's business strategy. Although the importance of strategic alignment of IT is acknowledged and widely accepted, it remains an issue within many organizations (Armstrong et al., 2002).

Burgleman et al. (2001) stated, "Technological issues only occasionally are included explicitly in typical corporate strategy reviews, and only rarely are they among the regular inputs to corporate planning and development." Gates (1999) wrote: "It is impossible to align IT strategy with business strategy if the CIO is out of the business loop."

Management's attitude towards IT and IT strategy need to be changed (Cosgrove Ware, 2001). A "model of attitude change", described by Nash, Gwilt, Ludwig, and Shaw (2001), listed five steps to affect attitude change:

- Attention and awareness - subject managers to advertising, publications, and word of mouth about IT;
- Comprehension and knowledge - teach managers about IT and its uses;
- Yielding - managers try IT;
- Use of IT - managers use IT; and finally,
- Reinvention - where IT is improved or its use is varied for maximum benefit.

The lack of IT alignment with business can result in late market entry, lost market opportunities, or an unsustainable market advantage (Conarty, 1998).

Some (Bocij, Chaffey, Greasley & Hickie, 1999) view IT strategy and business strategy as two distinct strategies, with IT strategy either supporting or influencing business strategy. Other authors, such as Pukszta (1999), stress that IT strategy must be completely and seamlessly integrated with business strategy at all organizational levels.

IT and business strategies should not be aligned but should, in fact, be one harmonious strategy. IT strategy has to lose its distinctness; in this way, it will gain prominence and exert greater influence within organizations (Pukszta, 1999). Each organization should have a single harmonized strategy.

IT planning should be in harmony, not merely aligned with business strategy.

BACKGROUND

Organizations need to recognize changing business climates, fluctuating resources, and the need to expand or grow (Heske, 2001). Organizations that plan and then move in the right direction at the right time survive. All factors including IT have to be considered and taken into account holistically.

Key tasks of managers within an organization are to acquire, develop and allocate organizations' resources, and to develop and exploit the organizations' capacity for innovation (Burgleman et al., 2001). The acquisition, development, allocation and exploitation of IT should be part of any business strategy. Many new products and services such as online banking have been based on IT (Laudon & Laudon, 2002). IT can contribute to the overall performance of the organization by tying operations of various business units together harmoniously so the organization can act as whole (Laudon & Laudon, 2002). This could lower costs, increase customer access, and speed up the marketing process of new products and services. It is unlikely that these contributions and possible innovations will occur by chance; they need to be planned.

Tallon and Kraemer (2000) found that organizations with focused IT goals achieved higher payoffs from IT. Their results indicated that unfocused organizations achieved consistently lower payoffs at each point along the value chain than focused organizations.

Linear planning is useless; organizations must plan holistically (Hartman et al., 2000) or harmoniously in order to survive.

WHERE, WHY, WHAT, HOW?

Where should an organization do business ": locally, nationally or internationally? Organizations should be thinking in terms of where it makes good business sense and where the organization will survive. A vision of where the organization is going needs to be developed and communicated, and everyone in the organization needs to understand the vision and implement it (Rollins, Bognanno & Lockwood, n.d.).

A business strategy needs to be defined, including all the capabilities (forces/tools/resources) of an organization, so that approved plans may be executed as effectively as possible (Henderson & Venkatraman, 1999). Strategy articulates ways in which opportunities can be exploited using the organizations' capabilities (Burgleman et al., 2001). Strategy without capabilities is meaningless (Burgleman et al., 2001), and excluding the IT capability from the organization's strategy renders the strategy less effective at best. Similarly, having capabilities without strategy makes them aimless (Burgleman et al., 2001).

The IT strategy and capability must, therefore, be part of the overall strategy, or IT will become an aimless capability of the organization and, at best, will be run according to the CIO's aims. Managing the IT resource is a basic business function (Burgleman et al., 2001), which should be the responsibility of all managers within an organization.

Organizations plan in order to anticipate change beyond the control of the organization, so changes within the organization (such as changes to business processes and organizational structure) can be initiated and controlled (Ivancevich & Matteson, 1999).

A number of elements must fit together in a balanced way in order for an organization to function effectively. Sawy (2001) uses the Leavitt Diamond framework to illustrate the balance. This framework has four sets of organizational variables: IT use, organizational form, people skills, and business processes. When any one of these is changed, the other three need to be adjusted to maintain "functional harmony" (Sawy, 2001).

Ward and Peppard (2002) suggest guidelines to align business and IT strategies. They state that, at the very least, the following four domains need to be aligned: business strategy, organizational infrastructure, IT strategy, and finally, IT infrastructure. The business strategy should decide where the business is headed and why, what the businesses competitive advantages are, as well as how the business will be governed. The organizational infrastructure and business processes need to be designed to support the business strategy. The IT strategy should decide what IT is important and required by the business, and how it will used and managed or governed. The IT infrastructure details how IT can be delivered •the architecture, processes and skills required. Strategy needs to be formulated concurrently in all four of these domains (Ward & Peppard, 2002).

Organizations need to define exactly where they are going, why they wish to go there, what resources they will use to get there, and how they will utilize those resources.. Management needs to ensure that all stakeholders are aware of the plan.

STRUCTURE

Organizations need to decide on internal structures that support the plan. Structure and order are necessary for the survival of the organization.

"A gap has developed between the power and choice enjoyed by individuals as consumers and citizens on the one hand, and that available to them in the workspace on the other" (Chowdhury, 2000). This gap has to be reduced. Employees will have to be included in decisions regarding the structure of organizations.

Organizational design and structure have always been important factors that influence the behavior of groups and individuals. It is through structure that management establishes expectations of achievements for individual employees and departments, and decides how the organization's strategy is to be accomplished. The purpose of structure is to regulate, or reduce, uncertainty in the behavior of employees (Ivancevich & Matteson, 1999). Where and how IT is placed in the organizational structure determine the role and influence of IT.

Each organization requires a structure, and when that is ignored, the organization will not be able to crawl, much less fly! No organization will last if everyone acts independently; a structure needs to be developed preferably with the employees who will support the strategy and vision of the organization.

Employees cannot survive alone within an organization; they need to be in some sort of formation. Organizations only "fly" when all the employees are in formation.

Organizations need tradition, ritual, and structure to retain their identity. A department in which the author worked had a daily meeting where employees met each other and offered encouragement, support, guidance and feedback. The meetings were stand-up, 15-30 minute affairs with a fixed, regular program. On Mondays, projects and work for the week ahead were discussed; Tuesdays were "thinking" days, and employees had to solve puzzles in groups; Wednesdays were "learning" days, where one employee had to teach the others something; Thursdays were to announce and discuss change; and Fridays were for external focus or external speakers. Each employee had an opportunity to lead a Tuesday and Wednesday meeting. Rollins et al. (n.d.) claim that 50% of all employees receive no formal feedback on their performance, and of the 50% who do receive feedback, only 20% believe that it is effective. In groups where there is encouragement, the production is much greater.

Organizations need to fly with employees who want to be in the organization, who know where the organization is headed, and who want to fly in formation.

TIMING

Organizations understand that they cannot change or fight the seasons. Organizations need to develop strategies anticipating "winter" and unseasonable changes. Organizations must respond to external demands quickly, adapt their organizations, and redirect their employees and IT to achieve competitive advantage (Rollins et al., n.d.).

Organizations need to understand that IT change is one external factor, which affects competitive position. In order to survive, organizations need to adapt timely to change. Therefore, strategic planning must be a dynamic process, and IT and IT change must form part of the process. Successful organizations balance a well-defined business focus with the willingness and the will to undertake major and rapid change.

Organizations need to be ready to respond to continual changes. Prerequisites are leadership, governance, competencies and technology (Hartman et al., 2000). The first prerequisite is leadership; outstanding companies are associated with their leaders (Welch, Gates & Bezos). Leaders create a vision that is shared and accepted within the organization. Governance is the operating model that defines the organization. The formation or structure of the organization must be clear. People roles, responsibilities, and authority levels must be defined. Organizations need to have methods for assessing, selecting, allocating and monitoring resources. Competencies are the ways in which the organization responds to change, exploits available resources and opportunities, and accommodates reality. Technology needs to be robust and comprehensive.

"The reality of a strategy lies in its enactment, not in those pronouncements that appear to assert it" (Burgleman et al., 2001). Strategic intent needs to be converted into strategic action to be meaningful.

Organizations need strategies to deal with obstacles and may, in some cases, need to revise their strategies in order to be successful.

SUCCESS

The organization has to expect some casualties, but if the organization survives and looks likely to continue surviving, the strategy is successful. To succeed, the energy, creativity and resources of the organization must be used. If there are parts of the organization that are not being used, the question must arise as to why they are in the organization.

Burgelman et al. (2001) ask and answer the question, "What strategies, policies, practices, and decisions result in successful management of high-technology enterprises?" Six themes of success are listed:

- business focus,
- adaptability,
- organizational cohesion,
- entrepreneurial culture,
- sense of integrity, and
- hands-on top management.

All are controlled or influenced by the organizational strategy. Unless each and every one of the organization's resources is in harmony, an organization cannot succeed. If IT strategy (and all other strategies) is harmonized into a single business strategy, then the organization can claim to have a holistic business focus, to have organizational cohesion, and to have a sense of integrity. A disharmonized strategy certainly cannot be regarded as being honest, fair or open, or having other attributes of integrity.

FUTURE TRENDS

Organizations will develop single evolving harmonized strategies, to which all employees have contributed. Organizational strategy will be a continual, changing, probing neverending cycle involving all in the organization.

CONCLUSION

Organizational success must include the ability to harmonize the organization and mobilize the work force (Reich & Benbasat, 2000). Organizations and individuals can only realize their potential for greatness and goodness when they join the flock, fly in formation, and contribute something for the common good (Nash et al., 2001; Sawy, 2001). Business and IT strategies will be in harmony when IT is seen as contributing positively to the organizations business strategy. IT strategy must form a harmonized part of the organizations overall strategy (Ward & Peppard, 2002).

KEY TERMS

Alignment: The arrangement or position of different separate elements (strategies) in relation to each other.

Business Process: A collection of business activities which take several inputs and create one or more outputs.

Business Strategy: A description of the plans, actions or steps an organization intends to take in order to strengthen and grow itself.

CIO: Chief Information Officer, the head of the IS department in an organization.

Harmony: A pleasing combination of elements in a whole. The combination of elements intended to form a connected whole, as opposed to alignment where the elements remain separate.

IT: Information technology, the collection of all systems in an organization

IT Strategy: A description of the plans, actions or steps an organization intends to take in order to make the best use of IT within itself.

Strategy: A plan to create and manage change, and exploit opportunities.

Heuristics in Medical Data Mining

Susan E. George
University of South Australia, Australia

HISTORICAL PERSPECTIVE

Deriving—or discovering—information from data has come to be known as data mining. Within health care, the knowledge from medical mining has been used in tasks as diverse as patient diagnosis (Brameier et al., 2000; Mani et al., 1999; Cao et al., 1998; Henson et al., 1996), inventory stock control (Bansal et al., 2000), and intelligent interfaces for patient record systems (George at al., 2000). It has also been a tool of medical discovery itself (Steven et al., 1996). Yet, it remains true that medicine is one of the last areas of society to be "automated," with a relatively recent increase in the volume of electronic data, many paper-based clinical record systems in use, a lack of standardisation (for example, among coding schemes), and still some reluctance among health-care providers to use computer technology. Nevertheless, the rapidly increasing volume of electronic medical data is perhaps one of the domain's current distinguishing characteristics, as one of the last components of society to be "automated."

Data mining presents many challenges, as "knowledge" is automatically extracted from data sets, especially when data are complex in nature, with many hundreds of variables and relationships among those variables that vary in time, space, or both, often with a measure of uncertainty, as is common within medicine. Cios and Moore (2001) identified a number of unique features of medical data mining, including the use of imaging and need for visualisation techniques, the large amounts of unstructured nature of free text within records, data ownership and the distributed nature of data, the legal implications for medical providers, the privacy and security concerns of patients requiring anonymous data used, where possible, together with the difficulty in making a mathematical characterisation of the domain.

Strictly speaking, many ventures within medical data mining are better described as exercises in "machine learning," where the main issues are, for example, discovering the complexity of relationships among data items, or making predictions in light of uncertainty, rather than "data mining," in large, possibly distributed, volumes of data that are also highly complex. Large data sets mean not only increased algorithmic complexity but also often the need to employ special-purpose methods to isolate trends and extract "knowledge" from data. However, medical data frequently provide just such a combination of vast (often distributed) complex data sets.

Heuristic methods are one way in which the vastness, complexity, and uncertainty of data may be addressed in the mining process. A heuristic is something that aids discovery of a solution. Artificial intelligence (AI) popularised the heuristic as something that captures, in a computational way, the knowledge that people use to solve everyday problems. AI has a classic graph search algorithm known as A* (Hart et al., 1968), which is a heuristic search (under the right conditions). Increasingly, heuristics refer to techniques that are inspired by nature, biology, and physics. The genetic search algorithm (Holland, 1975) may be regarded as a heuristic technique. More recent population-based approaches have been demonstrated in the Memetic Algorithm (Moscato, 1989), and specific modifications of such heuristic methods in a medical mining context can be noted (Brameier et al., 2000).

Aside from the complexity of data with which the medical domain is faced, there are some additional challenges. Data security, accuracy, and privacy are issues within many domains, not just the medical (Walhstrom et al., 2000). Also, while ethical responsibility is an issue in other contexts, it is faced by the medical world in a unique way, especially when heuristic methods are employed. One of the biggest ethical issues concerns what is done with the knowledge derived combined with a "forward-looking responsibility" (Johnson et al., 1995). Forward-looking responsibility is accountable for high-quality products and methods and requires appropriate evaluation of results and justification of conclusions.

George (2002) first identified and proposed a set of guidelines for heuristic data mining within medical domains. The proposed guidelines relate to the evaluation and justification of data-mining results (so important when heuristic "aids to discovery" are utilised that "may" benefit a solution) and extend to both where and how the conclusions may be utilised and where heuristic techniques are relevant in this field. The remainder of this article summarises some heuristic data-mining applications in medicine and clarifies those proposed guidelines.

BACKGROUND

First, we will explain some of the heuristic methods that have been employed in medical data mining, examining a range of application areas. We broadly categorise applications as clinical, administrative, and research, according to whether they are used (or potentially used) in a clinical context, are infrastructure related, or are exploratory, in essence. We also note that with the exception of some medical imaging applications and mining of electronic medical records, the databases are small.

There is a wide variety of automated systems that have been designed for diagnosis—systems that detect a problem, classify it, and monitor change. Brameier and Banzhauf (2000) described the application of linear genetic programming to several diagnosis problems in medicine, including tests for cancer, diabetes, heart conditions, and thyroid conditions. Their focus was upon an efficient algorithm that operates with a range of complex data sets, providing a population-based heuristic method that is based upon biological principles. Their heuristic method is based on an inspiration from nature about how "introns" (denoting DNA segments with information removed before proteins are synthesised) are used in generating new strings. They suggest that introns may help to reduce the number of destructive recombinations between chromosomes by protecting the advantageous building blocks from being destroyed by crossover. Massive efficiency improvements in the algorithm are reported.

An interesting administrative application of data mining in a medical context comes in the area of interfaces for electronic medical records systems that are appropriate for speedy, accurate, complete entry of clinical data. At the University of South Australia, George et al. (2000) reported on the use of a data-mining model underlying an adaptive interface for clinical data entry. As records are entered, a database is established from which predictive Bayesian models are derived from the diagnosis and treatment patterns. This heuristic is used to predict the treatment from new diagnoses that are entered, producing intelligent anticipation. The predictive model is also potentially incremental and may be re-derived according to physician practice. This application addresses issues in incremental mining, temporal data, and highly complex data with duplication, error, and nonstandard nomenclatures.

One interesting ongoing database mining project at Rutgers is the development of efficient algorithms for query-based rule induction, where users have tools to query, store, and manage rules generated from data. An important component of the research is a facility to remember past mining sessions, producing an incremental approach. They are using heuristics for efficiently "re-mining" the same or similar data in the face of updates and modifications. In their trials, a major insurance company was trying to explore anomalies in their medical claims database. The new data-mining techniques aided the isolation of high-cost claims and scenarios in each disease group that would lead to high-cost claims. They also identified characteristics of people who were likely to drop out of their health plans and locations where there were higher dropout rates. This is a general approach to mining, where information from prior mining is utilised in new mining to prevent the need to compute relationships from scratch every time data is added to the database. This is, naturally, a general approach to mining large-scale changing databases that may be considered in a variety of fields.

Medical data mining is a natural method of performing medical research, where new relationships and insights are discovered in human health. The University of Aberdeen address the problem of mammographic image analysis using neural nets together with conventional image analysis techniques to assist in the automated recognition of pathology in mammograms (Undrill, 1996). The group also addresses the use of genetic algorithms for image analysis, applying this powerful general optimisation technique to a variety of problems in texture segmentation and shape analysis in two-dimensional and three-dimensional images (Delibassis, 1996). Mining information from the data in these tasks must address many of the problems of finding patterns within large volumes of highly complex data.

Banerjee et al. (1998) described the use of data mining in medical discovery. They reported on a data-mining tool that uncovered some important connections between diseases from mining medical literature. The data-mining tool compared the article titles in various medical journals. Medical discoveries were made, such as the connection between estrogen and Alzheimer's disease, and the relationship between migraine headaches and magnesium deficiency. Ngan et al. (1999) reported on medical discovery using data mining based upon an evolutionary computation search for learning Bayesian networks and rules. They were able to discover new information regarding the classification and treatment of scoliosis as well as knowledge about the effect of age on fracture, diagnoses, and operations and length of hospital stays.

Kargupta and colleagues (1999) were interested in an epidemiological study that involved combining data from distributed sources. Their study investigated what affects the incidence of disease in a population, focusing upon hepatitis and weather. They illustrated the collective data-mining approach, emphasising the importance within medicine of merging data from heterogeneous sites. Their solution minimises data communication using decision-tree learning and polynomial regression. As more hospitals and general practitioners, pharmacists, and other health-care-related professions utilise electronic media, mining ventures are going to have to cope with mining across data sources. They will have to address issues such as those addressed by this study, such as minimising data exchange and adopting suitable heuristic approaches.

GUIDELINES FOR HEURISTIC MEDICAL DATA MINING

Responsibility is clearly an issue in medical data mining given the unique human arena in which the conclusions are outworked. If medical data-mining products are ever produced by "professionals" or are ever exploited "commercially," there may be serious legal consequences for their creators in the wake of harmful consequences from information produced. In the context of software engineering, the computer field seeks to promote high-quality software products, so too, should data miners seek to guarantee high-quality data-mining techniques.

Johnson and Nissenbaum (1995) distinguished "backward-looking" responsibility from "forward-looking" responsibility. A "backward-looking" responsibility asks questions in the wake of a harmful event and seeks to discover who is to blame for the harm and who should be punished. It is often conducted in the context of discovering legal liability. The Therac-25 computer-controlled radiation treatment is a shocking example of a malfunction disaster that resulted in loss of life for people who were receiving computer-controlled radiation treatments for cancer. In contrast a "forward-looking" responsibility addresses the particular responsibilities in advance. It defines guidelines for creating quality products; measures the quality of the product; defines the method of evaluation, and the limitations and scope of the operation in advance of harmful incidents.

One of the biggest ethical issues in medical mining concerns what is done with the knowledge derived. There is tremendous potential for good in improving quality of human life, managing disease effectively, efficiently administering programs, and preserving life, but the same knowledge can also be put to less-constructive ends, or benefit only a few, or conform to the contemporary political agendas influenced by the philosophy of the age. Forward-looking responsibility requires not only making ethical uses of data but also ensuring the quality of automated techniques and knowing the limitations and scope of methods in advance of harmful consequences.

Crucial to forward-looking responsibility is a way to evaluate products. This is not as pertinent as when heuristic methods are utilised to derive that knowledge. Whatever is ultimately done with the conclusions, we know that heuristics do not guarantee "optimality" or even the "accuracy" or "validity" of the conclusion. Forward-looking responsibility within medical data mining will address, among other things, how knowledge is evaluated, how conclusions are justified, what is the scope of validity, and the limitations of "products." One of the best forms of evaluation for clinical data-mining solutions is a clinical trial. Another approach to evaluation makes use of benchmark data sets, where various techniques (heuristic and other) could be compared to assess quality and efficiency of solutions. Additionally, some types of specialist data may be invaluable resources for data-mining researchers. It is also important to define the scope, including justification of explanations, and limitations of systems, from technical to clinical applicability of algorithms (in terms of patient populations and other), especially under heuristic conditions.

CONCLUSION

This article has reviewed heuristic medical data mining and some of the applications of medical mining, identifying administrative, clinical, and medical areas of applicability, focusing on the guidelines for use of heuristics in such a field. Forward-looking responsibility is vital, focusing upon appropriate use of knowledge, a means to evaluate the heuristic solutions and assess the scope and limitations of the system, including explanations of the behaviour.

H

KEY TERMS

Backward-Looking Responsibility: When backward-looking, we seek to discover who is to blame in wake of a harmful event. There are frequently connotations of punishment, legal intervention, and determination of guilt.

Data Mining: Analysis of data using methods that look for patterns in the data, frequently operating without knowledge of the meaning of the data. Typically, the term is applied to exploration of large-scale databases in contrast to machine-learning methods that are applied to smaller data sets.

Data-Mining Guidelines: A set of standards by which medical data mining, in particular, might be conducted. This is a framework that adopts a forward-looking responsibility in the evaluation of methods and explanation of conclusions, especially in the context of heuristic methods (with outcomes that may be ill-defined). This extends not only to the methods of the data-mining procedure, the security and privacy aspects of data, but also to where and how the results of data mining are utilised, requiring that an ethical reference be made to the final purpose of the mining.

Forward-Looking Responsibility: Addresses the particular responsibilities of individuals, groups, and partners in advance of a product's use or a system's implementation; it defines guidelines for creating quality products, measures the quality of the products, and defines the method of evaluation, the limitations, and the scope of the operation in advance of harmful incidents.

Heuristic: From the Greek "heuriskein," meaning "to discover." A heuristic aids discovery, particularly the search for solutions in domains that are difficult and poorly understood. It is commonly known as a "rule of thumb." Unlike algorithms, heuristics do not guarantee optimal or even feasible solutions and frequently do not have a theoretical guarantee.

Medical data: Frequently demonstrate increased complexity (e.g., uncertainty) and occurrence in large volumes, possibly distributed over many sources. There may be images involved and a high frequency of nonstandardisation (especially in the context of electronic medical records) in coding schemes and other medical concepts utilised. Data security, accuracy, and privacy are particular issues with medical data, as are the ethical issues involved in what is done with the data.

Medical Data Mining: This is the application of data-mining methods to medical data, typically for clinical or administrative and medical research investigation use, particularly in epidemiological studies.

Hierarchies in Multidimensional Databases

Elaheh Pourabbas
National Research Council, Rome, Italy

INTRODUCTION

Hierarchies play a fundamental role in knowledge representation and reasoning. They have been considered as the structures created by *abstraction processes*. According to Smith and Smith (1977), an abstraction process is an instinctively known human activity, and abstraction processes and their properties are generally used for multilevel object representation in information systems. An abstraction can be understood as a selection of a set of attributes, objects, or actions from a much larger set of attributes, objects, or actions according to certain criteria. Repeating this selection several times, that is, continuing to choose from each subset of objects, another subset of objects with even more abstract properties, we create other levels of (semantic) details of objects. The complete structure created by the abstraction process is a *hierarchy* and the type of hierarchy depends on the operation used for the abstraction process and the relations. As for the relations, the best known in the literature are *classification*, *generalization*, *association* (or *grouping*), and *aggregation*. Their main characteristics are briefly listed in the following.

Classification is a simple form of data abstraction in which an object type is defined as a set of instances. It introduces *an instance-of* relationship between an object type in a schema and its instances in the database (Brodie, Mylopoulos, & Schmidt, 1984).

Generalization is a form of abstraction in which similar objects are related to a higher level generic object. It forms a new concept by leaving out the properties of an existing concept. With such an abstraction, the similar constituent objects are specializations of the generic objects. At the level of the generic object, the similarities of the specializations are emphasized, while the differences are suppressed (Brodie, et al., 1984).

This introduces an *is-a* relationship between objects. This relation covers a wide range of categories that are used in other frameworks, such as inheritance, implication, and inclusion. It is the most frequent relation resulting from subdividing concepts, called *taxonomies* in lexical semantics. The inverse of the generalization relation, called *specialization*, forms a new concept by adding properties to an existing concept (Borgida, Mylopoulos, & Wong, 1984).

A particular type of generalization hierarchy, named *filter hierarchy*, is defined by the so-called filtering operation. This operation applies a *filter function* to a set of objects on one level and generates a subset of these objects on a higher level. The main difference from the generalization hierarchy is that the objects that do not pass the filter will be suppressed at the higher level (Timpf, 1999).

Association or grouping is a form of abstraction in which a relationship between member objects is considered as a higher level set of objects. With this relationship, the details of member objects are suppressed and properties of the set object are emphasized. This introduces the *member-of* relationship between a member object and a set of objects (Brodie, 1981).

Aggregation is a form of abstraction in which a relationship between objects is considered as a higher level aggregate object (Brodie et al., 1984). Each instance of an aggregate object can be decomposed into instances of the component objects. This introduces a *part-of* relationship between objects. The type of hierarchy constructed by this abstraction is called an *aggregation hierarchy*.

Like data warehousing and OLAP (online analytical processing), the above-mentioned aggregation hierarchies are widely used to support data aggregation (Lenz & Shoshani, 1997). In a simple form, such a hierarchy shows the relationships between domains of values. Each operation on a hierarchy can be viewed as a mapping from one domain to a smaller domain. In the OLAP environment, hierarchies are used to conceptualize the process of generalizing data as a transformation of values from one domain to values of another smaller or bigger domain by means of drill-down or roll-up operators. In the next sections, the roles of aggregation hierarchies in analysis dimensions of a data cube will be analyzed.

BACKGROUND

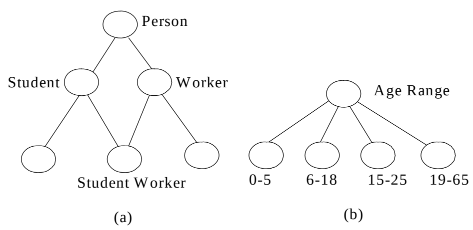
The core of the aggregation hierarchy revolves around the partial order, a simple and powerful mathematical concept to which a lot of attention has been devoted (see Davey & Priestley, 1993). The partial ordering can be represented as a tree with the vertices denoting the elements of the domains and the edges representing the ordering function between elements. The notion of levels has been introduced through the idea that vertices at the same depth in the tree belong to the same level of the hierarchy. Thus, the number of levels in the hierarchy corresponds to the depth of the tree. The highest level is the most abstract of the hierarchy and the lowest level is the most detailed.

As in data warehousing and OLAP, the notion of partial ordering is widely used to organize the hierarchy of different levels of data aggregation along a dimension. Sometimes, hierarchies have been perceived structurally as trees, that is, no generic object is the immediate descendant of two or more generic objects, and where the immediate descendants of any node (supposing any hierarchy is represented by a graph) have classes which are mutually exclusive. A class with a mutually exclusive group of generic objects sharing a common parent is called a *cluster*. Generally speaking, many real cases cannot be modeled by these types of hierarchies (see Figure 1). For this reason, usually, a dimension hierarchy is represented as a directed acyclic graph (DAG). Sometimes, it can be defined with a unique bottom level and a unique top level, denoted by ALL (see Gray, Bosworth, Layman, & Pirahesh, 1996).

One of the most important issues related to the aggregation hierarchy is the *correct aggregation* of data (see Lenz & Shoshani, 1997; Rafanelli & Shoshani, 1990). It is known as *summarizability*, which intuitively means that individual aggregate results can be combined directly to produce new aggregate results.

As subsequently discussed in Lenz and Shoshani (1997), summarizability conditions are the conditions upon which the summarization operation produces the correct result. The authors affirm that three necessary conditions of summarizability have to be satisfied. They are disjointness of levels (or category attributes) in hierarchies, completeness in hierarchies, and correct use of measure (summary attributes) with statistical functions. Disjointness implies that instances of levels in dimensions form disjoint subsets of the elements of a level. Completeness in hierarchies means that all the elements

Figure 1. Two typical structures of hierarchies



occur in one of the dimensions and every element is assigned to some category on the level above it in the hierarchy. Correct use of measures with statistical functions depends on the type of the measure and the statistical function.

More recently, the problem of heterogeneity in aggregation hierarchy structures and its effect on data aggregation has attracted the attention of the OLAP database community. The term heterogeneity, as introduced by Kimball (1996), refers to the situation where several dimensions representing the same conceptual entity, but with different categories and attributes, are modeled as a single dimension. According to this description, which has also been called *multiple hierarchy* and recalled in the next section (see Agrawal, Gupta, & Sarawagi, 1997; Pourabbas & Rafanelli, 2003), dimension modeling may require every pair of elements of a given category to have parents in the same set of categories. In other words, the roll-up function between adjacent levels is a total function. The hierarchies with this property are known to be regular or *homogeneous*. For instance, in a homogeneous hierarchy, we cannot have some cities that roll-up to provinces and some to states, that is, the roll-up function between City and State is a partial function.

In order to model these irregular cases, some authors introduced *heterogeneous* dimensions and tackled the summarizability issue by proposing several solutions.

The proposal of Lehner, Albrecht, & Wedekind (1998) consists of transforming heterogeneous dimensions into homogeneous dimensions in order to be in *dimensional normal form* (DNF). This transformation is actually performed by considering categories, which cause the heterogeneity, as attributes for tables outside the hierarchy. On the flattened child-parent relation, summarizability is achieved for dimension instances.

Pederson and Jensen (1999) considered a particular class of heterogeneous hierarchies, for which they proposed their transformation into homogeneous hierarchies by adding null members to represent missing parents. In their opinion, summarizability occurs when the mappings in the dimension hierarchies are *onto* (all paths from the root to a leaf in the hierarchy have equal lengths), *covering* (only immediate parent and child values can be related), and *strict* (each child in a hierarchy has only one parent). The proposed solutions consider a restricted class of heterogeneous dimensions, and null members may cause a waste of memory and increase the computational effort due to the sparsity of the cube views.

Hurtado and Mendelzon (2001) extended the notion of summarizability for homogeneous dimensions in order to tackle summarizability for heterogeneous dimensions. They classified five classes of dimension schemas, which are

- *homogeneous*, if, along a dimension, the roll-up function from the member set of a level to the member set of its immediate higher level is a total function;
- *strictly homogeneous*, if it is homogeneous and it has a single bottom level,
- *heterogeneous*, if it is not homogeneous;
- *hierarchical*, which allows heterogeneity but keeps a notion of ordering between each pair of levels and their instances; and
- *strictly hierarchical*, if the ordering relationship among different levels is transitive.

Then, a class of constraints on dimension instances is introduced. These constraints are statements about possible categories to which members of a given category may roll up. In Hurtado and Mendelzon (2002), the authors reexamined inferring summarizability in general heterogeneous dimensions. They introduced the notion of *frozen* dimensions, which are minimal homogeneous instances representing different structures that are implicitly combined in a heterogeneous dimension. This notion is used in an algorithm for testing implications of dimension constraints. In a recent work, Hurtado and Guitérrez (2004) proposed a notion of hierarchical equivalence that allows the comparing of dimension schemas with respect to their information contents. In order to achieve this equivalency, an algorithm that transforms heterogeneous dimension schemas into homogeneous schemas is defined.

CHARACTERIZATION

In this section, we discuss the characterization of classification hierarchies from two different perspectives with respect to the above-mentioned proposals: The first is the mapping between domain values, that is, total and partial classification hierarchies, and the second is the hierarchical structure. In relation to them, we represent the characterization of two main OLAP operators, which refer to hierarchies in order to maintain data cube consistency.

Classification Hierarchies

Dimensions have often been associated with different hierarchically organized levels. The name of each level is expressed by the corresponding *variable* name. Generally, the shift from a lower (more detailed) level to a higher (more aggregate) level is carried out by a mapping. A mapping between two variables can be complete or incomplete.

Definition: A mapping between two variables of a hierarchy defines a *containment function* if each variable instance of a lower level corresponds to only one variable instance of a higher level, and each variable instance of a higher level corresponds to at least one variable instance of a lower level. In such a case, it is called *full mapping*.

Note that the containment function satisfies the summarizability conditions discussed in the previous section.

Definition: A *total classification hierarchy* on a given dimension indicates that there is a full mapping between each adjacent pair of variables. If there is no full mapping between at least one adjacent pair of variables, then the hierarchy is called a *partial classification hierarchy*.

In the context of classification hierarchies, we can introduce two specializations given by the following definition.

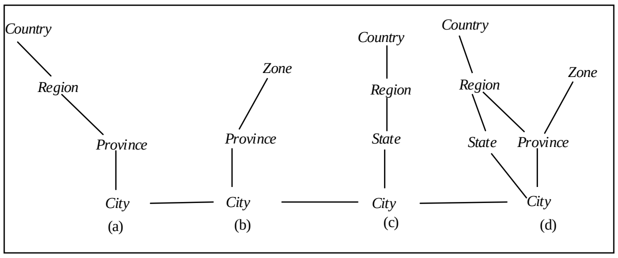
Definition: Let H and H' be two hierarchies. H' is a *multiplicity* of H if they are defined by the same-level domains, and the variable name associated with each level of H' is a specialization of the variable name associated with the corresponding level in H. They form a *multiple hierarchy* if they have at least one variable in common.

In Figure 2, the first three hierarchies represent different partitions of the same location dimension. A possible multiplicity of the hierarchy shown in Figure 2a is City of residence → Province of residence → Region of residence → Country of residence. Figure 2d shows a multiple hierarchy, where the level Province is common in a and b, as well as Region in a and c.

OLAP Operators

The OLAP operators that are involved principally in manipulating dimensions are *roll up* and *slice* (see Agrawal et al., 1997; Cabibbo & Torlone, 1998; Olap Council, 1997). The roll-up operator decreases the detail of the measure, aggregating it along the dimension hierarchy. A problem arises in the case of a partial classifi-

Figure 2. Example of different partitionings of location dimension (a, b, c), and a multiple hierarchy (d)



cation hierarchy, where the domain values of a given level of a dimension hierarchy is a subset of all the possible values that this level can assume in the database, called the *primitive domain*. In particular, when the roll-up operator is applied to change such a level to a higher level, no information about the noncompleteness of its domain is stored. Therefore, the result of this operator incorrectly will be referred to as the primitive domain.

A solution to this problem is to save the information about the domain values that cause the incompleteness of the hierarchy. This can be achieved in two different ways. The first is to add a *note* (the clause “where < variable name > is-a subset of the primitive domain”) to the title of the cube. The second is to add the same note to each variable of the hierarchy whose level is higher with respect to the variable with the incomplete domain.

Example: Let us consider a nation-wide drink company that owns chain stores located in all cities. Let us assume that all stores in the chain sell the same beverages. Figure 3 shows part of the total number of sales in 1997 and 1998.

Let us refer to the classification hierarchy shown in Figure 2c. We suppose the domain of City contains only three instances, San Francisco, San Jose, and San Diego. It is a subset of the primitive domain of City, in which all the cities of California are stored. Let us consider the following query:

“Select vendors for which the sales is >10,000 units in the West.”

It is solved as follows:

Roll-up from City to Region, Dice Region = “West,” Dice Sales > “10000,” Dice Vendor.

The title of the cube obtained from the above query becomes “Vendors with sales > 10,000 units in the West, *where city of California is-a subset of the primitive domain*,” or we have to add the same clause to the variables State, Region, and Country.

The slice operator reduces the dimensions of a cube by eliminating one dimension through its multidimensional space. If the domain of this dimension is a subset of the primitive domain, we lose information about that and the result seems to refer to the whole primitive domain of the omitted dimension. To overcome this problem, a specialization of the slice operator, called *implicit slice* (or *I-Slice*), is introduced, which is based on the concept of *implicit dimension*. An implicit dimension is any dimension of a data cube that has only one instance in its domain. This instance can be single value or multivalued. The I-Slice operator keeps implicit the dimension on which it is applied.

Similarly to the roll-up operator, the same note is added to the title of the cube. For the symmetric reasoning of terminology, we use the term *total slice* (or *T-Slice*) when the domain of the omitted dimension coincides with its primitive domain.

Example: Let us consider the cube in Figure 3, where the primitive domain of Year is defined by the values <1990, 1991, 1992, 1993, 1994, 1995, 1996, 1997, 1998>. Instead, the domain value of Year in the considered cube is <1997, 1998>. Let us consider the following query: “Give the sales in all cities by Class and Vendor.” It is solved by Slice Year.

In this case, because the slice operator omits the dimension Year, we lose the exact information on the real period to which the result should refer. In accordance with the above definition, the query can be solved by I-Slice Year. The resulting cube is defined by the same set of dimensions of the primary one, where the title becomes “Sales by Class, Vendor, and Year *where Year is a subset of the primitive domain*.”

FUTURE TRENDS

One of the principal characteristics of hierarchies is their structural changing over time. The role of this feature is investigated in literature. Vaisman and Mendelzon (2003) address mainly only the temporal changing of the schema

Figure 3. Example of a data cube

Sales						
	Class	*City*	*Vendor*	*Year*	1997	1998
	Alcoholic	Los Angles	Smith		10,000	12,000
		New York	Wong		20,000	16,000
		…	…	...	…	…
		Detroit	Clifford		90,000	18,000
	Nonalcoholic	Los Angles	Smith		20,900	14,500
		New York	Wong		12,300	32,009
		...	...		...	...
		Detroit	Clifford		21,000	30,000

of dimensions. The problem of temporal changing of the levels and the relative domains in the context of different types of hierarchies forms an interesting issue to be considered in future work.

The hierarchical structures are extensively used in ontology databases (such as the pathology database which is defined from a large hierarchy of pathology terms). Such databases are primarily hierarchically structured, but can also have DAG structures. They are used in various application areas such as health care, banking, engineering design, and so on. In this framework, representing complex DAG structures as well as their changing over time form interesting issues to be examined.

CONCLUSION

In this paper, we focused on the rules of aggregation hierarchies in analysis dimensions of a cube. We then discussed the hierarchies from two different points of views: mapping between domain values and hierarchical structures. In relation to them, we introduced the characterization of some OLAP operators involved in the hierarchy manipulation.

KEY TERMS

Cube: A group of data cells arranged by the dimensions of the data. Assigning a value to each dimension of a cube, the measure is obtained by a mapping from this assignment.

Data Warehouse: A system for storing, retrieving, and managing large amounts of data using some sophisticated techniques of cleaning, filtering, hashing, and compression.

Data Warehousing: It refers to the process of extraction of data from different information sources (e.g., databases, files) and their integration in a single data warehouse.

Directed Acyclic Graph (DAG): A graph with one-way edges containing no cycles.

Fact Table: A member of the star schema data model, which records data about a set of phenomena of interest.

OLAP (Online Analytical Processing**):** A category of software technology that allows users to transform raw data according to predefined or user-defined functions, and quickly and interactively performs slice, dice, and roll-up operations in various dimensions.

Partial Order: A partial order on a set is a binary relation that is reflexive, antisymmetric, and transitive.

Star Schema: It represents a dimensional model that is composed of a central fact table and a set of constituent dimension tables.

Histogram Generation from the HSV Color Space

INTRODUCTION

Digital image databases have seen an enormous growth over the last few years. However, since many image collections are poorly indexed or annotated, there is a great need for developing automated, content-based methods that would help users to retrieve images from these databases. In recent times, a lot of attention has been paid to the management of an overwhelming accumulation of rich digital images to support various search strategies. In order to improve the traditional text-based or SQL (Structured Query Language)-based database searches, research has been focused on efficient access to large image databases by the contents of images, such as color, shape, and texture. Content-based image retrieval (CBIR) has become an important research topic that covers a large number of domains like image processing, computer vision, very large databases, and human computer interaction (Smeulders, Worring, Santini, Gupta & Jain, 2000). Several content-based image retrieval systems and methods have recently been developed.

QBIC (Query By Image Content) is one of the first image retrieval systems developed at IBM (Niblack et al., 1993). Color, texture, and shape features are combined to represent each image in this system. The VisualSeek system, developed at the Columbia University, is an image retrieval system based on visual features (Chang, Smith, Mandis & Benitez, 1997). The NeTra system is a prototype image retrieval system, which uses color, texture, shape, and spatial location information as features to retrieve similar images (Ma & Manjunath, 1997). Some of the other popular CBIR systems are MARS (Ortega et al., 1998), Blobworld (Carson, Thomas, Belongie, Hellerstein & Malik, 1999), PicToSeek (Gevers & Smeulders, 2000), and SIMPLIcity (Wang, Li & Wiederhold, 2001).

An analysis of these systems reveals that all of them give a lot of importance on the image color for retrieval. In fact, color is always considered to be an important attribute, not only in content-based image retrieval systems, but also in a number of other applications like segmentation and video shot analysis. In color-based image retrieval, there are primarily two methods: one based on color layout (Smith & Chang, 1996) and the other based on color histogram (Swain & Ballard, 1991; Wang, 2001). In the color layout approach, two images are matched by their exact color distribution. This means that two images are considered close if they not only have similar color content, but also if they have similar color in approximately the same positions. In the second approach, each image is represented by its color histogram. A histogram is a vector whose components represent a count of the number of pixels having similar colors in the image. Thus, a color histogram may be considered to be a signature extracted from a complete image. Color histograms extracted from different images are indexed and stored in a database. During retrieval, the histogram of a query image is compared with the histogram of each database image using a standard distance metric like the Euclidean distance or the Manhattan distance. Since color histogram is a global feature of an image, the approaches based on color histogram are invariant to translation and rotation, and scale invariant with normalization.

Color histograms may be generated using properties of the different color spaces like RGB (Red, Green, and Blue), HSV (Hue, Saturation, and Intensity Value), and others. In this article, we give an overview of the different histogram generation methods using the HSV color space. We first present a brief background of the HSV color space and its characteristics, followed by the histogram generation techniques for various applications.

BACKGROUND

A color space or a color model is a specification of a coordinate system and a subspace within that system where a single point represents a distinct color value. There are several well-known color spaces that are used to represent the pixels of an image. This representation is used for image analysis like extraction of color histograms. Each color space has its own merits and demerits depending on the application and hardware specification where it is going to be used. RGB, CMY, CMYK, and HSV are some of the popular color spaces. The RGB color space contains three color components, namely red, green and blue, each of which appears in its primary spectral components. Devices that deposit colored pigments on paper use CMY color space, and the representation of this color space is with the secondary colors of light, which are Cyan, Magenta, and Yellow. CMYK (Cyan, Magenta, Yellow, Black) color space is similar to CMY but is used to produce true black color, which is muddy-black in the CMY color space.

The HSV (Hue, Saturation, Value) color space, on the other hand, closely corresponds to the human visual perception of color. The HSV color space can be represented as a three-dimensional hexacone, where the central vertical axis represents intensity which takes a value between 0 and 255 (Shapiro & Stockman, 2001). Hue is defined as an angle in the range $[0,2\pi]$ relative to the red axis with red at angle 0, green at $2\pi/3$, blue at $4\pi/3$, and red again at 2π. Saturation is the depth or purity of color and is measured as a radial distance from the central axis to the outer surface. For zero saturation, as we move higher along the intensity axis, we go from black to white through various shades of gray. On the other hand, for a given intensity and hue, if the saturation is changed from zero to one, the perceived color changes from a shade of gray to the most pure form of the color represented by its hue. When saturation is near zero, all pixels, even with different hues, look alike and as we increase the saturation towards one, they tend to get separated out and are visually perceived as the true colors represented by their hues. Thus, the effect of saturation may be considered as that of introducing visual shadows on the image for any given value of hue and intensity.

The HSV model is an ideal tool for developing image and video processing algorithms based on color descriptions. A number of histogram generation methods from the HSV color space have recently been proposed for different applications. We next describe some of these approaches.

HISTOGRAM GENERATION FROM THE HSV COLOR SPACE

The HSV color space in general, and the HSV color histogram in particular, plays an important role in image analysis. A color histogram can be used in image retrieval, segmentation, video shot detection, color and intensity-based clustering, place recognition for topological localization, person identification and authentication using biometric techniques, as well as in many other applications.

For image retrieval applications, an HSV color histogram can be generated using an approach similar to the RGB color space. The hue scale is divided into eight groups, saturation scale is divided into two groups, and the intensity scale is divided into four groups. By combining each of these groups, we get a total of 64 cells to represent a 64-component HSV color histogram. The reason for having a different number of groups for the three scales is that, of the three axes, hue is considered to be the most important, followed by intensity, and finally, saturation. For the H, S, and V combination of values, the corresponding histogram component is determined. The respective histogram component is updated by one for each pixel having the corresponding color combination. An efficient indexing of the histograms can enhance the performance of a CBIR application to a great extent. Smith and Chang (1996) exploit this idea in their color set approach. This method extracts spatially localized color information and provides efficient indexing of the color regions. The large single color regions are extracted first, followed by multiple color regions. They utilize binary color sets to represent the color content as a color histogram. The H and S dimensions are divided into N and M bins, respectively, for a total of N×M bins (Ortega et al., 1998). Each bin contains the percentage of pixels in the image that have corresponding H and S colors for that bin. Intersection similarity is used as a measure to capture the amount of overlap between two histograms.

From the properties of the HSV color space, it is observed that for low values of saturation, a color is approximated by a gray value specified by the intensity level while for higher saturation, the color is approximated by its hue. This captures the human visual properties effectively and can be used to generate a histogram for image retrieval applications (Sural, 2003; Sural, Qian & Pramanik, 2002). The saturation threshold that determines this transition is once again dependent on the intensity. Thus, the value of saturation projected onto the hue and intensity plane is useful for the extraction of color information. A threshold function can be used to determine if a pixel should be represented by its hue or by its intensity in the color histogram. For an intensity value of zero, all the colors are considered as black, whatever their hue or saturation may be. On the other hand, with increasing values of intensity, the saturation threshold that separates hue dominance from intensity dominance goes down. This approach treats the pixels as a distribution of "colors" in an image where a pixel may be of a "gray color" or of a "true color." The histogram is a logical combination of two independent histograms—one for the true colors and one for the gray colors. One drawback of this approach is that for saturation values near the threshold, a pixel is neither a true color pixel nor a gray color pixel. In order to capture the fuzzy nature of human visual perception of color, there is a need for using a soft threshold to determine the dominant property of a pixel. In the soft threshold approach, two components of the histogram are updated for each pixel in an image, namely, a gray color component and a true color component. The quantum of update is determined both by the saturation and the intensity of the pixel, and the sum of the weights of the two contributions equals unity. Also, for the same saturation, the weight varies with intensity. For a lower intensity value, the same saturation gives a lower weight on the true color component and vice versa. This histogram has a high recall and precision of retrieval, and is effectively used in content-based image retrieval systems (Vadivel, Majumdar & Sural, 2003). The soft threshold approach can also be used for video shot detection (Sural, Mohan & Majumdar, 2004).

An input image in a content-based retrieval system may be textured or non-textured. Similarly, the images stored in a database can also be classified as textured or non-textured. When the query image is compared with the database images, the search should be restricted to the relevant portion of the database. An HSV histogram can be effectively used to classify an image into a textured or a non-textured class (Li, Wang & Wiederhold, 2000). In this approach, an image is first segmented into 4X4 pixel regions. HSV color histogram is extracted for each such region. When an image is a color-rich image, hue plays an important role in its representation. Although, hue can represent millions of colors, the human visual system cannot distinctly recognize all of them. The visually similar colors can be combined together in the same color band, as suggested by Gong, Proietti, and Faloutsos (1998). After combining the similar colors, the image is segmented and indexed for content-based retrieval. It is observed that human visual system can perceive distinct colors depending on the NBS (National Bureau of Standards) color distance. Colors with NBS distance below 3.0 are indistinguishable to the human eye. Besides hue, if the intensity axis is also divided into a number of bands, then segmentation, clustering, indexing, and retrieval of images can be done even more effectively (Zhang & Wang, 2000). In this approach, the histograms are generated separately—one from the hue component and the other from the intensity component. K-means clustering algorithm is then applied on these two histograms to obtain the center for each class for indexing.

It should be noted that the histogram of an image does not keep track of the spatial information of the pixels in an image. Two images with the same number of color pixels but at different locations would have the same histogram. This results in higher false-positives. If the spatial relationship is also captured during histogram generation, then the retrieval performance can be enhanced. Color correlogram is a type of histogram generated from the HSV color space that retains spatial information (Ojala, Rautiainen, Matinmikko & Aittola, 2001).

In addition to content-based image retrieval, the HSV histogram is used for a large number of other applications. One important class of applications is the domain of topological localization in robotics. Ulrich and Nourbakhsh (2000) use the HSV histogram for appearance-based place recognition. They first determine the candidate locations based on the current belief of a robot's location and transform the input image into six one-dimensional histograms. Then for each candidate location and for each of the two color bands, RGB and HSV, the reference histogram is determined that matches the input histogram most closely. In order to reduce the resource requirements for storage and transmission of image and video, various data compression techniques are used in practice. A fundamental goal of data compression is to obtain the best possible fidelity for a given data rate or, equivalently, to minimize the rate required for a given fidelity. Matching Pursuit (MP) image representation has proven to give good compression results. It is found that the MP coefficients are interestingly distributed along the diagonal of the color cube. Coding of the MP coefficients is done in the HSV color space, where V becomes the projection of RGB coefficients on the diagonal of the cube, S is the distance of the coefficient to the diagonal, and H is the direction perpendicular to the diagonal where the RGB coefficient is placed. MP coefficients are quantized and a histogram of the quantized coefficients is generated in the HSV space for efficient data compression (Rosa, Ventura & Vandergheynst, 2003).

FUTURE TRENDS

The HSV color space provides a close representation of human visual perception of color. New and effective algorithms are being developed to extract more useful information from the HSV color space. Recent research shows that the HSV color space can even be used to represent both color and texture information in a single histogram. An extension of this work could be in the domain of fuzzy feature extraction for segmentation and retrieval. Further theoretical and experimental comparisons should be made between the HSV and other color spaces.

CONCLUSION

We have discussed a number of histogram generation techniques using the HSV color space and made a critical assessment of their merits and demerits. Color histograms generated from the HSV color space have been used in a variety of image and video processing applications. Content-based image retrieval is one of the most popular domains in which the HSV histogram has been used effectively for high recall and precision of retrieval. The histogram may also be combined with other features for representing semantic contents in image and video.

KEY TERMS

Content-Based Image Retrieval: Retrieval of images similar to a given image based only on features present in the image and not any external information.

Histogram: A vector whose components represent similar colors in an image. The value of a component is the number of image pixels having that color.

HSV Color Space: A color space consisting of hue, saturation, and intensity value. It is a popular way of representing color content of an image.

Precision: The number of relevant images retrieved as a percentage of the total number of images retrieved.

Recall: The number of relevant images retrieved as a percentage of the total number of relevant images in the database.

Soft Threshold: A fuzzy approach to decide the importance of a feature. This is in contrast to a hard threshold where a yes/no decision is made.

History and Future Development of Group Support Systems

California State University, USA

INTRODUCTION

A group support system (GSS) is created with information technology (IT) and decision support techniques for assisting problem formulation and evaluation of alternative solutions in a group meeting (DeSanctis & Gallupe, 1987). The idea of GSS dated back to the 1970s; however, not until late 1980s did GSS take the form as we know it now. In 1987, two GSS systems were developed by researchers in different universities: Software Aided Meeting Management system at University of Minnesota, and GroupSystems at University of Arizona (Wagner, Wynne, & Mennecke, 1993). Since then, much research on GSS has been conducted and many organizations such as IBM, the Department of Defense, and the Internal Revenue Services, have used SAMM and GroupSystems in solving organizational problems.

GSS is an inter-disciplinary area that involves management sciences, organizational behavior, IT, and social psychology. The number of publications and presentations attests to the rapid pace of GSS research and development. As of mid-1998, more than 230 papers were published on the topic (Fjermestad & Hiltz, 1998 – 99). Major international conferences, such as ICIS, AMCIS, and HICSS, provide a GSS track on a regular basis. IBM's CEO claimed that groupware (a commercialized version of GSS) would be a direction of software development in the IT industry for the 21st century.

The rest of the chapter is organized as follows: First, the historical development of GSS research is presented. Next, relevant theories and findings of prior research are discussed. Current key issues are identified in section four. Then, future trends of GSS research are described. A recapitulation concludes this article.

DEVELOPMENT OF GSS RESEARCH

In the 1980s, researchers started to explore how computer, communication, and decision support technologies could be put together to improve group meetings. Those applications had been called Group Decision Support Systems, Electronic Meeting Systems, Computer Supported Cooperative Work, and Groupware. In 1993, the standardized term GSS was used to refer to the above-mentioned applications (Jessup & Valacich, 1993).

The GSS research has grown over six distinct phases (Dennis & Gallupe, 1993; Saunders, 2000). The first phase, "Roots," was the early research into computer messaging and individual support systems in the 1970s and formed the basis for the GSS work. Phase two, called "Initial Explorations," occurred during the early 1980s and focused on the impact of rudimentary GSS on group outcomes and processes. The third phase, from mid- to late-1980s, was known as the "Early Experiments". A series of experimental studies was conducted to compare groups supported by a GSS with unsupported groups. The fourth phase, from late 1980s to mid 1993, was called "Field Studies." Research focus was on the use of GSS technology in organizational settings and on the impact of GSS on organizations. Phase five, the "In-Depth Studies," started in mid-1993. In 1993, a group of researchers summarized lessons and experiences of the first decade GSS research in the book "Group Support Systems: New Perspective" (Jessup & Valacich, 1993). This book summarized studies on technical, behavioral, organizational, and social psychological aspects of GSS uses. One major conclusion from the review of the research was that while promising, the effect of GSS was mixed due to such factors as research settings, technologies employed, and group characteristics. This phase featured two developments

Table 1. Theories relevant to GSS

	Theories	Main thesis
Decision Theorist School	Media-Richness Theory (Daft & Lengel, 1986)	• The task performance depends on the extent to which the information richness requirement of the task matches the richness of the media used by the group.
	Task-Medium Fitness Theory (McGrath & Hollingshead, 1993)	• The optimal richness for each type of task is unique and the task performance depends on the extent to which the task fits the communication environment
	Information Exchange Theory (DeSanctis & Gallupe, 1987)	• A GSS may change the process of interpersonal information exchange and thus change the task performance.
	Task/Technology Fit Theory (Zigurs & Buckland, 1998)	• The task performance depends on the ideal fit between complexity level of the task and the GSS elements.
Institutionalist school	Social Information Processing Theory (Fulk, Schmitz, & Steinfield, 1990)	• Media characteristics as well as the attitude, statements, and behaviors of co-workers influence relational developmental perceptions.
	Information Technology Intervention Framework (Clapper & McLean, 1990)	• Group outcome depends on the informational and normative influence processes operating within the group
	Time, Interaction, and Performance (McGrath, 1991).	• Group processes are not necessarily linear or sequential process. The difficulty level of the task may force the group shift gear from one mode to another; thus, a richer medium required.
	Adaptative Structuration Theory (DeSanctis & Poole, 1994)	• Group outcomes are the results of group's attitude toward the technology and faithfulness of appropriation of social structures of the technology in the context of its use.

that responded to the above conclusion: First, more sophisticated research design was employed to examine particular aspects of GSS applications. Second, attempts were made to propose theories to explain the disparities in findings.

Furthermore, since mid-1990s, web technologies provide new opportunities for the deployment of GSS. The evolution of GSS research thus entered its sixth phase, being labeled as "New Frontier of GSS Research," which can be characterized by two main trends: First, the two developments in phase five continue (Chidambaram, Bostrom, & Wynne, 1990-91; Dennis, Wixom, & Vandenberg, 2001). Second, GSS research extends to the design of web-based GSS (Wheeler, Dennis, & Press, 1999), e-collaboration/collaborative commerce (Burke, 2001-02; Johnson & Whang, 2002; Chuang & Nakatani, 2004), and virtual teams (Saunders, 2000). These trends are shaping the future of GSS research.

MAJOR THEORIES ON GSS AND PRIOR RESEARCH FINDINGS

The review of first decade GSS research showed that there were no conclusive findings in prior research (Pinsonneault & Kraemer, 1990; Gray, Vogel, & Beauclair, 1990; Nunamaker, Dennis, Valacchi, Vogel, & George, 1993). Although the inconsistence could be attributed to the difference in technologies or research methods employed, many researchers attempted to explain the disparity with theories. Those theories can roughly be classified into two schools: decision theorist school and institutionalist school (Dennis, Wixom, & Vandenberg, 2001). The decision theorist school holds the view that the decision quality can be improved with aides of techniques or tools. In this sense, GSS is considered as an instrument that is capable of assisting decision makers to manage the complexity of decision. In contrast, the institutionalist school considers GSS as an opportunity for organizational change. The provision of GSS to a group of people engaged in teamwork does not necessarily improve the quality of group task. Instead, it is the way the technology is used that may help improve task quality. Theories in these two schools and their theses are summarized in Table 1.

While early research placed emphasis on the effect of GSS, lately, much research has been done to validate the theories. The effects of independent and intervening variables on group processes and outcomes are examined. Fjermestad & Hiltz (1998-99) presented a classification scheme of constructs that were studied in 200 experiments. The key factors in the scheme are shown Table 2.

Although numerous studies have been done, there are more unanswered questions than answered (Briggs, Nunamaker & Sprague, 1997-98). This section discusses critical issues of GSS in three areas: Traditional GSS, emerging technologies, and virtual team and e-collaboration (Table 3). First, many issues in traditional GSS need to be addressed. Those issues are either theoretical or methodological. A critical one is to validate and compare competing theories (Table 1). Also, recent research (Dennis, Wixom & Vandenberg, 2001) shows that an integrated approach might be more explanatory than a single theory from either the decision theorist school or the institutionalist school alone. Thus, what and how to integrate as a research foundation is another issue. Methodological

Table 2. Main factors of GSS research prior to 1998 (Adapted from Figure 1, Fjermestad & Hiltz, 1998-99)

INPUT	PROCESS		OUTPUT
CONTEXTUAL FACTORS	INTERVENING FACTORS	ADAPTATION FACTORS	OUTCOME FACTORS
1. Technology 2. Group 3. Task 4. Context	1. Research methods 2. Summary variables • Resultant communication dimensions • Group members perception & problem-solving • Organizing concepts • Operating conditions	1. Group adaptation process: • Structuration • Process variables • Process issues 2. Process gains/losses: • Process gains • Process losses 3. Intermediate role outcomes	1. Efficiency measures 2. Effectiveness measures 3. Satisfaction measures 4. Consensus 5. Usability measures

issues include the choice of technology, task types, and group characteristics in research design. Those issues are directly related to the external validity of GSS research. The major concern is that the task type or technology examined does not reflect what managers truly perform or use (Fjermestad & Hiltz, 1998-99). Future research also needs to address the issue of impact of GSS and task types on social and task interaction processes (Huang & Wei, 2000).

Second, from the viewpoint of developmental research (Nunamaker et al., 1993), the development of web-based GSS raises several issues. Due to the shift of processing activities to the server side and the use of a uniform user interface, one issue is how to assure the availability and the security of process and information processing supports (Zigurs & Buckland, 1998). Furthermore, rapid changes in web technologies make upgrades or re-development of GSS with new technologies a formidable task.

Third, coming along with the web-based GSS is the booming of virtual-team research (Sarker & Sahay, 2003). The unique nature of virtual teams entails more studies on distributed group structures and communication, as well as contextual and process factors (Tung & Turban, 1998). The transient life cycle of virtual team may change the interaction of team members (Piccoli & Ives, 2000). Thus, the resolution of technological, structural, and normative relational issues is critical to the success of virtual teams (Saunders, 2000). Another issue is how to incorporate team-building theory into the design of GSS supporting virtual teams (Huang, Wei, & Lim, 2003). Summarized from relevant literature, some key issues are shown in Table 3.

FUTURE DEVELOPMENT

The field of GSS has thrived in the past two decades and will continue to thrive. Issues indicated above will shape the future direction of GSS research. Based on the GSS literature, we identify the following trends of GSS development:

(1) Using GSS to support virtual teams (Saunders, 2000; Huang, Wei & Lim, 2003): Due to such reasons as strategic alliance, globalization, and outsourcing, virtually working together will become a norm rather than an exception (Saunders, 2000). Many web-based GSS are being developed (Woolley, 2004) and incorporated with multimedia capabilities (Burke, 2001-2002). Advantages of those tools (e.g., relatively low cost and more capabilities) will attract more organizations to adopt web-based GSS in virtual teams. Research opportunities exist in addressing issues identified above.

(2) Emergence of e-collaboration/c-commerce (Burke, 2001-2002; Johnson & Whang, 2002): The connectivity offered by the Internet provides a platform on which companies could collaboratively perform commercial activities beyond transactional level. E-collaboration (or c-commerce) could facilitate knowledge sharing, organizational learning, and product lifecycle management, and provide an opportunity for developing different types of partnerships. Research opportunities include structural issues of c-commerce (Chuang & Nakatani, 2004), coordination mechanisms of c-commerce, and the impact of e-collaboration technology on knowledge management and organizational learning.

Table 3. Key issues in GSS research

ISSUES IN TRADITIONAL GSS	
Theoretical Foundation Validate and compare competing theories	**Hybrid Theoretic Approach** What and how to integrate theories into theoretic foundations
External Validity of GSS Research Improve scope and external validity of research	**Effect of Mixed Communication Media** Impact of GSS with multiple media on group outcomes and processes
More Variant of Task Types Impact of complicated and variant task types	**Study on Group Process** Impact of GSS on influence distribution and (social) interaction process
Group Characteristics Impact of large group size of non-students	**GSS Adoption** Critical success factors for the adoption of GSS
ISSUES RELATED TO EMERGING TECHNOLOGIES	
Web-Enabled GSS Take advantage of new technology while maintaining minimum re-development	**Security and Privacy** Maintain a secure meeting environment
Integration of Web-Enabled GSS with Existing Systems How to integrate state-of-the-art systems with deployed GSS	**Business Value of Web-Enabled GSS** Justification for business value of web-enabled GSS
ISSUES RELATED TO VIRTUAL TEAM AND E-COLLABORATION	
Technological Choice and appropriation of technological infrastructure for virtual teams	**Structural** Managerial control mechanisms and role assignment in virtual teams
Normative What and how to develop norms and rules for virtual teams	**Design of Theory-Based Distributed GSS** Theoretical constructs and principles for the design of GSS
Cultural bridging GSS support to virtual teams with different culture	**Authentication** Security and verification of identification of team members

(3) Globalization of GSS research and applications: As GSS proliferates to regions culturally different from its birthplace, implementation issues and cultural impacts on the effect of GSS apparently need to be addressed. The increasing number of articles resulting from studies conducted outside North America attests to this trend.

(4) Multiple, rather than single, theoretical perspectives are adopted to investigate issues surrounding GSS: While numerous theories have been proposed (Table 1), most of them only partially explain the findings of prior GSS research. Thus, adopting multiple theories in research has been proposed and shown promising results. This may occur in the form of an integrated model or comparison of different theories. Thus, research opportunities include testing and comparing existing theories, and developing and empirically validating more integrated models.

CONCLUSION

The GSS research has evolved through various stages of early exploration, experimental and field studies, and theoretical development, and matured with the advent of computing and communication technologies and with the advance of business practices calling for the support for group activities. The GSS research in the past two decades has resulted in a formidable volume of literature; however, many issues remain to be addressed. Methodological issues in traditional GSS in the decision room must be resolved with more sophisticated research design. Various GSS theories need to be validated or modified to explain the disparity in findings of prior research. New technologies and applications of GSS will certainly present plenty of research opportunities in supporting virtual teams with GSS, e-collaboration, and globalization of GSS applications. Research efforts in these regards are shaping the future direction of GSS development.

KEY TERMS

Anonymity of GSS: Communicators do not know owners of expressed ideas in group interaction processes.

E-Collaboration/Collaborative Commerce: IT-enabled joint intellectual efforts between organizations for planning, design, development, production, and delivery of products and services.

Group Process Gains: The improvement in the outcome of group work that benefits from certain aspect of the meeting process (Nunamaker et al., 1993).

Group Process Loss: The impairment in the outcome of group work that is resulted from certain aspect of the meeting process (Nunamaker et al., 1993).

Group Structures: Structures refer to rules and resources (including software tools) that are used in group interaction process (Poole & DeSanctis, 1990).

GSS (Group Support System): Created with computer and communication technologies and decision support techniques for assisting problem formulation and evaluation of alternative solutions in group meeting (DeSanctis & Gallupe, 1987).

Structuration: The process by which rules and resources provided by technology are produced and reproduced in social life (DeSanctis & Poole, 1994).

Virtual Team: A team consists of members who are scatted in different locations that are across geographical boundaries, and who are working together mainly based upon information technology.

How Teachers Use Instructional Design in Real Classrooms

Patricia L. Rogers
Bemidji StateUniversity, USA

INTRODUCTION

"I've learned how to use the [insert new instructional technology here], so now how do I use it in class?"

From filmstrips and mimeographs, to computer-based simulations and virtual reality, technology seems to dominate teachers' lives as they master the new instructional media for use in their classrooms. Good teaching and learning practices tend to take a back seat while the focus on mastery of the technology reduces teaching into basic presentations and lectures, a format most easily controlled by the instructor. While most pre-K-12 and post-secondary instructors do develop effective courses in which students learn, many would be hard pressed to describe *how* they arrive at certain goals and teaching strategies.

BACKGROUND

The field of instructional design provides sound practices and models that, once modified for use by working teachers, can be used to design effective instruction in any content area (Rogers, 2002). The more difficult issue is helping teachers move beyond the tendency to focus on technology rather than instructional goals. Such focus occurs at lower levels of what can be described as a technology adoption hierarchy (summarized in Table 1): familiarization, utilization, integration, reorganization, and evolution (Hooper & Rieber, 1999).

Somewhere at the integration stage, a "magic line" is crossed and the focus is no longer on the technology but on the teaching and learning. A supporting practical design model can help teacher-designers cross this magic line more efficiently and with a high degree of success.

FUTURE TRENDS

A Modified Instructional Design Model

Prescriptive behavioral models in learning would seem, at first encounter, to be inappropriate in light of the more constructivist practices of current educators. However, most constructivists would concur that one must have solid building blocks or elements before construction of new knowledge can be achieved. Dick and Carey's (1990) original systems design model and subsequent modifications by Gagné, Briggs and Wager (1992) and others offer examples of all of the elements necessary for designing and evaluating effective instruction. What the models lacked, however, was a connection to real classroom teachers: those of us who are really teacher-designers and who must create and develop our courses without benefit of design teams and lengthy pilot tests with target audiences.

Figure 1 is a modification based on several interpretations of the most typical instructional design model (Dick

Table 1. A summary of the technology adoption hierarchy

EVOLUTION	Highest level: is most able to cope with change and has skills to adapt newer technologies as needed or desired in teaching and learning environment.
REORGANIZATION	Re-designs teaching strategies with focus on learning and goals of instruction. Students become more involved in the learning environment.
INTEGRATION	Beginning to accept the technology. Focus soon shifts from learning the technology (and fearing its breakdown) to effective use of the technology in teaching.
UTILIZATION	Basic trial of the new technology. Focus is on finding a use for the technology that may or may not continue, particularly if the technology breaks down.
FAMILIARIZATION	Lowest level of exposure to a technology.

& Carey, 1990). Notice that the five phases of design: analyze, design, develop, implement, and evaluate, are focused not on designing teacher-proof curricula but rather on teacher-designers staying focused on their own environment and learners.

The model helps teachers begin designing with the constraints, issues, community demands, and state and federal mandates in mind before thinking about instructional media or "activities". Once parameters are identified, teacher-designers move into the design phase as they document the overall goals of their course (or, in the case of primary teachers, their school year) while simultaneously considering their learners. What does it mean to be a 3^{rd} grade person? What skills should learners have as they move into 4^{th} grade? What new knowledge is gained in 4^{th} grade to allow learners to become 5^{th} grade students? And so on.

Within this phase, assessments are also considered. Effective design, as well as effective teaching, requires teacher-designers to carefully match goals and objectives to appropriate assessments. Desired types of learning, from basic verbal information to higher order thinking skills (Gagné, Briggs & Wager, 1992) must have matched assessments that allow learners to demonstrate their new skills and abilities. Mismatched goals and assessments are common errors in designing instruction.

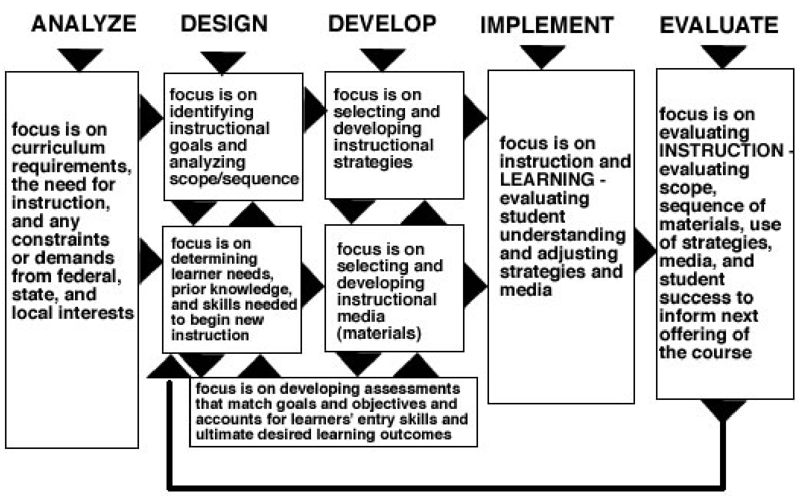
Using this model essentially forces us to wait until the development phase to select teaching strategies and instructional media. For those teachers who are struggling to leave the lower levels of the technology adoption hierarchy, this placement will seem uncomfortable. However, starting with the technology and trying to build an instructional environment is, as should be apparent, in essence turning the design process inside out! Once the focus is away from the goals and objectives and the *learners*, any further course development will likely result in a design that falls far short of the intended learning:

I am elated that I had the opportunity to work on curriculum design for the first time the right way and with a group of faculty members who supported my learning. I have watch[ed] part-time faculty members and even seasoned classroom teachers jump into material they are not familiar with, plan day by day, never really having clear objectives and methods of evaluation [in mind]. (A. Vidovic, personal communication, July 30, 2003)

Notice that the development of assessments also crosses this phase of the design. It is critical to select strategies and media that support the goals and objectives as well as allow students to demonstrate their understanding. Using strategies and media that are similar to the assessment situation strengthens the learning. For example, if students were learning to write poetry, a true-false test would be a very inadequate measure of their skills.

Implementation, *teaching*, is the phase of a teacher-designer's true test. It is here that this model is quite different from traditional instructional design models in that teacher-designers rarely have a chance to "try out" a course on a sample of students. Rather, they often have to simply try things and hope it all works well. However,

Figure 1. Modified instructional design model for teacher-designers. Modifications first introduced in Designing Instruction for Technology-Enhanced Learning*, Rogers, 2002, Idea Group Publishing. Further modifications by Patricia L. Rogers and Catherine E. McCartney, Bemidji State University, for the Online Graduate Program, 2002-2003).*



by following the model thus far, teacher-designers have an advantage over others who do not have clear goals and objectives in mind. During this phase, student achievement and perhaps student evaluations of the course should be examined as evidence that all elements of the design thus far actually form a cohesive course that meets the goals of the instruction. Teacher-designers should take notes on a daily basis regarding which strategies are working with learners, which activities supported new learning, and which instructional medium was appropriate for certain types of learning.

The evaluation phase in this model relies heavily on the evidence from the previous phase and includes a critical look at any notes from the teaching experience, comparison to a previous experience teaching the course, and so on:

In designing and developing this online class using the first couple assignments (objectives, goals, subgoals, etc.), I really feel like [my] course's material fits together much better than it has when I taught it in the past. Though this [instructional design] process took a fair amount of time, I know I would never tackle another class design without using this process first. It does seem to speed up the material/content piece considerably by doing this first. (N. Gregg, personal communication, July 28, 2003)

Barriers to Designing Effective Instruction in Distance Learning

By following a model that is based in practical, real-world experiences of teachers, teacher-designers are able to develop effective and well-documented instruction. However, we should note that there are many reasons good instructional design practices are not followed, and that most are out of the teacher-designer's control. Table 2 is a summary of some of the issues and barriers faced by teacher-designers.

Table 2. A summary of barriers to designing effective instruction

Fear of change Changing teaching methods (strategies) to accommodate newer technologies, different modes of delivery, and the reality of managing a larger student market carries a certain amount of risk and challenge. The human tendency to want things to remain the same introduces a fear factor in designing and delivering instruction in the 21st century (Dublin, June 2003). **Unfamiliarity with newer technologies** The introduction of newer technologies in teaching usually results in teachers defaulting to presentations and lectures. Once the "magic line" is crossed, teaching and learning with technology refocuses from the technology to learning (Dublin, June 2003; Hooper & Rieber, 1999; Strauss, June 2003). **Correspondence, Lecture, and Interactive Learning** Real classrooms rely on interactions among students and the instructor. Some online courses are actually stand-alone correspondence courses that are self-paced and lack high interactivity levels. Lecture courses tend to be one-way communications while other strategies emphasize interactivity. There is a critical need to be clear about levels of interactivity in learning environments (Cavalier, June 2003).	**Ill-defined goals and objectives** Defining goals and objectives is often a new experience for many faculty. Goals and objectives may not match teaching style or adequately address desired learner outcomes. **Unrealistic administrative, policy, or economic pressures** Some teachers have encountered serious constraints when designing instruction. A partial list includes: forced use of traditional "activities" that become the central focus of the instruction, district-wide adoption of specific texts or programs designed to be "teacher-proof" with little flexibility, limited development time for teachers, and a focus on state-wide test scores directly tied to school funding (Rogers, 2000). **Difficulty in translating from one environment to another, such as onground to online** Moving a course from onground delivery to the online environment sets up barriers for inexperienced teachers: some try to limit all transactions to real time and have a felt need to recreate their onground course exactly. Others err on the other side and resort to a type of glorified correspondence approach.

CONCLUSION

A strong case can be made for working with teacher-designers at all levels of education on sound instructional design practices. "Winging it" when it comes to designing effective instruction is ill-advised in the rarified air of the 21st century knowledge and information age, with many demands from learners for high-quality educational experiences. Educational institutions, particularly colleges and universities, are faced with harsh competition for the teaching aspect of their institution from for-profit companies. Such companies outspend higher education in development, maintenance, and marketing of educational offerings, particularly in online learning (Rogers, 2001). Non-profit educational institutions can compete most effectively by providing (a) affordable pricing, (b) greater accessibility to education, and (c) high-quality, personalized educational experiences for their learners. A and B are usually easily attained. High quality education (c) begins with great teachers and support staff and is built and sustained with solid instructional design practices.

KEY TERMS

ADDIE: The five phases of most instructional design models: analyze, design, develop, implement, and evaluate. Some models follow the phases in a linear fashion, while others may approach the phases in a holistic or phenomenologic manner.

E-Learning: A term used to describe learning that takes place usually online, but includes all forms of electronically-enhanced and mediated learning. Computer-aided instruction, just-in-time learning, and intelligent systems can be included in the term "e-learning".

Instructional Design: The field of instructional design includes a range of professions from programmers and graphic artists, to the instructional designer. Designers are able to analyze instruction, learners, environments, strategies, and media to develop effective instruction of training. Designers may or may not be subject matter experts.

Instructional Design Models: Traditional design models are prescriptive step-by-step processes, usually associated with behaviorist instructional strategies. Phenomenological models incorporate constructivist philosophies and practices. In either aspect, design models guide the user in designing effective instruction that takes all aspects of design (see ADDIE) and reminds the user of critical elements and decisions in designing effective instruction.

Instructional (Educational) Technology: Instructional technology is the theory and practice of design, development, utilization, management and evaluation of processes and resources for learning (Seels & Richey, 1994).

Teacher-Designer: "…if you have any experience with instructional design you know that the field and the various models of design associated with it seem most appropriate for teams of people working on the course materials together. Once in a while, some of us are fortunate enough to have instructional designers, subject matter experts, graphic artists, programmers and so on available on our campus or in our school district to assist us with our technology-enhanced course. But most often, it the teacher alone who must rethink and redesign his or her course for technology-enhanced learning. And very often it is the teacher who must also prepare the materials for the Internet, interactive television, or some other delivery medium. They often do not have any background in instructional design theory or practices and have only just mastered the skills for using the delivery medium. These are the people I call 'teacher-designers'" (Rogers, 2002, p. 2).

Technology Adoption Hierarchy: "The model…has five steps or phases: familiarization, utilization, integration, reorientation, and evolution. The full potential of any educational technology can only be realized when educators progress through all five phases; otherwise, the technology will likely be misused or discarded…The *traditional* role of technology in education is necessarily limited to the first three phases, whereas contemporary views hold the promise to reach the evolution phase" (Hooper & Rieber, 1999, p. 253).

Human Body Part Classification and Activity Recognition for Real-Time Systems

INTRODUCTION

Recent advances in camera and storage systems along with increased algorithmic and computational power of 3D graphics hardware are main factors driving the increased popularity of multicamera applications. Since prices continue to drop on components, cost-effective systems can be developed for a wide range of applications such as teleimmersion, humanoid robots systems, automated video surveillance, and interactive video games.

The increased importance of such applications that require fast, cheap, small, and highly accurate smart cameras necessitates research efforts to provide efficient solutions to the problem of real-time detection of persons and classification of their activities. A great effort has been devoted to three-dimensional human modeling and motion estimation by using multicamera systems in order to overcome the problems due to the occlusion and motion ambiguities related to projection into the image plane. However, introduced computational complexity is the main obstacle for many practical applications. Different applications require different levels of modeling-related performance metrics, that is, accuracy, speed, and robustness, hence different 3D techniques. Therefore, the relationship between the activity recognition algorithms and the architectures required to perform these tasks in real time is a fundamental design issue.

BACKGROUND

Human detection and motion recognition involve interpretation of elementary visual features such as shape, color, texture, and motion. A geometric model is an approximation of the shape and of the deformations of the object. This model can be two-dimensional (modeling the contours of the projections of the object in the images) or three-dimensional (modeling the surfaces of the object). Two-dimensional human shape models are generally made of curves, segments, sticks, snakes, and so forth, where 3D models are either systems of rigid bodies (e.g., spheres, superquadrics, etc.) or deformable surfaces (e.g., mesh). Template matching, chain coding, Fourier transform, boundary signatures, moments, and polygonal approximations are popular shape-matching algorithms. The required properties of a shape description scheme are invariance to translation, scale, rotation, luminance, and robustness to partial occlusion. Color and texture are mostly used to detect skin areas in human-detection tasks. The articulations may be modeled by joints or by the motion of control points (e.g., B-splines). Major approaches for analyzing spatial and temporal patterns include dynamic time warping, neural networks, hidden Markov models (HMMs), time-frequency analysis, template matching, and principal component analysis. The choice between a 2D or 3D model depends on the application, for example, the needed precision, number of cameras, or type of motion to be recognized.

Several researchers work with 2D features to recognize human movement (Gavrila, 1999). Goddard (1994) uses model-based recognition techniques, namely, stick figures. Other researchers who use 2D models are Comaniciu, Ramesh, and Meer (2000), Isard and MacCormick (2001), and Papageorgiu and Poggio (1999). Most of the work in this area is based on the segmentation of different body parts. Wren, Clarkson, and Pentland (2000) proposed a system, Pfinder, to track people by using blobs that represent different body parts. W4 is another real-time human-tracking system (Haritaoglu, Harwood, and Davis, 1998), where the background information should be collected before the system can track foreground objects.

Three-dimensional human and activity recognition systems can be classified in terms of the visual analysis of multiple cameras, that is, the projection of 3D models onto 2D images versus 3D visual reconstruction from stereo images. Aggarwal and Cai (1999), Gavrila (1999), and Moeslund & Granum (2001) present overviews of various methods used for articulated and elastic nonrigid motion detection. More background information on gesture recognition can be found in Wu and Huang (1999).

One of the early works on tracking articulated objects is proposed by O'Rourke and Badler (1980). The authors used a 3D model of a person made of overlapping spheres. Kakadiaris and Metaxas (1998) proposed a method to generate the 3D model of an articulated object from different views. The authors used extended Kalman filter for motion prediction. Gavrila and Davis (1996) used superquadrics to model the human body and dynamic time warping to recognize the human motion. Luck, Debrunner, Hoff, He, and Small (2002) obtained 3D models of the moving human body by extracting the silhouettes from multiple cameras. In this work, 3D information is used for HMM-based activity recognition in real time for different applications without requiring any specific pose or user interaction and using distributed processing. This method is explained in more detail in the next section with an emphasis on issues related to the relationship between the algorithms and design architecture.

Most of the previous work for human detection depends highly on the segmentation results, and mostly motion is used as the cue for segmentation. Most of the activity-recognition techniques rely on the successful feature extraction, and proposed approaches are suitable for a specific application type. There is a need for more robust techniques that can use model-based information feedback and connect low-level features to high-level semantics in real time.

MAIN THRUST OF THE ARTICLE

As previously stated, 3D human- and activity-recognition systems can be classified in terms of the visual analysis of multiple cameras, that is, the projection of 3D models onto 2D images versus 3D visual reconstruction from stereo images. Depending on the selected technique, different steps must be implemented. Visual reconstruction for virtual reality requires high accuracy while real-time activity recognition and trajectory estimation require high-speed techniques. Various aspects and challenges of 3D visual-analysis algorithms include instruction statistics, branch behavior, and memory access behavior of different program parts, for example, stereo matching, disparity map generation, reconstruction, projection, 2D or 3D human body part detection, 2D or 3D tracking, 2D or 3D activity recognition, and so forth.

Algorithmic and Hardware Issues

Algorithmic Issues

In general, we can classify 3D human detection and activity recognition methods into two categories (Cheung, Kanade, JBouguet, & Holler, 2000): off-line methods, where the algorithms focus on detailed model reconstruction, for example, wire-frame generation, and real-time methods with a global 3D human model reconstruction (Delamarre & Faugeras, 2001). The major challenge in many 3D applications is to compute dense range data at high frame rates, since participants cannot easily communicate if the processing cycle or network latencies are long. The works by Kakadiaris and Metaxas (1995) and Mulligan, Isler, and Daniilidis (2001) are examples for non-real-time methods. Most of the real-time methods use a generic 3D human model and fit the projected model to the projected silhouette features (Luck et al., 2002). The speed of the systems depends highly on the voxel resolution.

The algorithmic pipelines perform a wide range of disparate operations:

- pixel-by-pixel operations,
- pixel-region operations,
- mixed operations, and
- nonpixel operations.

Traditionally, the algorithms start with operations that are clearly signal oriented and should move steadily away from the signal representation until the data are very far removed from a traditional signal representation. In general, the volume of data goes down as image processing progresses.

Hardware Issues

Real-time implementation of image- and video-processing algorithms necessitates data- and instruction-level parallelism techniques to achieve the best performance for several application types. Besides the algorithm development, hardware design is one of the most important issues for a real-time system. Watlington and Bove (1997) proposed a data-flow model for parallel media processing. Davis, Borovikov, Cutler, and Horprasert (1999) developed a multiperspective video system. Fritts, Wolf, and Liu (1999) evaluated the characteristics of multimedia applications for media processors. Researchers also pay attention to multiprocessor architecture. Simultaneous multithreading is proposed by Tullsen, Eggers, and Levy (1995). An IMAGINE processor is being developed at Stanford University, which has an explicit, programmable communication structure (Khailany, Dally, Rixner, Kapasi, Mattson, Namkoong, et al., 2001).

The selection of an image and video processor must be based on a number of issues including power, cost, development tools, and performance-related features. Examples include Texas Instruments' DSPs (the TMS320C6201 and C6701) that use a VLIW (very long instruction word) architecture. Another VLIW processor is the Philips TriMedia processors that can execute up to five instructions per cycle. Besides the main CPU (central processing unit), there are other peripherals that can take the load from the main CPU for particular computations. General-purpose processors' (GPP) high power consumption and large size are the main disadvantages for portable image- and video-processing applications. Another important factor is cost. For cost-sensitive applications, Digital Signal Processing (DSP) devices are significantly less expensive than GPPs.

3D Visual Analysis and Synthesis Steps

Disparity Map Generation

One well-known technique to obtain depth information from digital images is the stereo technique. In stereo techniques, the objective is to solve the correspondence problem, that is, to find the corresponding points in the left and right image. The difference in the spatial position of the corresponding points, namely, disparity, is stored in a disparity map. Whenever the corresponding points are determined, the depth can be computed by triangulation. Attempts to solve the correspondence problem have produced many variations, which can be grouped into matching pixels and matching features, for example, edges. The former approach produces dense depth maps while the latter produces sparse depth maps. Even though stereo vision techniques are used in many image-processing applications, the computational complexity of matching stereo images is still the main obstacle for practical applications.

Two main performance evaluation metrics are throughput that is the frame rate times the frame size and the range of disparity search that determines the dynamic range of the distance measurement. There is still a great deal of research devoted to develop stereo systems to achieve the desired performance. Early real-time stereo systems do not provide a complete video-rate output of range as dense as the input image with low latency. Another major problem is that the depth maps obtained by current stereo systems are not very accurate or reliable. Newer methods that address these problems include the multibaseline stereo method (Kanade, Yoshida, Oda, Kano, & Tanaka, 1996) that requires local computation, block-matching approach with parallel algorithms (Koschan & Rodehorst, 1995), area-based stereo matching (Konolige, 1997), and hybrid recursive matching (Schreer, Brandenburg, & Kauff, 2001) with an efficient selection of a small number of candidate vectors.

Reconstruction and Calibration

Reconstruction involves computing for each corresponding point pair in the images a point in space. This requires calibration of the cameras. There are two major parameter sets for cameras, namely, intrinsic and extrinsic parameters. If both of the parameter sets are known, then the cameras are fully calibrated. By using the intrinsic parameters, the 3D depth map can be converted into Cartesian coordinates. The extrinsic parameters are used to convert the camera-centered position into a position in the world coordinates (Narayanan, Rander, & Kanade, 1998). These 3D points are converted into a surface representation via a triangular mesh. The algorithm calculates the correspondence that minimizes the geometric error subject to the epipolar constraint. Detailed information about cameras and camera calibration can be found in Hartley and Zisserman (2000). Although many algorithms are proposed for more accurate and reliable 3D object reconstruction, they are not suitable for practical applications due to their computational complexity. Depending on the application type, algorithmic solutions, for example, using constraints from prior information, and hardware solutions, for example, using a graphics hardware that effectively combines a plane-sweeping algorithm with view synthesis (Yang, Welch, & Bishop, 2002), are proposed.

Rendering

Rendering is the process of producing realistic 3D images. The rendering issues are related to the interaction between light and surface, intersection of viewing rays, and objects sampling of the scene and displaying techniques. There are four main rendering methods used in visualization, that is, ray tracing, volume rendering, radiosity, and polygon rendering. Due to the high computational requirements of traditional computer graphics, general-purpose computers are not efficient in rendering applications. Consequently, special-purpose graphics engines are developed primarily for polygon rendering. Similarly, special-purpose volume-rendering architectures are developed to meet the special needs of volume rendering in order to compute rapidly and repeatedly from a volume data set. A detailed survey on graphics hardware can be found in Thompson, Hahn, and Oskin (2002).

A Data Fusion Algorithm for 3D Human-Activity Recognition

In this subsection, we present our test bed architecture where a single camera node is composed of a standard camera and a TriMedia video-processing board. Multiple TriMedia processing boards can be installed to one host PC (personal computer) to provide multiprocessing ability. A TriMedia board has a TM1300 TriMedia processor with its own dedicated memory. A 32-bit TM1300 TriMedia processor has a five-issue VLIW CPU together with several coprocessors. The CPU in the processor has multiple functional units and 128 registers.

The proposed algorithm detects a wide range of activities for different applications. For this reason, the scheme detects different body parts and their movement in order to combine them at a later stage that connects to high-level semantics. Low-level processing steps include background elimination, skin-area detection, segmentation, finding connected components, ellipse fitting, and graph matching with invariant shape attributes (Ozer, Wolf, and Akansu, 2000). High-level processing is based on HMMs where each body part has its own freedom of motion, and the activity recognition for each part is achieved by using several HMMs in parallel. The Mahalanobis distance classifier is used for combining the activities of different body parts by assigning different weights for each activity. Different activity patterns can have overlapping periods (same or similar patterns for a period) for some body parts. Hence, the detection of start and end times of activities is crucial (Ozer & Wolf, 2002b). A global 3D ellipsoid model of the human body is generated from 2D ellipses obtained from orthogonal views, and the resulting 3D information is used to verify the fit of the real body parts with the actual model. Camera calibration and data synchronization are main issues in data fusion from multiple cameras.

FUTURE TRENDS

In this section, potential architectures, that is, VLIW, the symmetric parallel architecture, and macropipeline architectures, are discussed to exploit the parallelism resulting from the data independencies. Some pixel-level operations on different pixels may be independent. This independence can be converted into a different form of parallelism such as instruction-level parallelism, thread-level parallelism, process-level parallelism, as well as spatial parallelism, which can be utilized by array processors. When the input frame size is not large enough to make those additional costs ignorable, it is more preferable to convert this intraframe data independency into instruction-level parallelism, which can be explored by VLIW or superscalar architecture processors. While a superscalar processor is more efficient for processing dynamic instruction-level parallelism, a VLIW processor can achieve similar performance on the program with explicit parallelism with significantly less hardware effort. The first step is to use loop fusion, a way of combining two similar, adjacent loops for reducing the overhead, and loop unrolling, which partitions the loops to discover loop-carried dependencies that may let several iterations be executed at the same time, to increase the basic block size and thus increase available instruction parallelism. In the second step, we sought two methods to reduce the branches, which limit the basic block size in loops. A solution for this is to use conditional execution instructions, which require hardware support. Another technique to convert control flow dependency to data dependency is using lookup tables.

A coarse-grained data independency in multiple camera systems is the interframe data independency. The corresponding parallelisms are thread- or process-level parallelism. SMT (simultaneous multithreading) and CMP (single chip multiprocessor) architectures can exploit process-level parallelism. However, the SMT architecture seems not a good choice for this parallelism since the almost-identical threads content the same resource and do not increase the functional unit utilization over the single thread model. Therefore, the CMP architecture or even separate chip processors are more preferable to exploit such interframe parallelism.

The pipelined multiprocessor architecture exploits parallelism resulting from the data flow structure. The additional benefit of such an architecture over other parallel architectures is that the processor can be tailored to the requirements of the algorithm stages. Among all the architectures, the symmetric parallel architecture can provide the better speedup, while the pipelining architecture will be able to reduce hardware effort on processors. As we can see through discussion, those different architectures do not exclude each other. Thus, we would expect a better solution by combining them together. Another important point is the parallelism architecture aspect of the multiple-camera system. The interstage and interframe parallelism, communication cost between processors (i.e., amount of data to be transferred; synchronization), and workload balance should be taken into account to distribute the load between processors.

CONCLUSION

Three-dimensional visual analysis overcomes the problems due to the occlusion and motion ambiguities related to projection into the image plane. Three-dimensional human modeling and activity recognition offer new, emerging applications such as teleimmersion, humanoid robots systems, automated video surveillance, and interactive video games. These applications require fast, cheap, small, and highly accurate smart cameras and efficient algorithmic solutions. The issues related to algorithmic and hardware architectures discussed in this article offer many challenges for researchers. Different applications require different levels of modeling-related performance metrics, that is, accuracy, speed, and robustness, hence different 3D techniques. Exploiting the relationship between the activity-recognition algorithms and the architectures required to perform these tasks in real time is a critical issue for the success of 3D visual systems. An example study is presented where the available data independencies are analyzed and potential architectures to exploit the parallelism resulting from these independencies are discussed.

KEY TERMS

Camera Calibration: A process of setting digital imaging components to standardized settings that will produce accurate and predictable results in the output.

Data Fusion: The fully automated method of merging diverse data into a single, coherent representation of the tactical, operational, or strategic situation.

Disparity Map Generation: Solving the correspondence problem, that is, to find the corresponding points in the stereo images by finding the difference in spatial position of the points, namely, disparity.

Gesture/Activity Recognition: Dynamic body configuration that involves spatiotemporal analysis.

Posture Recognition: Static body configuration without a dynamic movement.

Rendering: A process of producing realistic 3D images. There are four main rendering methods used in visualization, that is, ray tracing, volume rendering, radiosity, and polygon rendering.

Visual Reconstruction: Computing for each corresponding point pair in the images a point in space.

Human Motion Tracking and Recognition

INTRODUCTION

Tracking and recognition of human motion has become an important research area in computer vision. In real-world conditions it constitutes a complicated problem, considering cluttered backgrounds, gross illumination variations, occlusions, self-occlusions, different clothing, and multiple moving objects. These ill-posed problems are usually tackled by simplifying assumptions regarding the scene or by imposing constraints on the motion. Constraints such as that the contrast between the moving people and the background should be high, and that everything in the scene should be static except for the target person, are quite often introduced in order to achieve accurate segmentation. Moreover, the motion of the target person is often confined to simple movements with limited occlusions. In addition, assumptions such as known initial position and posture of the person are usually imposed in tracking processes.

The first step towards human tracking is the segmentation of human figures from the background. This problem is addressed either by exploiting the temporal relation between consecutive frames—that is, by means of background subtraction (Sato & Aggarwal, 2001), optical flow (Okada, Shirai & Miura, 2000), or by modeling the image statistics of human appearance (Wren, Azarbayejani, Darrell & Pentland, 1997). The output of the segmentation, which could be edges, silhouettes, blobs, and so forth, comprises the basis for feature extraction. In tracking, feature correspondence is established in order to locate the subject. Tracking through consecutive frames commonly incorporates prediction of movement, which ensures continuity of motion, especially when some body parts are occluded. For example, when a person is walking, there are some moments when one of the legs occludes the other. So, some techniques try to determine the precise movement of each body part (Sidenbladh, Black & Sigal, 2002), while other techniques focus on tracking the human body as a whole (Okada, Shirai & Miura, 2000). Tracking may be classified as 2D or 3D. 2D tracking consists of following the motion in the image plain either by exploiting low-level image features or by using a 2D human model. 3D tracking aims at obtaining the parameters that describe body motion in three dimensions. The 3D tracking process, which estimates the motion of the body parts, is inherently connected to 3D human pose recovery.

3D pose recovery aims at defining the configuration of the body parts in the 3D space and estimating the orientation of the body with respect to the camera. This work will mainly focus on model-based techniques, since they are usually used for 3D reconstruction. Model-based techniques rely on a mathematical representation of human body structure and motion dynamics. The 3D pose parameters are commonly estimated by iteratively matching a set of image features extracted from the current frame with the projection of the model on the image plane. Thus, 3D pose parameters are determined by means of an energy minimization process.

Instead of obtaining the exact configuration of the human body, human motion recognition consists of identifying the action performed by a moving person. Most of the proposed techniques focus on identifying actions belonging to the same category. For example, the objective could be to recognize several aerobic exercises or tennis strokes or some everyday actions such as sitting down, standing up, walking, running, or skipping.

Next, some of the most recent approaches addressing human motion tracking and 3D pose recovery are presented, while the following subsection introduces some whole-body human motion recognition techniques. Previous surveys of vision-based human motion analysis have been carried out by Cédras and Shah (1995), Aggarwal and Cai (1999), Gavrila (1999), and Moeslund and Granum (2001).

This overview will present some of the techniques proposed in the bibliography, together with their advantages or disadvantages. The outline of this work is as follows. First, a survey about human motion tracking and 3D pose recovery are given. Next, human motion recognition is introduced, followed by a summary of some application works. Finally, a section with future trends and conclusion is introduced.

HUMAN MOTION TRACKING AND 3D POSE RECOVERY

Tracking relies either on monocular or multiple camera image sequences. Using monocular image sequences is quite challenging due to occlusions of body parts and ambiguity in recovering their structure and motion from a single perspective view (different configurations have the same projection). On the other hand, single camera views are more easily obtained and processed than multiple camera views. In Table 1, some recent techniques using only one camera are presented.

In contrast to single-view approaches, multiple camera techniques are able to overcome occlusions and depth ambiguities of the body parts, since useful motion information missing from one view may be recovered from another view. In Table 2, some recent approaches using multiple cameras.

Some currently published papers tackle specifically the pose recovery problem using multiple sensors. A real-time method for 3D posture estimation using trinocular images is introduced in Iwasawa et al. (2000). In each image the human silhouette is extracted and the upper body orientation is detected. Two of the three views are finally selected in order to estimate the 3D coordinates of the representative points and joints. In Rosales, Siddiqui, Alon, and Sclaroff (2001), multiple views are obtained by introducing the concept of "virtual cameras," which is based on the transformation invariance of the Hu moments. One advantage of this approach is that no camera calibration is required.

HUMAN MOTION RECOGNITION

Human motion recognition may be achieved by analyzing the extracted 3D pose parameters. However, because of the extra pre-processing required, recognition of human motion patterns is usually achieved by exploiting low-level features (e.g., silhouettes) obtained during tracking (see Table 3).

APPLICATIONS

Vision-based human body modelling has been used in an extensive spectrum of applications. Some recent works, grouped according to their applications field, are presented in Table 4.

Table 1. Monocular systems

Authors	***Description***
Sminchisescu and Triggs (2001)	A 3D human body model, consisting of tampered superellipsoids, is fitted on the image features by means of an iterative cost function optimization scheme. A multiple-hypothesis approach with the ability of escaping local minima in the cost function is proposed.
Cham and Rehg (1999)	This technique combines a CONDENSATION style sampling with local optimization. A 2D model with underlying 3D kinematics is used. The advantages are its suitability for high-dimensional state-spaces and that the use of discrete features is unnecessary.
Wachter and Nagel (1999)	A 3D model of right-elliptical cones is fitted to consecutive frames by means of an iterated extended Kalman filter. This approach copes with self-occlusions occurring between the legs of a walking person.
Howe, Leventon and Freeman (1999)	Self-occlusions are tackled in this Bayesian system. 3D reconstruction is achieved by establishing correspondence between the training data and the features extracted.
Sidenbladh, Black and Sigal (2002)	A probabilistic approach for modeling 3D human motion for synthesis and tracking, where learning of state transition probabilities is replaced with efficient probabilistic search in a large training set.

Table 2. Multiple-camera systems

Authors	Description
Okada, Shirai and Miura (2000)	3D translation and rotation of the human body is estimated using optical flow, depth, and prediction information. The problem of pose singularities is probabilistically tackled.
Cai and Aggarwal (1999)	Three synchronized cameras are used, but tracking is actually based on one at a time, since the camera providing the best view is always selected. Feature correspondence between consecutive frames is achieved using Bayesian classification schemes associated with motion analysis.
Dockstader and Tekalp (2001)	A distributed real-time platform for tracking multiple interacting people. The features extracted from each camera view are independently processed. The resulting state vectors comprise the input to a Bayesian belief network. Observation fusion follows.
Utsumi, Mori, Ohya and Yachida (1998)	Tracking is decomposed into three sub-tasks (rotation angle estimation, position, and body-side detection) and is based on Kalman filtering. Each sub-task has its own criterion for selecting viewpoints.
Delamarre and Faugeras (2001)	This technique incorporates physical forces to each rigid part of a 3D model consisting of truncated cones. The model's projections are compared with the silhouettes extracted from the image by means of a novel approach. This technique copes with self-occlusions, fast movements, and poor quality images.

Table 3. Human motion recognition

Authors	Description
Ali and Aggarwal (2001)	Continuous human activity (walking, sitting down, bending) in monocular sequences with lateral views of the human body is separated into individual actions and recognized using the angles subtended by the torso, and the upper and lower leg.
Park and Aggarwal (2000)	This technique separates and classifies human interactions (shaking hands, pointing at the opposite person) in indoor monocular grayscale images with limited occlusions. The aim is to interpret interactions by inferring the intentions of the persons.
Sato and Aggarwal (2001)	Classification of nine two-person interactions with motion perpendicular to the camera in outdoor monocular grayscale images. Identification is based on the feature's similarity to an interaction model using the nearest mean method.
Haritaoglu, Harwood and Davis (1998, 2000)	Real-time action/interaction recognition using outdoor monocular grayscale images from a visible or infrared camera. Grayscale textural appearance and shape information of a person are combined to a textural temporal template.
Ayers and Shah (2001)	Action identification in the office (entering the room, using computers, picking up the phone) by using prior knowledge about the layout of the room. Performance is affected if the skin area is occluded, two people get too close, or prior knowledge is insufficient. This approach may be applicable in surveillance systems.

FUTURE TRENDS AND CONCLUSION

The problem of human motion tracking and recognition has become an attractive challenge. The huge amount of articles published during the last few years demonstrates the increasing interest in this topic and its wide range of applications. In spite of this, many issues are still open. Problems such as unconstrained image segmentation, limitations in tracking, development of models including prior knowledge, modeling of multiple person environments, and real-time performance still need to be efficiently solved.

A common limitation in tracking, for example, is that the motion of a person is constrained to simple movements with a few occlusions. Occlusions, which comprise a significant problem yet to be thoroughly solved, may lead to erroneous tracking. The systems should be made robust enough to recover any loss of tracking. Another problem to be totally overcome is the initialization of the pose parameters, which must be automatically performed. Similarly, techniques must be able to automatically self-tune the model's shape parameters even in unconstrained environments.

Table 4. Human body model applications

Application	***Authors***	***Description***
Virtual Reality	Aubel, Boulic and Thalmann (2000)	Models with a high level of detail capable of conveying emotions through facial animation.
	Balcisoy, Torre, Ponedr, Fua and Thalmann (2000)	A combination of virtual reality with computer vision, called augmented reality system; it allows the interaction of real and virtual humans in an augmented reality context.
	Plänkers and Fua (2003)	Flexible framework for video-based modeling using articulated 3D soft objects.
Surveillance Systems	Gavrila and Philomin (1999)	Shape-based pedestrian detection for use in real-time vision on on-board vehicles.
	He and Debrunner (2000)	A robust technique for recognizing individuals from their periodic motions, specifically walking and running. The system can handle individuals independently of their direction, speed, or scene background.
	Yuan, Sun, Varol and Bebis (2003)	Vision-based surveillance system able to combine information from multiple camera units. It can be trained to detect pedestrians, vehicles, pets, and so forth.
User Interface	Weik (2000)	Fully automatic system to create 3D models of persons. By using 16 digital cameras and a shape-from-silhouette approach, 3D models are created. A principal component analysis is utilized to extract the skeleton from the models. The system is conceived for 3D tele-presence applications or multi-player games.
	Cohen, Medioni and Gu (2001)	Real-time 3D body reconstruction, from multiple views, for vision-based perceptual user interface. Highly realistic human body motions can be performed.
	Bobick and Davis (2001)	View-based approach to the representation and recognition of human movement. It is based on a temporal template representation and tested with aerobics exercises sequences.
Medical or Anthropometric Applications	Fouchet (1999)	3D scanner for generating 3D models of the whole human body or part of it. The main purpose of this system is to record and study the evolution of dermatological lesions.
	Durdle, Raso, Hill and Peterson (1997)	Stereovision system consisting of computer graphics and imaging tools for the assessment of human body deformities (e.g., curvature of the spine, axial rotation of individual vertebrae).
	Barron and Kakadiaris (2000)	Four-step technique for estimating humans' anthropometric measurements from a single image.
	Marzani, Calais and Legrand (2001)	System for the analysis of movement disabilities of a human leg during gait.

Future human motion recognition systems must be able to identify human motion even in unconstrained environments. These systems can have many useful applications in areas ranging from everyday life to medicine. Especially, robust real-time systems may offer many benefits. Of course, the reduction of processing time presupposes not only advances on computational techniques, but also improvements on the current technology.

KEY TERMS

Image Feature: A structure in the image with interesting characteristics. Examples of features are single points, curves, edges, lines, surfaces.

Occlusion: When one object is in front of another object in the direction of observation, a portion of the object that is behind cannot be seen. Then, the second object is occluded by the first one.

Real-Time System: A system that processes and updates information always within a given time.

Self-Occlusion: When a part of the object is occluded by another part of itself. For example, when a person is walking, one leg may occlude the other leg or the torso may occlude one arm.

Stereo Vision System: System devised to extract 3D information of a given scene. Allows recovering a 3D property such as surface shape, orientation, or curvature. In binocular stereo systems, two images are taken from different viewpoints, allowing the computation of 3D structure. In trifocal, trinocular, and multiple-view stereo, three or more images are available.

Tracking: The process of estimating the parameters of a dynamic system by means of measurements obtained at successive time instances. An example is the estimation of the position of a moving object based on an image sequence.

Training Set: A set of known, labelled examples used in classification. The training set is representative of the data that will be classified in the application.

Vision Surveillance: Computer vision application area that involves scene monitoring and activity detection.

Hyper Video for Distance Learning

Mario Bochicchio
University of Lecce, Italy

Nicola Fiore
University of Lecce, Italy

INTRODUCTION

In general, the production of hypermedia applications is a complex and expensive task, requiring both technical skills and communicative abilities (Bochicchio, Paiano & Paolini, 1999a, 1999b). Nevertheless, some specific kinds of multimedia production can give good quality results, even without specialized IT skills, at a low cost. We have concentrated on this particular field, with the goal of supplying a valid tool to teachers who want to publish their educational material easily and at a low cost.

It is easy for a good teacher to give a lesson and to explain concepts using images and slides to show objects, to write on the blackboard, and to use his body language to grab and hold the attention of his students.

In our opinion, these kinds of lessons can be effortlessly transformed into very usable and effective multimedia applications based on the video of the lesson, on a simple and regular navigation structure, and on a little set of user-friendly multimedia objects.

BACKGROUND

Various research and commercial tools, such as GRiNS (2001), MTEACH (Montessoro & Caschi, 1999), Video Madeus (Roisin, Tran-Thuong & Villard, 2000), and Real Presenter (PresenterPlus, 2001), are based on this assumption, but their effectiveness is limited by a number of issues:

- their technical complexity makes them unsuitable for a large number of teachers with low technical aptitude;
- in general, they are more data-driven than user-centered;
- the time and the budget needed for a non trivial production (e.g., a course of 10 hours or more) can be remarkable; and
- they are often limited to specific lesson styles (e.g., a frontal lesson based on MS PowerPoint presentations).

Moreover, it is well known that long video sequences (e.g., 1 hour or more) are not compelling and not interactive, and the usual linear cursors and VTR-like controls can be ineffective for navigating video sequences longer than a few minutes.

To solve these problems we created LEZI, an experimental tool oriented to the very easy production of video clips enriched with hierarchical indexes, hyper-textual elements and other multimedia objects (hypervideos).

LEZI PROJECT: REQUIREMENTS

An accurate analysis of both research and commercial tools permitted us to extrapolate the essential requirements of a good development environment based on indexed video.

Starting from these requirements, a LEZI prototype was developed at the Hypermedia Open Center (HOC) of the *Politecnico di Milano*, and a number of real lessons were produced and tested (Bochicchio, Paiano, Paolini, Andreassi & Montanaro, 2000). A project for a more complete prototype, called LEZI II, was then started at the SET-Lab of the University of Lecce, within a large research project focused on the development of innovative educational tools and applications.

The first fundamental requirement for LEZI is that it be very easy to use, so that it can be truly accessible even to users with very basic computer knowledge.

The second, even more important requirement is to keep production times down (ideally to about one hour of work or less for each hour of the lesson). In some cases (e.g., conferences or special events), it may be important to extend this constraint up to the “real time production” limit (i.e., the indexed hypervideo of the event should be available on CD/DVD, and online, by the end of the event itself!).

A third very important requirement is the ability to effectively support the most common “authoring situations”, like those in which a teacher:

- presents his lesson in a classroom, with a blackboard, or outside the classroom (on the field), if this is appropriate for the topic concerned;
- uses gestures to “animate” some concept expressed by “static schema” (typically a slide), so that students need to simultaneously view the two different information sources (the teacher and the schema);
- uses his PC to explain how to use a specific computer program when the attention focus is on the display of the PC, on the voice of the teacher and, optionally, on a blackboard; and
- uses his PC to make a PowerPoint presentation. The attention focus is on the display of the PC and on the voice of the teacher.

The fourth requirement relates to finding the various topics and subtopics in the lesson. The user needs a fast and effective way to find out the contents of the video lesson, so they can easily find and reach the subjects of interest without wasting time on uninteresting or already-known video sequences.

We maintain that the most common video players (Real Player, Microsoft Media Player and QuickTime player) generally do not offer an adequate solution to this problem.

The fifth requirement concerns the technical skills needed in the authoring phase; it is important to have a high-level authoring tool to simplify all technical tasks and to fully support teachers and lecturers, whatever technical knowledge they may have.

A final requirement concerns the possibility of linking suitable comments, bibliographic references, and other teaching materials to the indexed hypervideo. The most common digital document formats (PDF, HTML, PPT, etc.) should be supported.

CONCEPTUAL MODELING

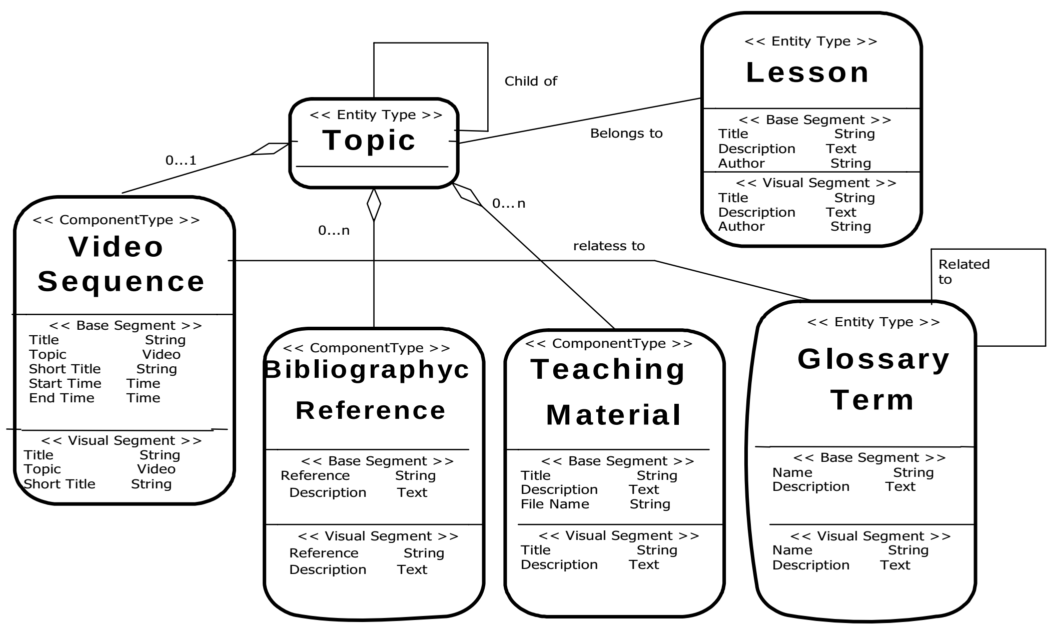
The W2000 (Baresi, Garzotto & Paolini, 2001) methodology has been adopted to refine the informal description presented so far, to obtain a suitable conceptual model for LEZI II, and to derive from it the current LEZI II prototype.

W2000 is a user-centered methodology for conceiving and defining hypermedia applications. It organizes the overall development process into a number of interdependent tasks. Each activity produces a set of related diagrams which describes some aspects of the hypermedia application, and is based on UML. The idea underlying W2000 is a requirements-driven, user-focused approach to design.

In brief, for the LEZI prototype we have identified the following roles:

- *Author:* manages his public/private lessons and related students;
- *Registered Student:* attends public/private lessons and can perform second level authoring (co-authoring) operations (Garzotto, Mainetti & Paolini, 1995).

Figure 1. LEZI II: Hyperbase in the large



- *Unregistered Student:* can only attend public lessons; and
- *LEZI Manager:* manages the system.

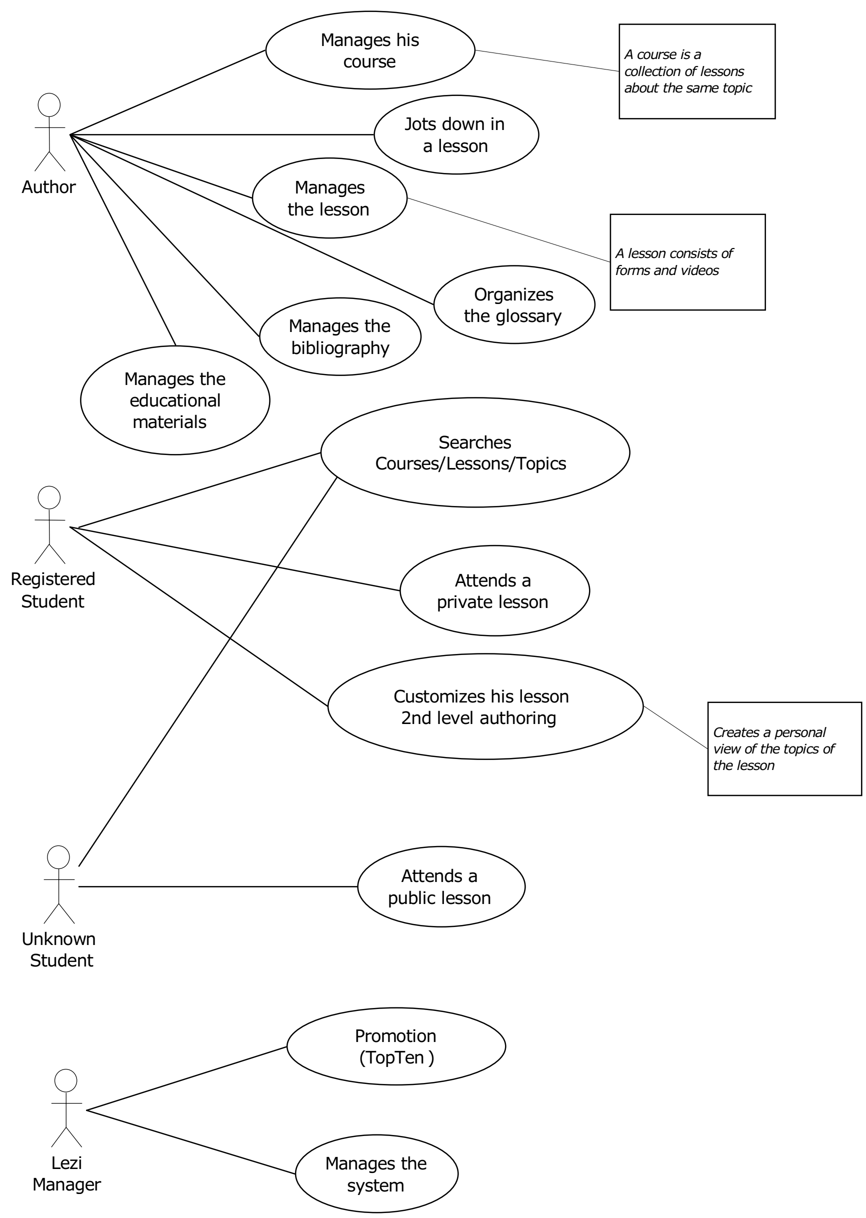
It should be observed that the users of the LEZI II system are not rigidly associated with a single role. A registered student of a given lesson, for example, could also play the role of author for a different lesson. Specifying roles is the best way to make user profiles explicit and to avoid duplicating functionalities.
In Figure 1, the hyperbase diagram of LEZI II is outlined in terms of HDM2000 primitives (Baresi, Garzotto & Paolini, 2001).

The hyperbase schema is adopted to specify:

- the information structures needed by the various classes of users (information design); and
- the navigation paths that allow users to find the piece of information suitable for their task (semantic navigation design).

In Figure 2, we show the main functional use-case diagrams, in which the main functionalities are associated with the previously identified roles.

Figure 2. W2000 functional use-case diagram of LEZI II



THE LEZI II PROTOTYPE

Different LEZI prototypes have been produced since July 2001 at the SET-Lab of the University of Lecce (*http://mb.unile.it/Lezi*).

Referring to the fourth requirement, in all prototypes the main access structure has been implemented as a tree, organized into topic and subtopic nodes. Each topic node corresponds to the sequence of the videos associated with its subtopics, and the root corresponds to the entire lesson. No more than four subtopic levels are allowed, and each leaf of the tree corresponds to 2-5 minutes of video. Each node (both topic and subtopic) of the tree contains a short textual description of the video associated to that node and the indication of its duration. This short description is very effective for finding the interesting topics and skipping the uninteresting (or the already-familiar) ones.

The tree-index acts as a hierarchical table of contents (TOC in the following). It can be generated manually or semi-automatically by creating a sequence of nodes equally-spaced in time. The authors of the lesson can then add/delete/modify the text associated with each node, as well as its duration and its start/end time.

Multiple tree-indexes can be created for a given lesson, so that the same lesson can be easily re-adapted for different purposes and different users.

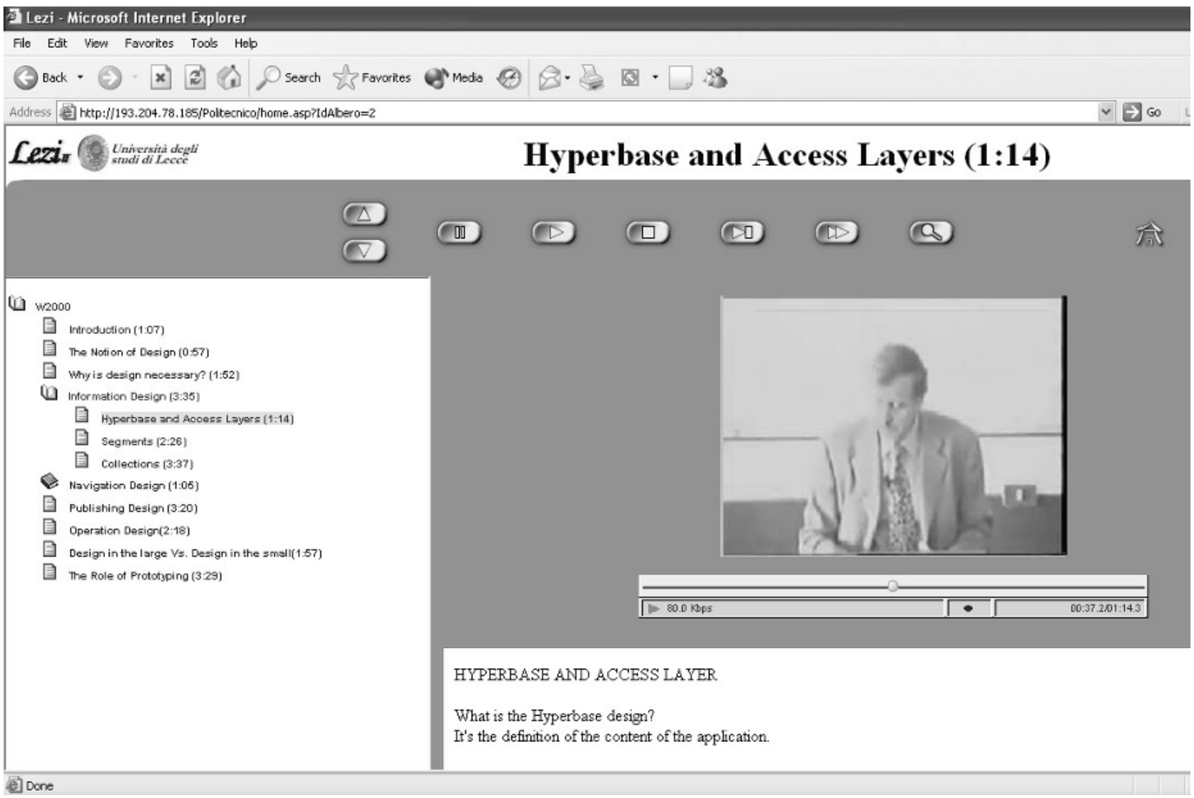
The prototype has two distinct parts: the authoring part, suitable for creating a new LEZI lesson, and the fruition part which may be used to navigate among existing lessons and to select and play the desired one.

From the technical point of view, the online LEZI environment requires a networked workstation, equipped with RealServer (for the video streaming) and Internet Information Server (for the lesson server), while the online LEZI client, suitable for both authoring and fruition, can be executed in any browser supporting JavaScript and equipped with the RealVideo plug-in.

Different user interface styles (multi-skin) and a customizable set of interface objects (background, buttons, colors, fonts, etc.) are supported to better adapt each LEZI II lesson to the expected audience.

From the implementation point of view, the online version is based on the MicroSoft-ASP object model for server-side scripting and on JavaScript and DHTML to implement the visual interface for the client. A SMIL program (SMIL, 2001) has been used to correctly synchronize the tree-index with the video streams.

Figure 3. The “Hyperbase and Access Layers” topic



In comparison with the MicroSoft-ASF format the RealVideo format was more reliable and performed better. In particular, with RealVideo it was very simple and effective producing video clips for multiple bandwidth targets, able to automatically switch to lower/higher bit-rates according to network conditions.

The first step in creating a lesson with the LEZI prototype is to produce the movie in RealVideo format. The lesson can be recorded on a PC or on a notebook equipped with RealProducer by means of a USB video-converter and a video source. If the lesson is already in digital format, they will have to be converted into the RealMedia format before other steps.

Further steps to produce the lesson with LEZI II, are:

- to create a tree index at the end of the recording session;
- to add teaching materials (if available as digital documents) and bibliographical references to the indexed video; and
- to generate the LEZI II lesson (both for CD/DVD and for online use).

VALIDATION

The University of Lecce has produced many applications with LEZI II, to empirically validate the proposed approach.

An example is the computer-graphics class given by Professor Paolo Paolini (Milano-Lecce-Como, 2001). The screen shot in Figure 3 is related to a group of topics on the design/modeling methodology W2000. The class is given to students at the university level.

In order to provide an example of TOC, let us consider the topic "Information Design" that is structured into sub-topics: "Hyperbase and Access Layers", "Segments", and "Collections".

The user is free to "attend" the lesson starting from any point he prefers.

For instance, if the paragraph "Information Design" is chosen, it is not necessary to run the video at higher hierarchical levels, which can be skipped over to go directly to the selected node.

The described LEZI application, that is very cheap and easy to produce, is used to support the normal ("in presence") teaching activity and is considered extremely useful from all involved students.

FUTURE TRENDS

The described idea is very simple: it is possible to publish good educational multimedia applications developed by academic staff with very little technical effort, in a short time, and with limited financial resources.

The future trends in this field come around to support the re-use of existing contents on the net. To better support the LEZI philosophy, it is important the adoption of a content-sharing model and the opening to the standards given by Advance Distance Learning (ADL, 2003) or IEEE (2003) to obtain a common interface for all the learning systems.

CONCLUSION

LEZI philosophy enables teaching staffs without specific technical preparation in multimedia production but with valid content and good teaching skills, to easily prepare good interactive multimedia lessons, both for disk-based (CD/DVD) or online (Web) purposes.

More generally, the widespread use of LEZI or other similar tools can effectively support the development and use of educational multimedia content in universities and schools.

Obviously, this kind of multimedia content is not intended to replace the publications of professional editors.

KEY TERMS

DVD (Digital Versatile Disc): An optical disc technology that is expected to rapidly replace the CD-ROM disc (as well as the audio compact disc) over the next few years. The digital versatile disc (DVD) holds 4.7 gigabyte of information on one of its two sides, or enough for a 133-minute movie.

HDM: The modeling language used by W2000 to describe the information, navigation and presentation aspects of a hypermedia application.

Hypervideo: Indexed video enriched with hypertextual and multimedia elements. It is a fast and effective way to "navigate" in long video clips and to find out the main contents of the video.

USB (Universal Serial Bus): A plug-and-play interface between a computer and add-on devices (such as audio players, joysticks, keyboards, telephones, scanners, and printers). With USB, a new device can be added to a computer without having to add an adapter card or even having to turn the computer off

Video Adapter: An integrated circuit card in a computer or, in some cases, a monitor that provides digital-to-analog conversion and a video controller so that data can be sent to a computer's display (alternate terms include *graphics card*, *display adapter*, *video card*, *video board* and almost any combination of the words in these terms).

Video Streaming: A video sequence that is sent in compressed form over the Internet and displayed by the viewer as they arrive

W2000: A user-centered methodology for conceiving and defining, at conceptual level, hypermedia applications.

Hypothetical Reasoning Over Databases

Suzanne M. Embury
University of Manchester, UK

INTRODUCTION

In recent years, the term *agile organisation* has been coined to denote an organisation which is able to change its working practices quickly in order to adapt to changing external pressures or to take advantage of new market opportunities that may arise (Perez-Bustamante, 1999). A key element of such agility is fast and reliable decision making; that is, the ability to determine *what* the new organisational behaviour shall be, as well as *how* the changes to it should be affected. In general, an organisation will be faced with several possible strategies for change, each of which has competing strengths and weaknesses. Management must then evaluate and compare each of these to determine which has the best forecasted outcome. This process is often referred to as "what if?" analysis (WiA), since it tries to answer the question: what will the outcome be if we adopt change X? (Codd, Codd, & Salley, 1993)

BACKGROUND

Perhaps the most familiar WiA tool is the spreadsheet, in which the user can enter different values for the parameters of a mathematical model and observe the changing results. For example, a manager might experiment with different discount rates on forecasted sales, to see how profit levels are affected. The applicability of this technique, however, is limited to situations that can be accurately characterised by a simple set of mathematical equations. A far more common context for such decision making is provided by a company database (or data warehouse), which records historical information about the performance of the organisation.

In order to perform WiA in this context, we would like to be able to update the database, to reflect the proposed changes in organisational behaviour, and then to query it, in order to determine the properties of the new state. Since we obviously cannot risk modifying the live data itself in this way, we need to find alternative methods of making these hypothetical changes to data and querying their composite effect. If the proposed change is sufficiently simple, for example, both the change and the query can be made inside a transaction that is aborted once the query result has been obtained. This will preserve the integrity of the live data, but it can have a performance impact on other business processing and it does not allow easy comparison of different scenarios.

An alternative approach that is commonly adopted is to make a copy of the data involved in the WiA scenario and to make the necessary changes to that, instead of to the live data. This is a much better solution if the change or the queries are large/complex, and it also allows a more *ad hoc* style of analysis, in which changes and queries are interleaved, and determined based on the results of the previous set of queries. If data sets are large, however, or if many different strategies are to be compared, then the disk space required can make this approach impractical. The effect of the data extraction on the performance and availability of the live database must also be considered.

Researchers have therefore considered the possibility of embedding facilities for this form of WiA within the DBMS itself, to provide the capability to perform *hypothetical reasoning* over the contents of the database without impacting the integrity or performance of the database as a whole. Such facilities must support both *hypothetical updates* (HUs), which create a pseudostate (called a *hypothetical state*, or HS) based upon the real database state but modified according to the updates requested, and hypothetical queries, which derive properties from hypothetical states.

A range of possibilities exist for implementing such hypothetical reasoning facilities, depending on how the updates and queries are specified, and to what degree the hypothetical states are materialised or not. In general, the proposals made in the literature so far can be divided into two broad categories: those which support extensional representations of HUs and those which support intensional representations of HUs. The former approach is based around the notion of a hypothetical relation (HR), while the second is focussed on the provision of hypothetical querying facilities. In the remainder of this article, we will present an overview of the principal contributions in both categories, followed by a brief discussion of some additional approaches that might be investigated in the future.

HYPOTHETICAL RELATIONS

The earliest proposal for hypothetical reasoning facilities for databases was based upon the notion of a HR (Stonebraker & Keller, 1980). An HR appears to the query system to be a normal relation, but its contents are in fact defined in terms of the contents of another relation (typically an actual stored relation), with some user-specified additions and deletions. The HR itself does not store data, but instead contains the additions and deletions that have been hypothetically made to the underlying database. Thus, if Add_R is the set of tuples that are to be hypothetically added to a relation R, and Del_R is the set of tuples that are to be hypothetically deleted from R, then the tuples present in the new hypothetical version of R are exactly those given by the query:

$$(R \text{ UNION } Add_R) \text{ DIFFERENCE } Del_R$$

Further queries can be posed against the HR (or a mixture of as many hypothetical and actual relations as are required) in order to understand the ramifications of a particular change in working practices.

Various methods of implementing HRs have been proposed, each with different performance and disk space characteristics. However, the basic concept is to store the details of the HUs in a special auxiliary relation (or relations), for use later in reconstructing the HR itself. In the earliest proposals (Stonebraker & Keller, 1980), a special relation called a *differential file* (DF) is created whenever a new HR is requested by the user (i.e. by making a HU to another relation). The columns of the DF are exactly the same as those of the relation that is being hypothetically updated, with the addition of a special *TupleID* column, which is used to match deleted tuples in the DF with their counterparts in the underlying relation, and a column indicating whether the tuple is an addition to or a deletion from the main relation.

The simplest method of querying an HR represented as a DF is to use a query rewriting approach (Stonebraker, 1981), in which any query involving HRs is transformed into an equivalent query that references only actual relations and DFs. This is done by replacing any references to an HR with a query similar to that given above to describe the contents of an HR. However, this approach (in conjunction with this simple DF design) has several disadvantages. The DF tracks all the updates made to a particular HR, and it may therefore be the case that a tuple in the underlying (actual) relation may appear several times in the DF, if (for example) it has been inserted and deleted many times. This means that the DF can grow much larger than the underlying relation itself, if HUs are numerous and frequent. A second disadvantage is that tuples which are deleted and then re-inserted into the same HR will not be picked up by the query mechanism, because all hypothetical deletions are always enacted after all hypothetical insertions. A later revision of the algorithm was proposed, which uses timestamps on tuples in the DF in order to allow the most recent changes to be visible in the HR (Woodfill & Stonebraker, 1983).

Later, these ideas were developed and extended to produce a more sophisticated form of HR, called an *Independently Updated View* (IUV) (Ramirez, Kulkarni, & Moser, 1991). IUVs are virtual relations defined over a conventional relational view (Kulkarni & Ramirez, 1997). As with HRs, HUs made to an IUV will not affect its *parental views* (i.e. the views or relations from which the IUV is built). The storage mechanism for HUs to IUVs is similar to the DF approach, except that IUVs can be materialised for higher querying performance, or stored in a separate auxiliary relation (called the *differential table*, or DT) for greater flexibility and speed of update. A further difference is that only accumulated net effects of updates are stored in the DT, so that IUVs require much less storage than HRs in the case of frequent repeated updates.

An additional problem which is present in HRs but resolved in IUVs is that of overlapping updates. These occur when the parent relations of an IUV (or HR) are updated normally (i.e. not through the hypothetical update facility). For example, suppose we have hypothetically added a new employee called Fred to a *Workers* relation, and after this the relation is actually updated to contain an employee called Fred. Which of the new Fred tuples should the HR contain? In general, the answer to this question will be application dependent. In some cases, we will wish to give priority to the real updates, while in other cases we will wish to block out any further changes and concentrate only on the HUs. In order to allow this, the designers of the IUV approach provide two options for hypothetical querying, an IUV-prioritised approach, which ignores changes to the parental views, and a Parental-View-prioritised approach, which forces a re-evaluation of the IUV in the light of the updates to the parental view.

HYPOTHETICAL QUERIES

The HR approach concentrates on the problems of representing and processing hypothetical updates in the form of sets of tuples to be added or deleted. However, many forms of WiA are more conveniently expressed using an intensional update specification. For example, rather than adding or deleting specific tuples, we often wish to ask questions such as, “what will be the net effect on profits if we increase the price of all non-fiction books by 2%?” This kind of a question is an example of a common form of hypothetical reasoning, important in many aspects of science and industry, called the *counterfactual condition* (or just *counterfactual*, for short) (Lewis, 2001). A counterfactual is a statement of the form “if A then B”, where A is a truth-valued statement that is contradicted by the current state of the world and B is any truth valued statement. For example, the statement “If Mars were the third planet from the Sun, there would be life on Mars” is a counterfactual. The counterfactual itself expresses the notion that if the world were changed only in ways necessary to make A become true, then B is also true in that updated world. The usual application of such counterfactuals is to determine the value of B for some given starting world, or across all possible worlds, and several languages have been designed for querying with counterfactuals, such as *Hypothetical Datalog* (Bonner, 1990) and *VCU*^{2} (Lewis, 2001).

The Heraclitus system (Ghandeharizadeh, Hull, & Jacobs, 1996) was inspired by previous work on both counterfactuals and the IUV system described earlier. It provides a mechanism for specifying and answering hypothetical queries. A hypothetical query in Heraclitus takes the form “Q when U”, which means “what would be the result of the query Q if it were executed against the current database state *after* it has been updated by the update U?” The key contribution of Heraclitus is that deltas – the descriptions of hypothetical changes required to the database – are elevated to be first class citizens. An extension of the C language is provided for expressing queries and deltas (including the hypothetical *when* operator given earlier), which allows hypothetical queries to be freely mixed with ordinary data access queries, and the compositional specification of deltas from other deltas. Different hypothetical states can be created and compared within a single expression, thanks to the ability to express deltas that exist across multiple transactions (similar to the characteristics of a static variable occurring across many scopes in a traditional programming language) so that different strategies can be easily evaluated against one another.

Two contrasting approaches to the evaluation of hypothetical queries have been proposed (Griffin & Hull, 1997). One of these, the “eager” approach causes hypothetical states to be fully materialized as they are encountered during evaluation of the hypothetical query, so that query operators can be evaluated directly in terms of the materialized state. In the other approach, “lazy” evaluation, materialization of hypothetical states is delayed as far as possible, and queries are transformed relative to the delta so that they can be evaluated directly in terms of the underlying state.

Each approach has its own strengths and weaknesses, and each approach is the most efficient in certain circumstances. For example, if many different hypothetical states are concerned in a relatively simple query then lazy evaluation may be best, since we will not need to materialize many states, most of which are not concerned in the query. However, if many queries are to be evaluated against the same hypothetical state, then it may be better to materialize it once, and use it for all query evaluation, rather than having to go through the complex process of transforming each query relative to the same delta. Because neither approach is best in all circumstances, the authors of Heraclitus have also investigated mechanisms for combining both approaches that allow useful intermediate results to be “cached” (i.e. materialized) while other elements of the query are handled by lazy evaluation.

Although Heraclitus has many advantages over HRs, it shares the problems of the earlier approaches concerning the difficulties of overlapping updates. In general, if the underlying database changes, then it will be necessary to re-evaluate all affected hypothetical queries, whether they have been lazily or eagerly evaluated.

FUTURE TRENDS

As yet, little of the technology described in this article has emerged into commercial database systems. Researchers have (sensibly) concentrated on backend implementation issues, and the attempt to design efficient and straightforward algorithms for query processing in the presence of hypothetical updates. However, there is also need for consideration of the user-interface aspects of hypothetical reasoning, including issues such as correct handling of overlapping updates as well as congenial graphical user interfaces for the creation, management and comparison of multiple hypothetical scenarios.

A number of back-end implementation issues also require further consideration. It is easy to envisage situations in which HRs are a more appropriate supporting technology than hypothetical queries, and *vice versa*, since each takes a slightly different approach to the representation of deltas. HR-based approaches are more suitable when the change to be investigated is best described as additions or deletions of large amounts of extensional data. An example might be when details of sales for some past year are copied forward to represent sales for a future year, without much modification. Hypothetical queries, on the other hand, are more appropriate when the change is most easily described intensionally, as some computation over existing data. For example, if we wish to amend the sales data as we copy it (perhaps increasing all prices to take into account of inflation, or modifying the quantities ordered to take into account forecasted changes in demand for different products), then this may be more easily specified using a hypothetical query approach.

However, the two approaches have much in common, and many real world WiA situations will have elements that are suited to both forms of HU. Ideally, then, we would like some hybrid of the two, which combines the strengths of both approaches, while avoiding their weaknesses. One possible means of achieving such a hybrid is to adapt and exploit new technology in the area of constraint databases (CDBs).

A CDB is a database management system that is extended so that constraint formulae can be used as a basic data type (Brodsky, 1997; Revesz, 2002); that is, the set of tuples in a table can be specified not only extensionally, as in conventional database management systems, but also intensionally, in terms of the constraints that the tuples present in the table must satisfy. As well as allowing very large, or even infinite, data sets to be represented finitely and efficiently, CDBs also allow us to describe new data sets in terms of existing data sets in far richer ways than are allowed by traditional view or derived data mechanisms (Revesz, 2002). This suggests that they may be suitable technology for supporting more advanced forms of hypothetical reasoning for WiA. CDBs have been mainly applied in geographical information systems, but there is an emerging trend in recent years where researchers are attempting to use CDB techniques in other fields, such as genome information systems (Ramanathan & Revesz, 2004), data mining (Leung, 2004) and also the integration of CDBs with traditional relational databases (Cai, 2004). Since several prototype CDB systems, such as MLPQ (P. Revesz et al., 2000), DISCO (Byon & Revesz, 1996) and PReSTO (Cai, Keshwani, & Revesz, 2000) are now available, the time is ripe for an exploration of this area.

CONCLUSION

Hypothetical reasoning over databases greatly depends on the availability of technologies that can maintain a number of hypothetical states simultaneously. With the help of HRs and hypothetical queries, researchers can create tools than can be used by decision makers to act out their imagined scenarios based on various strategies for change and improvement. Though as yet immature, such technology is a natural successor to current work on data warehousing, which collects together the raw material for scenario building in one easy-to-access environment.

KEY TERMS

Constraint Databases: A generalization of relational databases by finitely representable infinite relations, parameterized by the type of constraint domains and constraints used (Revesz, 1998).

Decision Support System: An interactive computer-based system intended to help managers make decisions. A DSS helps managers retrieve, summarize and analyze decision relevant data. There are five main classes of DSS: Communications-Driven, Data-Driven, Document-Driven, Knowledge-Driven, Model-Driven. These can be further divided by three secondary dimensions: Inter-Organizational vs. Intra-Organizational; Function-Specific vs. General-Purpose, and Web-Based (Power, 1997).

Hypothetical Queries (HQ): Queries against hypothetical states. They take the form Q when U, where U represents a hypothetical state specified by updates and Q is a query over the hypothetical state (Griffin & Hull, 1997).

Hypothetical Reasoning: The process of creating hypothetical scenarios based on hypotheses and hypothetical assertions, and of exploring the hypothesis space for results of given queries.

Hypothetical Relation (HR): A mechanism to allow users to generate alternate versions of real relations. Each version can be updated as if it were a real relation, but only the differences between the HR and the real relation on which it is defined are actually stored (Woodfill & Stonebraker, 1983).

Hypothetical Updates (HU): Proposed updates that will not be applied on the real database, but the hypothetical effect of which we wish to explore.

ICTs as Participatory Vehicles

Marc Holzer
Rutgers University, Newark, USA

Richard Schwester
Rutgers University, Newark, USA

INTRODUCTION

While citizen participation is central to democratic governance, there is a noticeable disconnect between elected representatives and the citizenry, as evidenced by voter apathy, decreased levels of civic participation, and widespread cynicism toward political institutions (Hudson, 2001; Putnam, 2000; Berman, 1997). Citizen participation advocates, however, are optimistic that information and communications technologies (ICTs) will facilitate direct interactions between citizens and government, thereby altering the dynamics of the policy-making process by affording the citizenry a stronger voice. This article examines the integration of ICTs and digital democratic applications in the context of citizen participation in government.

BACKGROUND

The Notion of Digital Democracy

As ICTs have rapidly developed, the public sector has sought to apply these technologies to digital service delivery, and ICTs have also afforded citizens a more direct means of participating in the public decision-making process. We use the term "digital democracy" instead of "electronic democracy" (Browning, 2002), "cyberdemocracy" (Ogden, 1998; Tsagarousianou, Tambini, & Bryan, 1998) or "teledemocracy" (Cross, 1998; Watson, Akselsen, Evjemo, & Aarsaether, 1999). Digital democracy simply encompasses the use of ICTs in the practice of democracy. Jankowski and van Selm (2000) suggested that while teledemocracy is more related to electronic polling and voting, digital democracy is more generally accepted as including activities related to the democratic process.

Democracy is a form of government in which citizens have a measure of influence over the policies that affect their lives. The relationship between government and citizens is foremost within a democratic system. In a digital democracy, the focus is on the processes and structures that define the relationships between government and citizens, between elected officials and appointed civil servants, and between the legislative and the executive branches of government.

According to Hacker and van Dijk (2000), digital democracy refers to "a collection of attempts to practice democracy without the limits of time, space and other physical conditions, using ICTs or computer-mediated communication instead, as an addition, not a replacement for, traditional 'analogue' political practices" (p. 1). In addition, Nugent (2001) referred to digital democracy as "processes carried out online—communicating with fellow citizens and elected representatives about politics" (p. 223). Digital democracy may be defined as all practices to improve democratic values using ICTs. Central to digital democracy are specific governance issues, which include government openness, citizen participation in governing processes, and digital elections (Arterton, 1988, pp. 620–626).

Government openness is central to digital democracy, and openness is predicated on improving access to government information. That is, well-informed citizens are more capable of playing an active role in government. Citizens can make their voices more powerful with well-informed, active participation in the policy-making process. Thus, citizens may be empowered via e-mails to elected officials, as well as by debating social issues in digital forums.

With digitally available information and advanced ICTs, citizens can participate more fully in the governing process and consult on policies at all levels of government. In addition, citizens can discuss social issues and government policies in digital forums that include public officials. The Public Electronic Network in Santa Monica, California, illustrates a public discussion forum. Launched in 1989, the Network enables citizens to interact with public servants. While initially designed to enhance public access to information, issue forums are now common (Docter & Dutton, 1998; Guthrie & Dutton, 1992; O'Sullivan, 1995; Varley, 1991). Further, the Digital City projects in Amsterdam enable citizens and politicians to interact with each other (Brants, Huizenga, & van Meerten, 1996; Francissen & Brants, 1998).

O'Looney (2002) compared the interaction between citizens and government within the context of traditional and digital democracy. While communications are filtered through representatives and the media in a traditional democracy, direct communications among citizens, public managers, and technical staff are now possible in a digital democracy. Therefore, while public servants' communications with citizens involve a one-message-fits-all approach in a traditional democracy, official communications within a digital democracy may be personalized based on an individual's interests and needs. In a digital democracy, citizens can potentially track and influence decision making at every step in the policy-making process, ranging from agenda setting to a final vote, thereby providing a basis for digital deliberation in government.

Digital Deliberation

Deliberation is the process of thoughtful discussion and consideration regarding an issue or course of action. Deliberative processes comprise discussion and consideration of arguments for and against a proposed measure. According to O'Looney (2002, p. 276), digital deliberation in government is characterized by the following:

- Access to balanced information
- An open agenda
- Time to consider issues expansively
- Freedom from manipulation or coercion
- A rule-based framework for discussion
- Participation by an inclusive sample of citizens
- Broader and freer interaction between participants
- Recognition of differences between participants, but rejection of status-based prejudice

In the context of this discussion, it is important to differentiate between static and dynamic digital deliberation. Static digital deliberation might typically include an online poll without public deliberation, a bulletin board for complaints and recommendations, or citizen participation by mail, fax, or e-mail. Dynamic digital deliberation meets the criteria for the public sphere as suggested by Habermas (1989). It includes applications that are two-way or dialogical, such as digital town hall meetings and digital policy forums. The roles of both public servants and professionals are key elements. True public deliberation includes all participants—citizens, politicians, bureaucrats, interest groups, and the media.

Deliberation is necessary when there is uncertainty, and it proves invaluable when choosing between two equally compelling courses of action (Adams et al., 2002). According to Reich (1990), deliberation is a process of "social learning about public problems and possibilities" (p. 8). Participants in deliberative processes are expected to be open to changes in their attitudes, ideas, and positions, although change is not a required outcome of deliberation. Rather, it is a process of fostering citizen growth both "in the capacity for practical judgment and in the art of living together in a context of disagreement" (Adams, et al., 2002; Roberts, 1997, pp. 124–132; Ryfe, 2002, pp. 359-377; Walters et al., 2000, pp. 349-359; Waugh, 2002, pp. 379-382; Weeks, 2000, pp. 360-372; Zifcak, 1999, pp. 236-272).

Deliberation has long been considered an important element of true democracy, and it is central to public realm theory (London, 1995, pp. 33-55). Scholars such as Arendt (1958) and Habermas (1989) regarded the public sphere as "both a process by which people can deliberate about their common affairs, and as an arena, or space, in which this can happen naturally" (London, 1995, p. 41). According to Habermas (1984, 1989), the public sphere includes requirements for authenticity, including "open access, voluntary participation outside institutional roles, the generation of public judgment through assemblies of citizens who engage in political deliberation, the freedom to express opinions, and the freedom to discuss matters of the state and to criticize the way state power is organized" (London, 1995, p. 42).

Habermas provided an historical and sociological description of European social institutions throughout the 17th and 18th centuries. He conveyed the importance of social institutions as mechanisms by which private individuals passed judgment on public acts. The English coffeehouses, the literary societies of Germany, and the salons of France are examples of such institutions, and they proved extremely egalitarian in the sense that "the

Table 1. Digital deliberation

Type of Deliberation	Characteristics
Dynamic digital deliberation (active)	• Digital town hall meeting • Digital policy forum • Online voting with deliberation
Static digital deliberation (passive)	• Online poll (instant results, presentation of previous polls) • Bulletin board for complaints • Bulletin board for recommendations

bourgeois met here with the socially prestigious but politically uninfluential nobles as 'common' human beings" (Habermas, 1989, p. 35). The salons, literary societies, and coffeehouses brought together diverse intellectuals, creating forums for ideas and opinions regarding the state of society.

Further, in accordance with his theory of communicative action, Habermas (1984) described the cultivation of a public discourse that falls outside of the associational matrices relevant to the state, market, and the bureaucracy. The institutions of deliberation (e.g., coffeehouses, literary societies, and salons) served to revive public opinion as a mechanism for shaping policy or influencing government in a meaningful and reasonable manner. The ideal public arena, in accordance with Habermas' writings, fosters inclusive and voluntary citizen participation within the context of influencing how government power is wielded. In such arenas, ICTs may emerge as mainstream conduits for policy deliberations, whereby elected officials, experts, and citizens can come together and voice their opinions.

Ideally, digital deliberation offers ignored groups a greater voice, thereby narrowing the democratic deficit (i.e., the participatory gap in public policy making). Having been applied in a number of cities throughout the United States and Europe (Tsagarousianou, Tambini, & Bryan, 1998), ICTs allow more citizens to participate in the policy discourse of deliberative governance, and they have the potential to reconnect citizens and decision makers, publicizing views presented by consultative parties and providing greater opportunities for citizens to influence public policy.

ICTs are emerging as more mainstream conduits for policy deliberations. A noteworthy example is Regulations.gov, which is "a one-stop Federal regulatory clearinghouse" that claims to facilitate citizen participation in Federal rule making and the American democratic process (http://www.regulations.gov/help.cfm). Citizens can view a description of proposed and final Federal regulations and read the full texts of the regulations. In addition, citizens can submit their comments to the Federal agencies responsible for the rule-making action through the Regulations.gov Web site.

Through the Regulations.gov Web site, citizens obtain descriptions or full text versions of proposed and final regulations for 75 agencies. Simplification and easy access are central components. According to Mark Forman, former Associate Director for Information Technology and E-Government for the Office of Management and Budget, "the guiding principles for achieving our e-government vision are also about simplifying the process and unifying operations to better serve citizen needs; that is, 'uncomplicating' government" (Forman, 2002, p. 2). Forman further stressed that accessing government information "should not take a citizen more than three 'clicks' of a mouse" (Forman, 2003, p. 2). In particular, through the Regulations.gov home page, citizens can identify regulations open for comment by performing a key word search or by selecting a Federal agency from the menu. For example, selecting "Internal Revenue Service" from the agency menu allows individuals to view proposed IRS regulatory changes (in either HTML or PDF format) that are open for public comment. Regulations.gov represents static digital deliberation, as there is no dialogical component.

Similar to Regulations.gov, the Virginia Regulatory Town Hall is a public space online that allows citizens and interested parties to obtain information regarding state regulations and proposed changes. It offers citizens a means of participating in the rule-making process. Presumably, the Town Hall helps the State of Virginia to manage the administrative rule-making process more efficiently and effectively. Information regarding proposed regulations and changes, agency background discussions, economic impact analyses of proposed regulations, and agency guidance documents, all help citizens interpret agency regulations. Those information services help encourage citizen participation in the rule-making process. Like Regulations.gov, the Virginia Regulatory Town Hall is static in nature.

The 21st Century Town Meeting exemplifies dynamic deliberation using ICTs. Developed by America Speaks, a nonprofit organization dedicated to enhancing citizen participation in the public policy process through the application of ICTs, the 21st Century Town Meeting is a digital democratic model designed to facilitate direct interactions between citizens and government. It affords all citizens a means by which they can impact the policy-making discourse. According to Lukensmeyer and Brigham (2002), "public hearings and typical town hall meetings are not a meaningful way for citizens to engage in governance and to have an impact on decision-making. They are speaker focused, with experts simply delivering information or responding to questions" (p. 351). In contrast, the 21st Century Town Meeting enables thousands of people to come together and voice their opinions through the use of networked computers, electronic keypads, and large video screens. Small group dialogues are a central component of the Meeting. Demographically diverse groups of 10 to 12 people are convened to discuss various issues. Each group is guided by a trained facilitator, who ensures that the dialogue is focused and that all participants are heard. Networked computers are used to record and transmit each group's viewpoints to a central computer. The data are coded into themes, and each individual (within his or her respective group) uses an electronic keypad to vote on each of the themes presented. The most visible application of the

Meeting, known as *Listening to the City*, dealt with rebuilding lower Manhattan following the World Trade Center attacks. In July, 2002, approximately 4,300 individuals from New York City and surrounding areas convened at the Jacobs Javits Center to participate in *Listening to the City*. The forum proved to be a dynamic and worthwhile experience, as a significant majority of participants (73%) expressed either a high or very high level of satisfaction with the process (Report of Proceedings, 2002).

FUTURE TRENDS

While ICTs have emerged as participatory mediums, are they conducive to deliberative democracy? The issues raised by this question are complex, abstract, and much more than matters of judgment. There are two broad viewpoints regarding the impact of ICTs on deliberative democracy. First, there are the technological optimists who believe that ICTs are easier and faster, and offer qualitatively better ways of existing, working, communicating, and participating in public life. According to Dahl (1989), "telecommunications can give every citizen the opportunity to place questions of their own on the public agenda and participate in discussions with experts, policy-makers and fellow citizens" (p. 339). Grossman (1995) further holds that the "big losers in the present-day reshuffling and resurgence of public influence are the traditional institutions that have served as the main intermediaries between government and its citizens: the political parties, labor unions, civic associations, even the commentators and correspondents in the mainstream press" (p. 15).

Cross (1998, pp. 139-143) discussed the relationship between ICTs and democracy, focusing on the following democratic norms: informing voters, representativeness, and participation. ICTs play an important role as a mechanism for disseminating government information to citizens (Charlton, Gittings, Leng, Little, & Neilson, 1997; Korac-Kakabadse & Korac-Kakabadse, 1999, p. 216; Langelier, 1996, pp. 38-45; Lips, 1997 recited in Ranerup, 1999, p. 179). McConaghy (1996) argued that publicizing information used in the development of government policies would allow citizens to be more fully involved in the democratic process. Further, in terms of representativeness, ICTs can alert policy makers as to the needs and preferences of the citizenry regarding potential policies. With respect to participation, McLean (1989, pp. 108-110) maintained that ICTs make direct participation possible because they overcome the problems of large, dispersed populations, while Arterton (1987, p. 189) argued that more citizens can participate because many of the burdens of participation are lowered, which increases equity in public decision making (Arterton, 1987, pp. 50-51; Barber, 1984).

The alternative view is less optimistic and is centered on the premise that bringing about change in institutions and behavior patterns is a slow and problematic process. According to Conte (1995, pp. 33-34), "It's so easy to imagine a scenario in which technology is used to get instant judgments from people. If it is used that way, we haven't seen anything yet when it comes to high-tech lynchings…. Real democracy is slow and deliberative." Unless carefully moderated, digital-based forums can become chaotic. Unmediated forums can potentially become abusive and unfocused. Politicians and other community leaders with whom citizens wish to interact are reluctant to participate in digital forums for fear of being "flamed," which refers to losing the luxury of "leading from behind." Then, there is the problem of dealing with the overload of undifferentiated and uncategorized information. In spite of the increasing amounts of information now available, its wide distribution, and the speed with which it is transferred, there is no evidence to suggest that the quality of decision making has improved or that decisions are more democratic given the integration of ICTs and digital-based applications. The current debate regarding the impact of ICTs on deliberative democracy provides the basis for future research opportunities.

CONCLUSION

Although citizen participation is central to a healthy democracy, our political system is characterized by declining voter turnout, decreased levels of civic participation, and cynicism toward political institutions and elected officials. Technological optimists are hopeful that ICTs will reverse those declines by facilitating direct interactions between citizens and government, providing a more effective means of participating within the policy-making process. Citizen participation via ICTs may foster an increased sense of public engagement as an egalitarian device that helps to engender a measure of societal collectivism necessary for a democratic system to thrive. Given the erosion of civic virtue and the proliferation of political apathy, online public spaces may serve to reenergize the body politic and reaffirm the importance of citizen participation.

Despite the potential benefits, the use of ICTs as participatory vehicles presents specific challenges, in particular, the digital divide. The digital divide is a challenge that democratic societies must address, and it refers to the divide between those with Web access and Web-related skills, and those without such capacities. Even though the online population is increasingly reflective of communities offline, the reality of a digital divide means that certain segments of the population are effectively excluded from online deliberation. This divide undermines the Internet as a mainstream and inclusive participatory medium, as it disproportionately impacts lower socioeconomic individuals who have historically played an insignificant role within the public policy process. For example, according to the Federal Reserve Bank of San Francisco, an Hispanic individual with a high school education and a family income less than $15,000 annually has only a 31% chance of using a computer at home, school, or within the workplace. This compares to a 94% chance for a white individual with a graduate education and a family income that exceeds $75,000 per year (FRBSF Economic Letter, 2003).

The issue of technological determinism complicates the digital divide. According to Warschauer (2003, p. 44), technological determinism holds that the "mere presence of technology leads to familiar and standard applications of that technology," which engenders social change. Consequently, significant capital has been spent providing computers and Internet access to those without such resources. And while on the surface this seems like a logical way of addressing the digital divide, inadequate attention has been paid to the "social contexts in which these technologies might be used" (Warschauer, 2003, p. 44).

Moreover, skeptics may argue that Internet-based applications will merely serve as another avenue of influence and control for the politically efficacious and the power elite. In spite of these criticisms and challenges, on balance, digital citizen participation represents a great potential for democratic renewal.

KEY TERMS

Deliberative Democracy: Refers to citizen participation in the context of cultivating a public discourse regarding governmental issues, policies, and courses of action.

Digital Deliberation: The process of thoughtful discussion regarding an issue or course of action through the use of ICTs. Digital deliberation in government is characterized by access to balanced information, an open agenda, time to consider issues expansively, freedom from manipulation or coercion, a rule-based framework for discussion, participation by an inclusive sample of citizens, broader and freer interaction between participants, and the recognition of differences between participants.

Digital Democracy: Encompasses the use of ICTs in the practice of democracy, whereby emphasis is placed on the processes and structures that define the relationships between government and citizens, between elected officials and appointed civil servants, and between the legislative and the executive branches of government.

Digital Divide: Refers to segments of the population lacking Internet access or Internet-related skills.

Dynamic Digital Deliberation: Includes applications that are two-way or dialogical, such as digital town hall meetings and digital policy forums.

Information and Communications Technologies (ICTs): These facilitate citizen participation in government. ICTs may include networked computer systems and Internet-based applications, such as policy or consultation forums, online voting with deliberation, bulletin boards, etc.

Static Digital Deliberation: Digital deliberation that is not dialogical in nature. It typically includes online polls offering instant results and bulletin boards for recommendations or complaints.

ICT–Supported Gaming for Competitive Intelligence

Jan Achterbergh
Radboud University of Nijmegen, The Netherlands

INTRODUCTION

Collecting and processing competitive intelligence for the purpose of strategy formulation are complex activities requiring deep insight in and models of the "organization in its environment." These insights and models need to be not only shared between CI (competitive intelligence) practitioners for the purpose of data direction, collection, analysis, and dissemination, but also between CI practitioners and strategy makers. Sharing these insights and models requires high-quality communication (both regarding content and process) between these parties. In this overview, we examine the potential of (ICT- [information communication technology] enabled) simulation games to improve the quality of communication between CI practitioners and strategy makers.

BACKGROUND

Organizations need to collect and process competitive intelligence about the environment to formulate their strategies. Moreover, the pressure to produce timely, accurate, actionable, and strategically relevant intelligence is growing because the complexity and dynamics of the environment is increasing rapidly (cf. Cook & Cook, 2000; Fuld, 1995; Kahaner, 1997).

CI processes produce this intelligence. Usually, these processes are broken up into four stages: direction, collection, analysis, and dissemination (Fuld & Company, 2002, Kahaner, 1997). In the direction stage, CI professionals establish what data are relevant for the purpose of strategic decision making. In the collection stage, relevant data sources are determined and data are collected from them. In the analysis stage, collected data are transformed into competitive intelligence that can be used by strategic decision makers. In the dissemination stage, the competitive intelligence resulting from analysis is disseminated over strategic decision makers so that they can incorporate it in the process of (re)formulating their strategies.

If CI is to deliver its contribution to the process of strategy formulation, a proactive mode of intelligence gathering seems most appropriate (Ellis, 1993; Hannon, 1997; Tessun, 1997). In this mode, intelligence practitioners try to anticipate environmental developments that may have a strategic impact and assess their consequences. Proactive intelligence requires, in our view, a deep insight into the organization in its environment. For instance, directing the search for information requires an insight into strategic problems the organization in focus has to cope with, and environmental factors having an impact on these problems. To direct the search for data, CI professionals need to construct models of these strategic problems and environmental factors. Analyzing collected information and transforming it into intelligence builds on these constructed models and requires an insight into possible effects of a multitude of states of affairs and events in the environment of the organization, on parties relevant to and the organization in focus itself.

Not only do CI practitioners need a model of the organization in its environment, it is also important that this model is shared among the different parties involved in the intelligence process. The model should be shared among CI professionals so that they have a common orientation toward performing their CI activities. Moreover, it should be shared among CI professionals and strategic decision makers for several reasons. Among these are (a) improving the understanding amongst CI professionals of strategic problems, (b) grounding the model in the strategic orientation of the organization, (c) facilitating the dissemination of the intelligence, (d) ensuring commitment of strategic decision makers to using the intelligence, and (e) improving the process of monitoring and maintaining the model itself.

Sharing the model among the relevant parties in the organization requires high-quality communication (both regarding content and process) between these parties. In this overview, we examine the potential of (ICT-enabled) simulation games to improve this communication process. As Geurts, Caluwé, and Stoppelenburg (2000) assert, simulation games may be a valuable tool contributing to improving the quality of the communication. Simulation games are organized procedures (involving all kinds of paraphernalia) allowing participants to improve communication about complex problems by providing a safe and controlled environment to experiment with different interventions under varying circumstances by means of models representing these complex problems. The element of simulation requires participants to interactively model the organization in its environment, systematically analyzing relevant variables, parties, processes, and their relations. The element of gaming allows participants to interactively experiment with the model in a relatively safe environment. Together, the simulation and the gaming elements can improve both the content and the process of communication required for proactive competitive intelligence. Although the use of games in supporting intelligence activities has been reported (e.g., Allgaier & Powell, 1998; Clark, 1998; Fuld, 1998), the link between simulation games and CI has not been treated thoroughly. In this overview, we examine this link.

To deliver its contribution to the intelligence process, simulation games may be supported by ICT in various ways (e.g., by groupware of various Web-based

Table 1. CI stages and required knowledge

	Description	Required knowledge
Directing	Determine strategic information requirements	Model of organization in its environment; how to use the model to derive required information
Collecting	Identify sources and retrieve data from them	How to select sources; how to approach sources
Analysis	Transform data into intelligence	Model of organization in its environment; how to use the model to assess the impact of specific constellations of environmental variables
Dissemination	Forward intelligence to strategic decision makers	Selection of what users get: what intelligence in what format

Table 2. Contribution of gaming and simulation to improving the quality of communication

		Increasing awareness and motivation	Training skills	Increasing knowledge and insight	Improving communication and cooperation	Integration of learning experiences
Building the simulation game	Model building Transforming model into game Scenario definition	Model building may increase awareness of the importance of knowledge and communication. Motivating to deal with the problem	Training in structuring complex problems in terms of simulations Training in making understandable complex models and making them transferable to other people	Increasing knowledge about the problem under consideration (What is the problem? Why is it a problem?) Increasing knowledge about relevant variables, parameters, events, and relations related to the problem	If participative methods for model building, transformation, and scenario definition are used, chances are created to improve communication and cooperation between parties dealing with the simulated problem.	Participative building allows for pooling knowledge and creating a shared language, improving discussions between parties dealing with the simulated problem.
Using the simulation game	Preparation Introduction Playing the simulation game Analysis and feedback	Awareness of differences between points of departure, differences between events, differences between lines of interventions and their effects Motivation providing a sense of control and security needed to deal with problems Focus is on habitualisation and tacit knowledge	Quickly picking up relevant aspects of a complex problem situation Operationally dealing with complex problems in different circumstances Dealing with unexpected events and interventions	Knowledge and insight in (constellations of related) variables causing certain effects given certain starting conditions, events, and interventions Focus is on analysis and explicit knowledge	Teams of players playing against or with each other need to cooperate, communicate, and get feedback on communication and cooperation and the results. Improvements can be monitored by playing the game more than once.	Shared understanding and awareness of the dynamics of the complex problem given different conditions, events, and interactions

applications). The role of ICT to enable simulation games is also discussed in this overview.

Linking Simulation Games to the CI Process

To explore the possible contribution of simulation games to improve communication in the different stages of the CI –process, we first need to explain what these stages entail and what knowledge is required in these stages. Second, we need to explain in what ways simulation games can improve communication. Given the knowledge requirements in the CI process and the possible contributions of simulation games to improving communication, it becomes possible to examine how communication in the different stages of the CI process can benefit from simulation games.

Tables 1 to 3 provide an answer to these questions. Table 1 provides an overview of the CI stages and of the knowledge required in them. Table 2 provides an overview of possible contributions of simulation games to improving communication. It lists the different functions simulation games can serve. Table 3 links the first two tables. It specifies how simulation games can enhance communication in the different stages of the CI process.

The two left columns of Table 1 present the stages of the CI process. In the right column, the knowledge required in these stages is presented.

Table 2 presents five different functions of simulation games (top row; see Geurts et al., 2000) and links them to the phases of building and using the simulation game (two left columns). In the rest of the table, the contributions of simulation games to enhancing communication are presented.

Table 3 links the knowledge requirements in the stages of the CI process (Table 1) to the possible contributions of building and using simulation games to enhance com-

Table 3. Gaming and simulation contributing to the acquisition of knowledge for the CI stages

	Directing	Collecting	Analysis	Dissemination
Building the simulation game	Participants develop a model of the organization in focus in its relevant environment in terms of parties, variables, and variables relevant for strategic decision making. Making this model can contribute to discussing and getting an awareness of environmental and organizational knowledge needed for strategic purposes, and thus enhances communication about the identification of relevant knowledge domains and data classes needed for directing purposes.	Participants identify possible sources for collecting information about the environment that can be used in the game. Identifying sources forces participants to discuss and evaluate their relevance and accessibility. Knowledge about relevance and accessibility of sources constitutes the core of the collection stage.	Participants model relations between the organization and environment .for gaming purposes. Developing the model enhances communication about variables relevant for strategic decision making and the interpretation of intelligence in terms of these variables in the analysis phase of the CI process.	Participants develop roles in the strategic decision-making process and rules for dissemination of intelligence to persons playing these roles. Developing roles and dissemination rules may focus participants on the importance and structure of different settings for disseminating environmental intelligence and their implications for the strategic decision-making process
Using the simulation-game	Participants identify and vary knowledge domains and data classes for making particular strategic decisions in different scenarios. Identifying knowledge domains and data classes and using them in the game can provide knowledge about the usefulness of these domains and classes in the strategic decision-making process and in varying scenarios.	Participants experiment with different sources of environmental data in different scenarios. Experimenting with these sources may enhance awareness of the usefulness of particular sources for particular problems in the strategic decision-making scenarios.	Participants experiment in different scenarios with giving meaning to environmental and organizational intelligence using the model developed in the building phase as a basis. Experimenting with the model in different scenarios may provide knowledge about the adequacy of the model for analysis purposes. Moreover, participants learn to use the model for analytic purposes in different contexts.	Participants vary who (which persons playing what role) has access to what intelligence in different scenarios. Varying access to intelligence may provide knowledge about the effectiveness and efficiency of different settings for the dissemination of intelligence and its use in the strategic decision-making process (in different scenarios).

Table 4. Examples of ICT applications supporting simulation games to arrive at knowledge for CI (the table builds on the contributions given in Table 3)

	Directing	Collecting	Analysis	Dissemination
Building the simulation-game	To build a model of the environment of the organization, forms of groupware may be used. To identify relevant (values of) variables and parameters, Decision Support Sytem (DSS) or system dynamics software may be used. ICT can also provide a virtual setting for gaming.	To identify possible sources for collecting information about the environment and to find relevant parameters, variables, and their values, ICT applications for monitoring the environment may be used (Internet, online databases, etc.).	Providing a model for analyzing information about the environment. The model used in the direction stage can be used for analysis purposes as well– (for ICT use, see "Directing").	Different forms of ICT may be part of the different settings for distributing environmental information and its use in strategic decisions (e.g., e-mail, electronic conferencing, dedicated software). The adequacy of the different forms may be tested during the game
Using the simulation game	To identify knowledge domains and data classes for making particular strategic decisions in different scenarios, participants may use groupware to support their communication and cooperation. DSS or System Dynamics (SD) software may be used to determine the effect of values of variables in order to direct the search activities. ICT can be used to generate information about autonomous events to the participants.	During the game, the participants may use specific software to monitor the game environment. Also during the game, ICT can be used to store the results about the usefulness of specific sources in different scenarios	ICT should be used to store knowledge about the adequacy of the model for analysis purposes in different scenarios. Groupware can be used to support the communication and cooperation during strategic discussions and the meaning of environmental information. DSS or SD software may be used to determine the effect of values of variables in order to make strategic decisions. Through ICT, common analysis tools can be made available (e.g., an automated Strengths, Weaknesses, Opportunities, and Threats (SWOT).	To store the knowledge about the adequacy of different settings for the distribution of the intelligence and its use (in different scenarios), ICT can be used

munication (Table 2). Table 3 specifies how simulation games can improve knowledge in the CI process for the purpose of strategic decision making.

Linking Gaming and Simulation to ICT

From Table 3, it follows that building and using simulation games can contribute to improving the quality of the content and the process of communication in the different stages of the CI process. Table 4 specifies how ICT may be used to support communication in these stages.

FUTURE TRENDS

As the process of globalization unfolds, the importance of sharing insight in the relations between the organization and parties about its relevant environment by means of high-quality communication between CI practitioners and strategy makers will probably increase. As the complexity and the intensity of these relations (that often include complex feedback mechanisms) increase, demands for model-building techniques and tools will increase as well. Two of the trends allowing for dealing with these increased demands are

- using CI-supported system dynamics instead of econometric models for the purpose of building complex feedback models flexibly handling different simulations and scenarios (Rouwette, 2003), and
- using group model-building for improving the quality of, commitment to, and communication between CI practitioners and strategy makers about the system dynamic models underpinning complex games (Vennix, 1996).

CONCLUSION

The purpose of this overview is to outline the relevance of simulation games for competitive intelligence and to examine the role of ICT to support simulation games for competitive intelligence. Simulation games can be a valuable tool for arriving at knowledge required in intelligence activities. Its main contribution is to build and test different scenarios regarding the impact of the environment on the organization. During building and testing these scenarios, awareness, knowledge, and insight may be gained about the underlying model of the organization in its environment and about the impact of different values of environmental parameters on relevant organizational variables.

Moreover, building and testing different scenarios may also enhance the communication and cooperation needed for intelligence activities. ICT can support delivering the contributions of simulation and games to competitive intelligence in various ways. In this overview, we discussed some possibilities to support the building and using stages, and to facilitate the dissemination and use of the knowledge resulting from the game to intelligence activities.

KEY TERMS

Analysis: The stage of the intelligence cycle in which the strategic significance of environmental data is determined. In this stage, the intelligence is produced. During analysis, intelligence professionals may use different models and techniques to interpret and value environmental data (e.g., SWOT analysis, growth-share matrix, or scenario analysis).

Collection: Stage of the intelligence cycle. In this stage, sources regarding the required environmental data are located and accessed, and the data are retrieved from them.

Competitive Intelligence: In the literature, two definitions are used: a product definition and a process definition. In the product definition, competitive intelligence is defined as information about the environment, relevant for strategic purposes. The process definition highlights producing and processing this environmental information. Process definitions often refer to the intelligence cycle.

Direction: Stage of the intelligence cycle. In the direction stage, one determines the strategic (external) information requirements; that is, one determines what environmental data should be collected.

Dissemination: Stage of the intelligence cycle. In this stage, the intelligence produced in the analysis stage is presented and forwarded to strategic decision makers.

Game Building: Stage in gaming and simulation. During the building stage, game constructors make a model of the problem they want to incorporate in the game. Next, they transform the model into a specific game, and, finally, they define different scenarios that can be played during the game.

Game Using: Stage in gaming and simulation. During the using stage, game facilitators make preparations for playing the game, and participants actually play the game (given a certain scenario).

Gaming and Simulation: The process of building and using simulation games as a means to deal with complex problems (see also "Simulation game").

Simulation Game: An organized procedure involving particular building blocks allowing participants to improve communication about complex problems by providing a safe and controlled environment to experiment with different interventions under varying circumstances by means of models representing these complex problems.

Impacts of Intranet on PDO

Khamis Al-Gharbi
Sultan Qaboos University, Oman

Abdulwahed Mohammed Khalfan
Public Authority for Applied Education & Training, Kuwait

INTRODUCTION

In developing countries such as Oman, the introduction of information technologies is very recent and their use and effect have not been systematically assessed or evaluated. Despite the importance of this subject to researchers and practitioners, the issue of evaluating and assessing the benefits of intranet is still an area that requires further and vigorous research (Blanning & King, 1998). The main aim of this chapter is to evaluate and assess the impact of intranet on one large Omani organisation. The findings are based on an in-depth case study looking at the evolution and the progress of the use of an intranet. The case study basically examines the impact that the use of an intranet has had to date and is likely to have in the next few years on one of the earliest organisations to adopt it in Oman. The impact model presented is a theoretical contribution that can guide other Omani organisations in benefiting from an intranet. Furthermore, the impact model prescribes the factors that need to be considered when implementing an intranet system.

DEVELOPING COUNTRIES CONTEXT

In developing countries such as Oman, the introduction of information technologies is very recent and traditionally, the preferred way of communication and knowledge conversation within a developing country organisational context is the face-to-face meeting. Furthermore, the organisational hierarchical structure is characterised by its rigidity and consequently, information flows from top to bottom (Al-Gharbi, 2001).

A number of studies have reported many obstacles prohibiting developing countries from benefiting from using Internet technologies that need to be considered, such as organisational culture, awareness, education, language, and social and psychological factors (Sharma, Wickramasinghe, & Kitchens, 2002).

The success of intranet will be closely linked to the potentialities of change in a culture to take full advantage of the technology. The culture that is intensively opposed to change, or is hostile toward or suspicious of outsider customers allowed directly to access, interact, and do business transactions with the company systems, must alter their ways and create a new culture in order to reap up the benefits and the rewards of intranet. The challenge of creating such a culture is not an easy job that can be left out to die (Al-Gharbi, 2001). However, management support, training, and organisational culture change are tools to minimise resistance and motivate employees to use the system, as we will see in the case of PDO (Petroleum Development of Oman).

PETROLEUM DEVELOPMENT OF OMAN

Petroleum Development of Oman is one of the largest companies in Oman, with more than 5,000 employees. The Omani government owns 60% of the company and the rest is divided between the Shell Petroleum Company Limited (34%), Total (4%), and the Partex Oman Corporation (2%). The daily oil production of PDO is 800,000 barrels, and the recoverable reserves amount to 5 billion barrels. The company adopted an intranet in early 1996 and currently has 4,500 intranet users.

RESEARCH METHODOLOGY

The qualitative approach is particularly suitable for studying phenomena in which little previous research has been conducted and it is not supported by a strong theoretical base (Benbasat, Goldstein, & Mead, 1987; Walsham, 1995). In addition, Walsham suggests that the case study is the preferred method in investigating the use of information technology in social context, and it can yield rich insight. Furthermore, McBride (1997) stated that to understand the evolution and the progress of information systems, it is far better served by a qualitative approach. The case study offers deep and rich insight, and understanding can be achieved rather than in using a quantitative approach.

In line of the above recommendations, a case-study approach based on frequent visits and face-to-face interviews has been used. The data were collected in two phases: first, through casual conversations and in-depth, informal, and unstructured interviews with PDO staff, which took around 2 weeks; second, through semistructured interviews. Interviews were conducted over a period of 6 months with key participants responsible for intranet adoption and development in the company.

MOTIVATIONS FOR THE INTRANET ADOPTION

One of the main hurdles facing PDO was how to effectively communicate and share information and knowledge with different individuals and groups inside and outside the country without increasing the costs. Thus, PDO has adopted an intranet in order to achieve the following goals: to improve communication and provide a means by which to help knowledgeable employees from different departments and locations to share information and knowledge; to share knowledge, resources, and expertise with the Shell group; to reduce costs; to eliminate duplication and redundancy of information; to enable cross-platform compatibility; and to improve business processes.

THE INTRANET IMPACT MODEL

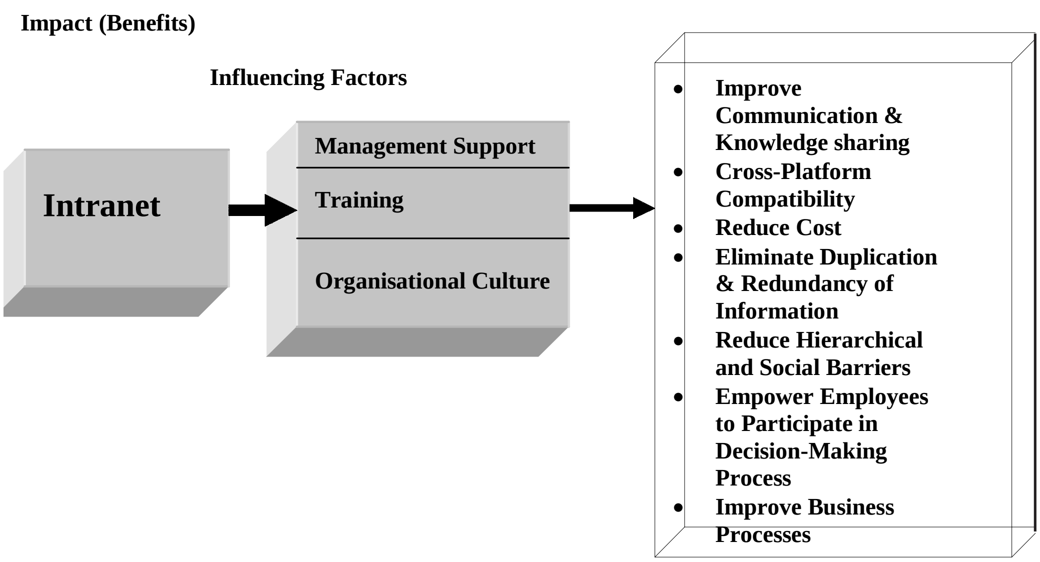
Most of the research on intranet adoption to date concentrates on organisations in the developed countries (Curry & Stancich, 2000; Davies, 2000; Hansen, Nohria, & Tierney, 1999). Among these articles, there is evidence to suggest that intranet has had an impact upon many business aspects and processes. For example, intranet improves access to updated information, improves communication, enables knowledge sharing and IT integration, flattens organisational hierarchies, reduces costs, improves decision making, empowers users, and facilitates organisational knowledge and learning. Furthermore, Callaghan (1998) states that intranets have broken down internal divisional barriers to communication.

The intranet impact model presented in Figure 1 shows that this technology has affected many processes and business aspects. In the following sections, each component of the impact model is discussed.

INTRANET IMPROVES COMMUNICATION AND KNOWLEDGE SHARING

PDO has 4,500 users who use its intranet to share, not only static information, but dynamic knowledge about engineering, oil exploration, and safety procedures. According to a senior manager, "The intranet enables our employees to know where to go to find what they need to know regardless of location and time barriers." The benefits can be accrued when one department is able to take advantage of the experience and understanding of another in the organisation. An organisation would have different entities of knowledge generated over the years by various groups and departments. These various and separate bodies of knowledge can be combined and shared

Figure 1. The intranet impact model



over the intranet and new knowledge can be born. "The intranet enables our employees to access and manage knowledge, and therefore enables them to respond to every situation with the sum total of everything anyone in the organisation has ever learned about situations of a similar nature."

One of the most used discussion groups is called "Speakers Corner," which is an open discussion about all matters concerning the company. Knowledge about oil exploration, engineering, safety rules, and regulations is discussed and shared. One senior manager commented, "Any employee can post anything on the Speakers Corner and this ensures democratic contribution and equal consideration of ideas. There is a big commitment from top management to make the Speakers Corner successful. Top management are participating in the Speakers Corner and providing answers for the issues discussed. Furthermore, top management are listening and benefiting from issues that are discussed via Speakers Corner to find solutions and feedback where it can be used to develop and improve services."

The idea is to make individual knowledge available to others. This concept is one of the most important principles in knowledge management. It is the main and the most important activity of the knowledge-creating company. According to Nonaka (1994), it should take place continuously and includes all levels of the organisation. Top management can take the opportunity and the potential presented by an intranet to communicate the company's mission, vision, and strategy directly and quickly, not only to the employees but also to business partners and customers.

The Speakers Corner is a knowledge- and information-sharing opportunity, which is open not only to PDO employees, but also to Shell personnel as well. Management felt that PDO is a learning organisation and that the intranet should be open to Shell users and vice versa to benefit the company.

One participant stated, "The intranet should be viewed as a learning opportunity for both companies. PDO can learn from the expertise of Shell Group about oil exploration, engineering, and safety procedures, and learn best practice by accessing to the Shell intranet." However, one must be careful and sensitive before importing other cultural approaches to solving local problems or needs without careful consideration for the usefulness of such an approach in a local context.

With top-management support and guidance, the intranet has enabled an appropriate new culture of openness to be accepted. The idea of openness to the outsider (Shell Group) is an important cultural transformation, which was difficult with previous technology. According to Davenport and Prusak (1998), the presence of knowledge-based technologies such as intranet can have a positive effect on organisational culture.

REDUCE HIERARCHICAL AND SOCIAL BARRIERS AND EMPOWER EMPLOYEES

The Speakers Corner became an opportunity to break organisational and social hierarchical barriers and to create knowledge by allowing employees to ask questions, provide (or propose) solutions, and transfer best practices, overcoming the barriers of distance and time.

The intranet helps open organisational boundaries, with many employees from different departments and hierarchical positions participating in the Speakers Corner discussing issues which, before the intranet, were limited to formal meetings that involved senior employees in the company in most cases. The intranet enables a wider audience to participate in the decision-making process and increase informal participation. Consequently, increasing individual autonomy is one important principle in knowledge management (Nonaka, 1994).

The diversity of participants can create an extremely unique opportunity where new ideas can emerge. The idea of wide participation is very important for organisational knowledge to grow, where individual knowledge can be consolidated with group knowledge through technology so that new ideas can be discussed, debated, and even discarded if necessary. In this way new knowledge could be born, which will have a higher possibility of survival and which can then be integrated into the organisation's knowledge (Inkpen, 1998).

The ability of Internet technologies in knowledge capturing and knowledge dissemination to a wider audience, which can transcend organisational boundaries (Earl, 1998), makes these technologies important tools for knowledge management. Indeed, these technologies facilitate knowledge building through the exchange of ideas, papers, hypotheses, data, messages, and even gossip (Earl).

The effect of the intranet on PDO employees is quite noticeable. IT empowers PDO employees to participate in the company strategy regardless of position and location. Before the intranet, information flowed vertically through the PDO hierarchical structure. The request for information had to flow up or down through the chain of command, which was usually rigid and took a long time. The intranet has changed this to a certain extent. Indeed, several empirical studies have reported the assertion that an intranet empowers employees to participate in the decision-making process (Callaghan, 1998; Scott, 1998).

REDUCING COST AND ELIMINATING DUPLICATION

Cost reduction has been achieved on paper printing, telephone directories, forms, policy and safety procedures, and inventory reports. With the intranet, one copy can be posted and any employee can access the document at anytime from anyplace. This helps to eliminate unnecessary duplication of information and costly, unwanted redundancy, while at the same time making it easy and quick to update.

The knowledge-management officer with PDO stated, "We have more than 4,000 different documents (document management, control documents, business records and reports, engineering and building drawings, etc.). These documents represent the company knowledge and information accumulated over the years. They contain vital business information, which now can be accessed by a wider audience. "About 60% of these documents today are on the intranet, which save the company a lot of money. Employees can easily search different topics contained in these documents by selecting a topic or a keyword."

"This is an important cost reduction for our organisation, but more importantly," comments a senior information advisor, "PDO is experiencing a huge cultural change moving from paper documents to almost all materials published on the intranet in a relatively short period of time. The company has achieved a 60% to 70% reduction of hard copy output so far."

The major benefit of intranet technology derives from its role as an online, on-demand information-dissemination tool. Using the intranet, the strategy of PDO has transformed from a calendar-based document-publishing strategy to one based on need. This transformation not only results in cost reduction of information dissemination, but also improves access to a wider audience with updated information.

IMPROVE BUSINESS PROCESSES

Human resources (HR) is one of the important departments using the intranet in PDO. The vision is to provide a quick and easy means of access to and awareness of HR information, activities, and services. PDO is exploiting information technology in order to achieve this goal. The human resources department has developed its own intranet called Infolink; the explicit strategy of Infolink is to "bring previously difficult-to-find information, policies, procedures, and forms directly to employees' computers," as one participant stated.

The designer of Infolink stated that the site promises that "human resources information can be accessed with just two clicks of the mouse." In isolating the company knowledge in one or two functional departments like IT or HR from those who need it, companies consequently risk losing its benefits (Gable, 1994). A better understanding of the interaction between different processes has allowed PDO to save time and money whilst providing better services to employees and customers.

The use of the intranet enables HR to eliminate many of the routine paper-processing tasks. According to a senior information advisor, the so-called "Smart Forms," which will be launched in a few months, "will be circulated in cyberspace, picking up signatures as they go and then, when they return, they are complete, automatically updating records." The Internet technologies have played an important role in changing business processes, which can save organisations and employees time and money.

Another important application of the human resources intranet is the SAPpHiRe online database, which, as part of Infolink, provides access to all PDO employees. SAPpHiRe enables "all the staff to access their own personal information." This self-access service provides the employee with all the information he or she needs. Furthermore, SAPpHiRe provides the employee with the ability to update specific information in his or her file (for example, address, telephone number, e-mail, etc.). SAPpHiRe also provides feedback to the company to enhance certain services and solve problems through the use of surveys. This facility enables the employee to give opinions and raise concerns. The results of the survey can be accessed by all employees through SAPpHiRe. Staff appraisal forms can be found on the intranet and the supervisor(s) can complete the form to evaluate the staff. The relevant staff member can, therefore, access the evaluation and give feedback on his or her performance.

CROSS-PLATFORM COMPATIBILITY

Exploration and production is another department that uses the intranet very heavily. Geologists and geophysicists are able to access and share information from different databases and different platforms (PCs [personal computers], Mainframes, and Macs) via the intranet. The intranet allows cross-platform compatibility, therefore it does not matter where knowledge resides. Tools such as browsers enable users to access and share information and knowledge from and between different platforms that have stored information and knowledge (Kim, 1998; Scott, 1998). Similarly, Davenport and Prusak (1998) stated that "Internet-based technology is ideal for publishing information across multiple types of computer platforms, for multimedia databases, and for displaying knowledge that is linked to other knowledge through hypertext links."

Geologists and geophysicists can easily access different topographical maps, which contain information about the oil fields in the country. Using the intranet, exploration, engineering, production, and economic solutions are easily provided and accessible.

PDO has adopted a holistic view, which consolidates the technology, human, and organisational factors required in using the intranet for knowledge management.

CONCLUSION

The case study has contributed to the literature concerning the impact of intranet by giving a detailed account of one Omani company's experience. The case study has demonstrated that the intranet empowers PDO employees to participate in the company strategy regardless of position and location, and it consequently has flattened the organisational hierarchy. Furthermore, PDO's 4,500 staff members are able to communicate with each other and share knowledge. On the other hand, the intranet has contributed to the elimination of internal divisional barriers. In addition, with top-management support and guidance, the intranet has enabled an appropriate new culture of openness to be accepted. The idea of openness to an outsider, the Shell Group, is an important cultural transformation, which was difficult with previous technology. This is an important cultural change in PDO's history. PDO and other Omani organisations can build on this experience to utilise the technology for future opportunities and collaboration at national and international levels.

The impact model shows that the intranet has affected many processes and business aspects. Furthermore, it shows the importance of top-management support to overcome the human and cultural barriers that stand against better utilisation of the intranet, as well as showing how to develop a culture of shared values that can be a benefit of the adoption of an intranet. Therefore, the model recommends the interaction of management support, training, and organisational culture to minimise resistance and motivate employees to use the system.

Tacit Knowledge: Knowledge that is difficult to express in words or communicate, and hard to articulate and share

Impediments for Knowledge Sharing in Professional Service Firms

Georg Disterer
University of Applied Sciences and Arts, Hanover, Germany

INTRODUCTION

Professional service firms (PSFs), where professionals (consultants, lawyers, accountants, tax advisors, etc.) work, are interested in knowledge management, because their businesses are heavily dependent on the knowledge of their employees. A core asset is their ability to solve complex problems through creative and innovative solutions, and the basis for this is their employees' knowledge. The "product" that PSFs offer their clients is knowledge (Kay, 2002; Ofek & Sarvary, 2001; Chait, 1999).

Sharing knowledge between colleagues improves the economical benefits a firm can realize from the knowledge of employees. This is especially true for PSFs (Huang, 1998; Quinn, Anderson, & Finkelstein, 1996), where broad ranges of knowledge must be kept to provide intellectual services, and real-life experiences with certain questions and situations are an important asset. The organizations and its members are spread over various offices across the country or the world. The necessity for sharing grows, because the network of professionals in most cases can offer significantly better professional advice than any individual. "We sell knowledge … the most valuable thing we can offer is the collective, institutional knowledge of our firm …" (Roger Siboni, KPMG executive, cit. in Alavi, 1997, p. 1). Working together openly without holding back or protecting vital pieces of knowledge will result in more productivity and innovation than could be reached individually.

BACKGROUND

No professional is denying the worth of using working documents and materials produced by others. All PSFs are trying to set up collections of knowledge acquired in projects in order to share it and conserve it for reuse. Knowledge databases can address what is sometimes called the traditional weakness of PSF: "… narrow specialists who see only their own solutions, self-centered egoists unwilling or unable to collaborate with colleagues" (Liedtka et al., 1997, p. 58). Many authors signal that sharing knowledge seems to be "unnatural" (Quinn, Anderson, & Finkelstein, 1996; Barua & Ravindran, 1996; Holloway, 2000).

However, attempts to use knowledge databases often fail. Only a few databases are accepted as up to date. The special fields of expertise are covered only in fragments. The access is laborious and uncomfortable. Heterogeneous sources (text, internal and external databases, journals, books, comments, codes of law, and so forth) cannot be integrated. The lack of actuality and completeness causes quality risks if dealt with thoughtlessly and if unreflected upon.

People issues are meant to be critical for successful knowledge sharing. According to Ruggles (1998), "In fact, if the people issues do not arise, the effort underway is probably not knowledge management. If technology solves the problem, yours was not a knowledge problem" (p. 88). Therefore, we analyze the reasons why knowledge sharing needs dedicated efforts and describe possible actions to foster knowledge sharing. Through our research (Disterer, 2000, 2001, 2002a) and analyses drawn from literature, we categorize and discuss the various impediments encountered by people sharing knowledge (see Figure1). There are some empirical results that confirm these impediments (APQC, 1996; Ruggles, 1998; KPMG, 2003; Govindarajan & Gupta, 2001). Then we show various approaches to overcome these impediments.

IMPEDIMENTS TO KNOWLEDGE SHARING

Loss of Power

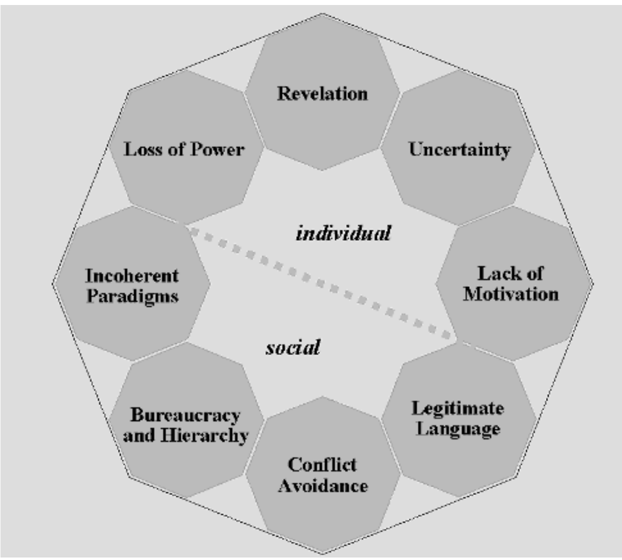
Knowledge can be used to take action and to enforce spheres of influence. Passing knowledge to colleagues might grant some of these potentials. Those who do not have this knowledge are deprived of the capacity to act or to influence. That applies for knowledge about customers, competitors, suppliers, procedures, recipes, methods, formulas, etc. In this sense, someone who passes on knowledge to a colleague loses the exclusiveness of his or her influence, which might have suggested some professional respect and job security. "Knowledge is power" is the well-known citation to describe situations in which experts with rare knowledge have the highest reputation, and monopolies of knowledge causes knowledge hoarding instead of knowledge sharing (Reimus, 1997; Andrews, 2001).

In industries like professional services, employees are competing directly with each other through their special knowledge, gifts, and talents. It might be part of the individual culture of high-performing employees that they voluntarily enter into the competition for scarce seats on their career paths because they like to compete and excel (Quinn, Anderson, & Finkelstein, 1996). But, the drawbacks of competition are obvious: Knowledge workers would be cautious to share their knowledge, because they could possibly give up an individual lead.

Revelation

Passing on knowledge to colleagues or entering working results into a knowledge database may be considered as a revelation, because it proclaims that this knowledge has a certain value and rarity. If this assessment is not shared by others, embarrassment may result (Rodwell & Humphries, 1998). Additionally, hasty colleagues rush to suggest "necessary" improvements to emphasize their expertise. For an individual, knowledge justified as "true belief" is not of particular concern. But in situations of knowledge sharing, more than one individual is involved. At this point, "… justification becomes public. Each individual is faced with the challenge of justifying his true beliefs in presence of other" (Krogh, 1998, p. 35).

Figure 1. Impediments to knowledge sharing



Uncertainty

Less experienced colleagues may feel uncertain, because they cannot judge if their working results and experiences represent valuable knowledge for others. They cannot estimate if their knowledge is too general or too well known or, on the other side, that some results are too specific for a special situation and therefore useless for colleagues in other situations. Positioning on the scale of "general" to "specific" is not trivial and, thus, results in uncertainty.

Lack of Motivation

Sharing knowledge is often seen as additional work because of the time necessary for reflection, documentation, communication, and so forth. Time is scarce, especially if the performance of an organization is measured by billable hours only. Reflection of work and sharing experiences are more an investment for future work than a billable action in the present. As stated in Dixon (2000), "In an organization with a bias for action, the time for reflection may be hard to come by" (p. 18; Hunter, Beaumont, & Lee, 2002).

Some employees do not expect reciprocal benefits from sharing, because they do not believe in these benefits or they did not experience it. Benefits of contributing to a knowledge database are gotten by a different stakeholder later on—the benefits will not be earned by the provider but by others (Nissen, Kamel, & Sengupta, 2000). Therefore, one precondition for contributing is the assumption of an equilibrium—a balanced give and take between colleagues. The insight that knowledge sharing can only be beneficial if everybody provides knowledge unselfishly may have charm only theoretically. In day-to-day practice, the benefit is too uncertain, and payback is not going to be immediate; therefore, the individual's commitment to share knowledge fails.

Legitimate Language

Some organizations lack a legitimate language (Krogh, 1998) that is known and accepted by all colleagues and can carry individual knowledge. This covers the need for a common language to communicate analogies and metaphors to externalize tacit knowledge hidden in individual mental models, viewpoints, working models, schemata, paradigms, and beliefs (Nelson & Cooprider, 1996; Nonaka, 1994; Haldin-Herrgard, 2000).

Conflict Avoidance

Attitudes of conflict avoidance and some conservative habits may prevent knowledge sharing, if the knowledge contains some new thoughts or innovative ideas. If most executives of an organization are not comfortable with change and are not willing to take risks, new ideas may be covered up easily. Different views and perspectives would be hidden, and knowledge not culturally legitimated may be suppressed ("do not rock the boat" attitude).

Bureaucracy and Hierarchy

Bureaucratic and hierarchical organizations show formal and administrative procedures that prevent the sharing of knowledge and new ideas. Strong hierarchical organizations prevent cross-functional communication, cooperation, and knowledge sharing.

Incoherent Paradigms

A lack of alignment between the personal intents of the individuals and the paradigms of the organization (strategic intent, vision, mission, strategies, values, etc.) can cause difficulties in articulating and justifying personal beliefs that do not fit with the ruling paradigms of the firm (Krogh, 1998).

ACTIONS TO FOSTER KNOWLEDGE SHARING

There is no complete methodology and no set of procedures and policies to address systematically all of the above impediments to knowledge sharing. Various approaches should be discussed further. Some of them sound like common sense but need to be emphasized because of their importance.

Concern and Trust

A precondition for knowledge sharing within organizations is an attitude of concern and trust among members of the organizations. Krogh (1998) called this "care" and defined it as serious attention, a feeling of concern and interest within an organization. His concept includes phenomena like trust among the people, interest in different viewpoints and experiences, access to help, lenience in judgment, courage to voice opinions, courage to allow experiments, and courage to take risks.

Organizations have to strive for a culture of accepting mistakes (Soliman & Spooner, 2000). They should not penalize errors to foster a climate of constructive conflicts, giving members the chance to "fall forward." Organizational development processes should build and establish a common set of ethical standards and values for an organization and should achieve a consensus of accepted working practices and habits.

Leadership

Knowledge sharing is based on the consistent, reliable, and plausible behavior of management. Members of management must positively communicate that they are thoroughly convinced that knowledge needs to be "nurtured, supported, enhanced, and cared for" (Nonaka & Konno, 1998, p. 53) and that they financially support knowledge management initiatives. Management must afford time for communication and reflection. There must be organizational slack that permits time for employees to network (Krogh, 1998; Wiig, 1997).

To openly share knowledge, mutual trust is necessary among all organization members. Trust results in common expectations of reliability, consistency, and plausibility. Trust reduces the fear that others will act opportunistically. Likewise, management must act as examples for knowledge sharing. They have to walk-the-talk and give up knowledge hoarding first. Members of a profession or a community accept standards of behavior and working habits from their peers (Quinn, Anderson, & Finkelstein, 1996); therefore, management must act as peers to be an example in knowledge sharing (McDermott & O'Dell, 2001).

Rewards and Incentives

Special rewards and incentive methods can act as extrinsic motivation for employees willing to share knowledge. Organizations are successful with the provision of personal recognition and reputation when people have contributed to knowledge databases or actively participated in knowledge sharing (Hunter, Beaumont, & Lee, 2002).

Some examples for direct rewards and how to provide chances to build reputation and fame include the following: Texas Instruments created an annual award named "Not Invented Here, But I Did It Anyway Award" (Dixon, 2000, p. 57) to reward usage of other employees' knowledge. Buckman Labs rewards the top 150 "knowledge sharers" (judged by knowledge managers) with a laptop and an incentive trip to a resort (Davenport, Long, & Beers, 1998). AMS honors contributors to the knowledge center with a bronze plaque at the headquarters and regularly publishes a top 10 list of most frequently used contributions (King, 1998). Forum, a consultancy in Boston, Massachusetts, holds a "World Cup Capture" to encourage its consultants to make explicit and sharable what they have learned from their latest engagements (Botkin, 1999). An Australian law firm honors individuals who contributed the most by having a star named after them (Robertson, 1999).

Contrary to this, there might be professions with different views: "A major concern of software engineers is the fear of being known as an expert" (Desouza, 2003,

p. 100). They fear being staffed to projects based on their past experience instead of being allocated more challenging tasks with room for learning. In this situation, the brand-like identity of a software engineer works to his or her disadvantage and builds a barrier to individual professional development.

Many organizations incorporate issues of knowledge sharing into their compensation plans and promotion policies. The big consulting and accounting firms commonly base their personal evaluations partly on how many contributions are made to knowledge databases, how many new employees people have tutored, and how many training courses have been designed (Quinn, Anderson, & Finkelstein, 1996; Whiting, 1999).

Tutoring and Mentoring

Administrative actions may define responsibilities for tutoring and mentoring in an organization. Ongoing programs that systematically develop employees can foster common habits and attitudes and can support communication among the members of the organization.

Project Experiences

At the end of bigger projects and transactions, time and effort for explicitly debriefing should be provided to learn systematically by experiences. The lessons learned could be systematically analyzed and stored for access by other employees. In other actions, it can help to use knowledge and experiences gained in projects (Disterer, 2002b).

Communities of Practice

A popular approach for fostering knowledge sharing is to develop communities of practice. These groups of professionals enhance the ability of its members to think together, to stay in touch with each other, and to share ideas with each other. These informal networks, sometimes also called knowledge fairs or clubs, competence centers, or creativity centers, consist of groups of professionals, informally bound to one another through a common class of interests and problems and a common pursuit of solutions. People who are exposed to a common class of interests and problems often develop a common language with which to communicate and develop a sense of mutual obligation to help each other (Manville & Foote, 1996; McDermott, 1999). These phenomena can be used to overcome some of the individual and social barriers to knowledge sharing within communities of practice.

Focus on Codification or Personalization

In PSFs, the knowledge of experts is a core asset, and therefore, careful management of this asset is important. Management is responsible for ensuring that the organization is as independent as possible from individuals. At the same time, these companies are operating in a "people business," where the personal and individual link between clients and professionals is critical (Morris & Empson, 1998). This special situation requires special approaches to manage knowledge. Quite popular are two approaches that consulting firms apply that address cultural issues differently (Hansen, Nohria, & Tierney, 1999).

One strategy ("codification") centers on information technology (IT): The knowledge is carefully codified and stored in knowledge databases and can be accessed and used by others. With the other strategy ("personalization"), knowledge is tied to the person who developed it and is shared mainly through direct person-to-person contact (Hansen, Nohria, & Tierney, 1999). With a codification strategy, knowledge is extracted from the person who developed it, is made independent from the individual, and is stored in the form of interview guides, work schedules, checklists, etc. Knowledge is then searched and retrieved and used by other employees. Personalization focuses on dialogue between individuals; knowledge is shared primarily in personal meetings and in one-on-one conversations.

Individual barriers are significantly lower with a personalization strategy, because professionals keep control through the whole knowledge management cycle. The individual is recognized as an expert and is cared for. In fact, focusing on personalization could be called a communication strategy, because the main objective is to foster personal communication between people. Core IT systems are yellow pages (directories of experts, who-knows-what systems, people finder) that show people with whom they should discuss special topics or problems.

Organizational Design

Some organizational designs can foster intraorganizational collaboration. Partnerships and other forms of ownership by employees can be utilized to produce involvement and commitment (Hildebrand, 1994; Miles et al., 1998). Moreover, these organizational forms address the hesitation of professionals with specialized knowledge to work within strong hierarchies and in working environments with strong regulations (Quinn, Anderson, & Finkelstein, 1996).

Office Design and Construction

To lower the disadvantages of bureaucracy and formal communications, modern office layouts reduce the distance between colleagues to foster ad hoc, informal, and face-to-face communication.

FUTURE TRENDS

Further research will be necessary to understand barriers to knowledge sharing, because cultural barriers are dominant over technical problems while implementing knowledge management initiatives. Today, appropriate reward and incentive systems and well-established communities of practice are the most promising ways to overcome the barriers.

CONCLUSION

Ways to support knowledge management with IT are manifold, but certain cultural aspects of knowledge sharing must be addressed. We describe some possible actions to overcome typical resistance often articulated with phrases like "this is client confidential," "only I know how to use it," "what is in it for me?," and "I have no time for documentation." The descriptions of the impediments and the possible actions make clear that knowledge management could not be seen as a technical field, as it is deeply social in nature.

KEY TERMS

Community of Practice: A community of practice is a group of people in an organization who are (somehow) held together by common interest in their work topic, purpose, and activities.

Culture: Covers the pattern of basic assumptions accepted and used about behaviors, norms, and values within an organization.

Knowledge Management: The systematic, explicit, and deliberate approach to creating, sharing, and using knowledge in order to enhance organizational performance.

Knowledge Sharing: The processes of transforming and transferring knowledge through an organization are designated by knowledge sharing.

Implementation Management of an E-Commerce-Enabled Enterprise Information System

Joseph Sarkis
Clark University, USA

R.P. Sundarraj
University of Waterloo, USA

INTRODUCTION

The integration of enterprise systems and the supply chain to an organization is becoming more critical in an ever-changing, globally competitive environment. Quick response will require close relationships, especially communications and information sharing among integrated internal functional groups as well as the suppliers and customers of an organization. Texas Instruments (TI), headquartered in Dallas, Texas, has come to realize this requirement for building and maintaining its competitive edge. Thus, it sought to implement an enterprise resource planning (ERP) system with a focus on linking it with a global electronic commerce (e-commerce) setting, an innovative and current issue (Weston, 2003).

There were a number of major players, including project management direction from Andersen Consulting Services, software vendors such as SAP and i2 Technologies, hardware vendors such as Sun Microsystems, and various suppliers and customers of TI.

The purpose of this case is to provide some aspects of implementation of strategic systems that provide valuable lessons for success. We begin and rely on the foundation of a strategic systems implementation model, which is initially described. A description of the case follows, with the various stages as related to strategic systems implementation described. We complete our discussion with implications and conclusions.

BACKGROUND

A process-oriented framework for ERP management is presented to help guide the discussion of this case (see Cliffe, 1998; Davenport, 1999; Miranda, 2002; Sarkis & Sundarraj, 2000).

The elements include the following:

- Strategy formulation and integration—One of the results of this step in the process is determination of an organization's core competencies that need specific technology support.
- Process planning and systems design—Also known as the reengineering phase, three studies are usually undertaken at this stage, and they are named AS-IS, SHOULD-BE, and TO-BE.
- System evaluation and justification—Here, analysis focuses on the economic, technical, and operational feasibility and justification of the system.
- System configuration—As a packaged software system, there are likely to be discrepancies (at the detailed level) between the needs of an organization and the features of the software. Hence, a significant amount of effort can be expected to configure the system or the organizational processes in order to produce an alignment between them.
- System implementation—The implementation stage can be classified into startup, project management, and a migration handing the switch over from the old to the new system.
- Postimplementation audit—This last "feedback" stage, although very important from a continuous-improvement perspective, is one of the more neglected steps.

As can be seen, the process suggested above can be arduous, but this necessary effort must be anticipated for the successful integration of complex and strategic systems into an organization.

IMPLEMENTING A GLOBAL ERP SYSTEM AT TI

Company Background

Texas Instruments Incorporated (TI) is a global semiconductor company and the world's leading designer and supplier of digital signal processing (DSP) solutions and analog technologies (semiconductors represent 84% of TI's revenue base). The company has manufacturing or sales operations in more than 25 countries and, in 1999, derived in excess of 67% of its revenues from sales to locations outside the United States. Prior to the implementation of ERP, TI had a complex suite of stand-alone nonintegrated marketing, sales, logistics, and planning systems consisting of thousands of programs that were based on many independent databases and were running on proprietary mainframe systems.

OVERVIEW

Since the 1980s, TI had used a highly centralized infrastructure utilizing proprietary mainframe computers for meeting its IT requirement. As the first step toward global business processes, certain planning processes and systems were standardized in 1989. Starting in 1996, TI underwent a company-wide reengineering effort that led to the implementation of a 4-year, $250 million ERP system using Sun Microsystems' hardware platform, SAP AG's ERP software, i2's advanced planning tools, and Andersen Consulting's implementation process. In 1998, Texas Instruments implemented the first release of the ERP system, which primarily consisted of a prototype implementation of the i2 system running on a Sun E10000 platform. In early 1999, TI began rolling out the second release. In the middle of 1999, TI completed the i2 Technologies software implementation as part of the third release. Finally, TI turned on the remaining financials, and new field sales, sales, and distribution modules. A high-level architecture of TI's pioneering ERP implementation consists of SAP and the i2 system for advanced planning and optimization. The system is a pioneering large-scale global single-instance implementation of seven modules (finance, procurement and materials management, logistics, planning, field sales, sales, and marketing) for all of TI's divisions, and it is in use by 10,000 TI employees to handle 45,000 semiconductor devices and 120,000 orders per month. This solution also enabled global Web access to information for TI's 3,000 external users at customer, distributor, and supplier sites.

STAGES IN MANAGING THE GLOBAL ERP SYSTEM IMPLEMENTATION

Strategy Formulation

Traditionally, TI was primarily running what was called a "commodity" business, wherein orders were received, manufactured, and shipped as a batch. Mass customization combined with the maturity of TI's business caused it to reexamine its goals and strategies. TI started its shift toward a more customized product environment.

Within this new customized product environment, TI had a number of customer needs that could not be met easily. Thus, the goal was to determine the appropriate processes and information systems that must be put in place in order to support such agile design and manufacturing strategies. Another goal was a move toward supplier-managed inventory and customer-managed orders. Finally, standardizing systems was another integrative corporate goal. TI made extensive use of metrics. Strategic goals are translated into tactical and operational quantifiable objectives.

Process Planning and Systems Design

TI conducted a massive reengineering effort for the whole organization, with the goal of setting standard processes globally. The major result of this effort was to declare that all inventory and manufacturing management be done globally.

TI decided to implement a single-instance ERP system so as to fully leverage the system's capabilities to support the flexibility and standardization demanded by global processes. After site visits by major ERP vendors, TI selected SAP mostly because of its scalability to handle voluminous amounts of data.

System Justification

A budget of approximately $250 million was set for the implementation. The justification of the system was done using a combination of tangible and intangible factors at both the enterprise and business-unit levels. Standard hard-justification measures such as ROI and IRR were used to ensure the financial viability of the project.

Through this business case justification, acceptable financial returns, along with strategic factors such as competing effectively within a given niche market, and operational factors, such as global inventory management, all played roles in ERP's justification at TI.

System Configuration

The goals and processes entailed numerous and significant changes to all aspects of the business process design of the system.

Implementation

In this phase, concepts and goals were translated into tangible action, and as a result, it is perhaps one of most difficult phases of the project. General principles such as global processes and standard systems need to be backed up by convincing and deploying the right people to implement the processes.

Startup

A number of key personnel, along with their families, were expatriated to the United States and stationed in Dallas, Texas, for a few years. About 250 people were transitioned from TI to Andersen Consulting that became the main provisioner of services with respect to the ERP system. IT outsourcing in this case involved Andersen Consulting taking over the employment and management of former TI people.

Project Management

Change management played a large role in this stage. The roles of training, planning, and communicating were of equal importance. All management levels were involved in this process as well as various vendors and suppliers. Some of the practices included the following:

- On-site experts were made available to new users of the system.
- A help desk was set up to handle problems that could not be addressed by these experts.
- A ticketing system for managing and prioritizing problems was also established (e.g., a system stop was a high-priority ticket that would get round-the-clock attention).

Handling Go-Live

To get prepared for "go-live," the key managers who were stationed in Dallas were sent back to their territories for educating the next level of users. Using selected experts, user-acceptance scripts were defined and tested, with problems, if any, being resolved as per one of the schemes outlined above. Daily conference calls were set up for 30 days prior to go-live to obtain status checks on progress and on the tickets.

Based on the results of these checks, a risk analysis was conducted weekly to determine the effects of various potential failures. The implementation plan was to have a few go-live dates one after another, but in relatively quick succession. Except for the planning system, in all the other stages, in this case, a direct conversion was employed. That is, with a downtime of about 2 to 3 hours during a weekend, the old system was turned off and the new one turned on.

Postimplementation Status

The system met most of its goals 9 months after the complete implementation. There are around 13,000 users on the system, with concurrent users ranging from 300 to 1,700. Some of the key performance measures and parameters evaluated were as follows:

- Productivity dip
- Ontime delivery
- Single-instance, global system
- Better response
- Inventory reduction

FUTURE TRENDS—MANAGERIAL IMPLICATIONS

The following lessons are summarized:

- Conduct a thorough strategic plan—The case illustrated how market forces had compelled the company to make radical shifts in its organizational environment and culture.
- Align IT plans with business plans—Conduct reengineering studies and develop strategic IT plans to align key IT needs with those of the business (Barker & Frolick, 2003).
- Get top management support—The prescription of top management support has been made ever since early IT implementations to the present (Mabert et al., 2001).
- Change management—Set realistic user expectations, such as the initial productivity dips. User involvement is critical. Andersen Consulting's process helped to ensure that such was the case. Make sure that the user was supported to help improve user satisfaction (Lee et al., 2003; Legare, 2002).
- Strong champion characteristics (Dean, 1987)—In TI's situation, the manager of the ERP project had over two decades of experience in various levels of the organization. This manager had broad knowledge of corporate operations. Previously, he was a vice president of one of TI's divisions.
- Rationalize business models and processes—Make sure the business models and processes fit within the strategic direction and goals of the organization. Time, mass customization, and flexibility concerns led to a global model (Gardiner et al., 2002). Global cultural issues were also a concern and needed to be managed (Davison, 2002).

- Manage external enterprises—Appropriate and well-planned involvement of consultants is important for keeping the project on a tight schedule. Further, with the advent of e-commerce, companies are more likely to ship and order goods on the basis of Web-based inputs.
- Manage using metrics (Skok et al., 2001; Hitt et al., 2002)—TI and Andersen Consulting have a corporate culture and policy that require the stringent and formal use of metrics in the management and evaluation of projects. They attribute this policy adherence as one of the key reasons for success of the ERP implementation. Key performance indicators included such issues as reduction in inventory, percentage of suppliers linked, and productivity of outputs.

CONCLUSION

TI's ERP implementation with an e-commerce perspective required a significant amount of features that added issues to its management:

- It is a single-instance system, providing access to the same data, irrespective of the geographic location of the user.
- It provides access to 3,000 external users (customers and suppliers), thereby enabling 70% of the transactions to be conducted electronically.

Management saw some problems in this implementation process and tried to address the issues. Some of the major problems included the following:

1. The software for supply chain management (Red Pepper) that was initially chosen did not meet expectations of TI. This system had to be scrapped, and this resulted in a multimillion dollar cost.
2. A productivity dip occurred, and the implementation had to address this issue for all managers throughout the organization who had some stake in the performance of the system. The expectations that this would occur were communicated through newsletters and messages. Consistent and continuous communication helped to mitigate a situation that could have caused a major project failure.
3. Getting buy-in from internal functions not directly associated with the implementation process was difficult. This occurred with the marketing function.

Future extension of developing appropriate infrastructure is another issue that needs to be faced (Kovacs & Paganelli, 2003). Lessons learned here may be appropriate for small or large organizations, but some differences appear in the practices of what is successful and not for ERP implementations in different size organizations. One of the major issues is that small companies get greater operational benefits from ERP, while larger companies get more financial benefits (Mabert et al., 2003).

KEY TERMS

Audit: Reviewing and monitoring the performance of a system.

Enterprise Resource Planning (ERP) System: An information system that spans organizational boundaries with various organizational functional modules and systems integrated and managed by one system application.

Go-Live: The actual operation of an information system.

Mass Customization: Producing basically standardized goods but incorporating some degree of differentiation and customization.

Reengineering: Activities that seek to radically change business processes and support systems in an organization.

Single Instance: A one-time full-fledged company-wide initial operation of a system, as opposed to incremental (functionally or organizationally) or modular implementations.

Strategic Justification: The process of evaluating and selecting systems based on tangible (financial) and intangible factors that have implications for long-term and broad management of the organization.

Implementing an Online Academic Evaluation System

William S. Lightfoot
International University of Monaco, Monaco

INTRODUCTION

The explosive growth of networks and the World Wide Web over the past decade has led to increased adoption of new applications by educational institutions. Critical uses of software including courseware such as Blackboard, WebCT, and others have led to an increase in computer literacy amongst faculty and staff. Consistent with this increased literacy, newer applications including the use of the web for tests, surveys, and student evaluation has been increasing. There are many benefits of using web-based surveying and online evaluation techniques (see Table 1). As Mehta and Sivadas (1995) have noted, response times can be reduced from days and weeks to minutes and hours. It is common practice in many universities to have students provide feedback about courses in the form of a questionnaire, at the end of each course. As Felton, Stinson, and Mitchell (2003, p. 2) note, "these surveys are assumed to measure a professor's performance and successfulness in his or her various classes." McGourty, Scoles, and Thorpe (2002, p. 5) cited one of the key benefits as the "immediate availability of data for analysis and reporting and more extensive qualitative responses from students to the open-ended questions." Other studies (see Handwerk, Carson, & Blackwell, 2000; Hmieleski & Champagne, 2000) had similar conclusions. And although not all e-mail users check their e-mail everyday (Kent & Lee, 1999), past research found that e-mail responses generally occurred within the first three days (Comley, 1997; Mehta & Sivadas, 1995).

Strauss (1996) cited an additional benefit to web-based surveying in that the researcher can create surveys that are adaptive – meaning the software can present different questions, as well as audio, video, and pictures based on the users' responses and reactions to questions.

Table 1. Benefits of online educational evaluation systems

- Speed
- Time
- Accuracy
- Adaptability
- Anonymity
- Data Collection
- Data Evaluation
- Reach
- Ability to personalize

Other benefits include the ability for real time interactions with geographically diverse consumer or respondent groups as well as information servers (Kannan, Chang & Whinston, 2000). Results can be tabulated immediately, and interventions can take place to modify questionnaires, add new links, stop the project altogether. Hmieleski and Champagne (2000) suggested that online evaluation systems would enable faculty to adjust courses more frequently, leading to a better overall educational experience for students. Kannan et al. (2000) noted the value of increased bandwidth and the ability to transmit video and audio enables real-time feedback from respondents that can help research firms produce customized services more rapidly and at much lower cost than traditional research projects. Hardwerk, Carson, and Blackwell, (2000) cited the advantage that students could complete the evaluation on their own time, which the authors found led to more comprehensive, qualitative comments by the students.

The process for implementing an online evaluation system has characteristics that are similar to paper-based evaluation systems. Numerous authors have noted that many of the same factors may help increase response rate including advance notification, and personalization of correspondence (Dillman, 2000; Mehta & Sivadas, 1995; Witt & Poytner, 1997). Other variables, including credentials, the e-mail message, subject line, and saliency may also affect response rate. All of these need to be considered when developing an online evaluation system. Additional factors, including the time allocated for completion of the evaluation may also be important. McGorty et al. (2000) noted that at Drexel University, students were given three weeks to complete the evaluation, and that they are sent reminders via email from the system administrator, then the department head, and finally the undergraduate associate dean until they have completed the evaluation. In the same article, the authors noted that Columbia University used a similar approach, over a two-week response window. Online evaluation systems also have a number of potential problems, including "student concerns for privacy and anonymity, the culture to support online student evaluation processes, and insuring that students are aware of the evaluation process." (McGorty et al., 2000, p. 7). McGorty at al. added that initial response rates at Drexel were "dismal" (p. 8) and that after the use of "a combination of technology-mediated communications, incentive packages, and internal marketing strategies," they were still only able to increase the response rate to 50%. They also found that women, and students in their final years were more likely to complete the web-based evaluation than men, or students in their first couple of years of school. Hmieleski and Champagne (2000) added another dimension in noting that faculty buy-in for any evaluation system is critical to student response rate.

This paper examines the implementation of an online evaluation system at a small college in North Carolina. The online surveys used were adapted from paper-based instruments. Therefore the focus of this paper is on the implementation of the system from a technical and organizational perspective. And while the initial impetus was to convert paper-based student evaluations over to an online evaluation system, as the process of implementation moved forward, other applications were identified that were also suitable for an online educational evaluation system.

BACKGROUND ON THE PROJECT

With the rapid evolution of software, many options exist which allow a wide range of users to develop surveys, tests, and evaluation tools without any programming knowledge. Solutions range from open source software available on the web, to web site design tools like Macromedia Dreamweaver and Microsoft FrontPage, to embedded collaborative and communication systems in Microsoft's .net operating system (Sharepoint) and courseware applications (see Blackboard, and WebCT), and finally, to hosted solutions which allow users to create a wide range of tailor made instruments, or to choose a pre-made template designed for specific solutions. (*see Empliant.com or Zoomerang.com*)

ACADEMIC USES OF ONLINE EVALUATION TECHNIQUES

In academia, there are many needs for internal and external assessment of the overall state of the institution and its programs (Table 2). Career services is interested in gathering data on the success of their graduates, as well as information from employers about their needs from the institution; alumni affairs is interested in maintaining a current database of information about alumni; curriculum review committees seek input from alumni, employers, and students alike to help refresh and renew courses, and curricula; the enrollment management and admissions team may use surveys to gather data from prospective students, and their parents; individual departments within the college may also use the tools for specific, departmental assessment and data gathering purposes. Online, blended, and traditional classes may also use surveys for student evaluations of faculty, faculty evaluation of students (i.e. quizzes, tests, and exams), or for other purposes including market research.

Table 2. Academic uses of online survey instruments

- Student evaluation of faculty
- Faculty assessment of student performance (i.e. quizzes, tests, exams)
- Career progress of alumni
- Alumni updates
- Curriculum review
- Market research
- Program assessment

Many colleges struggle to implement any new information system. Finally, government education departments, accrediting bodies, and other stakeholders involved in the institution may require frequent feedback on the overall success of the institution. The biggest challenge lies in the implementation of a system that is easy to use, reliable, and produces the desired results.

The use of computers in research and assessment is well established. The use of online survey and evaluation systems, while frequently used, is still evolving consistent with the rapid changes in technology (Dillman, 2000). Regardless of the method used, there are some common steps that are critical to the proper implementation of any evaluation system:

1. The establishment of goals for the system. This helps insure that the results from the instruments are relevant and useful.
2. Determine the target population(s) and sample size(s) needed for useful results. To ensure external validity, the sample must be representative of the population from which it is drawn.
3. Choose the appropriate methodology to gather the data.

Failure to follow these steps may result in error or provide misleading and useless information.

Table 3. Comparison of response rates

Delivery Method	Sample Size	Response Rate
Online Evaluation	157	73%
In Class Evaluations	2443	86%

AN EXAMPLE: IMPLEMENTATION OF A ONLINE EVALUATION SYSTEM AT A COLLEGE

The first step in implementing an online evaluation system at the college was a challenge from the President to increase the use of technology across all departments. In parallel with this, the President increased funding for information technology initiating a port to pillow campaign for students, which was funded by the Parents Association. Funds were also raised for the complete renovation of computer facilities, and the upgrading of all personal computers (PCs) on campus. This happened within a 6-month time frame.

The second step was the creation of a Faculty Technology Committee that was initially charged with assessing the level of technology use by the Faculty. The committee then developed a web-based survey on the use of technology by faculty using a hosted survey from application service provider (ASP) Zoomerang.com, both to initiate the use of technology with faculty, and to assess their relative level of literacy with specific applications.

This led to two things: first, more faculty became interested in the use of the web for evaluations; and second, the committee identified specific areas of training needed amongst the faculty. A twelve month plan was initiated that included a combination of formal sessions on topics ranging from Microsoft Office applications, to the use of the web in the classroom, to less formal, personal coaching sessions between designated faculty members and their colleagues.

The interest in the use of online evaluations then accelerated greatly, as more and more faculty and staff members became familiar with its potential. This led to several pilot projects during the following academic year. The first involved piloting student evaluations of faculty. Three faculty members from the same academic division agreed to participate in this initial survey. The survey was developed using Microsoft FrontPage 2000 (FrontPage). The purpose of using FrontPage was initially due to limitations in Zoomerang.com, with regards to the number of questions that could be asked. An additional benefit to using FrontPage was that the survey could be customized in appearance and the data could be stored in a Microsoft Access database hosted on a campus server for more complete access to the data.

For this initial pilot test, a total of 157 students from 12 classes were asked to take the evaluations. A mixed delivery mode, including verbal and electronic notification of students, was used to ensure a suitable response rate. Students were given one week to complete the evaluations. The process was as follows:

1. Students were notified in class that an email would be sent out with instructions to complete the evaluation, and with a link to the evaluation.
2. The email was then sent out, with a one-week time frame during which they were expected to complete the evaluation.
3. The professors then reminded students in class, about the email, and the importance of completing the survey.
4. The administrator of the survey checked the results database daily, and provided the professors feedback on the completion rate for their courses.
5. Once the evaluation period was completed, the data was then tabulated, and compared to traditional in-class evaluations for response rate, and response quality. (Table 3)

The quality, as measured by the ratings assigned by the students to specific questions on the evaluation form (related to course content, the Instructor, and the class room facilities) was found to be comparable between the pilot group (Table 4) and the Division and the Institution as a whole. The means were within the first standard deviation, which suggests that the student responses were comparable. Issues of validity, bias, and reliability

Table 4. Comparison of pilot survey results versus institution/division averages

	Course Content	Instructor	Facilities
Institution	4.36 +/- .69	4.49 +/- .66	4.25 +/- .90
Division	4.33 +/- .76	4.44 +/- .73	4.55 +/- .57
Pilot Group	4.59 +/- .64	4.66 +/- .47	4.52 +/- .78

were also evaluated, and as all students were required to take a class in computer literacy, and as there were no students that did not have Internet access, these issues were not considered as major barriers.

While this pilot was going on, two other surveys were being piloted using the same software (Microsoft FrontPage). The first was for a survey of alumni for the alumni association administrator, and the second was for one of the professors who was completing her doctorate in philosophy. These were both identified by the technology committee as important initiatives - on the one had to support the administrative branch of the college, and on the other hand, to encourage external use of web-based surveys by faculty as a part of the professional development process.

After these initial pilot tests, the technology committee reviewed the results, and identified two significant barriers that could limit the effective adoption of web-based surveys at the college:

1. Dependency on a specific professor with FrontPage skills;
2. Lower than desired response rate to surveys.

One professor had led the technical aspects of the implementation with FrontPage. As no other professor had the skills, the concern was that too much support would be expected from this professor, and that it would take a significant effort to educate other faculty members on how to use FrontPage. Since one goal of implementing a web-based system was equal access to all faculty, staff and students, this was considered a major barrier.

The second issue of a lower than expected response rate was also considered a major barrier, as the school considered 80% the lowest acceptable response rate for student evaluations. While extending the time allowed for completion of the evaluations was a possible solution, the general belief was that if students were not asked to complete the evaluation when they were physically in class, then many would not.

THE SOLUTION

As a result of the evaluation of the pilot test, third party software packages, and hosted solutions were evaluated. The technology committee determined that at a minimum, any software had to have the following characteristics:

1. All users needed to be able design and implement surveys;
2. The surveys had to be accessible to all students, regardless of bandwidth;
3. Student anonymity had to be ensured;
4. Results were needed in two formats:
   a. Online for immediate access to faculty and staff;
   b. Downloadable for further analysis;
5. The supplier had to be reliable, with sufficient technical support;

After a thorough review of several options, Empliant was chosen because they met the technology committee's criteria, and also because they agreed to hire a student as an intern to assist in implementation for the college.

The next pilot test using Empliant's hosted solution was expanded to 10 faculty members. In addition to students being given one week to complete the survey, all classes included at least one 15-minute period in which the class was held in a computer lab so that students could complete the survey. The overall response rate increased to over 85%, with only a couple of classes below the required level of 80%. Further comparisons of the overall quality of data, yielded similar results to the first pilot test. This led to a decision to fully implement the new online evaluation system for all courses beginning with the next academic year.

CONCLUSIONS

The successful implementation of an online evaluation system was the result of a lot of time and energy by a few dedicated people. The institution where it was implemented had the right combination of critical success factors (Table 5). Executive support, coupled with the necessary funds, and a collaborative culture that encouraged experimentation helped ensure success.

The use of web-based surveys and online evaluation systems has increased the speed at which information can be processed and analyzed. This enables faculty members to receive feedback from their courses more quickly. It also helps assist other administrative departments in

Table 5. Critical success factors

- Executive Support
- Key investments in IT
  - Upgraded PC's/software
  - Support staff
- Collaborative culture
- Sense of empowerment
- Understanding of Student and Faculty Needs
- Well defined process
  - Pilot
- Faculty initiative
- IT department support
- Developmental funding

surveying alumni and other institutional stakeholders. This helps the college gather meaningful data that supports the institutions mission, and also accreditation and marketing processes.

FUTURE TRENDS

Future efforts that use additional media – including audio and video, plus more adaptive surveys may open up new opportunities for increasing the use of such systems. The key technical point for researchers to remember is that not all stakeholders have Internet access, and therefore the population is a subset of the whole. Total dependency on online systems can lead to response bias, by excluding critical input. Knowing the capabilities and limitations of the institution, and the technology will allow institutions to determine the level of utilization of an online evaluation system, while also increasing the speed at which data is gathered, and feedback provided.

KEY TERMS

ASP: Application service provider.

Bandwidth: The amount of data that can be passed along a communications channel in a given period of time. (Dictionary.com)

Courseware: Educational software designed especially for classroom use. (Dictionary.com)

Critical Success Factors: A key area where satisfactory performance is required for the organization to achieve its goals (Austin, 2002).

Open Source: Method and philosophy for software licensing and distribution designed to encourage use and improvement of software written by volunteers by ensuring that anyone can copy the source code and modify it freely.

Pilot Study: Serving as a tentative model for future experiment or development: a pilot project; The pursuit of knowledge, as by reading, observation, or research. (Dictionary.com)

Reach: To succeed in getting in contact with or communicating with. (Dictionary.com)

Web-Host: A computer containing data or programs that another computer can access by means of a network or modem. (Dictionary.com)

Implementing the Shared Event Paradigm

Dirk Trossen
Nokia Research Center, USA

Erik Molenaar
Technical University of Aachen, Germany

INTRODUCTION

For collaboration among users, sharing audio-visual, textual, graphical, or even interface-related information is the essence of *computer-supported collaborative work* (CSCW). Since most applications that are being used in private and work life these days are merely usable on the computer on which they are executed, collaboratively working with a single application is the most challenging part of CSCW. This is not only true because these applications are unaware that they are executed in a distributed environment, but, in particular, because of the numerous possibilities of data to be shared among the distributed users. Thus, the distribution of the application's functionality over the network must be added transparently and, more important, subsequently without changing the application's semantic. The effect has to be created at each remote site that the application is running locally and, therefore, can also be controlled by any remote user with a more or less immediate effect to the application. This problem is referred to as *application sharing* in the remainder of this article.

BACKGROUND

The realization of application sharing faces several challenges to be solved, as explained in more detail in Trossen (2001):

- *Amount of transferred data* is part of the indicator for the generated network load.
- Each technique adds certain *interception points* to the local system to gather required information to be distributed among the session members. The number of these points serves as an indicator of the generated network and processor load (Trossen, 2001).
- *Heterogeneity*: Sharing applications independent from each member's operating system is crucial for wide applicability of the technique.
- *Latecomer's support*: Joining the session later should be supported without leading to inconsistencies of the application's state.
- *Shared data problem*: Using any kind of input data within the shared application should not lead to inconsistencies of the distributed copies of the application.
- *Synchronization*: The shared instances of the application have to be synchronized to ensure consistency of the workspace due to the different processing speed of the sites and the different delays of the transmission lines.

Two different paradigms can be distinguished to tackle the earlier mentioned challenges, namely, *Output Sharing* and *Event Sharing*. In Trossen (2001), a qualitative comparison and detailed presentation of both paradigms is available, including the different application scenarios for both paradigms.

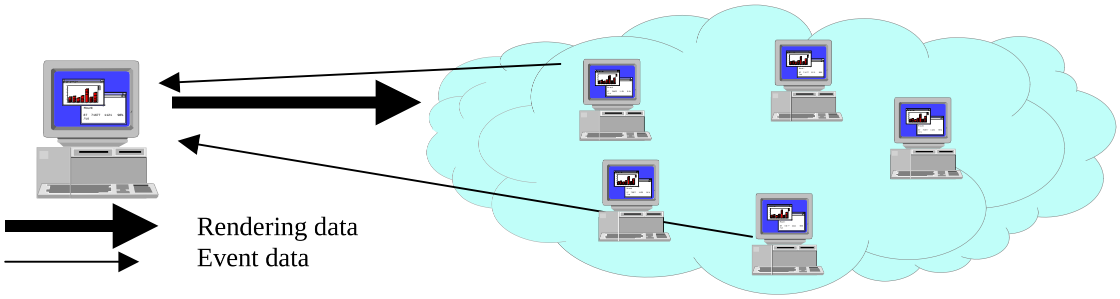
GUI Sharing Technique

The first technique is to share the server's application's output. For feedback from the receivers, any input data like mouse or keyboard events is transferred back to the sender and fed into its local event loop for control, subject to the current floor control policy. Rendering data is transferred from the server to the receiver group, preferably using a reliable multicast protocol.

For that, as indicated in Figure 1, *event data* is sent back to the server to be fed into its local event loop for a remote control of the application. Usually, transferring event data to the server is controlled by means of *floor control* (Hao & Sventek, 1996), that is, the appropriate host is selected based on a *social protocol* (Dommel & Garcia-Luna-Aceves, 1995) with an associated floor, representing the right to control the application.

Latecomer's support is provided by invoking a full refresh of the local GUI, resulting in a transfer of the entire GUI content to the receiver group. Furthermore, the shared GUI approach allows a heterogeneous receiver group,

Figure 1. GUI sharing approach



assuming appropriate rendering engines on the client's side. As shown earlier, the input event data is the only data to be synchronized with the local application, which is realized by means of floor control. Any additional data, like files or local device data, is held locally with the server's host. Hence, there is no *shared data* problem to deal with. However, the different processing speeds of the client rendering engines have to be considered for synchronization of the workspace. For that, *synchronization points* can be used, which have to be acknowledged by each member.

Event Sharing Technique

The assumption being made is that if a set of identical applications is executed with the same start state and evolves using the same sequence of events, its timeline evolution is identical on each site. Hence, the following statement is valid (Proof in Trossen, 2001):

- Theorem 1: A set of application instances that behaves deterministically can be held in a stable state if the starting state and all events can be captured.

In contrast to the shared GUI approach, there is no central server. The initiator of the session is merely used for defining the application's start state. Any input data is transferred from the current floor holder to *all* group members. There is no central entity to which the data is sent first to determine the new output. In this, *homogeneity* of the environment is crucial due to the requirement of having a local application instance.

Applicability of the Techniques

Each approach for tackling the application sharing problem has its specific advantages and weaknesses. The GUI sharing approach is well suited for heterogeneous environments and when using input data which cannot be shared among the other participants.

However, the event sharing approach has also specific advantages, which makes this technique attractive for specific scenarios. Due to the local copy of the application, the additional load on each host is expected to be much lower, which increases the responsiveness of the system and thus improves the user's perception of the system. However, the problem of ensuring the consistency of each user's view when using shared data restricts the applicability of the approach either to not using shared input data or to use the technique in local environments where data sharing is feasible to some extent. Furthermore, this technique is not applicable in heterogeneous scenarios.

Table 1 shows typical scenarios for shared applications and the applicability of both paradigms in these scenarios. It is worth mentioning that the list is only meant to outline sample scenarios; thus, the list is neither exhaustive nor exclusive.

It can be seen that the event sharing technique is not applicable to the last two scenarios due to the heterogeneous character of these situations, while the first three scenarios are fairly good examples as the shared event approach promises to provide a higher responsiveness of the system and, therefore, an improved user's perception. Specifically, the multimedia presentation is hardly conceivable using the shared GUI approach due to the large amount of data to be transferred, which is avoided by the local copy of the application when using the shared event technique. Furthermore, due to the local character of the scenarios, the shared data problem can be handled much easier.

It can be summarized that the event sharing technique is better suited for local environments and high demands on the responsiveness of the shared application, while the GUI sharing approach is preferred in heterogeneous environments and when having problems with data to be shared.

Related Work

In the past, several toolkits have been developed in this problem space, such as the *X Windows* system (Israel & Fortune, 1992), comprised of a central server on which the application is executed. The application's output is redirected to *X Windows clients* for rendering. Extending this system to a multipoint scenario, which occurred in Altenhofen et al. (1993), Minenko and Schweitzer (1994), and Wolf, Froitzheim, and Schulthess (1995), enables a shared application system for cooperative working. However, floor control capabilities have to be added for coordinated control (Altenhofen et al., 1993; Minenko & Schweitzer, 1994).

Despite the wide deployment of X Windows systems, their applicability is mainly restricted to Unix systems. Although X Windows client software is available, the problem remains to share, for example, MS Windows software on other platforms. To tackle this heterogeneity problem, the ITU proposed a multipoint application sharing protocol (ITU-T, 1998a), defining platform-independent rendering and interception functionality. However, the overhead on the server system and the usage of an ineffective transport system, which is defined in the ITU T.120 standard (ITU-T, 1998b), are the main disadvantages of this solution.

The work in Hao and Sventek (1996) replicates the entire data workspace before starting and executing application copies at each computer, as defined earlier as the *event sharing* paradigm. Synchronization among the different copies is ensured for every incoming event, leading to a significant overhead instead of using specific synchronization events for overhead reduction. Moreover, the event mapping and distribution is realized on a central server. Hence, the proposal follows a distributed application but a centralized control approach.

GENERAL REQUIREMENTS FOR A SOLUTION

Apart from the major requirement that the application to be shared must behave deterministically, the following requirements can be defined for an event sharing solution:

- All instances must start in an equivalent state.
- All events changing the application's state must be captured and broadcast to all participants.
- If events access resources, these must be provided to all participants.
- Synchronization of instances must be offered.

In addition, the following minor requirements have to be addressed:

- An interface with the participant must be offered.
- Latecomer's support must be addressed.

Since a shared application service is using resources from existing conferencing systems, such as Trossen (2000), the following requirements for this part of the system can be derived:

- Conference management should be provided.
- Floor control is required to prevent concurrent control of the application.
- Reliable message transport will be provided.
- If possible, multicast capabilities will be utilized.

SAMPLE SOLUTION: THE MULTIPOINT EVENT SHARING SERVICE (MESS)

The earlier mentioned requirements are used as a foundation for the design of the *Multipoint Event Sharing*

Table 1. Scenario examples and paradigms applicability

Scenario Description	Shared GUI	Shared Event
Multimedia presentation in a local environment	--	++
Programming environment in a lecture	-	++
Development environment in a closed user group	-	+
Spreadsheet in an heterogeneous Internet environment	++	-
Accompanying presentation in an Internet lecture	++	-

Service (MESS), which is presented in the next section as a sample solution for implementing the event sharing paradigm.

Architecture

Figure 2 left shows the components of the MESS architecture. The concept of capturing the start state and distributing the evolving state is reflected through the *Starter/StaticReplicator* and the *DynamicReplicator* components. The former takes care of all instances of the application to be in an equivalent state upon startup. It decides what resources to distribute, and it takes care that the local settings for each participant are brought in a consistent state. The *DynamicReplicator* is responsible for keeping all participating applications in an equivalent state after the session has started.

At the currently controlling application side, the *Interceptor* gathers required event information. Two types of events need to be handled, namely *user events* and *system events*. Examples for the former are mouse movement or keyboard keys pressed. The system events are used to keep the application instances in synchronization by monitoring the speed of the end systems. The resources that are used by both events are recognized through the *ResourceGrabber*. The actual sending of needed resources and events is prepared by the *Sender/Synchronizer*. This component also takes care of the synchronization and offers latecomer support. The required conferencing and data transmission functionality is provided by the *Conferencing* component, and the interaction with the participant and coordination of components are performed through the *Controller*.

This component architecture can be transformed in a UML framework, shown in the right part of Figure 2. It is a straightforward mapping of the components onto classes with dedicated methods.

Realization and Lessons Learned

The proposed MESS architecture is implemented as a prototype. Although the current design allows for sharing all types of events and resources, the actual implementation must make certain tradeoffs to keep the realization simple and feasible, but to demonstrate the potential of the proposal. As a consequence, no system events are shared at this time, and there is no synchronization capability. Moreover, resource distribution is not provided. This basic functionality reflects the most important part of the service, namely the evolution of the application's state, and, therefore, demonstrates the ability of the concept to provide application sharing for certain scenarios (see also Trossen, 2001).

As demonstration scenarios, simple text-editing as well as rotation of complex 3D objects are performed. The latter happens in shared engineering scenarios, as described in Trossen, Schueppen, and Wallbaum (2001), and is well suited to demonstrate the potential since it generates heavy graphical output that is difficult to capture appropriately with output sharing systems. However, due to the missing synchronization functionality of our prototype, the computers usually run out of sync after a certain timeframe.

The performance can be evaluated in two dimensions. First, the added overhead to the system due to the interception to gather and distribute event information is a major performance measure. The demonstration application shows that this additional overhead is fairly small; however, adding more system events and resources certainly decreases the overall performance. As a second measure, bandwidth consumption is important. For that, assume a reasonable amount of entered text, for example, 250 characters per minute. Further, assume one sync event after each pressed key as a conservative approach. Thus, the bandwidth consumption would be less than 700 bits per second with an event size of 16 bytes and a synchronization message size of 2 bytes. In the example of rotating 3D objects, this consumed bandwidth is even smaller since user events are generated with a smaller frequency.

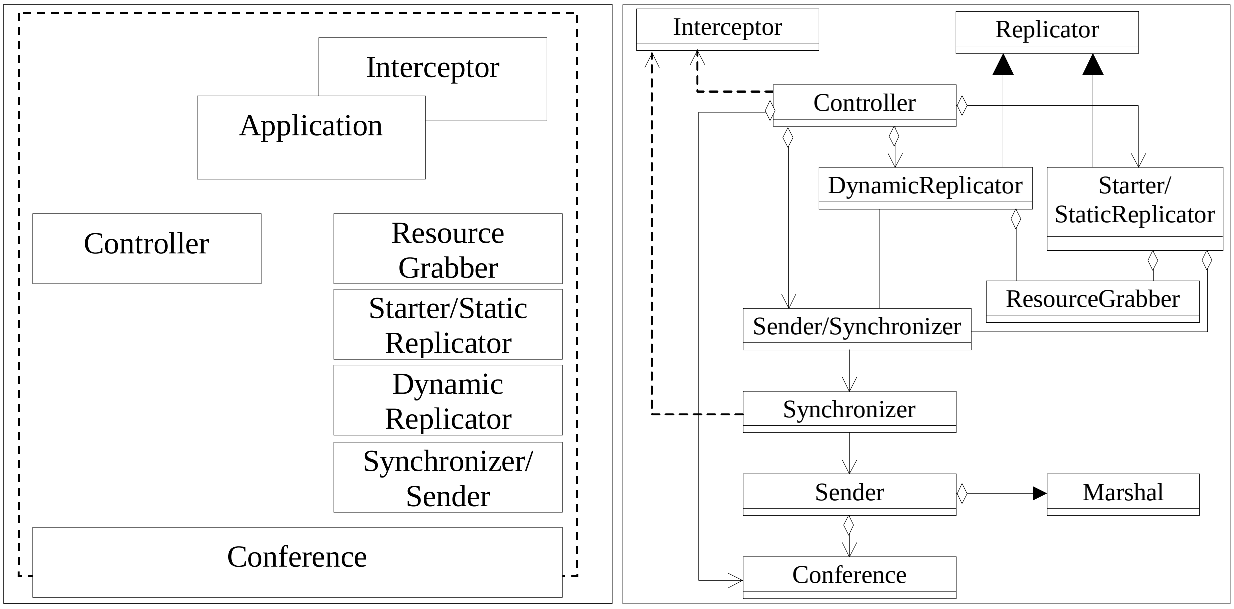
To summarize, the realization of the MESS architecture showed that the basic concept of event sharing works with an impressive speed by leveraging local processing speed for the application functionality. However, the integration of some system events with an additional synchronization to cope with different processing speeds is likely to increase the spectrum of applications that can be used with the system.

FUTURE TRENDS

We see the future trends in collaborative workspaces evolve towards studying integrative approaches of the different collaborative technologies involved. This particularly concerns integration of the different solutions into the Internet Multimedia Architecture, placing the application layer functionality on top of standard signaling and transport protocols.

In our particular future work, the restricted functionality of our demonstrator is to be increased, starting with synchronization functionality to cope with out-of-sync

Figure 2. MESS architecture



effects. Moreover, finding some optima for the applications that can be served by MESS while keeping the used bandwidth to a minimum is a field of future work. In addition to enriching functionality, more systematic evaluation scenarios must be defined to determine a clear view of the added system overhead. In addition, the demonstration system is used within a project, realizing a workspace for shared engineering (Trossen, Schueppen, & Wallbaum, 2001), to show its feasibility in a real-life use case.

CONCLUSION

This article presents issues around implementing the event sharing paradigm as an approach to solving the application sharing problem in the Internet. For that, we have outlined the basic techniques of two different paradigms to tackle the problem of sharing applications remotely, namely sharing an application's output or sharing the application's state via the network. In this, the event sharing paradigm seems to be a promising candidate to increase the efficiency of application sharing in particular for scenarios that have an inherent locality of shared data and a homogeneity of end-systems. For the realization of this paradigm, we have defined a set of general requirements that we see must be fulfilled by an event sharing solution. These requirements are the foundation for our MESS architecture design and implementation, which is presented as a proof-of-concept solution. The components of this architecture are outlined together with the realized objects.

Our prototype shows promising results with respect to its simplicity on the one hand and the increased performance on the other hand, although the simplicity must be re-evaluated when considered in a full-blown implementation. However, it is shown that with a fairly simple set of events, a wide spectrum of applications is enabled. Although there remains future work to be done, we show with our implementation that the concept of sharing application events in order to share the application remotely is a viable one.

KEY TERMS

Application State: Current snapshot of the application itself and all of the resources it addresses.

Deterministic Behavior: If a set of a shared application is started in an equivalent state, and the same set of events is presented to those instances, then if the same state transitions will happen for all instances, the application has deterministic behavior. It is important to note that this definition is more relaxed than other ones, in the sense that resources that an application might need are considered as part of the environment. Where other definitions might assume that an application is no longer behaving deterministically if, for example, the system time of the local machine is used, this definition regards the system time as a part of the environment.

Events: A phenomena that changes the application's state.

Event Sharing Paradigm: Shared applications that are realized based on the event sharing paradigm instantiate a copy of the application on each participating host, distribute an initial start state among all copies and further distribute all future events among those copies that result in a state transition of the applications.

Floor Control: Functionality that allows for resolving concurrent access to common resources, such as mouse pointers in shared applications. A floor is usually assigned to such resource together with a policy for access authorization.

GUI Sharing Paradigm: A shared application follows the GUI sharing paradigm if the output of a centralized application is shared among all participants of the conference. Feedback from the participants is sent to the centralized server to be incorporated in the control of the application, if desired.

Resources: Anything that is not the application itself, but is changed or used by the application to determine its behavior. Examples are files, registry entries, or the system time.

Stable State: A stable state of the shared application is given, if the execution behavior of all instances is equivalent. For example, if a menu entry is selected, the same action belonging to the corresponding menu entry should be performed on all machines. Other terms are *consistent* or *equivalent state*.

Improving Public Sector Service Delivery through Knowledge Sharing

Gillian H. Wright
Manchester Metropolitan University Business School, UK

W. Andrew Taylor
University of Bradford, UK

INTRODUCTION

Since the publication of the first knowledge management article in *Harvard Business Review* (Nonaka, 1991), the world has witnessed a revolution in management practice. While the origins of knowledge management extend further back in history (see Prusak, 2001; Wiig, 1997), it is certainly true that in the last decade the creation, sharing and application of knowledge are increasingly seen as a source of competitive advantage. However, knowledge management is largely a private sector innovation at the present time, although gradually moving towards the public service sector (Bate & Robert, 2002; Hartley & Allison, 2002). The implementation of knowledge management places an emphasis on organizational factors such as learning capability, culture and leadership as well as renewed focus on the importance of information quality (Alavi & Leidner, 2001). The ability to manage the sharing of information (and hence knowledge) effectively remains one of the most important but still least understood activities in modern organizations, no less so in public services.

BACKGROUND: KNOWLEDGE SHARING IN CONTEMPORARY PARTNERSHIP ORGANIZATIONS

Public services represent a significant economic sector in most countries and public demands on services are increasingly consumerist. This has led to escalating scrutiny of the performance of public services. Consequently, the strategic use of information and knowledge to improve service delivery and financial performance has become a key skill for managers in this sector. Partnership working represents a formal departure from the traditional compartmentalized approach to public service delivery. Often referred to as joined-up thinking, partnership working challenges existing hierarchies, encouraging the partner organizations to work together at all levels, including strategy, service planning and service delivery to enhance efficiency and improve user experience and satisfaction. For partners to work effectively together, knowledge of best practices must be shared and utilized towards the common goal of improving the overall quality of service delivery.

Our research has focused on health and social care as an area of public service in which organizations responsible for commissioning and delivering all aspects of care are increasingly expected to work together, to reduce fragmentation of access to the user. Management of the provision of high quality public services continues to be a major social and political issue in many countries. Our research was conducted in the context of UK national policies for performance management (DETR, 2001a), partnership working (DETR, 2000, 2001b; Fordham, 1998), the reduction of health inequalities (DoH, 1998a, 1999), and overall improvements in service quality (DoH, 1998b, 2000). We have concentrated particularly on the issue of making public service partnerships work effectively, to achieve strategic objectives, that is, to improve individual health and personal well being as well as to achieve gains in public health. Specifically, our research questions relate to assessing the readiness of the partners to work together, and to share knowledge that each possesses about their part in the overall service delivery process. By understanding the factors that influence effective knowledge sharing, managers can take practical steps toward improving these antecedent preconditions.

MANAGING THE ANTECEDENTS TO KNOWLEDGE SHARING

The key to partnerships is a focus on the creation of an explicit understanding of what needs to be done to meet strategic objectives –akin to Choo's concept of a "knowing organization" (Choo, 1988). We conceptualize the role of knowledge in the partnership process (Figure 1) in terms of two core aspects, viz:

- The effective management of information to support the vertical deployment of organizational strat-

Figure 1. The public service partnership: The knowing organization

egy in terms of communication and development of meaningful performance measures, and
- The wider organizational culture to support attitudes conducive to new ways of working.

We have identified six key factors that are associated with successful knowledge sharing in public sector partnerships (Wright & Taylor, 2003), namely:

- Innovative culture
- Change readiness
- Information quality
- Clarity of responsibility
- Strategy formulation and deployment
- Accountability

Innovative Culture

An innovative culture is one where people are receptive, rather than resistant to, new ideas, and where they are motivated to embrace and develop these ideas and shape them into improved working practices. Such cultures provide people with time to reflect, to learn from both success and failure, providing supporting systems to facilitate reflection and capture lessons learned. Finally, innovation is focused on the user or customer, whereby people actively search for new ways of improving service delivery. The legal and political constraints on public service managers and persistent demands for strict oversight can lead to rigidity and bureaucracy in public sector organizations that counter the development of an open and inclusive culture (Scott & Falcone, 1998).

Change Readiness

Change and innovation are closely linked. An innovative culture needs to be able to implement changes to working practices and behaviors generated by innovation. This requires a positive attitude to doing things differently, rather than seeking to maintain the status quo. Change requires leadership, to proactively seek opinions and listen to views whilst engendering an atmosphere where ideas are freely expressed and there is no perception of a need for staff to cover their backs to protect themselves from criticism and retribution. Involvement and commitment will decline and the organization's innovative potential will be diminished if there is a culture of reluctance to challenge current ways of working. High levels of media scrutiny of public sector organizations (Perry & Rainey, 1988) and the top-down nature of government-imposed changes (Collier, Fishwick & Johnson, 2001) can reduce public sector employees' receptivity to change (Halachmi & Bovaird, 1997). Being ready to change implies a concomitant sensing of the need to change. Information about performance gaps, that highlights the need for change, must be communicated throughout an organization. If people feel that managers pay little attention to performance statistics, they too will ignore them and continue working in ways that maintain the status quo. The nature of the change and the benefits that it will bring need to be understood.

Quality of Information

Good quality information facilitates performance review, and reflection on service delivery. It supports people in their work tasks and it provides a medium for the capture and dissemination of lessons learned. If timely and meaningful information is not provided, people will find it difficult to know how well they are performing, and they will spend extra time searching for the information they really need. Public sector organizations often place less importance on the quality of information and perceive less need to invest in information systems (Rocheleau & Wu, 2002). Unless there is clarity about the basis of performance measurement, information systems will not be perceived as providing appropriate support.

Clarity of Responsibility

It is important for people to understand their specific roles and responsibilities and to know whom to contact elsewhere in the service value chain. People need to see clearly how their jobs fit into the bigger picture, to have their responsibilities delineated clearly in relation to the organizational strategy, and to see how their roles contribute to its achievement. Thus clarity of responsibility is concerned with the effectiveness of strategy delivery. Managers must ensure that people can grasp the significance of strategy in relation to their own responsibilities, and that the performance measures that derive from the strategic process (see Figure 1) are useable for managing service delivery. All too often, public sector performance measures are regarded by employees as vague and of limited utility (Townley, 2002). To achieve clarity of responsibility in partnerships there needs to be:

- A joint strategy developed, and owned by all partners
- Re-definition of the service value chain and its business processes
- Re-examination of roles and responsibilities within the value chain
- Development of partnership-based performance measures
- Logical and explicit derivation of performance measures from the joint strategy

Strategic Connections

This factor addresses communication gaps in the strategy formulation and deployment process. Public sector managers must ensure that people feel involved in the strategy formulation process and do not feel that strategy is imposed from on high, as is often the case in public services. Staff need to understand the meaning of strategy in their own situations. Strategic plans need to be living documents, owned by all, rather than uninspiring rhetoric that gathers dust on a shelf in the strategist's office. In public service partnerships, strategy must be communicated in terms of improved relationships and outcomes for service users, rather than a structural end in itself.

Accountability

People need to know where the buck stops. In an integrated service delivery chain that crosses organizational boundaries, it must be made clear who is ultimately accountable for performance. Poor redefinition of accountability is symptomatic of, and consistent with, top-down imposition of strategy with little staff involvement, and poor deployment of strategies into meaningful processes and activities.

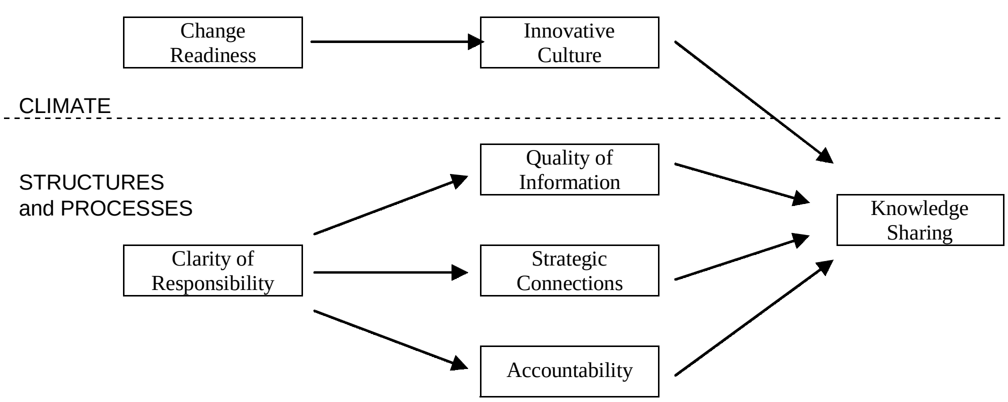
FUTURE TRENDS: MANAGING KNOWLEDGE SHARING

Six antecedents to successful knowledge sharing are illustrated in Figure 2, and these form a basis for the management of knowledge sharing. Increasingly, organizations will move from simply practicing knowledge management and knowledge sharing, toward an emphasis on evaluating its effectiveness. Using this model as a basis for diagnosing an organizational climate that is supportive of knowledge sharing, a targeted, proactive approach can be developed for implementing and maintaining effective knowledge sharing.

This empirically validated model indicates that these six factors are important precursors in the development of an effective knowledge sharing process and can give guidance to managers about where they should focus their efforts. We have found that an innovative culture is the strongest factor in explaining knowledge sharing, with acceptance of new ideas being the strongest element within this factor.

Our research identified the issues of trust and power as being underpinning and tacit impacts on knowledge sharing and our factors include items that embody trust and power (Dirks & Ferrin, 2001). For example, trust can result in higher levels of co-operation, increased willingness to take risks (Mayer, Davis & Schoorman, 1995), increased involvement of employees in decision making (Spreitzer & Mishra, 1999), increased sharing of informa-

Figure 2. Predictors of knowledge sharing



tion and greater satisfaction with organizational change programs (Rousseau & Tijoriwala, 1999). Thus this model incorporates the effects of trust and power in the ways in which they are experienced in a knowledge sharing environment.

CONCLUSION: A MANAGEMENT AGENDA FOR KNOWLEDGE SHARING AND INNOVATION

There are some clear antecedents to the management of effective knowledge sharing in partnerships developed to enhance public services. The change implications of knowledge sharing are very important, and are represented strongly in the innovative culture and change readiness factors. These factors are well established as key strategic management challenges and underline that knowledge sharing is a key strategic issue, rather than an IT-centred initiative, as it is often portrayed. While public policy usually addresses structural and process issues, our research suggests that this may inadvertently be misguided and that the key to improved service delivery lies in changes to the underlying culture, particularly with regard to an innovative orientation and change readiness. Applying structural solutions to behavioral problems is not recommended.

This model of knowledge sharing suggests a management agenda to improve service delivery through knowledge sharing. To develop an innovative culture, there must be a climate where both motivation to innovate and acceptance of new ideas are equally strong, and further, there must be appropriate systems in place to facilitate learning and reflection. To generate a shared understanding of best practices and a sharing of knowledge about lessons learned, staff in such partnerships need to be given time and opportunities to engage in socialisation processes that facilitate learning (Nonaka & Takeuchi, 1995). Organizations need to take on board Garvin's assertion that while much knowledge can be generated from reflecting upon success, there is even more to be gained from reflection on failure (Garvin, 1993). The changes needed to move from a departmental focus to an inter-organizational one point very forcibly to the organizational culture and especially the role of senior management.

Public services are embedded in an environment wherein government requirements for performance reporting and accountability often seem to have little relevance for informing staff about what needs to be improved. The intangibility of public services means that public service managers rely very much on knowledge – insight, understanding and empathy. Extant studies of knowledge have generally focussed on the private sector. However, the prominence of a knowledge sharing culture is clearly a key element in achieving a partnership-based, user-focused public service.

KEY TERMS

Accountability: Transparency of responsibility for performance, the management of performance and resulting implications for the deployment of future resources.

Change Readiness: An organizational mindset that welcomes challenges to established structures and processes and administrative orthodoxies.

Clarity of Responsibility: An understanding of the roles and responsibilities of individuals and business units working together to deliver a holistic service proposition.

Information Quality: The accuracy, completeness, timeliness and utility of performance related information that is used as the basis of management decision making.

Innovative Culture: An organizational climate that fosters new ideas and reflection on learning from experiences.

Knowledge Sharing: Formal, deliberate and systematic activities of transferring or disseminating knowledge from one person, group or organization to another.

Partnership Working: A network of organizations working together to provide a total service offering to a targeted group of users.

Public Services: Social infrastructure services, delivered wholly or partly with the benefit of public funds and strategically driven through national or regional administrations.

Strategic Connections: The relationships between the strategy formulation process and the deployment of resources to achieve it.

Improving Virtual Teams through Creativity

Teresa Torres-Coronas
Universitat Rovira i Virgili, Spain

Mila Gascó-Hernández
Open University of Catalonia, Spain

INTRODUCTION

Many studies have already shown how a team can become more creative, and therefore more efficient, but only a few researchers have focused on how a virtual team can use creativity techniques to perform better. In this article, we study what differences there are (both in terms of processes and in terms of results) when creativity techniques are used in the management of traditional and virtual teams. To do this, we discuss three main elements: the definition of creativity and its relationships with team performance, the variables that enhance creativity in a virtual team, and the most suitable creativity techniques for a virtual environment.

BACKGROUND

Most researchers and practitioners believe that the key to organizational success lies in developing intellectual capital and acquiring a new set of thinking: the creativity to produce an idea and the innovation to translate the idea into a novel result (Roffe, 1999). Explaining the meaning of creativity is not straightforward; there are thousands of definitions of the term. So, for the purpose of this article, we will understand creativity as the shortest way to search for unconventional wisdom and to produce paradigm-breaking ideas and innovation. This unconventional wisdom through the generation and use of creative knowledge is the key to building sustainable competitive advantages (Carr, 1994).

In order to develop more innovative products, services, or processes, organizations must encourage their employees to become more creative. During the last few decades, several researchers (Andriopoulous, 2001; Nemiro & Runco, 2001; McFadzean, 1998; Amabile, Conti, Coon, Lazenby & Herron, 1996) tried to describe contextual factors largely under the control of managers that influence creativity, though as creativity is a multidimensional concept, there is not a universal theory yet (Walton, 2003). This section focus on how managers and/or team leaders can improve creative climate within virtual structures.

The literature review conducted by Andriopoulous (2001) highlights five major organizational factors that enhance creativity in a traditional work environment: 1) organizational climate, or designing a working atmosphere that fosters participation and freedom of expression; 2) a democratic and participative leadership style; 3) an organizational culture that nourishes innovative ways of solving problems; 4) new resources and skills through the development of human resources creative talent; and 5) a structure and systems that include building flat structures, and rewards, recognition, and career systems that emphasize people creative thinking. Scholars argue that these factors create conditions that enhance creativity both at the team and individual levels.

From a study of the social psychology of creativity, Amabile (1996) cites the three main origins of creative performance as: task motivation, domain-relevant skills, and creativity-relevant skills. She differentiates between intrinsic and extrinsic motivation, proposing that the intrinsic motivation enhances creativity. In Amabile's research, the work team environment is also considered to exert a powerful impact on creativity by influencing the employee's intrinsic motivation. Management practices indicate that performance can be fostered by allowing freedom and autonomy to conduct one's work, matching individuals to work assignments, and building effective work teams that represent a diversity of skills and are made up of individuals who trust and communicate well with each other, challenge each other's ideas, are mutually supportive, and are committed to the work they are doing (Amabile & Gryskiewicz, 1987). Creativity is best achieved in open climates (Feurer, Chaharbaghi & Wargin, 1996).

These studies have not specifically addressed dimensions that may be necessary when groups no longer interact in traditional structures (Nemiro, 2001). In fact, so far, the only research that has been seriously conducted about this issue is that by Nemiro (2001), who identifies several key elements that influence creativity in virtual teams and therefore result in effectiveness and high levels of performance. Table 1 summarizes some of these factors as described by Nemiro (2001, p. 94).

A creativity-based management aimed at fostering virtual team creativity and performance must manage the above environmental variables in order to enhance employees' internal drive to perceive every project as a new creative challenge (Andriopoulos & Lowe, 2000).

A quick analysis of the variables shown in Table 1 gives rise to the conclusion that there are no meaningful differences between the factors that affect creativity in traditional environments and those that affect creativity in virtual contexts. On the other hand, most of the factors that influence creativity (such as work characteristics and situational constraints) are also considered as factors that impact team performance, as the conceptual model of Prasad and Akhilesh (2002) shows. Nevertheless, due to the particular way virtual teams work, there is a need to consider some elements related to the previous variables. Thus, communication and trust become very relevant issues.

In this sense, Henry and Hartzler (1998) find that keeping the synergy and creativity flowing, without frequent face-to-face interaction, is the greatest challenge a virtual team has. Virtual teams lose non-verbal communication and, as has been argued, electronic communication increases the level of social isolation. Schein (1993) points out that most communication workshops emphasize active listening, which means paying attention to the spoken words, the body language, the tone of voice, or the emotional content. Virtual teams that want to communicate successfully cannot actively listen in this sense. Other tools must therefore be explored¾for example, the use of multiple media or several communication technologies (Bal & Teo, 2001). However, as Van der Smagt (2000) showed, it is crucial to ensure that dialogue is the primary form of interaction between team members and that two-way monologues are avoided. Rich media—those that transmit nonverbal cues—are not the solution.

"In a dialogue, the difficult part is to make one's own assumptions manifest, not the exchange of insights with others. The attitude in relation to other actors is one of openness, which makes it relatively easy to get behind the position and possibilities of actors." (Van der Smagt, 2000, p. 155)

Collaborative work also requires a level of personal familiarity and trust. Without trust, building a true team is almost impossible (Duarte & Snyder, 1999). For most newly forming virtual teams, achieving an effective level of trust is not an easy task. Increasingly, virtual teams will form without the advantage of prior face-to-face team building opportunities, but with the added challenges of geographic isolation, time zone differentials, and cultural diversity (Holton, 2001). With virtual team heterogeneity there is a high probability that team members are confronted with mistrust (Prasad & Akhilesh, 2002), though such diversity within a team has the potential to increase opportunities to be innovative and creative (Lipnack & Stamps, 1997), if trust can be established (Dyer, 1995). But how can trust be built? The qualitative research project of Holton (2001) concludes that standard team-building tools

Table 1. A summary of factors that can foster creativity in a team context

Autonomy and Freedom. Allowing individuals responsibility for initiating new ideas and making decisions; a sense of control over one's work.

Challenge. Work that is stimulating, engaging, and meaningful; a sense of having to work hard on challenging and important tasks.

Clear Direction. Goals that facilitate creativity are clear, negotiated, attainable, shared, and valued.

Diversity/Flexibility/Tension. Diversity, both in terms of the work assignments offered and the people one interacts with, and a tolerance of differences. In order to be tolerant of differences, flexibility is needed. Both diversity and flexibility can lead to creative tension.

Support for Creativity. An organizational focus on support for or encouragement of creativity.

Trust and Participative Safety. Especially crucial for group creativity is trust and participative safety. The emphasis is on encouraging participation in a non-threatening, non-evaluative environment.

can be used to enhance collaboration and trust in a virtual team. The book of Simon Priest (2001) is full of examples for virtual team building. But, as with all team building, there is no quick fix for virtual teams.

These difficulties related to communication and trust are only an example that illustrates the need to conduct in-depth studies on the rest of environmental factors that, in non-virtual contexts, have been proven to directly impact teamwork creativity.

TOOLS AND TECHNIQUES TO IMPROVE CREATIVE PERFORMANCE

How can team creativity be encouraged? Until now no serious research has been conducted into which creativity techniques are the most suitable in a virtual environment. In traditional environments, one method of achieving this is to encourage teams to utilize creative problem-solving (CPS) techniques such as synectics, brainwriting, or wishful thinking.

In this context, McFadzean (2000, 1999, 1998) explores creative problem solving and presents a model that helps facilitators and team members choose appropriate techniques. McFadzean (1996a, 1996b) classifies creative problem solving (CPS) techniques into three categories: paradigm preserving, paradigm stretching, and paradigm breaking. Paradigm preserving techniques do not tend to change a participant's perspective. Paradigm stretching techniques encourage users to stretch the boundaries of the problem space. Paradigm breaking techniques allow participants to completely break down the boundaries of the problem space and to look at something entirely new.

In a virtual environment, three variables must also be considered when selecting a technique (Gascó-Hernández & Torres-Coronas, 2004): 1) the effectiveness of the method in finding innovative solutions, considering that quality solutions require the right balance between knowledge of the business issue and novelty (Kim, 1990); 2) the technological context or support system through which the technique can be implemented; and 3) the level of interaction that the technique requires. It is also important that the virtual facilitator has experience in running virtual creative sessions. Team members must also be taught about the dynamics of virtual interactions and about the use of technological tools, such as chats, e-mail, video conferencing, or interactive whiteboards.

Next, McFadzean's creativity continuum (1996a, 2000) will be used to summarize how virtual teams can choose among different techniques, which will be briefly described, to generate ideas. To make valuation accessible, the techniques will be classified according to the above three criteria. They will be rated as well (low, medium, and high). Finally, common technological tools by which each technique can be used will be shown.

It is a fact that there is a remaining need for in-depth research studies that help clarify which is the best creative problem-solving tool in terms of virtual team creative performance. Table 2 intends to be the basis to start evaluating the creativity continuum in a virtual context.

The use of these techniques will only be effective if the organization has a creative culture (McFadzean, 1998). Environmental factors that help managers to build a creative climate within virtual communities and creative problem-solving tools are two sides of the same coin.

FUTURE TRENDS

Virtual teams can use creativity in order to perform better. Nevertheless, there is a need to adapt those tools and techniques to a virtual environment. In this article, we have approached some of the issues that must be considered when studying the relationship between teams that work online and creativity. Nevertheless, several questions still remain unanswered and, in this sense, further research is required. In particular, three important issues need further development. First, the relationship between creativity and virtual team performance needs to be thoroughly explored. Successful studies will determine how structural and environmental factors influence team creativity. Second, although virtual teams are already using idea-generation techniques, their strengths and weaknesses need to be carefully and academically explored. Finally, it is also important to consider the effects of technology on both individual and team creativity. Technology has risks that can sometimes outweigh its benefits. When applying creativity techniques, people need to focus on the creative process, not on the technology being used. Technology must be easy to use, it must be effortless and unsophisticated—the simpler the technology, the better.

CONCLUSION

The emergence of tools based on the new information and communication technologies is currently affecting team creative processes. Nowadays, achieving high levels of creative performance is still an unresolved problem within virtual teams. Only a few researchers have focused on how a virtual team can use creativity techniques to perform better or how to build a creative virtual environment to foster creativity. The critical issues discussed in this article summarize many challenges to implement creative

management within both virtual teams and organizations. With greater emphasis being placed on creative thinking and processes, team creative performance will increase day by day, allowing organizations to succeed and to become more innovative and adaptable.

KEY TERMS

Autonomy and Freedom: Allowing individuals responsibility for initiating new ideas and making decisions; a sense of control over one's work.

Challenge: Work that is stimulating, engaging, and meaningful; a sense of having to work hard on challenging and important tasks.

Clear Direction: Goals that facilitate creativity are clear, negotiated, attainable, shared, and valued.

Converging Thinking Techniques: Tools used during the convergent phases of the CPS to improve the evaluation and selection of the most relevant ideas, thoughts, or data. Pluses, potentials, and concerns (PPC); highlighting; and the evaluation matrix are some of the most common converging thinking techniques.

Creative Performance: High level of capability in an idea or solution, applied to solve a problem in an imaginative way, resulting in effective action. Environmental factors such as autonomy and freedom, challenge, clear direction, diversity/flexibility/tension, support for creativity, trust, and participative safety directly affect the creative performance within work teams.

Creative Problem Solving (CPS): A systematic process model to solve problems and to harness creativity. Its six steps include objective-finding, data-finding, problem-finding, idea-finding, solution-finding, and acceptance-finding. Each step has a divergent and convergent phase. During the divergent phase, a free flow of ideas is elicited. Convergent phases involve the evaluation and selection of the ideas with the greatest potential or relevancy. The defer-judgment rule separates idea generation from idea evaluation.

Creativity: The production of something new or original that is useful; the act of creating recombining ideas or seeing new relationships among them. Creativity is usually defined in terms of either a process or a product and at times has also been defined in terms of a kind of personality or environmental press. These are four Ps of creativity: process, product, person, and press.

Divergent Thinking Techniques: Tools used during the divergent phases of the CPS to improve the generation of ideas, thoughts, or data without evaluation. These tools are classified according to their primary use of related or unrelated problem stimuli. Brainstorming, brainwriting, forced connections, analogies, and metaphors are some of the most used divergent thinking techniques.

Diversity/Flexibility/Tension: Diversity, both in terms of the work assignments offered and the people one interacts with, and a tolerance of differences. In order to be tolerant of differences, flexibility is needed. Both diversity and flexibility can lead to creative tension.

Support for Creativity: An organizational focus on support for or encouragement of creativity.

Trust and Participative Safety: Especially crucial for group creativity is trust and participative safety. The emphasis is on encouraging participation in a non-threatening, non-evaluative environment.

Virtual Team: A group of people who are geographically separated and who work across boundaries of space and time by utilizing computer-driven technologies such as desktop video conferencing, collaborative software, and Internet/intranet systems. How these teams interact defines them as "virtual."

Inclusion Dependencies

Laura C. Rivero
Universidad Nacional del Centro de la Provincia de Buenos Aires, Argentina and Universidad Nacional de La Plata, Buenos Aires, Argentina

INTRODUCTION

Inclusion dependencies support an essential semantics of the standard relational data model. An inclusion dependency is defined as the existence of attributes (the left term) in a table R whose values must be a subset of the values of the corresponding attributes (the right term) in another table S (Abiteboul, Hull & Vianu, 1995; Codd, 1990; Connolly, Begg & Strachan, 1999; Date, 2000). When the right term conforms a unique column or a primary key (K) for the table S, the inclusion dependency is key-based (also named referential integrity restriction, *rir*). In this case, the left term is a foreign key (FK) in R and the restriction is stated as R[FK] <<S[K]. On the contrary, if the right term does not constitute the key of S, the inclusion dependency is non-key-based (simply, an inclusion dependency, *id*). Ids are expressed as R[X]$\subseteq$S[Z], being R[X] and S[Z] the left and right terms respectively. Both, *rir*s and *id*s, are often called referential constraints.

*Rir*s and referential actions are important because they contain basic local semantic aspects, which have been elicited from the Universe of Discourse (UofD). They are sufficient to symbolize many natural semantic links such as the relationships and hierarchies that are captured by semantic models (Abiteboul, Hull & Vianu, 1995). In a different scenario, late changes of the logical design, disregarding the conceptual design, usually promotes some denormalization degree or the presence of complex n-ary relationship constructs. The decomposition and the synthesis coming from that process may add other restrictions, frequently adopting the form of *id*s that misrepresent objects and the corresponding inter-object relationships.

*Rir*s can be declaratively defined via the SQL foreign key clause (SQL:1999-1, 1999, SQL:1999-2, 1999) and are enforced by most current database systems:

FOREIGN KEY (<referencing column list>) REFERENCES <referenced table name> [(<referenced column list>)]
[MATCH <match type>]
[ON UPDATE <update referential action>]
[ON DELETE <delete referential action>]

The *rir*s can be specified with respect to different match types: SIMPLE (implicit if no match option is declared), PARTIAL and FULL. As it has been stated in the SQL:1999 standard document (SQL:1999-2, 1999): If <match type>(SIMPLE) is not specified, then for each row in the referencing table, either the referencing column has at least one null value or its value matches the value of a corresponding row in the referenced table. If PARTIAL is specified, then for each row in the referencing table the value of each foreign key column is null, or it has at least one non-null value that equals the corresponding referenced column value. Finally, if FULL is specified, for each row in the referencing table, either all foreign key columns have been instanced with null or the foreign key value equals the value of the corresponding referenced column.

When an integrity restriction is violated, the usual response of the system is the rollback of the data manipulation intended by the user. In the case of *rir*s, some other alternative actions are possible. These actions, named referential actions or referential rules, specify the behavior of the left and right relations under the deletion or the updating of a referenced row (in the right table), or the insertion in the referencing (left) table. Possible actions are: cascade, restrict, no action, set null, set default (Date, 2000; Markowitz, 1994; SQL:1999_2, 1999; Türker & Gertz, 2001).

With the cascade option, the referencing rows will be deleted (updated) together with the referenced row. With the set null (set default) option, all references to the deleted (updated) row will be set to null (default) values. Restrict and no action rules disallow the deletion (update) of the referenced row, if there exists rows in the left table referencing it. The unique referential rule for insertions is restrict: inserting a row into the referencing table is possible only if the referenced tuple already exists in the right term.

On the other hand, *id*s are usually defined with check statements

CHECK (<referencing column list> IN (SELECT <referenced column list> FROM <referenced table>))

or triggers, thus complicating the development of application programs and integrity maintenance (Connolly, Begg & Strachan, 1999; Date, 2000; Date & Darwen, 1997; Elmasri & Navathe, 2000).

The objective of this entry is to provide an overview of *id*s, summarizing main research on this topic.

BACKGROUND

The comprehension of the syntactic and semantic issues related to referential restrictions is facilitated by the study of the structure of their terms.

Structure

Considering a relation shape, there are five possible placements of a non-empty set of attributes with regard to the key placement. Being W such set of attributes, and K the primary key of R, the five placements are depicted in Figure 1: I) W≡ K (W coincides with K); II) W≡ Z, being Z a subset of non-key attributes (W and K have not common attributes); III) W≡ K_1, being K_1 a proper subset of K, $K_1 \neq \emptyset$ (the set of attributes in W is a proper subset of the set of attributes in K); IV) W≡ K ∪ Z (W attributes include the complete set of attributes of K); and finally V) W≡ $K_1 \cup$ Z, $K_1 \neq \emptyset$ (W and K partially overlap). In all cases, Z $\neq \emptyset$.

Let R and S be the left and right terms of a referential constraint, respectively. Taking into account the placements in Figure 1, 25 pairs <R[W_R], S[W_S]> corresponding to left and right terms of a referential constraint can be derived. The five cases having S[W_S] as the primary key for S (numbered 1 to 5 in Table 1) correspond to *rir*s.

Semantic Perspective

*Rir*s of types I, II and III represent typical relationships in semantic models (Abiteboul, Hull & Vianu, 1995). Type I depicts subtype relationships such as "every salesman is also a person". Type II corresponds to designative relationships such as 1:1, N:1 or n-ary relationships with at least one 1 cardinality. Type III appears in associative relationships such as N:N and n-ary relationships and weak entities (Date, 2000; Elmasri & Navathe, 2000). Types IV and V deserve a different analysis, as they appear as a result of late irregular alterations of logical designs (Rivero, Doorn & Ferraggine, 2004). The remaining cases correspond to *id*s, which cannot be obtained via a semantic model, but as a consequence of similar reasons as types IV and V of *rir*s (Rivero, Doorn & Ferraggine, 2001, 2004).

MAIN CHARACTERISTICS AND APPLICATIONS OF INCLUSION DEPENDENCIES

Following, there is a description of main issues about inclusion dependencies and relevant applications of this concept.

Referential Actions and Global Semantics

Update operations promote the execution of specialized triggers -the referential actions-, for the programmed maintaining of referential integrity. The actions are: *cascade, restrict, no action, set null, set default* (Date, 2000; Markowitz, 1994; SQL:1999_2, 1999; Türker & Gertz, 2001).

Despite the fact that the local effect of such rules is precisely defined, when update operations are executed on the database state, the global effects those interacting actions promote may show ambiguities (Lüdascher & May, 1998; Markowitz, 1994; May & Lüdascher, 2002; Reinert, 1996).This problem has been - and currently is - a matter of profuse research, from the beginning of the relational databases era. While in Markowitz(1994) the

References: K_*(key); Z_* (non-key attributes); K_*^1 (a proper subset of K_*). $_*$ = l, r (left, right)

anomalies caused by the use of referential actions (in some cases interacting with null constraints) are completely described and some solutions for its treatment are presented, in Reinert (1996) this study is revised by showing that the problem of deciding if a relational schema may or may not have an instance leading to ambiguities is undecidable. Recently, the whole understanding of the global behavior of referential actions based on the local characterization of that rules has been formalized in Ludäscher and May (1998) and May and Ludäscher (2002).

Inclusion Dependencies and Functional Dependencies: Interaction, Inference Rules and the Implication Problem

Levene and Loizou (1999) affirm that "the interaction between functional and inclusion dependencies is a complex problem, and there is not a complete and sound system of axioms for functional and inclusion dependencies at all". While some interactions may result in a new (functional or inclusion) dependency being obtained, other cases derive in redundant attributes. Pullback, Collection and Attribute-Introduction rules capture significant interactions between such restrictions (Levene & Loizou, 1999; Levene & Vincent, 2000).In Levene and Loizou (1999) may be found the relational database theory needed to understand the inference rules and the implication problem for *id*s.

Use of Inclusion Dependencies as Domain Constraints

Some relationships have the semantics of *id*s or *rir*s symbolizing, essentially, domain restrictions that indicate the legal values for an attribute. UofD business rules associated to specific domain restrictions over dynamic and voluminous set of values are frequently written as *id*s or *rir*s. For example,

CHECK (LeftAttrList IN (SELECT RightAttrList FROM R))

would indicate that the set of allowable values for LeftAttrList is conformed by the current set of instances of RightAttrList in the relation R (Rivero, Doorn & Ferraggine, 2001, 2004).

Basis for the Database Reengineering

This application is strongly related to the previous one. A deep analysis of the referential constraints helps find hidden objects and misrepresented relationships. While the structure of the left and right terms of *id*s is a key concept for the reengineering of relational database schemas, cases IV and V of *rir*s reveal relationships hiding specific business rules. A careful examination of the structure of these constraints allows the reconstitution of a subject schema into an enhanced form and the subsequent enrichment of the whole system (Rivero, Doorn & Ferraggine, 2001, 2004; Tari et al., 1997).

Referential Integrity in Object-Oriented and Object-Relational Databases

Object-oriented literature typically uses the term "relationship" to mean relationships supported by foreign keys in a relational system. This implementation, the unique available in a SQL-92 system, may be used in an object-relational DBMS (ORDBMS) (Date, 2000; Stonebraker, 1996). Object-relational systems, in compliance with the current standard – SQL:1999 - provide the *reference* as a natural surrogate for primary key-foreign key relationships. In these systems, a column in a table may contain a value that is a *reference* to an instance of a type stored in another table. This implementation is supported by the unique object identifier (OID) of rows (SQL:1999-1, SQL:1999-2).

Triggers for referential integrity are an alternative to the use of foreign key constraints, despite the fact that foreign key constraints are preferable to explicit triggers since they are declarative and then easier to manage.

FUTURE TRENDS

From its beginnings the relational technology has experimented a fantastic process of evolution to finally become a mature environment. Main commercial (and open source) software offer referential constraints and triggers to fully maintain referential integrity. On the other hand, while object-oriented (OO) programming and semantic models are now the standard for best developers and programmers, OO databases constitute just a small portion of the market, albeit they have gained popularity in recent years. One of the reasons why the OO paradigm has been adopted to extend the relational technology is because it allows developers to cope with the growing capacity of current software development. As a consequence, the OO paradigm has been the basis for current research on models that integrate the relational data model and SQL query languages with features coming from the object-oriented world. As a result, a next generation of database systems - object-relational (ORDBMS) - has emerged (Stonebraker, 1996).

This evolution has posed new challenges related to the referential integrity maintenance. Referential actions, defined in the relational context, must be efficiently implemented in the object-relational context. Different strategies suggest implementing integrity rules following the principles of the relational side of ORDBMS. Another, coming from the OO technology, recommends the implementation following the business logic, that is, within the objects. Triggers, specific metadata, and so forth are other ways to implement these concepts. The decision about the choice of the best strategy taking into account the structure of relations, their variability and other performance issues is a novel research field.

The degree of distribution and heterogeneity of the DBMS and the variety of data that current DBMSs can manage are two of the current directions of developments and advances in DBMS technology. With respect to the first issue, the definition and implementation of a consistency checking service is particularly difficult whenever data are stored in a heterogeneous collection that is not controlled by a single DBMS. On the other hand, multimedia databases (Dunckley, 2002), spatio/temporal databases, XML databases (Graves, 2001; Williams et al., 2000) and active databases (Paton & Diaz, 1999; Widom & Ceri, 1996; Zaniolo et al., 1997) are recent examples that illustrate the variety of data information that a DBMS should be able to manage. Efficient implementation of integrity issues, and mainly referential integrity constraints to deal with heterogeneous data sources in centralized or distributed environments, represent a challenge and a promising research area.

The World Wide Web, lacking specific guidelines to enforce referential integrity (Aldana, Yagüé & Gómez, 2002); newer multilevel security strategies posing a different scenario to the integrity maintenance (Lee, Kim & Kim, 2004); and the recent development of applications and DBMSs for mobile databases (Pitoura & Samaras, 1998) have given rise to interesting challenges and research opportunities in the area of database management and particularly in the area of data consistency.

CONCLUSION

This work presents an overview of inclusion dependencies and the particular case of referential integrity restrictions. It sketches some topics related to its structure and semantics and describe relevant issues related to inclusion dependencies interacting with functional dependencies. The version of this concept in third generation databases is briefly described. Atypical behaviors generated as a consequence of design flaws should encourage users to consider referential constraints not only as merely integrity constraints but also as the basis for a good practice on database design and reengineering.

Finally, current and future directions of database evolution are succinctly mentioned to describe the scenarios in which the integrity issues must mature.

KEY TERMS

Business Rules: Statements that model the reaction to events that occur in the real world, having tangible side effects on the database content. They respond to application needs.

Database Schema Reengineering: The process of analyzing a subject database schema to recover its components and their relationships. It guides the reconstitution of such system into an enhanced one, with a higher level of abstraction and semantically closer to the Universe of Discourse.

Global Semantics of Referential Actions: The whole effect interacting referential actions lead to under update operations on the database state.

Inclusion Dependency: Defined as the existence of attributes in a table whose values must be a subset of the values of the corresponding attributes in another (or the same). Expressed as $R[X] \subseteq S[Z]$. R and S are relation names (possibly the same); R[X] and S[Z] are named the inclusion dependency's left and right sides respectively. X, Z are compatible attributes.

Inconsistency: Database state that does not reflect a real-world state.

Integrity Constraints: Statements that specify the set of valid values in a database. They must be satisfied to protect the database against inconsistencies.

Referential Action: Specialized rule used to automatically maintain referential integrity. Define specific reactions to compensate referential integrity violations. They may be Cascade, Restrict, No Action, Set Default or Set Null.

Referential Integrity Restriction: A special case of an inclusion dependency, when Z is the primary key K of S. In this case, X constitutes a foreign key FK for R. This restriction can be stated as $R[FK] << S[K]$.

I

Incorporating Data Stream Analysis into Decision Support Systems

Damianos Chatziantoniou
Athens University of Economics and Business, Greece

George Doukidis
Athens University of Economics and Business, Greece

INTRODUCTION

Traditional decision support systems (DSS) and executive information systems (EIS) gather and present information from several sources for business purposes. It is an information technology to help the knowledge worker (executive, manager, analyst) make faster and better decisions. So far, this data was stored statically and persistently in a database, typically in a data warehouse. Data warehouses collect masses of operational data, allowing analysts to extract information by issuing decision support queries on the otherwise discarded data. In a typical scenario, an organization stores a detailed record of its operations in a database, which is then analyzed to improve efficiency, detect sales opportunities, and so on. Performing complex analysis on this data is an essential component of these organizations' businesses. Chaudhuri and Dayal (1997), present an excellent survey on decision-making and on-line analytical processing (OLAP) technologies for traditional database systems.

In many applications, however, it may not be possible to process queries within a database management system (DBMS). These applications involve data items that arrive on-line from multiple sources in a continuous, rapid and time-varying fashion (Babcock, Babu, Datar, Motwani & Widom, 2002). This data may or may not be stored in a database. As a result, a new class of data-intensive applications has recently attracted a lot of attention: applications in which the data is modeled not as persistent relations, but rather as transient *data streams*. Examples include financial applications (streams of transactions or ticks), network monitoring (stream of packets), security, telecommunication data management (stream of calls or call packets), web applications (clickstreams), manufacturing, sensor networks (measurements), and others. In data streams we usually have "continuous" queries (Terry, Goldberg, Nichols & Oki, 1992; Babu & Widom, 2001) rather than "one-time". The answer to a continuous query is produced over time, reflecting the stream data seen so far. Answers may be stored and updated as new data arrives or may be produced as data streams themselves. Continuous queries can be used for monitoring, alerting, security, personalization, etc. Data streams can be either *transactional*, i.e. log interactions between entities, such as credit card purchases; web clickstreams; phone calls; or *measurement*, i.e. monitor evolution of entity states, such as physical phenomena, road traffic, temperature, network.

How to best model, express and evaluate complex queries over data streams is an open and difficult problem. This involves data modeling, rich querying capabilities to support real-time decision support and mining, and novel evaluation and optimization processing techniques. In addition, the kind of decision support over data streams is quite different from "traditional" decision-making: decisions are "tactical" rather "strategic". Research on data streams is currently among the most active areas in database research community. We believe that flexible and efficient stream querying will be a crucial component of any future data management and decision support system.

BACKGROUND

The database research community has responded with an abundance of ideas, prototypes and architectures to address the new issues involved in data stream management systems (DSMS). STREAM is Stanford University's approach for a general-purpose DSMS (Arasu et al., 2003); Telegraph and TelegraphCQ (Madden & Franklin, 2002; Chandrasekaran et al., 2003) are prototypes focused on handling measurements of sensor networks, developed in Berkeley; Aurora is a joint project between Brandeis University, Brown University and MIT (Carney et al., 2002) targeted towards stream monitoring applications; AT&T's Hancock (Cortes, Fisher, Pregibon, Rogers & Smith, 2000) and Gigascope (Cranor, Johnson, Spatscheck & Shkapenyuk, 2003) projects are special-purpose data stream systems for network management; Tribeca (Sullivan, 1996) and NiagaraCQ (Chen, DeWitt, Tian & Wang , 2000) are other well-known projects from Telcordia and University of Wisconsin respectively. The objective of all these projects is to develop systems that can support the challenging analysis requirements of streaming applications.

Furthermore, a plethora of articles, papers and tutorials appeared recently in the research literature. Some of the most well known survey articles follow. Faloutsos (2004), discusses indexing and mining techniques over data streams; Koudas and Srivastava (2003), present the state-of-the-art algorithms on stream query processing; Muthukrishnan (2003), reviews data stream algorithms and applications; Babcock et al. (2002), present an excellent survey on data stream prototypes and issues; Garofalakis, Gehrke and Rastogi (2002), discuss various existing models and mining techniques over data streams.

APPLICATIONS

Stream applications span a wide range of everyday life. Real-time analytics is an essential part of these applications and becomes rapidly more and more critical in decision-making. It is apparent from the list of areas below that efficiently querying and processing data streams is a necessary element of modern decision support systems.

- **Telecommunications.** The telecommunications sector is undoubtedly one of the prime beneficiaries of such data management systems due to the huge amount of data streams that govern voice and data communications over the network infrastructure. Examples of stream analysis include fraud detection, real-time billing, dynamic pricing, network management, traffic monitoring and so on. Streams (calls, packets) have to be mined at real-time to discover outliers and patterns (fraud detection); correlated, joined and aggregated to express complex business rules (billing, dynamic pricing); and monitored – computing averages and min./max. values over periods of time - to uncover unusual traffic patterns (network management).
- **Sensors.** Sensor technology becomes extremely wide-spread and it will probably be the next killer app: large number of cheap, wireless sensors attached to products, cars, computers, even sport players and animals, tracking and digitizing behavior, traffic, location and motion. Examples involve electronic property stickers (super markets, libraries, shopping carts, etc.), vehicle sensors (to pay electronically tolls, route traffic, set speed, etc.) and location-identification sensors (to report location, serve content, detect routes, etc.) A "sensor" world leads to a "stream" world. Millions of input data every few seconds need to be analyzed: aggregate (what is the average traffic speed), correlate (two products sell together), alert (quantity of a product is below a threshold), localize and monitor.
- **Finance.** Financial data streams come in many different forms: stock tickers, news feeds, trades, etc. Financial companies want to analyze these streams at real-time and take "tactical" business decisions (opposed to "strategic" decisions, associated to OLAP or data mining). For example, Charles Schwab wants to compute commission on each trade at real-time; Fidelity would like to route content in trades at real-time. Traderbot (www.traderbot.com) is a web-based financial search engine that evaluates queries (both traditional and continuous) over real-time streaming data (e.g. "find all stocks between •20 and •200 where the spread between the high tick and the low tick over the past 30 minutes is greater than 3% of the last price and in the last 5 minutes the average volume has surged by more than 300%.")
- **Web Management.** Large web sites monitor web logs (clickstreams) online to enable applications such as personalization, performance monitoring, and load balancing. Some web sites served by widely distributed web servers (e.g. Yahoo) may need to coordinate many distributed clickstream analyses, e.g. to track heavily accessed web pages (e.g. CNN, BBC) as part of their real-time performance monitoring. (Babcock et al., 2002}
- **Network Management.** Network traffic management systems monitor a variety of continuous data streams at real-time, such as packet traces, packet flows and performance measurements in order to compute statistics, detect anomalies, adjust routing, etc. The volume of data streams can be humongous and thus, query processing must be done very carefully.
- **Military.** One of the most interesting applications in military is battalion monitoring – where sensors are installed on every vehicle, human, etc. – having thousands of sensors reporting state in real-time. In these applications we want to know each time where vehicles and troops are. Examples include queries such as "tell me when 3 of my 4 tanks have crossed the front line" and "tell me when someone is pointing a gun at me".

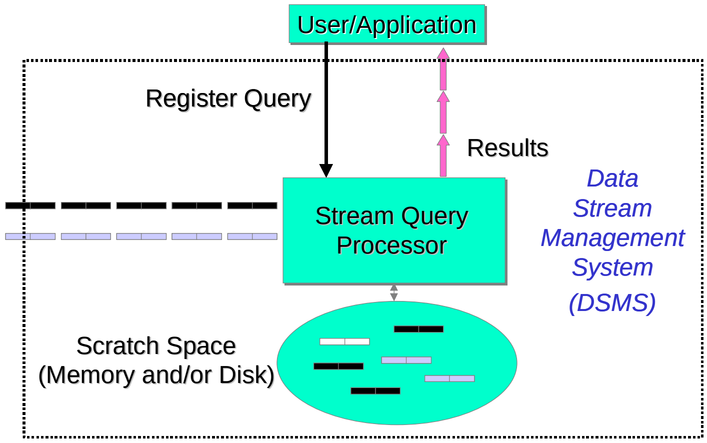
ISSUES AND CHALLENGES

Performing decision-making queries on top of data streams is a major challenge. For example, only one-pass algorithms are allowed (because data can be seen only once) and memory has to be managed very carefully (what to keep and what to discard). The need for a data stream

Table 1. Differences betweens DSMS and DBMS

DBMS	DSMS
Persistent relations	Transient streams
One-time queries	Continuous queries
Random access	Sequential access
“Unbounded” disk store	Bounded main memory
Only current state matters	History/arrival-order is critical
Passive repository	Active stores
Relatively low update rate	Possibly multi-GB arrival rate
No real-time services	Real-time requirements
Assume precise data	Data stale/imprecise

Figure 1. A generalized DSMS architecture



management system comes in two forms: either the volume of data is huge and can not be stored in persistent relations (e.g. packet network traffic) – but still some data analysis has to be carried out, or an answer is required for a report at real-time (e.g. monitoring, alerting, fraud-detection.) As a result, DSMS are quite different in nature from traditional DBMS. Data is transient instead of persistent; queries may be “continuous” instead of “one-time”; processing techniques differ significantly, primarily due to main-memory management requirements. In Table 1 we list the differences between traditional database and data stream management systems (Babcock et al. 2002).

A generalized DSMS architecture is shown in Figure 1 (Babcock et. al.).

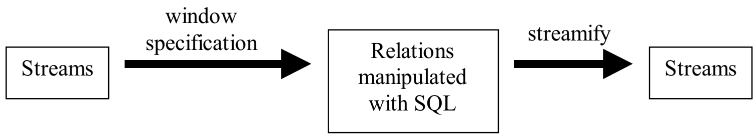
A user or application registers a (continuous) query with the stream system. As new stream data arrives, the answer of the registered query is updated. The stream query processor deals with the incoming data and has to decide on a significant number of important issues: should it shed data to keep up with the rate of the stream (leading to approximate answers)? What is the best way utilize main-memory space? What is the best way to handle multiple registered queries in an optimal way (maximizing resource utilization)? Finally, some scratch space may be required for intermediate computations.

The differences between DSMS and DBMS present several novel challenges for a system handling and analyzing data streams, both in terms of functionality and processing.

In terms of functionality (how to *use* data streams, i.e. reporting):

- Defining complex stream sessions (e.g. a network “flow” or a finance “burst”.)
- Representing nested stream structures (e.g. a sub-session within a session.)
- Defining hierarchical statistical stream functions (similar to roll-up, drill-down in OLAP).
- Allowing multiple sources and/or multiple formats, possibly combine with persistent data.

Figure 2. Turning streams to relations



- Allowing user-defined functions – UDFs (e.g. a non-traditional financial computation).

In terms of evaluation (how to *process* data streams):

- Handling multiple, continuous, rapid, time-varying, ordered streams.
- Having computations only in main-memory.
- Queries may be continuous (not just one-time):
  • Have to be evaluated continuously as stream data arrives.
  • Answer updated over time.
- Queries may be complex:
  • Beyond element-at-a-time processing.
  • Beyond stream-at-a-time processing.
  • Beyond traditional decision making queries (scientific, data mining).
- Queries may involve nested structures.
- Users may select for query answers to be:
  • Exact (worst performance, sometimes not possible due to the stream rate).
  • Approximate (requires load shedding, i.e. discarding data, better performance).

QUERYING AND EVALUATING DATA STREAMS

The challenges mentioned in the previous section lead to a number of major issues in querying and processing data streams. Understanding these aspects is crucial in developing a stream system. Different systems follow different methodologies in processing data streams (as presented in the "Systems Prototypes" section below).

Windows

Being able to formulate queries on top of data streams is a major component of any stream system. Most system prototypes extend SQL in some way in order to make it suitable for stream processing. For example, AT&T's Gigascope defines GSQL and Stanford's STREAM proposes CQL. Most stream query languages reference and produce both relations and streams. Please see the figure below.

It is important however to transform infinite, unbounded streams to finite relations which then can be manipulated by a query processor. Defining windows of streams through some window specification syntax is the mechanism to turn (part of) a stream to a relation. For example, one could define a window as the one-thousand most recent stream tuples. Figure 2 graphically shows this concept.

Windows can be based on ordering attributes (e.g. a sliding or shifting window), tuple counts, explicit markers (called punctuations), etc. An application or a query may define more than one window and "join" them together.

Query Evaluation

The unique characteristics of data streams lead to different evaluation algorithms and query processing: data elements arrive continuously, possibly at variable arrival rate; data streams are potentially unbounded in size; general retrieval of past elements is very difficult, if not impossible. As justly pointed out by Garofalakis et al. (2002), "you only get one look". This does not exclude the presence of conventional data stored in some traditional database systems.

As a result, algorithms operate mainly in main-memory and involve one-pass techniques (or few-passes, if the input data stream can be organized in input blocks). Operators include – besides the traditional ones (selection, projection) – operations specific for combining and aggregating multiple streams, such as sliding window join and merging. Optimization is very different than traditional DBMS. The goal in DSMS is to maximize the tuple output rate for a query, i.e. instead of seeking the least cost plan, seek the plan with the highest tuple output rate. Specialized data structures (synopses) that allow fast modifications and summarize efficiently information are frequently used. Finally, architectures are usually data-

Relations, Streams → ***Stream Query Languages*** → Relations, Streams flow oriented, i.e. operators are assembled together in a workflow-style diagram.

Adaptive Query Processing

Traditional query processors use a request-response paradigm for query answering, where users pose a query, the optimizer finds the "best" query plan and proceeds with query evaluation. However, the introduction of continuous queries along with the possibility of a large number of registered queries with the stream manager changes this model significantly. An aspect of continuous query is the need for adaptivity to change: unbounded queries will run long enough to experience changes in system and data properties as well as system workload during their run. A continuous query engine should adapt gracefully to these changes, in order to ensure efficient processing over time (Madden, Shah, Hellerstein & Raman, 2002). The goal of an adaptive query processing system is to maximize utilization of storage and computation (in terms of operator sharing) of multiple simultaneous queries present in the system.

Exact vs. Approximate Answers

Traditional database systems compute exact answers for queries. However, there are cases that approximate answers are either "good enough" (e.g histograms, sketches, traditional DBMS) or "the only possibility" (e.g. DSMS where main-memory limitations and one-pass algorithms reduce the class of queries with exact answers). High-quality approximate answers are often acceptable instead of exact answers. Several approximation algorithms for data streams applications have been developed in recent years. This work has led to some general techniques for data reduction and synopsis construction, such as sketches, random sampling, histograms, and wavelets. The research on these summarization techniques led to some work on approximate query answering.

Load Shedding

Systems have a limit on how much incoming stream tuples can handle. As a result, when the arrival rate is too high (e.g. during spikes), queues will build up and the system will become overloaded. In this case, some load shedding - i.e. discarding some incoming stream data – is necessary for the system to continue functioning properly (Babcock, Datar & Motwani, 2004, Tatbul, Çetintemel, Zdonik, Cherniack & Stonebraker, 2003). In general, there are two kinds of load shedding, semantic and random. Semantic shedding is based on filtering, i.e. there is a filter (a predicate) that is applied on each stream tuple with selectivity 1-p. Random shedding is based on dropping randomly incoming data with a probability p%, eliminating thus p% of the input load.

A stream system should be able to answer to three questions, when, where and how much load shedding. The first issue - when load shedding should take place – requires constant monitoring of the system. The second one involves deciding the place in a query plan that load shedders will be added. For example, Aurora, a DSMS prototype, defines a stream query as a network (a workflow) of operators. Load shedding can be modeled as another operator, placed within this network. Dropping tuples as early as possible saves resources but there may be a problem later, if streams fan out to multiple queries. The last issue has to do with estimating of how much shedding is required (percent of random drops or filtering appropriately).

Mining Streams

An orthogonal issue to processing streams is mining and indexing streams at real time (Garofalakis et. al., 2002). The goal of this topic is to find patterns in a sequence of measurements (financial, sensor, etc.) Besides the traditional mining patterns (classification, clustering and association rules), there exist many time series patterns that are of special interest in stream analysis (Faloutsos, 2004, Lerner, Shasha, Wang, Zhao & Zhu, 2004).

SYSTEM PROTOTYPES

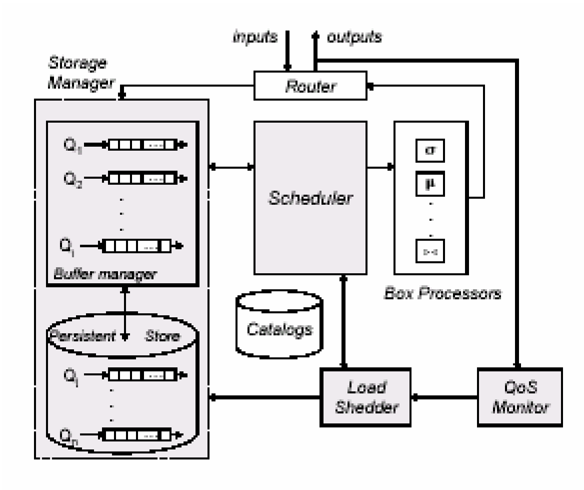
The interest on data streams has led many research organizations (mainly in the U.S.) in the development of data stream prototypes. We list below some of the most well known systems.

- **Aurora.** Aurora is a joint project between Brandeis University, Brown University and MIT targeted towards stream monitoring applications. The processing mechanism is based on the optimization of a set of operators, connected in a data flow graph. Queries (three modes: continuous, ad-hoc, view) are formulated through a graphical "boxes and arrows" interface. Aurora's architecture is shown in Figure 3 (Carney et. al., 2002).

The designers of the Aurora stream system claim five unique features that distinguish it from other stream proposals: a workflow-orientation, a novel collection of operators, efficient scheduling, quality of service concerns and novel optimization methods.

A workflow orientation is necessary due to the frequent preprocessing required for data streams. This way,

Figure 3. Aurora's architecture (Carney et al., 2002)



users design an application (a workflow) with a "boxes" and "arrows" GUI and the system can optimize it more efficiently. The set of operators include "boxes" for filtering, mapping, aggregation (windowed) and join, similar to other stream systems. However, there are some distinct features: windowed operations have a timeout capability, the system deals with "out-of-order" messages (delayed messages), extendability (user-defined functions) and resampling. Scheduling is a major component of Aurora system and it aims on reducing CPU cost of running the scheduler and maximizing the quality of service.

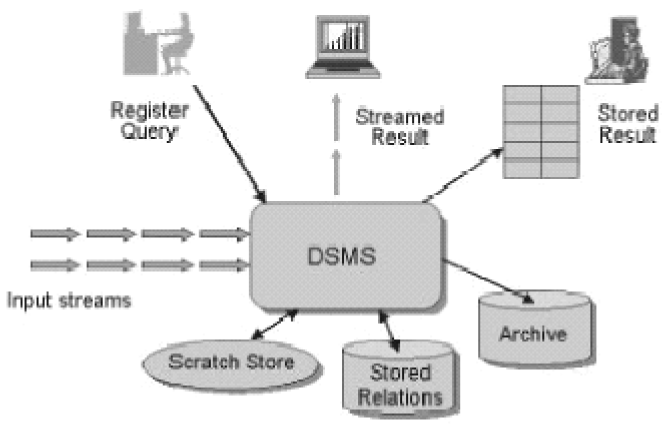
An Aurora workflow is a dynamic object. When new applications get connected to the workflow, the number of boxes and arrows changes. Also ad-hoc queries that are run just once and then discarded have a similar effect. Furthermore, Aurora workflows may be quite large. As a result, Aurora performs only run-time optimization.

- **Gigascope.** AT&T's Gigascope project is a special-purpose data stream system for network applications, such as traffic analysis, intrusion detection, router configuration analysis, network monitoring and performance monitoring and debugging. The central component of Gigascope is a stream manager which tracks the query nodes that can be activated. Query nodes are processes. When they are started, they register themselves with the registry of the stream manager.

Gigascope's query language, GSQL, is an SQL-like language with stream features. All inputs to and outputs of a GSQL query are data streams. Currently GSQL supports selection, join, aggregation and stream merge. A GSQL query is analyzed, translated to C/C++ code, and then executed. Optimization of GSQL queries consists of rearranging the query plan and generated-code optimizations. Another important optimization is pushing selections as far down as possible, even to the network level. To achieve this, the query processor of Gigascope "breaks" queries into high-level and low-level query nodes. Low-level query nodes are separate processes consisting of simple filtering conditions.

- **STREAM.** The STanford stREam datA Manager (STREAM) project at Stanford is developing a general-purpose DSMS for processing continuous

Figure 4. Overview of STREAM Architecture (Arasu et al., 2003)



queries over multiple continuous data streams and stored relations. The architecture of STREAM is shown in Figure 4 (Arasu et al., 2003).

The incoming input streams produce continuous data and drive query processing. Scratch store is used for the intermediate processing of the incoming data and can be stored in memory or on disk. An Archive storage is used for storing some (or all) of the data stream for possible offline processing of expensive mining queries. Users or applications may register continuous queries and get the answers as output data streams or relational results that are updated over time. During the processing of continuous queries, traditional relational tables can be utilized. Currently STREAM offers a Web system interface through direct HTTP, and a Web-based GUI to register queries and view results.

STREAM people developed a declarative query language, CQL (Continuous Query Language) for continuous queries over data streams and relations. They model a stream as an unbounded, append-only bag of (tuple, timestamp) pairs, and a relation as a time-varying bag of tuples supporting updates, deletions and insertions. The key idea is to convert streams into relations using special windowing operations, perform transformations on relations using standard relational operators and then convert back (optionally) the transformed relational data into a streamed answer (Arasu et al., 2003). CQL uses SQL as its relational query language, SQL-99 amendments provide the window specification language, and it includes three relation-to-stream operators. When a continuous query specified in CQL is registered with STREAM, it is compiled into a query plan. The query plan is merged with existing query plans whenever possible, in order to share computation and memory.

- **TelegraphCQ.** TelegraphCQ is a prototype focused on handling measurements of sensor networks. Developed in Berkeley, it is based on adaptive and multi-query processing and uses a mix of SQL and scripting programming languages for expressing complex queries. Its architecture is shown in Figure 5 (Chandrasekaran et al., 2003).

Telegraph, the predecessor of TelegraphCQ, consists of an extensible set of composable dataflow modules or operators that produce and consume records in a manner analogous to the operators used in traditional database query engines. The modules can be composed into multi-step dataflows, exchanging records via an API called Fjords (Madden & Franklin, 2002) that can support communication via either "push" or "pull" modalities.

TelegraphCQ supports continuous queries defined over relational tables and data streams with a rich set of windowing schemes (e.g. landmark and sliding windows).

Other stream projects include Tribeca, developed in Telcordia for network management; NiagaraCQ, a project of University of Wisconsin to monitor internet data (XML-format); Cougar and Amazon of Cornell University, aimed to monitor distributed sensor networks. We present in Table 2 a comparison table between Aurora, Gigascope, STREAM and Telegraph.

Figure 5. TelegraphCQ's architecture (Chandrasekaran et al., 2003)

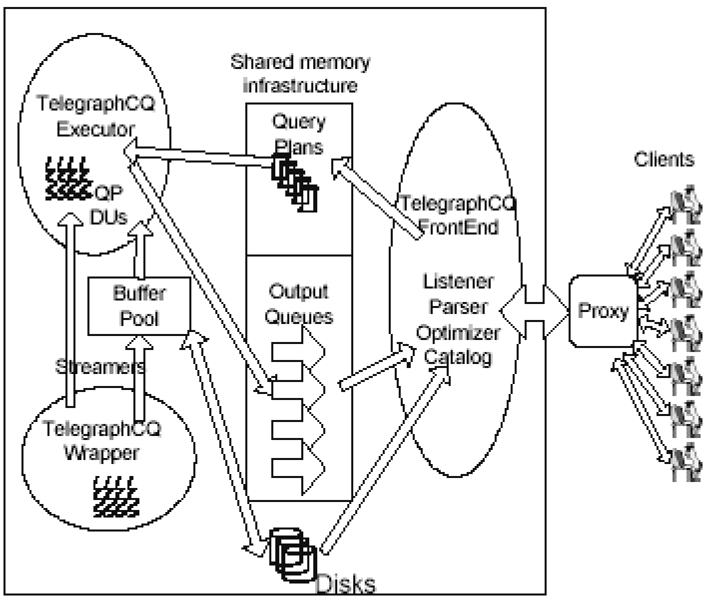


Table 2. Comparing different stream prototypes

Stream System	Input	Output	Query Language	Answers	Evaluation
Aurora	Relations, Streams	Relations, Streams	Operators (boxes and arrows)	Approximate	Run-time optimization
Gigascope	Streams	Streams	GSQL (SQL-like)	Exact	Splitting query to high- and low-level
STREAM	Relations, Streams	Relations, Streams	CQL (SQL-like)	Approximate	Static analysis, relational optimization
Telegraph	Relations, Streams	Relations, Streams	SQL-based, scripting	Exact	Adaptive query processing, multi-query

CONCLUSION

Equipping traditional database management systems with decision support capabilities has been studied extensively in the last decade. Building data warehouses, forming data cubes, creating data marts, carrying out data mining tasks and performing on-line analytical processing and multi-dimensional analysis are well-known subjects in the context of decision-making. However, an emerging trend in data management, data streams, is very different in nature from traditional database applications: queries are different, models and frameworks are special, query processing is peculiar and, subsequently, decision support is defined differently. The keywords in this domain are: real-time, continuous, tactical decisions. A lot of progress has been recently made in this field by several research institutions to build various (either general- or specific-purpose) data stream management systems with rich data analysis capabilities. Given the popularity of sensors and the need for real-time analytics, the ability of data analysis on top of data streams will be a crucial component of future data management and decision support systems.

KEY TERMS

Continuous Queries: The answer to a continuous query is produced over time, reflecting the stream data seen so far. Answers may be stored and updated as new data arrives or may be produced as data streams themselves.

Data Streams: Data items that arrive on-line from multiple sources in a continuous, rapid, time-varying, possibly unpredictable fashion.

Data Stream Management Systems (DSMS): A data management system providing capabilities to query and process data streams and store a bounded part of it.

Load Shedding: The discarding of input data by the DSMS when the input stream rate exceeds system capacity. It can either be semantic (based on certain semantic rules) or random.

Measurement Data Streams: Data streams representing successive state information of one or more entities, such as sensor, climate or network measurements.

Network Traffic Management: Monitoring a variety of continuous network data streams at real-time, such as packet traces, packet flows and performance measurements in order to compute statistics, detect anomalies and adjust routing.

Stream Window: A mechanism to extract a finite set of records from an infinite stream. This mechanism selects stream items based on time periods, counting, or explicit starting and ending conditions.

Transactional Data Streams: Data streams representing log interactions between entities, such as credit card transactions, phone calls and web click streams.

Incremental Expansion of a Distributed Database System

Amita Goyal Chin
Virginia Commonwealth University, USA

INTRODUCTION

Recent years have witnessed an increasing trend in the implementation of distributed database management systems (DDBMSs) for more effective access to information. An important quality of these systems, consisting of *n* servers loosely connected via a communication network, is to adjust to changes in workloads. To service increases in demand, for example, additional servers may be added to the existing distributed system and new data allocations computed. Conventionally, this requires a system shutdown and an exhaustive data reallocation. Such static methods are not practical for most organizations for these methods result in high costs and in periods of data unavailability.

We present the incremental growth framework to address incremental expansion of distributed database systems. Data is reallocated using one of two data reallocation heuristics—Partial REALLOCATE or Full REALLOCATE. Both heuristics are greedy, hill-climbing algorithms that compute new data allocation based on the specified optimization parameter of the objective cost function. Due to their linear complexity, both heuristics can be used to solve both small and large complex problems, based on organizational needs. The REALLOCATE algorithms in conjunction with the SimDDBMS simulator can be used to answer many practical questions in distributed database systems. For example, in order to improve system response time, a database administrator (DBA) may use SimDDBMS for parametric evaluation. For example, the DBA may analyze the effect of upgrading CPU processing capability, increasing network transfer speed, or adding additional servers into the distributed database system. Furthermore, SimDDBMS may easily be modified to evaluate heterogeneous servers with different CPU processing capabilities. A DBA may also use SimDDBMS to determine the impact and cost-benefit analysis of adding some number, $s \leq 1$, additional servers at one time.

BACKGROUND

Following the pioneering work in Porcar (1982), many researchers have studied the file or data allocation problem (Daudpota, 1998; Ladjel, Karlapalem, & Li, 1998; So, Ahmad, & Karlapalem, 1998; Tamhankar & Ram, 1998;). Since optimal search methods can only be used for small problems, heuristic methods are often used for solving large data allocation problems (Apers, 1988; Blankinship, 1991; Ceri, Navathe, & Wiederhold, 1983; Chin, 2001; (Chin) Goyal, 1994; Du & Maryanski, 1988). Researchers have studied both the static data allocation problem, in which data allocations do not change over time, and the dynamic data allocation problem (Brunstrom, Leutenegger, & Simha, 1995; Theel & Pagnia, 1996; Wolfson, Jajodia, & Huang, 1997), which may be adaptive or nonadaptive. Adaptive models (Babcock, Babu, Motwani, & Datar, 2003; Levin, 1982; Levin & Morgan, 1978; Son, 1988) are implemented when the system senses a substantial deviation in access activities; these models determine a one-time reallocation (for a relatively short period of time) in response to surges in demand. For example, the volume of reservations for a particular airline route may increase during a specific season. Therefore, an airline reservation system may temporarily store additional copies of the files associated with the route at a local server. However, this is a short-term situation, which is resolved by introducing replicated file copies. Nonadaptive models (Levin; Porcar; Segall, 1976) are employed at the initial system design stage or upon system reorganization; these models do not adjust to variations in system activities.

Most previous research on data allocation assumes a fixed number of servers in the distributed database system (Carey & Lu, 1986; Chu, 1969; Laning & Leonard, 1983; Lee & Liu Sheng, 1992; Rivera-Vega, Varadarajan, & Navathe, 1990). Experiments and simulations are designed to test DDBMS factors such as the degree of data replication, workloads per server, and different levels and classes of queries and transactions (Carey & Lu; Ciciani, Dias, & Yu, 1990). Simulation runs vary the number of servers to arbitrary values. However, these values are fixed per run and vary only between runs.

INCREMENTAL GROWTH FRAMEWORK

The incremental growth framework is invoked when system performance, as computed using the objective cost function, is below the acceptable threshold (specified by the DBA). To return to an acceptable state, new servers are introduced incrementally, one at a time, into the distributed database system. With the introduction of each new server, a new data reallocation for the system is computed. This process is iteratively executed until acceptable performance is achieved or the number of servers equals the number of relations in the distributed database system (the latter constraint can easily be relaxed in a distributed database system housing partitioned data). The incremental growth framework, which can easily be adapted for one-server or multiple-server systems, can be used by small, midsize, and large organizations, each having distributed database systems of varying size. In one-server systems, the initial data allocation locates all relations at the server. In multiple-server systems, the current data allocation is required as input into the framework. Additional input information required for the incremental growth framework includes: the database server or servers, including the local processing capacity; the network topology, including transmission capacity; the database relations, including relation sizes and selectivities; the query set; the optimization parameter; and the acceptable threshold for the optimization parameter.

DEFINITIONS

The relational data model is used to describe the data and query processing on the data. Only simple queries are considered. Queries are assumed to be independent and are solved independently. Queries are processed in parallel in the distributed database system. To simplify the estimation of query result sizes, the concept of selectivity (Blankinship, 1991; Chin, 1999; Date, 1991; (Chin) Goyal, 1994) is utilized. Attribute values are assumed to be uniformly distributed, and each attribute in a relation is assumed to be independent of all other attributes in the database. The simple query environment has been chosen because it has a manageable complexity while remaining realistic and interesting.

The parameters describing the simple query environment are (Blankinship, 1991; Chin, 1999; (Chin) Goyal, 1994; Hevner & Yao, 1979):

S_i: Network Servers, i = 1, 2, ..., s, s+1 (S_{s+1} = the new server joining the system),
R_j: Relations, j = 1, 2, ..., r

For each relation R_j, j = 1, 2, ..., r:
n_j: number of tuples,
a_j: number of attributes,
β_j: size (in bytes)

For each attribute d_{jk}, k = 1, 2, ..., a_j of relation R_j:
p_{jk}: attribute density, the number of different values in the current state of the attribute divided by the number of possible attribute values. So, $0 <= p_{jk} <= 1$ (Hevner & Yao, 1979). During join operations the density is used as a selectivity coefficient.
w_{jk}: size (in bytes) of the data item in attribute d_{jk}

For local transaction processing, each server in the distributed database system maintains a queue of incoming requests. Queries are maintained in queue until they are processed using a first in, first out (FIFO) order.

Finally, the distributed database system maintains a centralized data dictionary housing the following information (Blankinship, 1991; (Chin) Goyal, 1994; Hevner & Yao, 1979):

- for each relation R_j, j = 1, 2, ..., r: n_j, a_j, β_j, and S_j (server to which relation R_j is allocated)
- for each attribute d_k, k = 1, 2, ..., a_j of relation R_j: p_{jk}, w_{jk}, and b_{jk} (projected size, in bytes, of attribute $d\,j_k$ with no duplicate values)

Optimizing query strategies is not within the scope of this research. However, since the optimal data allocation is dependent on the implemented query strategy, when computing new data allocations, Algorithm Serial (Hevner & Yao, 1979) for query processing is implemented. Any query optimization algorithm from the research literature, however, can be used in place of Algorithm Serial.

Algorithm Serial (Hevner & Yao, 1979) considers serial strategies to minimize total transmission time in the simple query environment. For each query q accessing ψ relations, there are $\psi!$ possible combinations for processing q. The serial strategy consists of transmitting each relation, starting with R_1, to the next relation in a serial order. The strategy is represented by $R_1 \rightarrow R_2 \rightarrow \ldots \rightarrow R_\sigma$, where σ is the number of relations in the query (Hevner & Yao, 1979).

Consider, for example, a query which accesses relations A, B, and C. Then, the $\psi! = 6$ processing combinations for the query are: $A \rightarrow B \rightarrow C$, $A \rightarrow C \rightarrow B$, $B \rightarrow A \rightarrow C$, $B \rightarrow C \rightarrow A$, $C \rightarrow A \rightarrow B$, $C B \rightarrow A$. Therefore, given four queries—two of which access two relations, one of which accesses three relations, and one of which accesses four relations—the number of possible serial strategy combinations is (2!)(2!)(3!)(4!) = (2)(2)(6)(24) = 576. The serial order is computed so that $\beta_1 \leq \beta_2 \leq \ldots \leq \beta_s$, where β_j is the size of relation R_j, j = 1, ..., r (Hevner & Yao, 1978).

SYSTEM COST EQUATIONS

A fully connected, reliable communication network (Lee & Liu Sheng, 1992) with all servers having equal local storage and processing capacity is assumed. A single instance of each relation is allocated to the distributed database system (Blankinship, 1991; Cornell, 1989; (Chin) Goyal, 1994). (Data partitioning and data replication are not considered in this research.)

When measuring system response time, the objective cost function consists of three cost components: transmission costs, local processing costs, and queuing costs. Costs are measured in terms of the number of CPU cycles or time ticks ((Chin) Goyal, 1994) needed to complete a task. The system response time is equal to the number of CPU cycles needed to process $Q = \{Q_1, \ldots, Q_q\}$ queries.

Transmission cost equations are identical between any two servers (Blankinship, 1991; (Chin) Goyal, 1994), and costs are based on the amount of data transmitted. Local processing cost equations are also identical at any two servers, and costs are based on the amount of data processed. Queuing costs are based on the number of CPU cycles a query spends in queue at each server. Storage costs are considered negligible and are not considered in the cost analysis.

Using the additional notation:

CS_n: cumulative selectivity for Q_n
$n = 1, \ldots, q$
QR_n: query result for Q_n
$n = 1, \ldots, q$
QWT_{ni}: wait time in queue for Q_n at S_i
$n = 1, \ldots, q$; $i = 1, \ldots, s+1$
LPT_{ni}: local processing time for processing Q_n at S_i
$n = 1, \ldots, q$; $i = 1, \ldots, s+1$
NTT_{nij}: network transfer time for transferring Q_n from S_i to S_j
$n = 1, \ldots, q$; $i, j = 1, \ldots, S+1$; $i \neq j$
Θ_{ni}: transmission of Q_n to S_i
$n = 1, \ldots, q$; $i = 1, \ldots, s+1$

ρ: CPU rate per CPU cycle
μ: network transfer rate per CPU cycle

we state our cost equations as follows ((Chin) Goyal, 1994):

$QR_n = (CS_n)(\beta_j)$ $n = 1, \ldots, q$; $j = 1, \ldots, r$

$$LPT_{ni} = \frac{\beta_j + QR_n}{\rho} \quad \text{at } S_i \; n = 1, \ldots, q;\ j = 1, \ldots, r;\ i = 1, \ldots, s+1$$

$$NTT_{nij} = \frac{QR_n}{\mu} \quad \text{from } S_i \text{ to } S_j \; n = 1, \ldots, q;\ i, j = 1, \ldots, s+1;\ i \neq j$$

$$QWT_{ni} = T_{P_{ni}} - T_{Q_{ni}} \quad n = 1, \ldots, q;\ i = 1, \ldots, s+1$$

where,

$T_{Q_{ni}}$ = the CPU cycle S_i places Q_n into its queue
$T_{P_{ni}}$ = the CPU cycle S_i begins processing Q_n

The objective cost function when computing data allocations to minimize response time is to minimize:

$$RT = \sum_{t=1}^{T} C(t) + \varsigma$$

where,

$$C(t) = \begin{cases} 1 & if\,(Q_n \in Q \text{ in queue at } S_i) \\ \vee & (Q_n \in Q \text{ in process at } S_i) \\ \vee & (Q_n \in Q \text{ in transmission at } S_i \rightarrow S_j) \\ 0 & otherwise \end{cases}$$

and ς = system idle time while processing $Q = \{Q_1, \ldots, Q_q\}$.

DATA REALLOCATION HEURISTICS

We present two heuristics for data reallocation: Partial REALLOCATE and Full REALLOCATE. Both algorithms are greedy, iterative, "hill-climbing" heuristics that will not traverse the same path twice. With each iteration, they will find a lower cost solution, or they will terminate. Both algorithms require as input: the current data allocation, the relations, and the queries in the distributed database system.

We define the notation:

$S = \{S_1, \ldots, S_s, S_{s+1}\}$: set of servers ($S_{s+1}$ = the new server)
$R = \{R_1, \ldots, R_r\}$: set of relations allocated to S_i, $i = 1, \ldots, s$
$R' = \{R'_1, \ldots, R'_r\}$: set of relations allocated to S_{s+1}
$R \cap R' = \emptyset$

$R_j \Rightarrow S_i$: permanent allocation of R_j to S_i, $j = 1, \ldots, r$; $i = 1, \ldots, s$
$R_j \rightarrow S_i$: temporary allocation of R_j to S_i, $j = 1, \ldots, r$; $i = 1, \ldots, s$
$O_o = \delta(\forall_j \in R, R_j \Rightarrow S_i)$, $i = 1, \ldots, s$
$O_{(s+1)j} = \delta(R_j \rightarrow S_{s+1})$ $j = 1, \ldots, r$

where $d(R_j \rightarrow S_i)$ and $d(R_j \Rightarrow S_i)$ is the objective cost function evaluated for $R_j \rightarrow S_i$ and $R_j \Rightarrow S_i$, respectively.

Each relation R_j must be allocated to a server and can be allocated to only one server at any given time. Therefore, For each $R_j \in (R \cup R')$, $\sum_{i=1}^{s+1} X_{ij} = 1$ where

$$X_{ij} = \begin{cases} 1 & R_j \to S_i \vee R_j \Rightarrow S_i \\ 0 & otherwise \end{cases}.$$

PARTIAL REALLOCATE

The steps of the Partial REALLOCATE algorithm are:

Step 1: Compute O_o.

Step 2: For each $R_j \in R$, Compute $O_{(s+1)j} = \delta(R_j \to S_{s+1})$, where for $R'' = R - R_j$, "R_k's $\in R''$, $R_k \neq> S_{s+1}$, $1 \leq k \leq (r-1)$.

Step 3: Compare $O_\Delta = \underset{j}{MIN}\, O_{s+1}$ to O_o. If $O_\Delta{}^{3}\, O_o$, O_o is the local optimum. If $O < O_o$, update O_o to O_Δ, $R' = R' + R_j$, $R = R - R_j$, $R_j \Rightarrow S_{s+1}$.

FUTURE TRENDS

Much research has been conducted in the data allocation problem. Partial REALLOCATE and Full REALLOCATE are particularly interesting because they solve the data allocation problem in an expanding system environment. Expansion of these algorithms for heterogeneous computer and wireless (Lin, Hu, & Lee, 2004) environments will offer many challenges and benefits for current and future business environments. Due to their linear complexity, the Partial and Full REALLOCATE algorithms can be used for large, complex problems while achieving good results as compared to the exhaustive search optimal.

CONCLUSION

Over 5,800 simulation experiments were run using only Full and Partial REALLOCATE (Chin, 2001; (Chin) Goyal 1994). The experiments were run to minimize system response time in the simple query environment. A "base case" simulation was run for each problem. The "base case" assumed there was only one server in the distributed database system, with all of the relations allocated to this one server. The Exhaustive Search algorithm was used for benchmark comparisons. However, due to the exponential growth in the search space of the Exhaustive Search algorithm, Exhaustive Search computations were restricted to a maximum of four servers and five relations (a combined search space of 1+32+243+1,024 = 1,300 possible allocations). The effect on the system response time of each of the following parameters (as independent variables) was studied: CPU processing rate, network transfer rate, number of queries, number of relations. The parametric studies demonstrated the consistency of the REALLOCATE algorithms across a broad range of parametric values.

Simulation experiments have shown that Partial REALLOCATE and Full REALLOCATE provide good solutions as compared to Exhaustive Search optimums. The Partial and Full REALLOCATE algorithms considerably reduced problem search space and, hence, the cost of testing relation-server combinations. Given the cost of each test to be one unit, implementing Partial REALLOCATE over Exhaustive Search resulted in a cost savings of S^R - R units; implementing Full REALLOCATE over exhaustive search resulted in a cost savings of $S^R - \sum_{r=1}^{R} r$ units.

Partial and Full REALLOCATE have different strengths. If the cost of testing relation-server combinations is high, Partial REALLOCATE is the algorithm of choice. This is because Partial REALLOCATE has a much smaller search space than Full REALLOCATE (R vs $\sum_{r=1}^{R} r$, where R is the number of relations in the distributed database system). If the cost of adding additional servers is high, Full REALLOCATE is the algorithm of choice. As demonstrated by the simulation experiments, Partial REALLOCATE is a server-hungry algorithm. It generally requires two to three times as many servers as Full REALLOCATE in order to find a comparable solution.

KEY TERMS

Data Allocation: The process of determining what data to store at which servers in a distributed system.

Heuristic: An algorithm, particularly used to solve and achieve near-optimal solutions to intractable problems.

Incremental Growth Framework: A methodology for incrementally expanding a distributed database system. A new data allocation is computed with the introduction of each new server.

DBA (Database administrator): A person responsible for successfully maintaining a database system.

Partial REALLOCATE: A heuristic algorithm for computing a new data allocation, given some number of server and a system optimization parameter. This heuristic evaluates the effect of independently moving each database relation to the new server joining the distributed database system.

Full REALLOCATE: A heuristic algorithm for computing a new data allocation, given some number of server and a system optimization parameter. This heuristic is iterative, searching for stepwise solution refinement. This heuristic evaluates the effect of independently moving each database relation to the new server joining the distributed database system. It then holds this relation at the new server and reiterates with a reevaluation of moving an additional relation.

Inexperienced and Global Software Teams

INTRODUCTION

We dream of a way in which software can be quickly or even automatically produced. In the past, we achieved some success in some areas; however, we continue to face an excess of software demand over supply in general. The reason is obvious: Software is needed by not only home and commercial computers, but by almost every kind of electronic device, such as mobile phones, digital diaries, digital cameras, TVs, cars, and so on (Rischpater, 2001; Sapaty, 1999).

Given that the number of qualified programmers cannot be increased drastically and rapidly, software managers in most parts of the world will likely have to live with the human-resources shortage problem for some time (Information Technology of America, 2000). To deal with this shortage, we have to consider forming global software teams in which members are recruited from all over the world and software is developed in a "distributed" manner. Forming such a global software team can have many advantages. In addition to alleviating the problems caused by the scarcity of human resources, programmers on a global team would be free to work without the confines of physical location.

Although the idea of forming a global software team may increase the size of the pool of programmers that can be recruited, quality is a concern. Software managers want programmers who can deliver quality work. But software quality cannot be guaranteed and is hard to justify. Although the managers would prefer to establish a team consisting of experienced programmers, they are in reality faced with the problems of managing inexperienced programmers for a software project, especially in software-developing countries such as China, Poland, South Africa, and so forth.

It is not difficult to see that maintaining a team with a large proportion of inexperienced members significantly reduces running expenses (Figure 1) as there could be a tremendous salary gap between skilled and unskilled developers. Companies that operate with a tight cash flow will normally have an inexperienced software team as they try to minimize costs.

This paper discusses our experiences in running an inexperienced software team and a global software team. We believe that sharing our experience is useful to organizations thinking of exploiting relatively cheaper labor in developing countries such as China, Poland, and South Africa (Sanford, 2003).

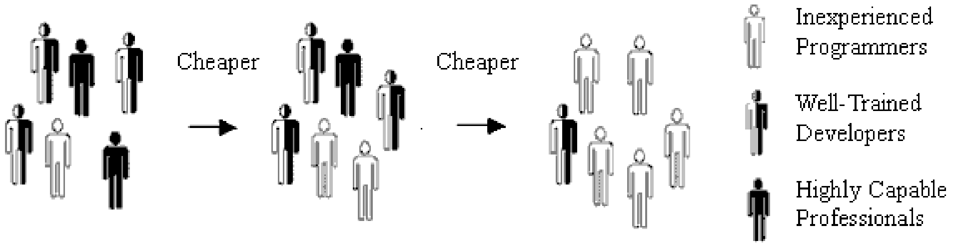
BACKGROUND

This section reviews real cases that have driven the formation of an inexperienced software team and a global software team. The mainstay of managerial decisions for building such teams is financial or environmental.

Discovering Developing Areas: Inexperienced Software Team

It has been a trend for active, rural industrialization, in which manufacturing plants move from more developed regions to less developed ones, to exploit the lower costs

Figure 1. From a professional team to an inexperienced team



of land, labor, and distribution channels (Otsuka, 2001). In order to manage these plants better, management information systems (MISs) need to be developed. Recruiting labor for manufacturing is easy in less developed regions, but recruiting IT professionals for developing an integrated, customized MIS in phases is difficult.

In developing countries, for example, China, the demand for IT professionals in larger cities is so high that it is almost impossible for any manufacturing plant in a rural area to recruit people. Workers in a poor rural area are usually inexperienced. Even though the alternative of employing expatriates might sound reasonable, it is not practical. Instead of in-house development, we might evaluate a third-party solution. The additional expenses incurred in purchasing vendor products, in consultancy services, maintenance, version upgrading, training, traveling, and so forth are expected to be much larger than what can be saved from exploiting cheaper labor. In less developed areas, many programmers do not receive proper training in computing. In addition, the turnover rate is typically high. As long as they have received some training, many workers will seek a job with better career prospects in a more developed city. This results in a vicious cycle in which the project manager always has to work with programmers who are inexperienced. The high turnover rate sometimes is aggravated by resignations without any advance notice. People tender their resignation and leave on the same day. They attempt to keep their current job while seeking any opportunity. Clearly, handing over work is very difficult if not impossible, and the team has to work understaffed constantly.

One may suggest that educating inexperienced people or allocating suitable jobs according to an individual's ability should fulfill the same purposes. However, when the knowledge and experience of staff members is not aligned with the tasks assigned, the learning curve can be steep and long (Amrine, Ritchey, Moodie, & Kmec, 1993). Nevertheless, when a staff member becomes well trained in some less developed regions in China or in a small company in Denmark, for example, his or her determination to look for better job prospects elsewhere will become stronger (Lui & Chan, 2000a; Lui & Chan, 2000b). Training, therefore, does not provide a promising solution in this case. Contradicting what we might expect in well-developed regions, certified professional programs psychologically encourage people to leave a company with little opportunity, or a less developed region, sooner. Some senior managers are disturbed by this phenomenon and say that they are always training another company's staff. The idea of allocating developers according to their skill set is not feasible when all team members are inexperienced. Human resource allocation can therefore be implemented only to a limited extent. Better knowledge management, rather than adopting conventional principles, is required.

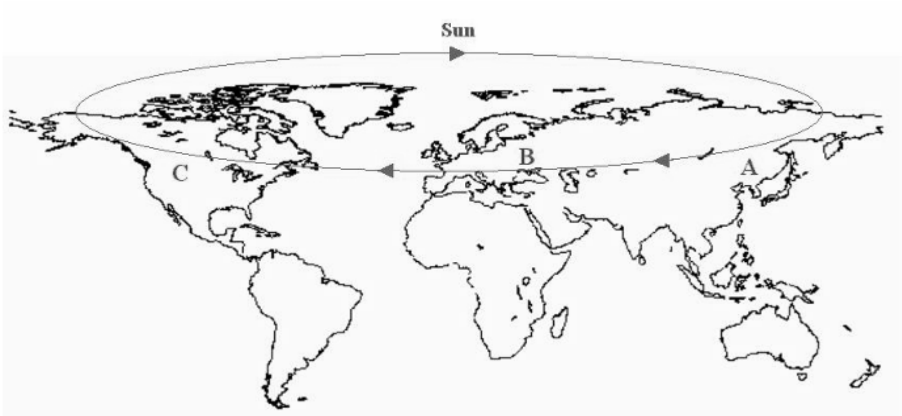
Around the Clock: Global Team

A small but ambitious company selling weight-loss and nutritional products, which was headquartered in New York, had a number of small offices of 40 employees in different parts of the world. For each such office, one to two staff members were hired to provide IT support. When the MIS system needed to be modified to meet requirements for local processing, requests for modifications would be sent to the head office. The result was that more resources were required at the head office to provide ongoing support to the branches. Although a larger software team was thus required at the head office, IT staff at the branches might have time to spare. The load-balancing problem got worse when the number of branches increased. The question, naturally, was to decide if it was possible to link people to establish a global software team. The ideal and more productive approach for the above could be a global software team. The team in each site then plays a role more or less as distributed agents following a communication scheme from a coordination agent.

A global software team can even be formed locally if the team is set up in different locations within the same country or in nearby countries or regions. This means that there may not be much difference in time zones and culture. In such situations, the term *multisite* software team can be used more generally to describe a software system developed by teams that are physically separated from each other in different cities of a country or in different countries. Compared with a global team, a multisite team in nearby time zones can be managed with less complexity and fewer challenges. Multisite software teams of this scale, when compared to global teams, have the constraint of relatively limited service hours. A client who sends a request over the Internet around the world normally demands a prompt reply. But if all teams are in the same time zone, meeting the demand immediately outside office hours is not easy. In any case, the management framework required for a global or multisite team should be very similar. To further explore around-the-clock development (see Figure 2) and global development, we realize the intrinsic difference is how synchronization of work in progress proceeds. We concluded that the challenges of managing around-the-clock tasking widely cover managerial and technical problems of non-around-the-clock global software development.

A global team with one site in Asia, one in Europe, and one in North America maximizes time use by working around the clock.

Figure 2. Around-the-clock development (also called around-the-sun development)



Around-the-clock development does release severe pressure to improve time-to-market by means of time zone differences. But, there has not been a model for this kind of global software development (Carmel, 1999; Karolak, 1998). It is easier to manage a global software team with less strict synchronization among different sites. For example, while waiting for the result from another site, this center could work on some other tasks for the same project. However, in around-the-clock development, the synchronization of work in progress and communications conforms to a rigid schedule based on natural rhythm, like the sun rising at 5:30 a.m. and setting at 6:00 p.m. The progress of a team relies on not only the team itself, but also on the progress of another team that posts the deliverables to the team by the end of the day.

A traditional framework does not provide a sound solution (McMahon, 2001). However, some light was shed when we recalled how quickly we copied our classmates' work at school to learn the part that would be included on an exam paper. For example, given a statistics question and its model answer, we are able to solve a similar problem by following each step of the standard solution, such as getting the sum first, then the mean, and the deviation, and so forth. If we are interrupted while solving that problem, any of our classmates can continue the calculation at the exact point where we stopped. When the problem has a large amount of data and needs a week to complete, the time of interruption will then be sunset. By forwarding our work to another colleague in a different time zone, the work can be continued. This process is repeated until it has been finished.

The above shows that the success of around-the-clock development greatly depends on what type of application we build and what methodology we use to manage a global team. Being too innovative implies that a similar system cannot be found for reference of development sites. In this case, our statistics example can be interpreted as the model answer corresponding to a generic system for a particular application such as a database or a Web system, and the similar assignment is a new IT project of the same type as that generic system. The bad news is that this approach is unable to cope with any new type of project completely. Fortunately, a high portion of information projects nowadays is related to commercial database applications and Web applications.

HOW THE TWO TEAMS ARE RELATED

At a glance, an inexperienced development team and a global software team conjure up two totally different pictures. However, some problems can be dealt with by the same common solution. We start with the examination of commonalities between them, shown in Table 1.

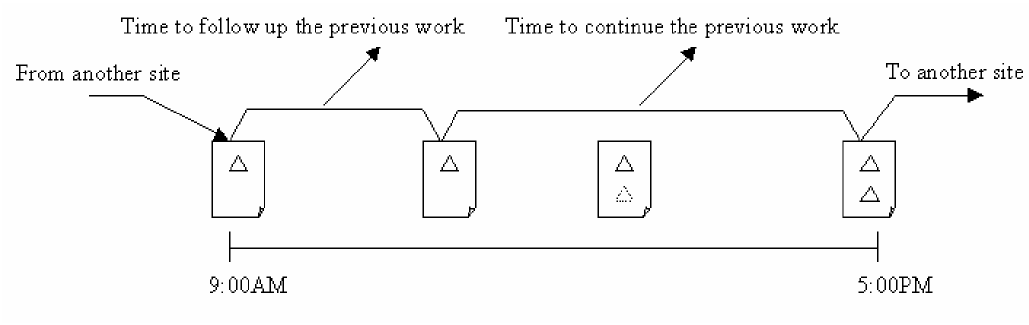
Turnover

Programmers are mostly inexperienced in less developed regions within the country. As long as they gain experience and receive some training, many of them will look for

Table 1. Characteristics of software development teams: An inexperienced team and a global team

	An Inexperienced Software Team in a Less Developed Region	A Global Software Team using Around-the-Clock Development
1	Personnel turnover	Task turnover
2	Weak IT knowledge and lack of IT project experience	Varied experience and knowledge at each site

Figure 3. Anatomy of the process of around-the-clock development



a new job in more developed cities in the same country or in other countries (Morris, 1995). As a result, the turnover rate is high. This situation is aggravated by the fact that many people who tender their resignation prefer to leave immediately in order to maximize their own benefits. Handing over work is very difficult if not impossible. In short, personnel turnover causes task turnover.

A phenomenon that shares the same characteristics of a rapid turnover rate is some global teams achieving around-the-clock software development. For the latter, a team that is to follow up on the work done by another team has to understand the code without being able to communicate with the other team, as the team members are asleep on the other side of the globe.

The basic challenge of around-the-clock work here is the time needed to follow up in order to continue the task delivered electronically from another site, and the remaining time for working and then relaying to another site at sunset, depicted in Figure 3. There are two unconventional problems. The subprocess in a site must be uninterrupted or not stopped; otherwise, the whole process will be suspended as is the progress. In addition, the sum of the working hours to follow up and to continue is just one day. Suppose each site works for 8 hours a day. The efficiency of around-the-clock development at one site will be as follows:

$$\text{Efficiency} = \frac{\text{8 hours} - \text{Time used to follow up previous works}}{\text{8 hours}} \times 100\%.$$

Around-the-clock software development has similar problems associated with a high personnel turnover rate. Neither guarantees that the expected outcome is achievable for sure, and both strongly require a very quick job hand-over without face-to-face, lengthy explanations from the previous developers. In the next section, we deliberate how plagiarism-based programming can be used to cope with a sudden hand-over.

Knowledge Management

To develop a database application, a software team may encounter many kinds of technical problems that require different skill sets, such as inserting records into a database, deleting records from a database, updating those records, controlling data integrity, controlling transactions, and the like (Taylor, 2003). In order to do programming, a software team should be equipped with minimum expertise that allows the team to complete part of, if not all, programming jobs. Developers below that level could do nothing by themselves. Figure 4 illustrates this idea.

Our goal is to lower the line of minimum expertise. But how? Let us look at an example. Suppose you have a group of people, say those with a learning disability, who are able to count numbers only but do not understand addition. If we want them to do the addition without a calculator, the best way seems to teach them the calculation. This would be the minimum expertise for this problem. Still, the learning curve may be long. (If they are your employees, your boss can not help but wonder why you would hire these people and make the office a learning center. Subsequently, you can not help but worry about the full support that your boss previously committed to you.) Another approach to getting the same work done is a mechanical method that asks the workers to follow a predefined mechanism for counting marbles. As for 4 + 3, the rule might be as follows.

Figure 4. Minimum expertise for programmers

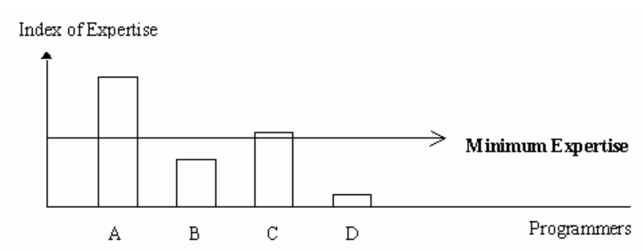


Figure 5. Lowering minimum expertise

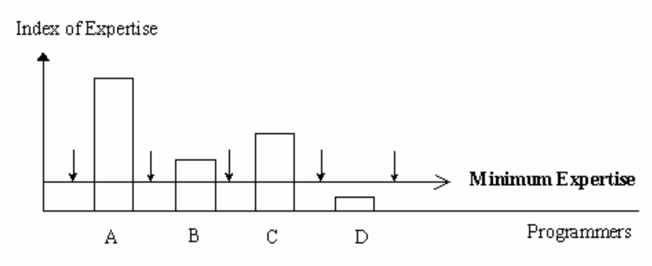


Step 1: Count four marbles and put them aside.
Step 2: Count three marbles and put them aside as in Step 1.
Step 3: Mix them and count all the marbles.

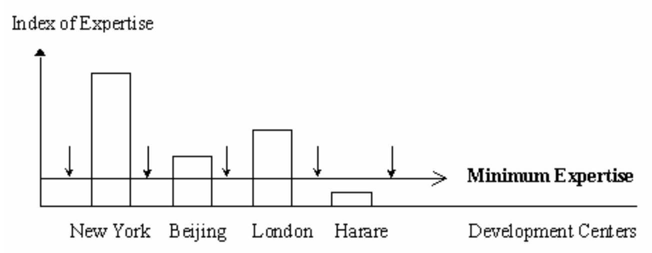
The minimum expertise is now counting marbles and putting counted marbles aside. Obviously, learning to add numbers requires the understanding of counting the numbers first. Putting counted marbles together means the workers follow the steps. In short, the minimum expertise is lowered to some degree, shown in Figure 5, although the approach might not appear to be intelligent. In fact, we found that management would be delighted with the approach as employees are able to start working and get the work done in a predictable way and time.

The problem of different technical skills among team members parallels the situation of different knowledge levels among many sites in the global software team, shown in Figure 6. For example, in Figure 6, programmers in Beijing may use some techniques in a program that developers in Harare would spend a whole day figuring out, whereas developers in London may follow up the work quickly and can continue to work.

FUTURE TRENDS

In the future, we expect the economic values gained from building those teams will become obvious when IT and our life are totally merged everywhere around the world. The demand for IT professionals can be predicted as an IT crisis if we now look at the rapid increment of Web sites. As a consequence, we can speculate that the number of job vacancies is huge. How many people are needed to develop and maintain them? There are two things we can do right away. One is resources reallocation, virtually (i.e., global software team) or physically. Another is to hire less qualified people who plagiarize the work of qualified professionals. One might argue this would be tricky. It is far from a long-term solution. Perhaps there is no long term in IT because it continues to advance almost every day. Remember, when you learn all the answers, IT has already changed all the questions.

Figure 6. Minimum expertise for development center



CONCLUSION

We addressed in depth some interesting problems in an inexperienced software team and in a global software team. Both require new managerial, technical, and social approaches at large. Knowing common relationships between two kinds of teams is the first step toward a framework for managing the team. Interested readers might consult the reference of our proposed methodology, called plagiarism-based programming (Lui & Chan, 2001, 2003).

KEY TERMS

Around-the-Clock Development: A software development style in which software teams that are geographically distributed make use of time zones to develop software.

Around-the-Sun Development: See "Around-the-Clock Development"

Efficiency of Around-the-Clock Development: An index used to indicate a ratio between the time required to follow up the previous work and time spent to continue the work.

Global Software Team: Software teams located in different countries collaborate as a single team for a clear objective project.

Inexperienced Software Team: Most members of a software team are graduates or inexperienced in disciplined software development.

Multisite Software Team: Software teams located in different cities and/or in different countries collaborate as a single team for a clear objective project.

Time-to-Market: A concept meaning to deliver a work product to the market the soonest or before the competitors do it to get more market share.

Infocratic Perspective on the Delivery of Personal Financial Services

Steve Gordon
Babson College, USA

Paul Mulligan
Babson College, USA

INTRODUCTION

In recent years, two factors – an increasingly relaxed regulatory environment and the growth of the Internet — have changed the competitive landscape of the personal financial services industry, particularly with regard to the potentiality of horizontal integration. Had financial regulation eased 10 years ago, most companies would have had little choice but to pursue a strategy of acquisition and merger to attain the capacity for providing integrated financial services. However, the Internet creates opportunities to build organizations, real and virtual, based on the control of information rather than the ownership of assets. Here we explore the potential for control of information to affect organizational strategy in the delivery of personal financial services.

BACKGROUND

The response of the financial service industry to deregulation is predicated, in part, on the will of companies to respond to consumer expectations and preferences. Pundits in the industry believe that consumers will demand a full integration of personal financial services. They believe, for example, that the consumer of the not-too-distant future would like, at a single Web site, to pay her bills, check her account balance, add money to her smart-cash card, check her credit card balance, check the current value of securities in her portfolio, buy and sell stocks and bonds, buy insurance, and issue instructions to reallocate the investment mix of payroll-deducted deposits into her 401K plan.

The quality of the integrated service experience will depend not only on the quality of the user interface, but also on the completeness of information and access to all the user's financial resources and on the features provided. Ideally, every financial instrument owned by a customer will be internally liquid and appear to be centrally located and controlled, restricted only by the legal and financial parameters of the instrument.

INTEGRATION OF PERSONAL FINANCIAL SERVICES – THREE MODELS

Three pure models and hybrids of these models can characterize the strategies of companies that have begun to offer integrated personal financial services (IPFS). The first model, which we call the Unified IPFS, describes companies that provide all or most of the services a consumer might want within a single corporate structure. Today, most Unified IPFS companies exist as holding companies, and, while their services are not yet well integrated, they are attempting to achieve a more seamless service delivery system through expanded investments in information technology. Unified IPFS providers currently differ in their degree of integration and the extent to which they can provide a full range of financial services.

The second model, which we call Allied IPFS, describes companies that provide diverse services through inter-organizational alliances. These companies focus on one primary area, such as banking, but provide a broad range of services through alliances with other companies. An example of such a company is Sovereign Bank, which provides, for example, investment products through their partner Lantern Investment Services and annuity products through IFS Agencies, Inc.

The third category, which we call Portal IPFS, describes companies that provide no direct, transactional services of their own but act as portals through which consumers can manage all of their financial services. An example of such a company might be Quicken, with its relationships with Ameritrade for brokerage services and Firstib.com for banking services. Although Quicken does not currently provide the seamless integration that we expect from the Portal IPFS firm of the future, it clearly hints at what this future might be.

Hybrid IPFS models are possible. For example, a company that appears to be a Unified IPFS provider might outsource some of its low volume products or services to companies that specialize in providing them. The result

Table 1. Customer perceptions

	Unified	Allied	Portal
Customer value proposition	One-stop shopping Lifetime relationships	Best in class Flexibility	One-stop viewing Unlimited providers
Perceived competitive vulnerability	Lost focus Exposure to niche players	Complex customer service Coordination/run costs Revenue sharing	Customer service Brand Ambiguous revenue model
Sources of customer resistance	Lack of diversity (performance) Perceived eggs in one basket	Customer servicing Limited choice in service providers	Security Privacy Permission granting

Table 2. Organizational components

	Unified	Allied	Portal
Anticipated competitive advantage	Cross-selling Brand development Integration options Full revenue capture	Internal focus Provider diversity Reduced start-up costs	Flexibility Lowest start-up costs Integration of non-financial data
Competitive Focus	Share of wallet	Share of customer	Share of information
Core Competencies	Intra-organizational integration	Inter-organizational integration	Cross-industry integration
IT Focus	Information management	Information transfer and integration	Screen scraping and presentation
Service focus	Service bundling	Service matching	Service aggregation
Examples	Schwab; Fleet; Citigroup	Sovereign Bank; Trustmark Bank	Quicken; InsurBank; Yahoo

would be a company that is dominantly Unified, but selectively Allied. A portal could also provide its own banking or brokerage services, creating a Portal/Allied or even a Portal/Unified hybrid.

Table 1 summarizes from the consumer's perspective the relative advantages, disadvantages, and risks of dealing with businesses pursuing each of the three IPFS strategies. Table 2 compares the strategies from the supplier's perspective as to competitive advantage, competitive focus, required core competencies, information technology focus, and service focus. It also provides some examples of organizations that are pursuing each strategy. The remainder of this section elaborates on each strategy.

Unified IPFS

A distinct advantage of the Unified approach is that a single corporate entity captures all revenues and maximizes its "share of wallet" with the customer. A unified company can increase the market share of each of the services it provides by cross selling. Such a company aims to "own" a customer from "cradle to grave," providing banking for the young, investment and retirement planning services for the middle-aged wealth accumulator, and trust management and reverse mortgage services for the elderly wealth distributor. The opportunity to establish brand recognition is also a benefit for a Unified IPFS provider.

The major disadvantage of the Unified IPFS strategy is the potential for a loss of corporate focus. The current diversity in investment products and continued advances in information technology make it difficult to be best in class for all products and services. The Unified providers compete directly with each other but also compete with more focused allied and portal players who, by incorporating product specialists into their networks, seek to provide premier service in a single product or market. From the consumer's perspective, the limitations in service and product options and choices and the thought of putting all one's financial "eggs" in a single basket can be problematic.

Allied IPFS

The primary benefits of the Allied approach are internal focus and external provision of choice to consumers. The enhanced focus gained by concentrating on a limited product-market offering eliminates resource deployment conflicts that may arise in more diverse Unified organizations. The firm can acquire, develop, and deploy human, capital, and technological resources in the development of a narrower set of competencies that are specific to their core business.

Proponents of the Allied model often boast of its apparent flexibility. Stronger partners can simply replace poor performing alliance members. However, this benefit is more illusory than real. Removing a partner for the alliance is extremely difficult unless all consumers opt to shift to the new alliance member. Adding a new member to provide alternatives to weak partners may violate contractual agreements or create confusion for customers.

The Allied model's major weakness for consumers, relative to the Unified strategy, is the challenge of providing a seamless integrative experience for the customer. Unified providers may find crossing internal *functional* boundaries difficult but the Allied firms face greater obstacles when crossing *organizational* boundaries. The coordination costs inherent in these relationships may impact financial performance by either shrinking margins, if prices are fixed, or compromising competitive position if the alliance raises prices to preserve margins. The goal for alliance members is to leverage focus such that the cost savings from internal operating efficiencies and excess returns earned by product specialists outweigh the added coordination costs.

Portal IPFS

The advantage of the Portal IPFS provider is that the choice of provider rests with the customer, as opposed to the Allied model in which the dominant provider preselects alliance partners. Furthermore, the portal model allows for multiple providers for the same product-service, which maximizes consumer freedom of choice. Portal IPFS providers also have the capability to incorporate non-financial services, such as frequent flyer accounts, news, and e-mail.

The major challenge for Portal providers is to placate consumer anxiety regarding privacy and security. The account consolidation benefits delivered by the Portal model also raise fears about identity theft. Customer servicing and accountability are also significant issues for this model. Today's Portal providers are not capable of providing customers service for such things as account registration changes, address changes and problem resolution. The technical standards imposed by the Internet enable this model but further establishment and maintenance of business process standards will be necessary to facilitate delivery on the Portal concept's full potential.

The Portal model is the newest of the three and currently services the smallest customer base. However, adoption rates continue to accelerate (Torris, Gross & Smit, 2001) as service levels improve and privacy concerns dissipate. The true power of the Portal will be realized when providers fully integrate account processing and augment transactional services with comprehensive add-on services.

THE COMING INFOCRACY

The viability of the organizational structures described previously depends as much on who controls the information central to the delivery of personal financial services as on who controls the other assets of the firms involved. Following Clawson, we use the term "infocracy" to describe a form of organization in which the basis of power is information (Clawson, 1999, 2000).

Clawson observes that the industrial revolution generated a shift in the dominant management paradigm from aristocracy to bureaucracy. He suggests that the information revolution is spawning a similar shift from bureaucracy to infocracy (see Table 3). In an aristocracy, with power derived from gender and lineage, decisions are made by those entitled to do so by birth. In a bureaucracy, decision-making authority is vested in those at the highest organizational levels; these office holders are assumed to know the most and to be best able to effect wise decisions. In an infocracy, decisions are made by those best equipped to interpret the relevant data, rather than those empowered to make decisions by dint of their positions.

The transition from bureaucracy to infocracy could have significant implications for how organizations oper-

Table 3. Clauson's management paradigms

	Aristocracy	Bureaucracy	Infocracy
Period	Pre Industrial Revolution (18th century and before)	Post Industrial Revolution (19^{th} and 20^{th} centuries)	Information Age (Now and future)
Power Source	Gender and lineage	Office and gender	Node Interpreter*
Assumption	"Father Knows Best"	"Boss Knows Best"	"Node Interpreter* Knows Best"

** Node interpreter: Person who has access to relevant and current data and the education and experience necessary to interpret and act upon them.*

ate. For example, Clawson hypothesizes that the most effective leadership styles will be those relying on information-based persuasion rather than command and control behavior. A large body of research has demonstrated that advances in information technology often affect the operation and structure of organizations (Bartezzaghi, Ciborra, DeMaio, Maggiolini & Romano, 1981; Carr, 2004; Dibrell & Miller, 2002; Drucker, 1988; Huber, 1990; Malone & Rockart, 1993; Wang, 1997; Whisler, 1970).

Clawson suggests that the transition from bureaucracy to infocracy will proceed faster than the move from aristocracy to bureaucracy. Bureaucracies, while designed to control information, are largely structured around the physical assets of the underlying organization. An infocracy has no comparable physical restrictions, which may explain the faster rate of transition. We believe that the information-intensive nature of financial services and lessening importance of associated physical assets positions this industry to be an early adopter of infocratic principles.

Yet there remains considerable research that affirms the value of bureaucracy in providing direction, structure, stability, and control (Adler, 1999), even in turbulent conditions (Perrow, 1970; Schellenberg & Miller, 1998). Despite predictions to the contrary, identifying any reduction in the bureaucratic structure of today's industry has proved to be devilishly difficult (Collins, 1997).

The internal adoption of and transition to infocratic organizational structures and processes does not ensure market acceptance. Many consumers accept, and perhaps derive assurance from, bureaucratic structure and policy. The movement to infocracy-supported channels and services will require firm investment in new skills for customer-facing employees and the acceptance of new rules of engagement for consumers. Service providers will require training, perhaps even licensing, in a broader set of products. Consumer education must address comfort and trust levels necessary to support increasingly disintermediated single-point-of-contact service encounters. Well-trained, efficient representatives will be needed to accelerate the development of consumer comfort and confidence.

FUTURE TRENDS

It is reasonable to expect a company's integration strategy to affect its ability to operate as an infocracy. The logical hypothesis is that a company's integration strategy should align with its strategy for control. A Unified IPFS, for example, might be expected to be bureaucratic, perhaps having a divisional structure, probably based on product rather than functional units, with responsibility and power delegated to those in charge of each division. Transactional and management information systems could be tightly integrated by the coordinated purchasing of enterprise systems. Although some matrix structures might be necessary to motivate and control cross-selling and joint product development, the overall control structure is likely to be highly bureaucratic.

An Allied IPFS would seem to require more dynamic control to respond to and nurture the inter-organizational fluidity inherent in its strategy. While each of the individual partners in the alliance might be somewhat bureaucratic, the governance of the alliance as a whole must have power both within and across organizational boundaries and must be sufficiently democratic to satisfy its respective partners. One might expect an Allied IPFS to exhibit a semi-bureaucratic or adhocratic structure, with distributed decision-making, some degree of democracy, and less control than one would find in a bureaucracy. Integration of transactional and management support systems would rely on adherence of all parties to emerging standards for XML and/or Web services, such as XBRL, IFX, and FpML.

A Portal IPFS, built solely on the flow of data with little to no control over its customers, would seem to require an infocracy if its internal structure, leadership, and decision making parallels the face it presents to the consumer. Transactional systems would require industry-wide adoption of standards pertaining to the exchange of data and the provision of secure e-commerce. Management systems would rely heavily on the widespread use of Web services to expose distributed data to the Portal entity.

An alternative hypothesis is that a company's integration strategy should oppose its strategy for information control. For example, one might hypothesize that a Portal IPFS would demand a bureaucratic structure to counterbalance the fluidity of its customer/supplier relationships by tightly controlling procedures and management oversight. Decision making would be based solely on the information that it collects as it executes Portal transactions, not on information supplied by its partners. Similarly, a Unified IPFS might need to operate as an infocracy to become nimble enough to compete with a Portal IPFS. This would imply, for example, that business units responsible for different types of financial transaction retain control over the information and the information systems that support their function. Rather than tightly integrated enterprise systems, these firms would rely on middleware and EAI products to provide an integrated view to the customer.

CONCLUSION

Regulatory change and the growth in the acceptance and use of the Internet have provided an environment in which financial service companies have the opportunity to pursue different strategic models for integrating the delivery of personal financial services. Three such models – Unified, Allied, and Portal – have been identified, and hybrids of these models have also been shown to exist. The financial services industry is identified as an ideal venue in which to study the coming infocracy – the movement from decision making based on official position and reporting structure to decision making based on information – because the different paradigms of service delivery provide different degrees of organizational control and have different needs for decision-making speed and flexibility.

KEY TERMS

Allied Model of IPFS: A model that describes the provision of integrated personal financial services through inter-organizational alliances.

Horizontal Integration: Horizontal integration in information management systems traditionally addresses information sharing across systems, which often means across functions or departments. In the context of organizational structure, horizontal integration typically refers to cross-business unit integration in pursuit of scope economies.

Hybrid Model of IPFS: The hybrid model is not, in the context of IPFS, simply a model that incorporates elements of two or more organizational forms. A hybrid IPFS model encompasses a more dynamic entity. Firms that adopt a hybrid IPFS structure typically maintain a general affinity towards a dominant form (e.g., Unified), but they temporarily create contrasting organizational relationships (e.g., Allied or Portal) that do not "fit" with the current organizational design. Much like evolution, the transition between dominant forms occurs over an extended period of time and as the result of numerous "hybridizations".

Infocracy: A form of organization in which information provides the underpinning of structure and the primary basis of individual power. In a more typical bureaucracy, hierarchical organizational structure dominates and is a primary driver of individual power. Information flows are then designed to support the structure and reinforce the power relationships. In an infocracy, information flows from point of origin to point of use, without regard to structure or pre-determined power relationships. As such, the organizational structure evolves to support required information flows.

Integrated Personal Financial Services (IPFS): The seamless integration of previously independent financial products and services. Prior independence of these financial products was a function of organizational, regulatory and/or technological constraints imposed upon the providers. For example, in a true IPFS relationship, funds would flow seamlessly between insurance, banking, investment and tax accounts.

Portal Model of IPFS: A model describing companies that provide no direct, transactional services of their own but act as portals through which consumers can manage all of their financial services.

Share of Wallet: The financial services industry defines "share of wallet" as the percentage of a customer's investable assets that are held by the provider. IPFS enables an organization to maximize their share of customer wallet by expanding the breadth of product and service offerings available.

Unified Model of IPFS: A model in which all or most of the financial services a consumer might want are provided within a single corporate structure.

Information and Communication Technology Tools for Competitive Intelligence

Dirk Vriens
Radboud University of Nijmegen, The Netherlands

INTRODUCTION

Competitive intelligence (CI) can be described as collecting and processing information about the environment for strategic purposes (cf. Kahaner, 1997). To formulate a strategy, an organization needs to collect and process information about its environment—about, for instance, competitors, customers, suppliers, governments, technological trends, or ecological developments. Collecting and processing environmental information has, of course, always been important. However, because of the increasing complexity and dynamics of the environment, the pressure to produce relevant, timely, "actionable" intelligence increases as well. At the same time, the amount of available data about the environment also increases.

To deal with this problem, it is necessary to structure intelligence activities, and many organizations use information and communications technology (ICT) to this end. They use, for instance, different types of Internet or intranet applications, so-called data warehouses, groupware applications, or applications specifically tailored to the organizations' intelligence needs. The number of possible ICT tools for CI is large, and an important question for organizations is which tools they should select and implement for their CI activities. Organizations face difficulties in selecting, implementing, and using these tools. Many ICT tools, for instance, lead to an information overload—to large collections of irrelevant data—or are expensive applications that only marginally contribute to the production of intelligence.

To select proper ICT tools for CI, an organization needs to understand the role of ICT for CI. This paper intends to address this understanding. In particular, it will present a short overview of the available tools and it will discuss a procedure for selecting appropriate ICT tools.

BACKGROUND

To understand the role of ICT for CI and to select proper ICT tools, the CI process needs to be clarified. To describe this process, several authors (cf. Fuld & Company, 2002; Gilad & Gilad, 1988; Herring, 1999; Kahaner, 1997) propose to use the intelligence cycle, consisting of four stages.

1. **Direction.** In this stage organizations determine their strategic information requirements; that is, they determine about what environmental aspects data should be collected. These aspects are also known as competitive intelligence needs (Fleisher, 2001) or key intelligence topics (Kahaner, 1997).
2. **Collection.** In this stage, the required data are collected. To this end, one needs to (a) determine what sources are available, and (b) access these sources and retrieve data from them.
3. **Analysis.** This stage focuses on interpreting data from a strategic point of view to determine their strategic relevance (if a piece of data is strategically relevant, the term intelligence is used; cf. Kahaner, 1997; Vriens, 2004). For this analysis, a model of what is relevant for the organization should be available. Often, tools such as Strengths, Weaknesses, Opportunities and Threats (SWOT) analysis, scenario analysis, war gaming, or competitor profiling are used to arrive at such a model (cf. Cook & Cook, 2000).
4. **Dissemination.** Here, the intelligence is made available for strategic decision making. That is, the intelligence should be presented clearly and distributed to relevant decision makers who use it to evaluate current strategic options and to generate, compare, select, and implement new ones.

Using this cycle as a background, many authors acknowledge the possible and actual use of ICT applications for CI activities (see, for instance, Chen, Chau, & Zeng, 2002; Cook & Cook, 2000; Fleisher & Blenkhorn, 2001; Fuld & Company, 2002). It is also a background for discussing the shortcomings of ICT applications for CI (e.g., Cook & Cook; Fuld & Company). In line with these authors, we will use this cycle of intelligence activities as a framework for reviewing, classifying, and selecting ICT applications, as will become apparent in the next sections.

A CLASSIFICATION OF ICT TOOLS FOR CI

ICT tools for CI can be classified according to two "dimensions": (a) their contribution to one or more stages of the intelligence cycle and (b) the specificity of the tool—that is, a tool can be either a general ICT tool used for intelligence activities (like a groupware application, used for direction activities) or a tool specifically tailored to one or more intelligence activities. Below, we first discuss the Internet as a "general" ICT tool for all CI activities. Next, we pay attention to other ICT tools, both general and specific. Finally, we discuss so-called business intelligence applications as a specific set of ICT applications.

The Internet as a Tool for CI

CI practitioners rely heavily on the use of the Internet for their intelligence activities. Some authors report the use of the Internet for supporting the direction, analysis, and dissemination stages, for example, Web Enabled Technology (WET) applications enhancing communication and collaboration regarding results of this stages (e.g., Teo & Choo, 2001). However, most attention has been paid to the use of the Internet for collection activities. Among the reported uses of Internet applications for collection activities are the following.

- **Search engines**
  The CI literature discusses many types of search engines and their application for CI (cf. Chen et al., 2002; Cook & Cook, 2000).
- **Tools for outsourcing collection activities**
  A part of the collection activities can be outsourced to some (automated) service or tool offered via the Web. Particularly popular is the use of commercial online databases (Kahaner, 1997; Chen et al., 2002). Another example is the use of Web robots or agents that "automatically traverse the hyperlink structure of the WWW [World Wide Web] to locate and retrieve information" (Tan & Kumar, 2002, p. 9).
- **Tools for text analysis**
  Tools supporting the collection of data in (large) Internet-based text files are used.
- **Tools for monitoring changes on the Web**
- **Tools for collecting data about the electronic behavior of Internet users**. These tools work, for instance, by identifying users' navigational patterns (cf. Tan & Kumar, 2002).
- **Internet tools for collaboration in collection activities.** Internet applications can be used to facilitate the collaboration in collection networks (networks of people performing collection activities).

General and Specific ICT Tools for CI

Besides using general Internet applications for CI purposes, other general ICT applications can be used as well. Examples are tools supporting the following.

- **Supporting the process of identifying strategic information needs** such as different types of groupware or software supporting group model building (e.g., Vennix, 1996).
- **Supporting specific methods used in analysis**, for instance, system-dynamics software enabling CI professionals to run simulations with certain data, and thus helps to establish their relevance.
- **Supporting (management of and collaboration in) the process of analysis**. Specific groupware applications may serve this purpose.
- **Supporting the dissemination of intelligence**—for example, applications supporting (a) the presentation of the intelligence in a suitable format and/or (b) the transmission of reports throughout the organization

There is also a class of ICT applications specifically designed for one or more CI activities. Fuld & Company (2002) analyzed and evaluated a number of such dedicated CI software packages. They concluded with the following.

(1) The "CI software cannot drive the CI process" (p. 2), but it can help in collecting data, in reporting and communicating intelligence, and in supporting the work flow and collaboration.
(2) No application can deal with all the intelligence stages adequately.
(3) No application can "truly conduct qualitative analysis" (p. 10), but some tools seem promising in assisting CI analysts to see novel linkages.

Business Intelligence Applications

For some time, the terms competitive intelligence and business intelligence (BI) were used as synonyms. Nowadays, however, the term business intelligence is often used to indicate a specific set of ICT tools. These BI tools refer to ICT tools enabling (top) management to produce overviews of and analyze relevant organizational data needed for their (strategic) decision making. BI tools typically include data warehouses and tools for extracting and presenting information from them (cf. Cook & Cook, 2000; Zanasi, 1998). In essence, a data warehouse is a large database in which data from many different databases (e.g., transactional, financial, or personnel databases) are copied and stored in such a way that they are readily accessible. To access, view, and analyze these data, specific tools are developed (e.g., data-mining tools for finding relations between classes of data). Using data warehouses and their associated tools to produce intelligence is not unproblematic. Examples of reported problems are the following (cf. Cook & Cook; Fuld & Company, 2002).

1. Most data warehouses only cover internal data (generated in the transactions of the organization; Fuld & Company, 2002). This is a major drawback when treating BI tools as CI tools. However, once data warehouses incorporate relevant *external* data, they may become valuable CI tools as well.
2. The focus of BI software is primarily on quantitative analysis while CI relies heavily on qualitative data.
3. Data warehouses cause cost and implementation issues: They require large budgets and much implementation time and effort.
4. Cook and Cook (2000) assert that one cannot expect BI software to produce intelligence. Data resulting from analyzing data in a warehouse should still "be analyzed and directly applied to a specific problem to become intelligence" (p.165).

HOW TO SELECT ICT FOR CI

To select appropriate ICT tools for CI, given specific organizational CI needs, organizations can use three classes of criteria: (a) criteria regarding the contribution of ICT applications to one or more stages of the intelligence cycle, (b) criteria regarding the CI infrastructure, and (c) criteria pertaining to costs. These three classes correspond to the criteria used in the selection of ICT applications in general (cf. Parker, Benson, & Trainor, 1988).

Criteria Regarding the Contribution to One or More Stages of the Intelligence Cycle

A (candidate) ICT application should contribute to one or more stages of the intelligence cycle. Criteria to evaluate the contribution of an ICT application for one or more stages may refer to its appropriateness to deliver the desired products for the stage, and to whether it fits the process leading to these products (cf. Fuld & Company, 2002). For example, collection applications should be evaluated regarding their appropriateness to collect the desired data (e.g., patent data). Applications should also match process aspects. For example, if particular methods are used to analyze data, such as a SWOT analysis, candidate applications can be evaluated regarding their appropriateness in supporting these particular methods.

Criteria Regarding the Relation with the CI Infrastructure

The CI infrastructure consists of three parts: (a) the technology supporting the CI activities (ICT hardware, software, and telecommunications technology), (b) the human resources needed to carry out the CI activities, and (c) the organizational structure of these activities, that is, how CI tasks and responsibilities are divided and allocated. Each possible ICT application should match all three parts—from these three parts, specific criteria can be derived.

The criteria regarding the technology part of the infrastructure focus on the question of whether the candidate application fits the current technology. This fit depends on the current set of ICT applications used to support the CI activities. Does the application fit into this set? Does it deliver more functionalities than this set? Is an easy link between the applications in this set (if desirable) possible? Other questions for judging the fit to the technology have to do with the implementation and maintenance of the application: Does the current hard- and software permit the implementation of the application, or does it require large changes? Is the application reliable? Yet another question for judging the fit to the technology has to do with the contribution of an application to the improvement of the infrastructure; for example, through a particular application, obsolete applications are replaced (or may be replaced more easily), or through a particular application, other state-of-the-art applications can be implemented and used more easily. A data warehouse, for instance, can be seen as a contribution to the current infrastructure because it enables all kinds of tools for visualizing and analyzing (internal) data.

The second set of criteria reflects the fit of the application to the human resources, that is, whether it fits the existing skills, knowledge, and attitudes of those who are carrying out CI activities. Important questions are, for instance, whether the required knowledge and skills are acquired easily, or whether the CI staff is motivated to integrate the ICT application into their daily routines.

The third set of infrastructural criteria reflects the fit of the application to the current definition and allocation of CI tasks and responsibilities (see Gilad & Gilad, 1988, for several ways of defining and allocating them). It does not make sense to install groupware for the direction stage if direction is not seen as a group process. The same holds for using ICT tools structuring the collection and analysis activities if the whole CI process has a highly informal nature. In some cases, the CI task structure may be designed poorly and ICT can act as a leverage to change it. An ICT tool can be valued because of its contribution to the improvement of the task structure. For instance, a groupware application may be valued for its contribution to structure the direction stage as a group process.

Criteria Pertaining to Costs

These criteria refer to the costs of the application itself, its implementation (e.g., project costs, training, etc.), and its maintenance. These costs may be calculated by different methods (cf. Parker et al., 1988).

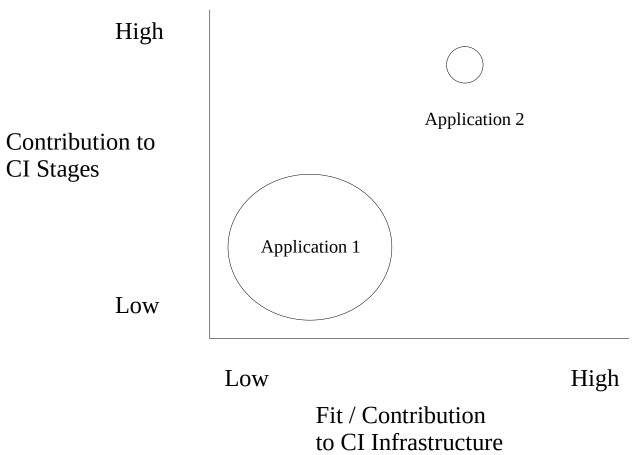
Selecting ICT for CI Using the Three Types of Criteria

To evaluate the appropriateness of an application for CI in a particular organization, the application should be "scored" regarding all three classes of criteria. To this end, the individual criterion in a class should each be identified, valued, and integrated into an overall score for the class. We will not treat all these substeps in this section; rather, we will indicate how these overall scores can be used to select of ICT for CI.

The overall scores of each class express (a) the contribution of a particular application to one or more of the intelligence stages, (b) the fit of the contribution to the CI infrastructure, and (c) the costs related to an application. These scores can be plotted in a graph (see Figure 1).

In this figure, the scores of several applications are depicted (the size of the circles reflects the costs related to the application). For instance, Application 1 may be a data warehouse (with an internal focus). This application

Figure 1. Classification of ICT applications for CI using three dimensions (see text)



may be very expensive, contributes only partly to the intelligence stages (it contributes to the collection stage, but due to its internal focus, its contribution to the CI stages is low). The data warehouse may contribute to the general infrastructure, but, in our view, contributes only partly to the CI infrastructure. In contrast, a data warehouse with explicit external linkages would still be very expensive, but may score higher on both other dimensions. Application 2 may be a groupware application. These applications are moderately expensive, may contribute to the direction stage, and fit the infrastructure in several ways.

An organization may treat several ICT tools to support their CI activities in this way and eventually select some.

FUTURE TRENDS

Many organizations recognize the importance of supporting CI activities by means of ICT. Although many ICT applications are already available, the possibilities of using ICT for CI will increase rapidly. Some of the trends that may be acknowledged are the following.

- A convergence of BI and CI applications (e.g., data warehouses and associated software also tied to external and qualitative data; cf. Li, 1999)
- Using ICT for qualitative data may increase (e.g., Chen et al. 2002)
- Using the Internet for more than just collection activities (e.g., for collaboration and dissemination purposes; cf. Teo & Choo, 2001)
- Improvement of Internet applications for collection (More efficient and effective collection applications will continue to emerge.)
- Implementing CI applications can be seen as a process by means of which the CI process and infrastructure can be reanalyzed.
- Improvement of analysis applications (cf. Fuld & Company, 2002)

CONCLUSION

To select and use proper ICT tools for supporting the CI process, organizations should know (a) what the CI process is, (b) what the role of ICT (tools) in this process can be, and (c) how to evaluate the role of ICT (tools) for their own CI process. In this chapter, we discussed the role of ICT tools in the CI process. We classified several types of ICT tools relevant for supporting CI activities: the Internet, general and specific applications for supporting CI activities, and business intelligence applications. In the last part of this chapter, we discussed three classes of criteria organizations can use in evaluating and selecting ICT tools for their CI processes.

The possibilities of ICT to support CI activities will probably only increase. To make full use of its potential and to avoid many of the pitfalls associated with using ICT for CI, organizations should be careful in selecting and implementing ICT applications for CI purposes. They should know the possibilities of ICT to deliver internal and external data and its capacity for supporting CI activities, and they should treat ICT as a part of the whole infrastructure.

KEY TERMS

Business Intelligence: The term business intelligence is used in two ways: (a) as a synonym for competitive intelligence and (b) to indicate a specific set of ICT tools to support managerial decision making. This set of tools often consists of a data warehouse and the tools to store, retrieve, and present the information it contains (e.g., data-mining software).

Competitive Intelligence: In the literature, two definitions are used: a product definition and a process definition. In the product definition, competitive intelligence is defined as information about the environment, relevant for strategic purposes. The process definition highlights producing and processing this environmental information. Process definitions often refer to the intelligence cycle.

ICT (Information and communication technology)**:** Can be used to indicate the organization's technological infrastructure (comprising of all hardware, software, and telecommunications technology) and to indicate one or more specific collections of hardware, software, and telecommunications technology (i.e., one or more ICT applications).

ICT Selection: The process of selecting proper parts of the technological infrastructure and/or specific applications. In the context of CI, specific criteria are used: criteria regarding costs, appropriateness in supporting intelligence activities, and their fit or contribution to the CI infrastructure.

Intelligence Cycle: This is a cycle of four stages (collections of intelligence activities). The stages are direction (determining the strategic [external] information requirements), collection (determining, locating, accessing, and retrieving sources to obtain data about the environment), analysis (determining the strategic significance of the environmental data), and dissemination (of the intelligence to strategic decision makers).

Intelligence Infrastructure (CI Infrastructure): The intelligence infrastructure comprises all technological, human-resources, and organizational means needed to manage, support, and perform the intelligence activities. It consists of three subinfrastructures: the technological, the human-resources infrastructure, and the organizational infrastructure.

Information Laws

Andrew S. Targowski
Western Michigan University, USA

INTRODUCTION

Humankind progresses in proportion to its wisdom which has roots in practice, acquired skills, available data and information, concepts and knowledge. To be wise, humankind needs to be informed and knowledgeable; otherwise it will not survive its own failures. Progress in knowledge was painfully slow as long as the racial memory was transmitted only by oral tradition. With the invention of writing and books the process of knowledge discovery and dissemination has been accelerated. Today, computers and their networks speed up that process far beyond our imagination. In the 2000s the Information Wave significantly controls the Agricultural and Industrial Waves through millions of computers. IT supports decision-making based on knowledge-oriented systems such as data mining that, for example, discovers knowledge about customers, organizational dynamics, and so forth to achieve competitive advantage.

Information and knowledge become the strategic resource as engineering science was in the Industrial Wave. However, the discovery of human cognition potential must be guided by knowledge science, which just emerges. One of the signs of any science is its set of scientific data, universal rules, laws, and systems of rules and laws. Hence, this article offers the first attempt to develop main laws of information that should increase our awareness about the Information Wave, which is a new stage of civilization's dynamics that is taking place at the beginning of the third millennium. The article also provides the framework for the analysis of the human capital from the information perspective. This set of considerations reflects a new emerging approach that I call macro-information ecology.

BACKGROUND

Macro-Information Ecology

Macro-information ecology is based on the premise that the growth rate in the new information (knowledge) discovery is the key determinant of macroeconomic activities in the service-industrial-global economy (so called the new economy). This new emerging school of macroeconomics can be called knowledgism.

Macro-information ecology is the study of information (cognition) as a whole and it is concerned with *aggregates* across nations and markets. Macro-information ecology studies the behaviour of society and economy (nationally and globally) — wide measures, such as:

- the value of human capital,
- the potential efficiency of human capital,
- knowledge output,
- economy output driven by knowledge in a given period, and so forth.
- It also studies measures derived from many individual nations:
  - markets such as the price of human capital or
  - the total structure of employed workers by such categories as production workers, in-person service workers, and information workers.

To control national output with the development of the global economy, knowledgists stress the need to control the growth of new knowledge discovery. Given the "long and variable lags" of knowledge and information policies and the difficulty in forecasting future economic events (such as recession), knowledgists question the ability of industrial or service-oriented macroeconomics to implement the "correct" economic policy.

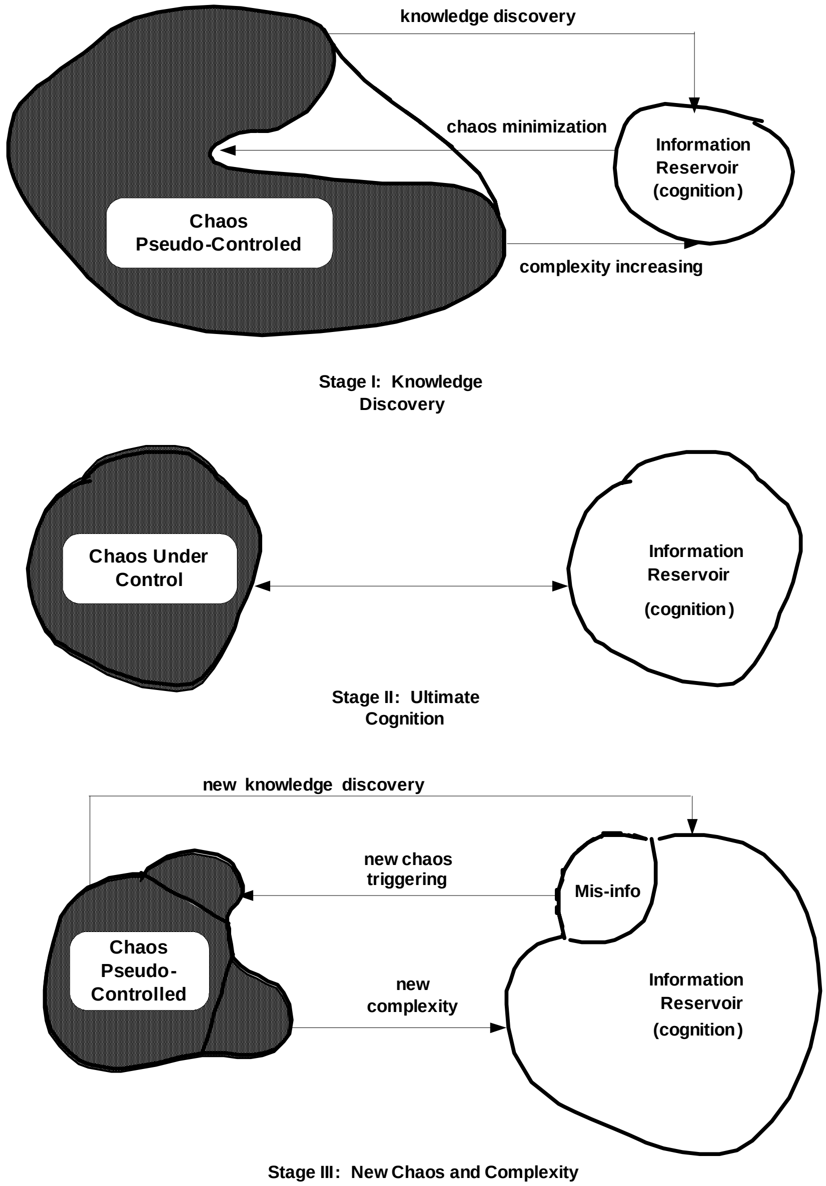
The knowledge approach suggests that direct government intervention within the economic system should be guided by the "predicted history of the futures". The knowledge policy is the key to this intervention; in this sense, the knowledge policy is closer to Keynesian interventionists than to "conservative" monetarists.

The supply and demand of information (knowledge) is the most basic model of information ecology (IE). However, prior to this model, we have to examine the stages of the information reservoir development. Figure 1 illustrates this process.

GENERAL INFORMATION LAWS

At the stage of knowledge discovery, the information reservoir (IR) minimizes or tries to "control" the chaos. Every increase in new information also increases a level of complexity of understanding. Based on the analysis of

Figure 1. The stages of information reservoir development



knowledge dynamics provided by Wojciechowski (1989), one can define the following laws of information:

- Law I: The complexity of the ecosystem (human, material, cognition, and nature) is growing accordingly with the level of the existing information reservoir.

The complexity is the state of a system whose components and relationships co-evolve through an enormous number of interconnections, creating dynamic structures either chaotic or orderly. The more information we have at our disposal, the more complex the ecosystem is perceived to be. The more we know, the less we understand. The founders of the Santa Fe Institute, which explores the new science of complexity, investigates such questions as why ancient ecosystems often remained stable for millions of years, only to vanish in a geological instant—and what such events have to do with the sudden collapse of Soviet Communism in the late 1980s.

- Law II: Information generates consequences, which it cannot foresee.

One of the forms of information is knowledge, for example, such as atomic physics. Atomic physics produced rules and techniques that allowed man to build the atomic bomb. The consequence was the tragedy that befell thousands of Japanese who lost their lives or, at the very least, their health in 1945. On the other hand, the Cold War, sustained by the balance of atomic weaponry, was practically bloodless. Should science stop research on atomic physics or gene engineering because consequences can get out of control? Or, being under control, can said research produce positive results, such as the Cold War, which eliminated another Bloody War?

- Law III: The precision and certainty of information is growing accordingly to the simplicity of the described object or inversely declining due to the complexity of the object.

Relatively simple material objects can be described by relatively simple information in natural science. On the other hand, complex social phenomenon requires complex description; this is sometimes contradictory if description is provided by more than one observer. For example, in the 1991 Persian Gulf War, there was a question among the Allied forces about whether to go to Baghdad and seek the surrender of the Iraqi military regime. Almost every observer of this war had his or her own answer (information) to this question.

- Law IV: The progress of the Information Wave generates relative ignorance and interdependence among people and globalizes humanity.

The advancement of mediated information requires information skills to access information infrastructure, systems, and services. People without this access are becoming more ignorant than those who can retrieve and apply required information anytime and anywhere in the synchronism of events. The information poor are becoming more dependent on the information rich; the latter are motivated to globally seek more useful information to become even richer. A college professor or a graduate who knows end-user computing has more chances to increase his or her material well-being than someone who does not know how to apply computers to gather and process important information and is ignorant about possible opportunities for him or her. Even a well-meaning businessperson who is ignorant about information technology may lose resources or at least not increase them if he/she does not know how to transform his/her business from *brick ’n mortar* to *brick ‘n click* format.

At Stage II — Ultimate cognition, the amount of information is equal to the amount of chaos. From humankind’s point of view, the equilibrium in macro-ecology never happens since the amount of time in which such equilibrium can be attained is infinite; in such disciplines as business management, perhaps, one can achieve short-term equilibrium. Therefore, the next law can be defined:

- Law V: The information reservoir has no saturation point.

Since the ecosystem is imperfect and still developing, the information about it has not become definite. What was right in the 19th century is revised in the 20th century, and what is right in the 20th century, perhaps, will be redefined in the 21st century, and so forth. Examples of Newtonian physics critique or post-modernism’s challenge of “scientific truth” provide data that prove this law in the 20th century. Each new discovery not only decreases the chaos; it also increases the confusion about the new directions and, *ipso facto*, requires more information to improve understanding.

Stage III — When the capacity of the information reservoir should exceed the capacity of chaos, new chaos and complexity are created by misinformation, which begins to penetrate the IR. It is only an assumption since, according to Law V, such a situation should not happen.

MACRO-INFORMATION ECOLOGY MODEL

The macro-ecology of the information equilibrium model (Figure 2) indicates that civilization, most of the time, operates in darkness. The mathematical model of the information reservoir is as follows:

Stage I: $I < E$

where: I = Information Reservoir capacity
E = Entropy, a measure of chaos
D = Darkness (or net entropy E-I)

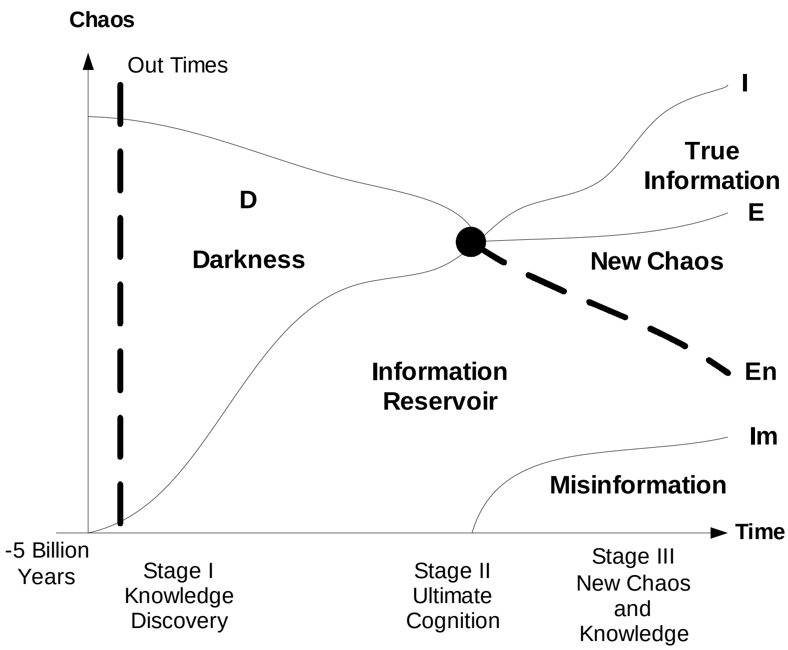
The macro-ecology goal is Dt ’! 0 and the task is to determine the elasticity of the increased entropy or information and how a user or organization responds to changes (+, -) caused either by the increase of information reservoir or by its “enemy” — entropy.

D (Et) = f (IMt, Ct) or D (It) = f (Et, Ct)

where: IM = Misinformation[1]
C = Complexity
t=time

The elasticity of information is a measure of the sensitivity or responsiveness of the information value de-

Figure 2. Information macro-ecology model



manded to create changes in price, revenue, unemployment, and in other factors of the Information Wave. Information elasticity will be one of the major indexes of the emerging Information Wave.

Macro-information ecology is also interested in the creation of human capital as a medium of knowledge generation and application. Particularly, a relation between human capital and economic development is a strategic inquiry of Information Ecology.

The mechanism of the material civilization in modern capitalistic theory was built on the rule that market growth triggers the specialization of human capital and the growth of its income as well as its level of living. In the Information Wave, the situation is different. The new motoric forces of economy can express the following law of the human capital.

INFORMATION LAW OF HUMAN CAPITAL

- Law VI: The human capital's growth in knowledge generates specialization and productivity and sustains the growth of income.

As Kevin Murphy [1] noticed that the old sequence in economic development in the Industrial Wave:

- (old) material sequence: market growth - specialization - more income transforms the Information Wave into a new sequence in economic development:
- (new) early information sequence: knowledge growth - specialization - more income

The new sequence is true as long as the specialization of human capital sustains the increase of productivity in the material sector or in the information sector. The necessary co-ordination of specialists, particularly those in the information sector, may consume the new "speed" of knowledge and not only contribute to the economic growth, but misguide it.

The most important question, however, is whether or not we should apply new knowledge to promote economic development by growth or whether we should just apply that knowledge's message, which says that zero growth is wiser and the only appropriate policy to achieve a sustainable society and economy.

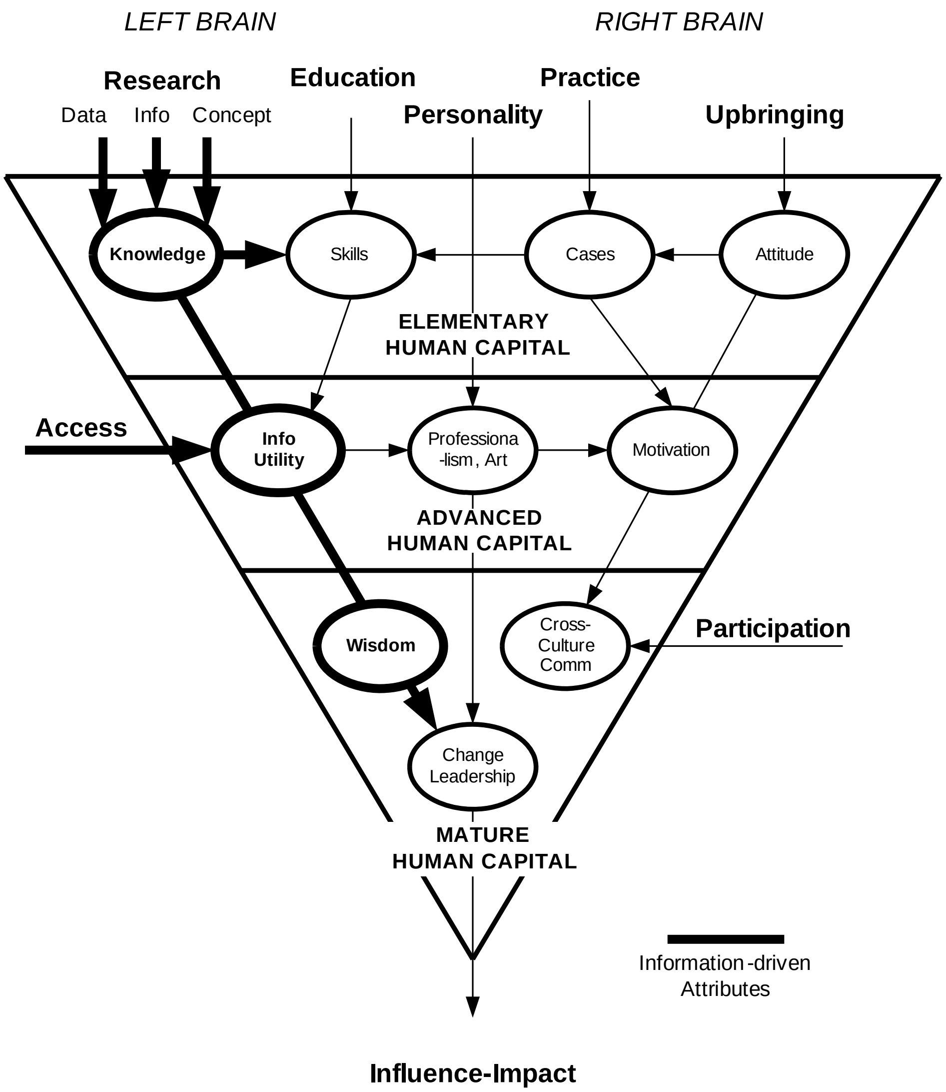
The uncontrolled development of the Information Wave may lead to another economic sequence:

- further information sequence: knowledge growth - specialization - collapse of economy (?)

This sequence produces an economy that is too specialized and productive, requiring a small work force without the means to create a demand for economic output. In current practice, robots and computers do not pay taxes.

Information ecology has to include a human dimension of the Information Wave in its inquiry. Better knowledge should provide a better level of living, not inspire self-destruction and limit progress to technology

Figure 3. The human capital in development stages



alone. Technology is not neutral; the new knowledge should define info-comunication tools of honourable and sustainable living. This is possible if we consider the Electronic Global Village as a tool of information and knowledge creation and distribution (bottom-up and top-down), and as a globally interconnected aware tribe.

The steered Information Wave should offer the following sequence of events:

- expected information sequence: knowledge growth - solutions - sustainable economy

If "human capital" becomes wise enough, this sequence should probably be implemented in the 21st century. Otherwise, population and ecological bombs (about 2050) will return us to the beginning stages of the history of humankind.

HUMAN CAPITAL DEVELOPMENT

Human capital in the 21st century will become the most important economic resource. This is a medium that generates and applies knowledge. Its architecture of "organs" is depicted in Figure 3.

Human capital develops in three stages:

- Stage I: Elementary Human Capital: Knowledge, Skills, Cases, Attitude

- Stage II: Advanced Human Capital: Info Utility Access, Professionalism and Artistry, Motivation
- Stage III: Mature Human Capital: Wisdom, Cross-Culture Communication, Change, Leadership

Only four attributes are information-driven: knowledge, skills, information utility access, and wisdom. This means that the development of human capital cannot be limited only to issues of information. The process of socialization plays a very important role in the estimation of human capital values; this process is culture-driven.

The measurement of human capital value can be done through the estimation of the value space of work force (macro-ecology) or through a given person (micro-ecology). Figure 4 illustrates the value space of human capital.

Each attribute (A) can be measured on the five-point scale. A sum total of all attribute points provides a value of given human capital (V). This is a comparative unit of human capital value. It can be applied in comparisons of economies, organizations, or persons. It can also be applied in the analysis of human capital efficiency potential.

FUTURE TRENDS

Along with the further development of the Information Wave, more laws of information should be defined and applied.

CONCLUSION

Macro-information ecology is just emerging, along with the development of Information Wave practice, and research should turn its attention into the application of the information laws and their further discovery and corrections in the analysis and design of values and tools of the Information Wave and civilization in general.

NOTE

[1] During his public lecture at Western Michigan University (13-12-1992).

KEY TERMS

Ecosystem: The entire ecological community composed of all living organisms interacting with the physical environment as one system.

Entropy: A measure of the degree of disorder or tendency toward the breakdown of any system. In physics this term is defined in the second law of thermodynamics, which states in part that "the entropy of the universe tends to a maximum".

Human Capital: Reflects a human potential in knowledge, skills, and attitude that can provide better solutions (meaning), efficiency (time) and effectiveness (money) of work.

Industrial Wave: A phase of civilization in which industries based on material processing and handling are dominant factors in the economy.

Information: A comparative unit of cognition that defines a change between the previous and present state of the natural, artificial, or semiotic systems.

Information Reservoir: A container of data, information, concepts, knowledge, and wisdom.

Information Wave: A phase of civilization in which industries based on information processing and handling are dominant factors in the economy.

Knowledge: A reasoning unit of cognition that creates awareness based on facts scientifically proven, rules, laws, coherent inferences, and well-defined methods.

Macro-Ecology of Information: The study of information (cognition) as a whole and concerned with *aggregates* across nations and markets.

Micro-Ecology of Information: The study of information (cognition) at the individual level of decision-making in professional, social, and personal undertakings.

Wisdom: A pragmatic unit of cognition that generates volition, a chosen way of acting and communicating. It is a process of choosing ordered routines that provide success and eliminate obstacles in performance.

Information Modeling in UML and ORM

Terry Halpin
Northface University, USA

INTRODUCTION

The *Unified Modeling Language* (UML) was adopted by the Object Management Group (OMG) in 1997 as a language for object-oriented (OO) analysis and design. After several minor revisions, a major overhaul resulted in UML version 2.0 (OMG, 2003), and the language is still being refined. Although suitable for object-oriented code design, UML is less suitable for information analysis, since it provides only weak support for the kinds of business rules found in data-intensive applications. Moreover, UML's graphical language does not lend itself readily to verbalization and multiple instantiation for validating data models with domain experts.

These problems can be remedied by using a fact-oriented approach for information analysis, where communication takes place in simple sentences, each sentence type can easily be populated with multiple instances, and attributes are avoided in the base model. At design time, a fact-oriented model can be used to derive a UML class model or a logical database model. *Object Role Modeling* (ORM), the main exemplar of the fact-oriented approach, originated in Europe in the mid-1970s (Falkenberg, 1976), and has been extensively revised and extended since, along with commercial tool support (e.g., Halpin, Evans, Hallock & MacLean, 2003).

This article provides a concise comparison of the data modeling features within UML and ORM. The next section provides background on both approaches. The following section summarizes the main structural differences between the two approaches, and outlines some benefits of ORM's fact-oriented approach. The following section uses a simple example to highlight the need to supplement UML's class modeling notation with additional constraints, especially those underpinning natural identification schemes. Future trends are then briefly outlined, and the conclusion motivates the use of both approaches in concert to provide a richer data modeling experience, and provides references for further reading.

BACKGROUND

Detailed treatments of UML are provided in Booch, Rumbaugh, and Jacobson (1999); Jacobson, Booch, and Rumbaugh (1999); and Rumbaugh, Jacobson, and Booch (1999). The UML notation includes hundreds of symbols, from which various diagrams may be constructed to model different perspectives of an application (e.g., use case diagrams, class diagrams, object diagrams, statecharts, activity diagrams, sequence diagrams, collaboration diagrams, component diagrams, and deployment diagrams). This article focuses on data modeling, considering only the static structure (class and object) diagrams. UML diagrams may be supplemented by textual constraints expressed in the Object Constraint Language (OCL). For a detailed coverage of OCL 2.0, see Warmer and Kleppe (2003).

ORM pictures the world simply in terms of objects (entities or values) that play roles (parts in relationships). For example, you are now playing the role of reading, and this article is playing the role of being read. Overviews of ORM may be found in Halpin (1998a, 1998b) and a detailed treatment in Halpin (2001a). For advanced treatment of specific ORM topics, see Bloesch and Halpin (1997), De Troyer and Meersman (1995), Halpin (2000, 2001b, 2002a, 2002b, 2004), Halpin and Bloesch (1999), Halpin and Proper (1995), and ter Hofstede, Proper, and van der Weide (1993).

DATA STRUCTURES

Table 1 summarizes the main correspondences between high-level data constructs in ORM and UML. An uncommented "—" indicates no predefined support for the corresponding concept, and "†" indicates incomplete support. This comparison indicates that ORM's built-in symbols provide greater expressive power for capturing conceptual constraints in graphical data models.

A *class* in UML corresponds to an *object type* in ORM. ORM classifies objects into *entities* (UML objects) and *values* (UML data values—constants such as character strings or numbers). A *fact type* (relationship type) in ORM is called an *association* in UML (e.g., Employee works for Company). The main structural difference between ORM and UML is that ORM avoids *attributes* in its base models. Implicitly, attributes may be associated with roles in a relationship. For example, Employee.birthdate is modeled in ORM as the second role of the fact type: Employee was born on Date.

The main advantages of attribute-free models are that all facts and rules can be naturally verbalized as sentences, all data structures can be easily populated with multiple instances, models and queries are more stable

Table 1. Comparison of the main data constructs in ORM and UML

ORM	*UML*
Data structures:	**Data structures**:
object type: entity type;	object class
value type	data type
— { use fact type }	attribute
unary fact type	— { use Boolean attribute }
2^{+}-ary fact type	2^{+}-ary association
objectified association (nesting)	association class
co-reference	qualified association †
Predefined Constraints:	**Predefined Constraints**:
internal uniqueness	multiplicity of ..1 †
external uniqueness	— { use qualified association } †
simple mandatory role	multiplicity of 1^{+}.. †
disjunctive mandatory role	—
frequency: internal; external	multiplicity †; —
value	enumeration, and textual
subset and equality	subset †
exclusion	xor †
subtype link and definition	subclass, discriminator etc. †
ring constraints	—
join constraints	—
object cardinality	class multiplicity
— { use uniqueness and ring } †	aggregation/composition
—	initial value, changeability
User-defined textual constraints	**User-defined textual constraints**

† = incomplete coverage of corresponding concept

since they are immune to changes that reshape attributes as associations (e.g., if we later wish to record the historical origin of a family name, a family name attribute needs to be remodeled using a relationship), null values are avoided, connectedness via semantic domains is clarified, and the metamodel is simplified. The price paid is that attribute-free diagrams usually consume more space. This disadvantage can be offset by deriving an attribute-based view (e.g., a UML class or relation scheme) when desired (tools can automate this).

ORM allows relationships of any *arity* (number of roles). A relationship may have many readings starting at any role to naturally verbalize constraints and navigation paths in any direction. Fact type readings use *mixfix* notation to allow object terms at any position in the sentence, allowing natural verbalization in any language. Role names are also allowed. ORM includes procedures for creating and transforming models (e.g., verbalization of relevant information examples—these "*data use cases*" are in the spirit of UML use cases, except the focus is on the underlying data).

In an ORM diagram, roles appear as boxes, connected by a line to their object type. A predicate appears as a named, ordered set of role boxes. Since these boxes are set out in a line, fact types may be conveniently populated with tables holding multiple fact instances, one column for each role. This allows all fact types and constraints to be *validated by verbalization as well as sample populations*.

While supporting binary and longer associations, UML uses Boolean attributes instead of *unary* relationships. For example, the fact instance expressed in ORM as "Person 'Sam Spade' smokes" would typically be rendered awkwardly in UML as "SamSpade: Person.isSmoker = true." To be business friendly, UML should support unary fact types directly (e.g., Room has a window, Person smokes, etc.).

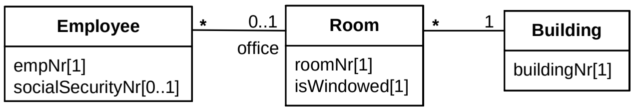
Each UML association has at most one name. Verbalization into sentences is practical only for infix binaries. Since roles for ternaries and higher arity associations are not on the same line, directional verbalization and multiple instantiation for population checks are ruled out. UML does provide object diagrams for instantiation, but these are convenient only for populating with one or two instances.

Both UML and ORM allow associations to be objectified as first class object types, called *association classes* in UML and *objectified* (or *nested) associations* in ORM. UML requires the same name to be used for the association and the association class, impeding natural verbalization, in contrast to ORM nesting based on linguistic nominalization (a verb phrase is objectified by a noun phrase).

CONSTRAINTS AND IDENTIFICATION SCHEMES

Business people communicate about things using value-based identification schemes, not memory addresses or

Figure 1. What semantics are missing?



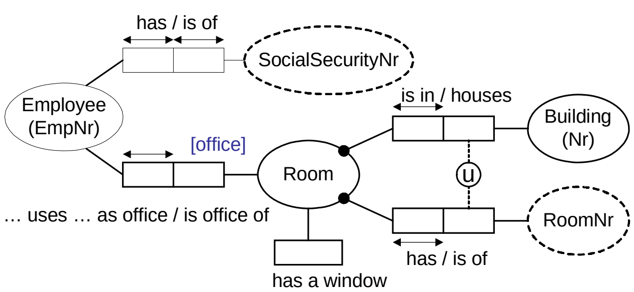
hidden object identifiers, and hence these need to be supported in any conceptual model. This entails rich support for what ORM calls internal and external uniqueness constraints, which may be used as a basis for identification of entities. UML 2.0 includes only a restricted form of internal uniqueness (maximum multiplicity of 1) and an even weaker form of external uniqueness (via qualified associations). Moreover, UML 2.0 does not require any value-based identification scheme for a class.

For example, consider the UML class model in Figure 1. Classes are depicted as rectangles, with the class name in the top compartment and attribute names in a lower compartment. Binary associations are depicted as lines connecting the classes involved. *Multiplicity constraints* may be applied to attributes and roles (association ends), using "1" for "exactly one," "0..1" for "at most one," and "*" for "zero or more.

Here, the attribute multiplicity constraints tell us that each employee has exactly one employee number and at most one social security number, each room has exactly one room number and exactly one value for isWindowed (a Boolean attribute to indicate whether a room has a window), and each building has exactly one building number. The multiplicity constraints on the associations tell us that each employee has at most one office, each room is the office of zero or more employees, each room is in exactly one building, and each building houses zero or more rooms. What semantics are missing?

To begin with, there is no declaration of how entities are identified by business people. In the business domain, employees are identified by their employee numbers, and rooms are identified by combining their local room number with the number of the building in which they are housed. The lack of the ability to declare these identification

Figure 2. ORM model captures the semantics lost in the UML model



schemes prevents an understanding of these business rules, and excludes any formal way to populate the data structures with fact instances. Moreover, the uniqueness constraint that each social security number applies to at most one employee is lost, because UML cannot declare the 1:1 nature of an association that has been modeled as an attribute.

One solution to this problem is to add additional constructs in UML to apply uniqueness constraints to arbitrary combinations of attributes or binary association roles that may be considered properties of the same class.

For comparison purposes, an ORM model for the same domain is shown in Figure 2. Entity types are depicted as named ellipses and value types as named, dotted ellipses. Fact types are depicted as role sets with at least one reading. Each role is depicted as a box connected to the object type that plays it.

Here we have one unary fact type: Room has a window. The other fact types are binary. For example, "Employee uses Room as office" and "Room is office of Employee" are forward and inverse readings of the same fact type. Role names may be added (e.g., office). Employees are identified by their employee number, and buildings by their building number. Simple identification schemes like these may be abbreviated in parentheses as shown. The arrow-tipped bars over roles depict internal uniqueness constraints (e.g., **each** Room is in **at most one** Building), and the solid dots are mandatory role constraints (e.g., **each** Room is in **at least one** Building). The external uniqueness constraint (circled "u') enables the composite identification scheme for Room. Even if we introduced a simple identifier for Room, this external uniqueness constraint still needs to be declared.

Given an n-ary association (n > 2), UML's multiplicity notation cannot express a mandatory role constraint on any association that has between 1 and n-2 mandatory roles. This is because multiplicity on one role is defined in terms of the other n-1 roles. This is fine for binary associations, but not for ternaries and beyond. For practical examples of such constraint patterns, see Halpin (2001b).

ORM includes many other graphical constraint primitives that go far beyond those found in UML class diagrams (e.g., inclusive-or, subset, exclusion, ring, and join constraints). Moreover, ORM's constraint primitives are far more orthogonal than those of UML. For discussions of these features, see Halpin (2000, 2001b, 2002a, 2004).

UML and ORM both permit users to add other constraints and derivation rules in a textual language of their choice. UML suggests OCL for this purpose (Warmer & Kleppe, 2003). Although OCL is an unambiguous language, its mathematical syntax renders it unsuitable for validating rules with non-technical domain experts. ORM's conceptual query language, ConQuer, is both formal and readily understandable to non-technical users, and its attribute-free nature makes it much more *semantically stable* than an attribute-based language such as OCL (Bloesch a& Halpin, 1997; Halpin & Bloesch, 1999).

FUTURE TRENDS

The OMG recommends its Model-Driven Architecture framework as a way to facilitate the generation of software artifacts from high-level models, starting with a Computation-Independent Model (CIM), and then moving down to a Platform-Independent Model (PIM), and finally the Platform-Specific Model (PSM) used in the actual implementation. For reasons given earlier, although useful for code design, UML currently has some shortcomings with regard to conceptual data analysis and the specification of business rules to be validated by business domain experts.

With a view to providing better support at the CIM level, in early 2003 the OMG received submissions to provide a truly semantic layer for business rules. Two of the three submissions incorporated features from ORM's fact-oriented approach, and at the time of writing it seems likely that a number of key aspects of fact-oriented modeling (e.g., support for unaries and high-level verbalization of business rules) will be included in the final adopted submission.

Many companies are now looking to model-driven development as a way to dramatically increase the productivity, reliability, and adaptability of software engineering approaches. It seems clear that both object-oriented and fact-oriented approaches will be increasingly utilized in the future to raise the percentage of quality code in software applications that can be generated from higher level models.

CONCLUSION

UML class diagrams are often more compact than ORM models, and they can be adorned with implementation detail for engineering to and from object-oriented programming code. Moreover, UML includes mechanisms for modeling behavior, and its adoption by the OMG is helping it gain wide support in industry, especially for the design of object-oriented software.

ORM is based on a small set of easily mastered, orthogonal concepts; its attribute-free nature facilitates model validation by verbalization and population and conveys semantic stability; and its graphical constraint language can formally capture many business rules. UML modelers willing to learn ORM can get the best of both approaches by using ORM as a front-end to their information analysis and then mapping their ORM models to UML, where ORM constraints with no UML counterpart can be captured in notes or formal textual constraints. This option will become more attractive once commercial tools provide automatic transformation between ORM and UML.

KEY TERMS

Arity: The number of roles in a fact type (unary = 1, binary = 2, ternary = 3, etc.). In ORM, fact types may be of arity 1 or more. In UML, fact types (associations) may be of arity 2 or more.

Business Rule: A constraint or derivation rule that applies to the business domain. A static constraint restricts the possible states of the business, and a dynamic constraint restricts the possible transitions between states. A derivation rule declares how a fact may be derived from existing facts, or how an object is defined in terms of existing objects.

Conceptual Schema: Specification of the structure of a business domain using language and terms easily understood by a non-technical domain expert. A conceptual schema typically declares the fact types and business rules that are relevant to the business domain.

Elementary Fact Type: In ORM, an elementary fact is an atomic proposition that applies a logical predicate to a sequence of one or more objects of a given type; it cannot be split into smaller facts without information loss. An elementary fact type is a kind of elementary fact. For example: Person smokes; Person was born in Country; Person introduced Person to Person. In UML, an elementary fact type is known as an elementary association or elementary relationship type.

Entity Type: An entity is a non-lexical object that in the real world is identified using a definite description that relates it to other things (e.g., the Country that has CountryCode 'US'). Typically, an entity may undergo changes over time. An entity type is a kind of entity, for example, Person, Country. In UML, an entity is called an object, and an entity type is called a class.

Object-Role Modeling (RM): A fact-oriented approach for modeling information at a conceptual level, using language that is easily understood by non-technical domain experts. ORM includes rich graphical and textual languages for modeling facts and business rules, and provides procedures for creating conceptual models and transforming them to lower level models for implementation.

Object Type: In ORM, an object is either an entity (non-lexical thing) or a value (lexical constant, such as a character string), and an object type is a kind of object (e.g., Person, CountryCode). In UML, the term "object" is restricted to entities (instances of classes), while the term "data value" is used for instances of data types.

Role: In ORM, a role is a part played in a fact type (relationship type). In UML, this is known as an association-end. For example, in the fact type *Person works for Company*, Person plays the role of employee, and Company plays the role of employer.

UML: The Unified Modeling Language adopted by the Object Management Group as a modeling language for object-oriented analysis and design of software systems. UML includes several sub-languages and diagram notations for modeling different aspects of software systems.

Information Resources Development Challenges in a Cross-Cultural Environment

Wai K. Law
University of Guam, Guam

INTRODUCTION

Western management theory considers information the lifeblood of organization. The sharing of information lubricates the interlocking divisions within the organization, promoting the effective achievement of organizational goals with external business partners. However, in many regions of the world, information represents power, and managers often try to accumulate as much of it as they can while denying access to others (Oz, 2002). For others, the disclosure of information is considered a threat to the span of management control (Rocheleau, 1999). In some cases, administrators could be more interested in the scale of the information system and its associated budget, than in the capability and functionality of the system (Kalpic & Boyd, 2000). These are examples of conflicting cultural values in a cross-cultural environment. The introduction of Western management approaches conflicts with regional administrative styles, diminishing the effectiveness of information systems (Shea & Lewis, 1996; Raman & Watson, 1997). Sensitivity to cultural differences has been recognized as an important factor in the successful global deployment of information systems. Minor information management issues potentially resolvable through improved communication in the West often manifest as major challenges in a cross-cultural environment.

BACKGROUND

The literature provided thorough coverage on designs, development, and implementation of computer-based information systems (CBISs). Numerous studies examined various systems solutions for organization needs (Applegate, 1995; McLeod, 1998; O'Brien, 2002). However, the projected value of information technology has been formulated based on a rough assessment of the possibilities without full appreciation of the limitations due to resistance to organizational and social changes (Osterman, 1991). Increasingly, management realized that massive deployment of information systems on a global basis, even with prudent management of the systems, has not been producing the desirable outcomes of value generation. Recent studies revealed the significant influence of cultures toward the success of transferring information technology beyond the Western world. National culture, organization culture, and MIS culture induced influence over the successful development and management of information resources (Hofstede, 1980; Raman & Watson, 1997). Shea and Lewis (1996) suggested the desirability of paying close attention to the user absorptive rate in the transfer of new technology into a different cultural environment. It became apparent that adaptation of information system designs to new cultural environments was insufficient to guarantee successful implementation. User selection of technological features, driven by cultural preferences, could be a key factor for designing information systems in a multicultural environment. Other studies reported the numerous obstacles of developing CBISs under various cultural settings, even with highly motivated leaders to support the deployment of information systems (Raman & Watson, 1997; Al-Abdul-Gader, 1999).

The information system function must enhance user effectiveness and efficiency in utilizing the information to improve value delivery for the organization (Parker, 1996). New challenges emerged as nontechnical issues and clouded the measurement of information system performance. A typical information system would be designed to provide information to users with common needs. Good data reports should contain all the required information with accurate representation of events. The reports needed to be generated in a timely fashion and in a format usable by the users (McLeod, 1998). However, individual users tended to value information systems for providing custom reports to meet individual needs in specific circumstances (Heeks, 1999). Inconsistent expectations in a cross-cultural environment crippled the effective management of information resources. Cultures carried different interpretations for timeliness, completeness, and relevancy of information.

Makeshift management decisions generated new dynamics in several ways. In the spirit of promoting free information exchange, the department that owned the information system became obligated to provide information to others (Oz, 2002). However, the new responsibility seldom came with additional resources. The information owners became reluctant to supply information, because doing so would take away that resource from other regular tasks (Davenport, 1997). Some managers shifted the data reporting responsibilities to other divisions, creating a bureaucratic nightmare for the users. Some ignored data requests, and others manipulated the data flows with respect to organizational politics (Oz, 2002; Rocheleau, 1999). Those working in the public sector faced the challenge of maintaining a delicate balance as they attempted to fulfill their responsibilities for both confidentiality and access to data (Osterman, 1991; Duncan, 1999). The problems would be more severe under a relationship-based culture, where favors could not be declined.

Cultural backgrounds shaped the preferential information system model. In some cultures, managers would be intuitive and feelings based and would have vague expectations for the performance of the information system. There would be more emphasis on group harmony and saving face than on actual problem solving (Bjerke, 1999). Others would be more interested in meeting obligations, ignoring the source and validity of the reports. The controlling manager seeked a complex and broad information system that provides qualitative data (Kluckhohn & Strodtbeck, 1961; Lane & DiStefano, 1992; Shea & Lewis, 1996). All these personality extremes coexist in a cross-cultural setting, making it more challenging to design systems than in a single-culture environment. The perceived value of information resources became less predictable in a cross-cultural environment.

CHALLENGES IN CROSS-CULTURAL INFORMATION SYSTEMS MANAGEMENT

The rapid expansion of Western influence on a global basis created an environment under the cross-currents of Western corporate culture and regional cultures. Nations in the Pacific Basin have established close relationships with the Western world. Heavy Western investments have transformed these nations into showcases for Western systems. However, underneath the formal display of the Western culture, local cultures retained strong influence on their societies. An influx of immigrants holding on to their traditions further diluted the penetration of Western influence in these regions. The predominating regional workforce challenged Western corporate culture through their deep-rooted traditions and work habits. For example, a massive absenteeism could be expected on festival days, even without approved leaves or holidays. Timely arrival at a meeting would be accepted as 15 minutes to several hours after the scheduled time. Mandated reports could be excused without penalty, and the uttermost concern, over efficiency, was to preserve group harmony. Sometimes, this meant ignoring facts to restore stability and group harmony. Periodic acquisition of technology would be celebrated even without the appropriate infrastructure support, preventing usage of the technology. Experience in the Pacific Basin provided a sampling of information resources management issues that became significant challenges in cross-cultural environments.

Challenge One: The design objectives of an information system must expand from efficiency orientation to adaptive accommodation of cultural habits. It becomes desirable to allow and to track dynamic modification of data-processing procedures according to shifting organizational and cultural influences.

While a primary design objective of an information system was to provide efficient transaction processing, often, the affected human system was slow to accept the implicit MIS culture embedded in the system design. Western culture emphasized timeliness and accuracy, which were less important to many cultures. For example, it often took months to update databases from paper documents. Some users relied on the information system for information, while others insisted on paper documents only. Hence, circulation of multiple versions of reports was common depending on the sources of the reports. Parallel operations to accommodate parallel cultures generated organizational conflict. Influential users and administrative interventions threatened the integrity of information systems. The full potential of the information system was suppressed to a preference for cultural norms, and only system features that would not threaten cultural practices would be allowed to remain. Some local cultures emphasized protecting family members more than performance appraisal. The value of information was not as much for improving decision making, but to endorse group position, to preserve relationship, and to avoid embarrassment.

Challenge Two: There is a need for clear definitions of data ownership and responsibilities for data acquisition, data quality control, and data distribution. This is especially challenging in cultural environments, where the political attributes of information interfere with the communicative value of information.

In many Eastern cultures, credible information was deferred to leaders and elders with power and status. Political relationships dictated the availability of information and the accessibility to organizational data. This was contrary to the basic assumptions of CBISs that promoted the free exchange of information (Oz, 2002; Osterman, 1991; Rocheleau, 1999). The bureaucratic procedures for the approval of data usage defeated the designed roles of the information system. A fully developed database supported very limited applications. The lack of explicit system objectives coupled with the practice of delegating data management responsibility to the lowest-level unskilled workers created data integrity problems. For example, withholding information to gain and maintain power was acceptable among many Asian cultures. Openness would be considered a sign of weakness. It would be critical to formally establish the credibility, relevancy, and accessibility of the data resource.

Challenge Three: Management must meticulously plan data acquisition, data preparation, data distribution, and data usage, and fully understand the required organizational incentive and associated costs for maintaining information flow within the organization. This is especially important in a cultural environment where data-driven decision making is a new practice.

An uncoordinated approach to information resource management created fragmented entities to process information for narrow applications. The fad of data-driven decision making created a mad race for data reports using every available political connection. The result would be a great assortment of data reports with massive details. Inconsistency occurred among data reports, depending on the data-processing methods and storage formats. For example, a report from an off-line, static database in a remote office could be given equal credibility as a report generated from a current database from the data center. In a cross-cultural environment, influential individuals would compete to justify the merit of their reports from their cultural perspectives. The heated debates, along with discrepancies among the reports, frustrated the end users and led to distrust of the information systems for the inability to produce usable information reports. Regretfully, the information systems were seldom designed to generate reports for decision support.

Challenge Four: Management must take leadership in establishing precise, formal data definitions, and communicate them to all potential data users and those assigned roles in data distribution. This is especially important where mastery of languages, cultural predisposition, level of information literacy, and social attitude could strongly influence the group dynamic of data usage.

Technology evolution increasingly placed information systems under the direct control of end users. However, end users often lack technical expertise, and few were committed to the development of information resources. Events and samples were confused with statistics. Relaxed practices in standards and data definitions created issues in data validity and data quality. Potential information was lost when processed data replaced raw data, while the time sensitivity of dynamic data was ignored. Time series data were deleted to preserve storage space. The information system would be blamed for the unfortunate chaos. In one incident, a user group maintained multiple versions of a database with the assistance of the data center. However, only selected workers in the user group and the data center were aware of the special arrangement. The different versions of the database were discovered only when two identical requests for information were returned with different outcomes. Top management, unwilling to escalate cultural tension, ignored the potential seriousness of the data integrity issue. In another incident, several users entered an unresolved dispute on their interpretations of a data definition according to their understanding of the language. The data definition used by the data center in maintaining the database was rejected.

Challenge Five: The increased complexity and frequency of usage of information reports is, in reality, a severe drain on budgetary resources. Management needs to develop a mechanism to track data usage and adjust resources appropriately. This could be more challenging under cultural environments that lack sophistication in information processing.

Modern management practices seek opportunities to replace physical resources with information. When management failed to adjust budgets to support the information services, those affected would try every means to discontinue information services. On the other hand, uncontrolled access encouraged abuse, wasting valuable resources. Ethics, disciplined usage, and an understanding of information value supported the information practices in Western society. The problems would be crippling in a culture with different appreciation for information under different ethical standards. A local culture of generosity would insist on the free distribution of fully colored documents. Another practice was to circulate printed copies of e-mail to avoid offending anyone. The practices quickly depleted the budget for supplies.

Challenge Six: Management must take an active role in controlling the flow of organizational data, both within the organization and to the external environment. Management should consider endorsement of an official organizational data to ensure consistency rather than leave the official data report to random actions. This is especially important in a cultural setting where it is impractical to correct public statements of social leaders, regardless of facts.

In cultures where subordinates would not question the positions of leaders, an information system must implicitly support the decisions and public statements of the leaders (Gannon, 2001). Officials of a local organization proposed an expensive marketing campaign, pointing to a decline in demand in the primary market. However, published data actually attributed the demand decline to the collapse of an emerging market. It would be an embarrassment to point out the omission, and the wrath of the society could be on those who allowed the facts to be publicized.

Challenge Seven: Management needs to play an active role in data planning and closely align the information report designs for decision support. This is especially challenging in a cultural environment that lacks appreciation for operational planning and control.

In cultures where gesture would be more important than details, systematic failure to collect information would be accepted and forgiven. Information systems applications were limited to payroll and accounting (Kalpic & Boyd, 2000). In some cases, the lack of adequate information was the key to assuring continued financial support. Organizations were unprepared to collect and store data to support meaningful decision support applications. Information systems were seldom utilized to their full potential under such cultural settings.

CHALLENGES IN PERCEPTION OF INFORMATION RESOURCE

Potential cultural myopia required great efforts when communicating the principles of information resource management.

Challenge One: Information Resources Solely as an Investment Issue

A common response to deficiencies in organizational data was to seek capital investment for new technology. This perception underestimated the requirements for system and facility maintenance, technical support, user training, data architecture development, data security, and distribution. Lack of organizational readiness stalled the deployment of information systems. Inflated expectations and uncoordinated usage of data services nullified the value of the information system. Erratic funding patterns destroyed development projects, making it extremely difficult to retain technical personnel. Poor maintenance damaged equipment and threatened data integrity. Cultural managers eager to modernize without fully understanding the implications of information resources management eventually abandoned their support for the Western ideas.

Challenge Two: Information Resources Development by Delegation

Management seeking an easy fix to the organizational data problem mandated data compilation activities by the functional divisions. Besides undermining information resources as a critical organizational asset, little technical assistance was provided. Unmotivated managers neglected data quality and resisted data distribution. The turnover of administrators caused discontinuity in data resources development.

Challenge Three: Limited Appreciation for Information Resources

Information resources could be compared to utility services, such as water, the value of which was suppressed until serious issues developed in quality and supply. Often neglected was the accountancy of the value contribution of the information system, beyond periodic technical improvements. Benchmark studies should identify cost performance as well as the critical roles of information resources within the organization.

FUTURE TRENDS

The historical development of information systems has followed the model of a rational manager (Kepner, 1965), with emphasis on openness, clear structure, innovative practices, and logical thinking. In regions where traditions and relationships resisted changes, information systems designers must consider the needs of emotional decision makers, with heavy emphasis on the concern to maintain social and cultural stability. Some cultures demand tight control of the information flow, while other cultures are casual about the absolute data quality. Some organizations integrate information systems to become organizational backbones, and others prefer to separate information in isolated pockets. Some prefer simple information systems, while others invest in sophisticated intelligence systems. Information systems for cross-cultural environments must deliver value to users with diversified backgrounds. Comparative study on information system features valued across cultural settings should improve the value delivery of the information system function.

CONCLUSION

Despite rapid technological development, information resource management is still a relatively new concept. Data reports preparation is often a laborious activity, and accepted practices and administrative preferences still drive decision making. Organizations that anticipate increasing exposure to multicultural environments should allow a longer time for organizational adjustment to technical development. Information systems originally developed as productivity tools, for data processing and report generation must undergo radical design evaluation to meet the diversified user expectations and information skills. An information resource manager must also carefully consider data ownership and data distribution issues. Cultural preferences and information values should be carefully considered in the justification of information services. The information system objective should be clearly distinguished from the information system capabilities, especially with different cultural interpretations of information value. Top management should play an active role in defining organizational data flow, with implementation of appropriate incentives. Special attention should be given to precise data definition, especially with a workforce with different training backgrounds under different cultural and language settings. Last, it is critical to emphasize strict standards for data quality, due to differences in expectations for information system performance.

KEY TERMS

Cross-Cultural Environment: The coexistence of more than one cultural influence in different segments of a society, or the simultaneous adoption of different cultural practices at work, social events, and family life.

Cultural Habit: Accepted behaviors within a group of people, sharing some common background, such as language, family heritage, education, and living and socializing environment.

Data Definition: An elaborate statement of the representation of each piece of data, its source, storage method, and intended usage.

Data-Driven Decision Making: The practice of purposefully collecting, analyzing, and interpreting data according to accepted criteria, and using the outcomes to select and justify decisions.

Data Planning: The projection of expected future needs for data, with specifications on data sources, data collection and storage, data processing and presentation, data distribution, and data security.

Information Resources: Resources required to produce information, including hardware, software, technical support, users, facilities, data systems, and data.

Official Organizational Data: A selected version of dynamic data released for both internal and external usage to maintain consistency in communication.

Transaction-Processing System: This is a computer system designed to support the recording and completion of value exchange activities.

Information Resources Development in China

INTRODUCTION AND BACKGROUND

In its several thousand years of social progress, China has put continuous efforts on cultural development, which to a certain extent contributed to the exploitation and utilization of information resources.

Since the founding of the People's Republic of China in 1949, the government has been attaching great importance to information resources development. In 1956, the government set "Marching Towards Science" as the directing principle for the course of information resources management, and made a conscientious plan in information resources development with the emphasis on collecting, rearranging, analyzing, indexing, and reporting scientific and technical documents from home and abroad to serve the needs of professionals in various disciplines. By 1987, the scientific and technical information sector alone had already possessed 26,000 foreign periodicals, 6,000 domestic periodicals, 120 million patent manuals, and more than 32 million books. There were 236 abstracting and indexing journals published annually, covering more than 1.2 million documents and articles. Further, there were 2,038 public libraries at county and higher levels, collecting more than 200 million books. There were 745 academic libraries, collecting 250 million books. There were also more than 4,000 libraries in research institutes (Guan, 1988).

In late 1980s and early 1990s, however, information resources development was affected by the readjusting of China's economy. Non-profit libraries and information service institutions suffered from a severe shortage of money for collection development. As a result, information resources development was captured in severe logjam or even retrogress. Types of document collections in some libraries dropped by a half or even two-thirds (Fu, 1996). Many abstracting and indexing journals stopped publication. On the other hand, some new abstracting and indexing journals emerged, along with bibliographical databases, which catered to market demand.

Under the promotion of the international information technology revolution, China has been experiencing an upsurge in information development since the last decade of the 20th century. Information infrastructure construction keeps a rapid pace in development. The ownership of telephone, cellar phone, and computer has been increasing steadily. The overall scale of China's information infrastructure in terms of network capacity and number of users now ranks first in the world (China Telecommunications Yearbook, 2003; He, 2004). On the other side, however, information resources development is lagging far behind. The lack of information, especially Chinese information, in networks and information systems influences the benefit of investment in information technology, which has become a major obstacle not only to China's informationalization drive, but also to the competitiveness of Chinese economy.

Since the mid-1990s, under the promotion of the tide of information superhighway construction in many countries, information resources development in China entered a new phase. In 1997, the Chinese government constituted the "Draft on China's Informationalization," drawing the outline of China's information infrastructure (Zou, 1997), which includes six elements: information resource, national information network, information technology (IT) application, information industry, information professional, and information policy code and standard.

Information resource was set as the primary element among the six, which showed the state's emphasis on its development. This also indicated that people once again realized the importance of information resources development. Several years later, the proposal was accepted as a part of China's tenth "five-year plan," which marked that information resources development became the central task of China's informationalization drive.

The concept "information resources development" used in this item refers to collection, processing, organization, and dissemination of document resources, as well as their digitalization and networking. Factual and data resources ought to be included in the concept. However, China's progress in these aspects is relatively slow. In recent years, people started to realize the importance of factual and data resources development. The departments concerned have started to work out a plan for constructing the National Data Center.

MAJOR INITIATIVES IN CHINA'S INFORMATION RESOURCES DEVELOPMENT

Under the guidance of the policies introduced in the last section, the Chinese government initiated several major information resources development projects to change the current situation of inconsistency between information resources development and information network construction, as well as to lessen the discrepancy between information resources available and those required by the public.

CALIS (China Academic Library and Information System)

CALIS is an initiative under China's plan to build 100 key universities in the 21st century (named "211 Project" by the Ministry of Education). It aims at constructing a networked information resources sharing system based on the China Education and Research Network (CERNET) so as to parallel the development of a communication network and an information resources network, and provide university faculty and students as well as professionals in research institutions with easy access to a national information service system characterized by abundant information resources, advanced technologies, and a convenient service system.

The service system consists of a CALIS national management center, four CALIS national information centers (covering sciences and social sciences, engineering, agricultural science, and medical science, respectively), and seven CALIS regional information centers (in Beijing, Shanghai, Nanjing, Guangzhou, Xi'an, Chengdu, Wuhan, and Changchun, respectively). The system will also be linked to major information service systems outside China to form China's Academic Library and Information System. The construction of CALIS will greatly increase the amount of information available to academic libraries and also improve their capability in information services (data from www.calis.edu.cn).

Digitalization Projects

The China Digital Library Project was carried out under the coordination of the Ministry of Culture. In July 1997, the National Library of China (then Beijing Library), together with Shanghai Library and a few other institutions, started the Chinese Pilot Digital Library Project (CPDLP). Later in 1998, the Ministry of Culture formally put forward the proposal of constructing the China Digital Library. Various enterprises and organizations—such as China Telecom, the National Library of China, the Chinese Academy of Sciences, China Aerospace Industrial Corporation, Peking University, and Tsinghua University—participated in the project, called the China Digital Library Project.

As for the achievements of the project, it was expected that some 20 resource databases would be made available on the "China Cultural Information Network," which included the China Medical Science Resource Database, China Tourism Resource Database, China Economic Resource Information Database, among others. The network will become a significant channel of spreading the Chinese culture and strongly support China's project of "rejuvenating the nation through science and education" (Xu, 1999, 2000; Sun, 1999).

Besides the China Digital Library Project, various other digital library projects were also carried out. The construction of the Chinese National Science Digital Library (CSDL) was started in late 2001. The project, as part of the Knowledge Innovation Project of the Chinese Academy of Sciences, aims to build a digital information service system that meets the international developing trends of digital libraries, and caters to the development of the Chinese Academy of Sciences. It should be able to serve the needs of researchers and professionals in information accessing and knowledge innovation when it is finished in three to four years' time (Zhang, 2002).

In China's Taiwan Province, eight digital library initiatives are currently under way, including the construction of a Digital Library and Information Center and building of the Haoran Digital Library at Jiaotong University. Objectives of the initiatives are to promote information exchange among learning and research institutions in Taiwan, and coordinate their purchase of information resources such as databases from foreign countries. Another objective is to promote the research on Chinese culture, especially on Chinese history (Lv, 1999).

There are also digitalization projects other than construction of digital libraries. In January 1999, the Geology Department of the Chinese Academy of Sciences raised to the State Council a proposal on strategies of China's "Digital Globe" development, indicating the importance of building a national global information infrastructure and establishing a digital global spatial information sharing system (*Information Industry Newspaper*, November 22, 1999). In November 1999, the first "Digital Globe" International Conference was held in Beijing, showing that the Chinese government attached great importance to international cooperation in this area (*China Computer World*, December 6, 1999).

Construction of the China National Science and Technology Library (NSTL)

In June 2000, the China National Science and Technology Library was formally established through the cooperation of China's Ministry of Science and Technology, State Committee of Economics and Trade, Ministry of Agriculture, Ministry of Health, and the Chinese Academy of Sciences. As a virtual scientific and technical resource center, it consists of eight library and information institutions, including the Library of the Chinese Academy of Sciences, National Engineering Library of China, Library of the Chinese Academy of Agricultural Science, Library of the Chinese Academy of Medical Science, and Institute of Scientific and Technical Information of China. The center utilizes advanced technologies and methods to collect information from domestic and foreign sources. It also makes standards and criteria in information sharing. Moreover, the center serves as a bridge of cooperation between Chinese information resources management professionals and their foreign counterparts (Yuan, 2001).

Special-Topic Information Resources Development

Government Information Resources Development—China Online Government Project

On January 22, 1999, the China Online Government Project Start-Up Conference was held in Beijing, sponsored by China Telecom and the State Economic and Trade Commission, together with the information sectors of more than 40 ministries. During the conference, the China Online Government Project was started. Subsequently, the main Web site of the China Government Portal, *www.gov.cn*, was established in 1999.

According to the "White Paper on China Online Government Project," accessed through the portal, the project refers to the practice by the government at all levels to establish their formal Web sites to promote office automation in government work, offer public services via the Internet, and fulfill the roles of management and service in the fields of society, economy, and social life.

Patent Information Resources Development

Patent information is an essential part of a country's technical information resources. To meet the users' requirement of searching and utilizing patent information, China Patent InfoNet was established by the Retrieving and Consulting Center under the State Intellectual Property Office in May 1998. In January 2002, its new version (*www.patent.com.cn*) was published online and started to offer to patent users and researchers comprehensive services, such as patent information retrieval, introduction of patent laws and regulations, guidelines for patent application.

Construction of the National Institute for Information Resources Management

Three national research centers for information resources management have recently been set up in Beijing, Nanjing, and Wuhan to promote research on theories, applications, policies, and technologies in IRM, affiliated to the Department of Information Management of Peking University, Department of Information Management of Nanjing University, and School of Information Management of Wuhan University.

INITIAL IMPACT OF SOME INITIATIVES

CALIS

Started in November 1998, CALIS completed its first phase of construction by the end of 2001. Currently, the system can provide an online public access catalog, interlibrary loan (ILL), Internet navigation, online cataloging, cooperative literature purchasing, and various other services through digitalization of information resources, networking of information services, and cooperation among participating academic libraries. As a result, universities and colleges in China now possess information resources greatly, more than ever before: the variety of foreign periodicals increased by one-third, 95% of the Chinese literature and 80% of the foreign literature are now available, and more than 100 academic libraries offer 24-hour online information services. In addition, 25 distinctive databases and 194 disciplinary navigation databases are built.

In its second phase of construction starting from 2002, CALIS aims to further strengthen the document-supporting ability of academic libraries. It plans to automate and network about 1,000 academic libraries, among which 100 will be completely automated and networked, becoming the backbones in information resource sharing. Some 20 academic libraries will be developed into digital library bases, acting as the kernels of information service systems and distributing centers of information resources. Besides, digitalized information resources imported from foreign countries are expected to cover all subject areas, while domestic information resources will be as much as several Tera Bytes (Zhu, 2001).

China Digital Library Project and NSTL Construction

Construction of the China Digital Library and the National Science and Technology Library have been advancing smoothly. In April 1999, the China Cultural Information Net started operation as the top level of the China Digital Library. In November 1999 and February 2000 respectively, the Capital Library and China Radio International (CRI) became experimental units of the China Digital Library Project. It should include information resources not only from libraries, but also from the government, even from international channels. The ultimate goal of the project is to build a "Digital China."

The National Culture Information Resources Sharing Project has been carried out. The culture information resources base composed of 40 multimedia resource bases has included 300 films, 132 local operas, 300,000 pictures, and nearly 100 lectures. All resources have been published through Web pages to allow access for people in rural and remote areas.

The initiative of building the National Science and Technology Library is near conclusion. Through two years of construction, participating libraries now collect more than 16,000 types of foreign scientific and technical literature (including periodicals, conference proceedings, technical reports, etc.), as compared to no more than 4,000 types in 1996. Some 6.5 million bibliographical records had been put online by the end of March 2002, and this number is expected to increase at a rate of two million per year. The network service system provides 24-hour, free secondary literature retrieval service to Internet users. In March 2002 alone, 1.37 million users visited the system, as compared to 150,000 when the system was started in January 2001. More than 60,000 users have received full-text document service.

Development of Commercial Information Products

Information resource development in a market-oriented approach achieves great effect. Many database and information service providers (such as ICP, ISP) come into operation, among which the China Academic Journals CD-ROM database, ChinaInfo Group, Chongqing Weipu Information Consulting Corporation Ltd. (*www.vipinfo.com.cn*), Beijing Scholar Sci-Tech Co., Ltd., and China Infobank enjoy nationwide recognition. The Chinese Journal Full-Text Database includes more than 6.1 million articles from 6,600 major periodicals published in Mainland China since 1994, as well as more than 15 million bibliographical records. The database is available both online and in CD-ROM form.

In a broader context, Internet-based information resources have also undergone rapid development. According to statistics from the "Survey on Information Resources in China," which was released by the China Internet Network Information Center (CNNIC) in September 2001 (www.cnnic.net.cn/tj/rep2001.shtml), there were 692,490 registered domain names, 238,249 Web sites, 159,460,056 Web pages, and 45,598 online databases within China. A recently released report shows that the number of Web sites has increased to 293,213 by June 2002 (www.cnnic.net.cn/develst/2002-7e/index.shtml).

FUTURE TRENDS AND CONCLUSION

The projects that we have introduced above lay a solid foundation for the further development of information resources in China. Recently, the Ministry of Science and Technology has started up the Science and Technology Documents Resource and Service Platform. Founding of the National Informationization Directing Committee also boosted the development and utilization of information resources.

Looking into the future, we can feel the long way ahead for China to improve its information resources. Efforts need to be made in a number of areas: first, the digital library projects need to be further expanded; second, the government should continue its support for information resources development projects; and third, the issue of nationwide cooperation across industries needs to be addressed properly as one of the most important problems in information resources development.

KEY TERMS

Digital Library: A cultural infrastructure that collects and stores information in electronic format and supports its users in accessing a large collection of information effectively through digital means.

Information Resource: A collection of valuable information generated by human activities. In a broader sense, it also includes related equipment, personnel, and capital.

Information Resources Development: The process of collecting, processing, storing, disseminating, and utilizing information resources according to the need of the society.

Information Resources Management: The planning, organization, allocation, and utilization of information and related resources through legal, technological, and other methods to support institutional goals and missions.

Information Service: The activity of providing information products and related services according to users' needs. In a broader sense, it refers to providing users with information through any forms of product or service.

Informationalization: The process of social advances in which human society transforms from industrial society to information society.

Information Systems and Small Business

M. Gordon Hunter
University of Lethbridge, Canada

INTRODUCTION

The subject area of the application of information systems to small business is a thoroughly interesting, yet relatively under-researched topic. Small business is an important part of any economy. In the United Kingdom, 25% of the gross domestic product is produced by small business, which employs 65% of the nation's workers (Ballantine et al., 1998). In Canada, 43% of economic output is accounted for by small business, employing 50% of private sector employees (Industry Canada, 1997). Further, governments view the small business sector as that component of the economy that can best contribute to economic growth (Balderson, 2000). Given the importance of this sector of the economy, it is incumbent upon researchers and managers of small business to develop a better understanding of how information systems may contribute to the operation and growth of individual businesses as well as the overall sector.

The objective of this article is to provide an overview of information systems used by small business. Research projects are presented that describe the current situation. Recommendations are then proffered for various stakeholders who should contribute to a more effective use of information systems by small business.

BACKGROUND

There does not seem to be a commonly accepted definition of a small business. Thus, individual researchers have adopted a definition for their specific projects. Some definitions include annual revenue, amount of investment, or number of employees. The definition mostly used is number of employees (Longnecker et al., 1997). The European Parliament (2002) has also adopted number of employees as a definition and has further refined the category. Thus, 0 to 10 employees represent micro businesses, small businesses include 10 to 50 employees, and medium businesses have 50 to 250 employees.

Beyond the size aspect of small business, there are others that differentiate them from large businesses. Stevenson (1999) has determined that from a strategic perspective, managers of small businesses tend to respond to opportunities presented by their environment in a multi-staged approach by committing a minimum of resources. Another differentiating factor is "resource poverty" (Thong et al., 1994). This term refers to the lack of time, finances, and human resources.

Laudon and Laudon (2001) suggest that an information system is "interrelated components working together to collect, process, store, and disseminate information to support decision making, coordination, control, analysis, and visualization in an organization" (Laudon & Laudon, 2001, p. 7). As indicated previously, managers of small businesses emphasize short-term decisions in their allocation of scarce resources. However, most information systems require a long-term plan with a significant one-time initial financial commitment. This conflict may result in inefficient investment in information systems, which in turn may negatively impact the financial situation of the small business.

Recent research has supported the contention that the use of information systems by small business represents a unique approach. For instance, Belich and Dubinsky (1999) and Pollard and Hayne (1998) determined that the issues being faced by small business managers (lack of time, skills, and financial resources) are different than those faced by large business managers. Further, Taylor (1999) investigated the implementation of enterprise software in small businesses and found that neither the businesses themselves, nor the software vendors were fully cognizant of the unique problems (matching system capability to functional requirements) encountered by small business managers. Finally, Hunter et al. (2002) identified two major themes regarding small business use of information systems. These themes are "dependency" and "efficiency". The authors suggest that the adoption of information systems increased the small business' dependency on an internal champion, and a series of external stakeholders, including consultants and suppliers. Hunter et al. (2002) suggest this increased dependency results from the approaches to business (Stevenson, 1999) taken by the manager and the concept of resource poverty (Thong et al., 1994). The efficiency theme suggests that small business managers primarily use information systems as an operational tool to help complete daily activities.

Earlier research (Nickell & Seado, 1986) determined that small business was mainly using information systems for accounting and administrative purposes. Research conducted in the 1990s (Berman, 1997; Canadian Federation of Independent Business, 1999; Fuller, 1996; Lin et al, 1993; Timmons, 1999) noted a growing interest by small business in employing information systems for daily operations. While small business has been more than prepared to exploit the use of information systems to support daily operations (El Louadi, 1998), there exists little evidence that they are prepared to employ the technology in a strategic manner (Berman, 1997). Bridge and Peel (1999) determined that small businesses employed computers mainly to support daily operations and tended not to use them to support decision-making or long-term planning. Current research suggests this situation has not changed. For instance, Dandridge and Levenburg (2000) found that information systems were being employed for daily operations and there was little use of computerization for competitiveness aspects such as accessing the Internet.

A number of research projects have identified that small businesses have not adopted Internet use because of lack of knowledge and experience (Damsgaard & Lyytinen, 1998; Iacovou et al., 1995; Kuan & Chau, 2001). Another set of contributing factors relates to the lack of personnel and time (Bennett et al., 1999). Even when time and personnel are available, there seems to be reluctance by small businesses to investigate the use of the Internet (Chapman et al., 2000).

Burgess and Trethowan (2002) examined the use of Web sites by small businesses, represented by general practitioners, in Australia. They found that while there was reasonably high use of computers to improve efficiency and lower costs, there was not much use of computers for Web sites. Those who had Web sites mainly employed them to provide basic information and contact details.

FUTURE TRENDS

This section presents a number of recommendations for various stakeholders intent on increasing the use of information systems within the small business sector. These recommendations represent suggestions for the future and reflect a synthesis of available literature, presented in the previous section, in the area in conjunction with, and in the specific context of, previous research (Hunter, 2002; Hunter & Long, 2003;Hunter et al., 2002).

Small Business Manager

To overcome the limitations of being dependent upon others' expertise, managers need to gain an understanding of the capabilities of information systems. While managers do not need to know how to design or develop information systems, they do need to understand how technology might be used as a key resource in adding value to the firm's core business products or services.

Further, the small business manager should establish a relationship with a specific individual regarding a source for advice. The recommendation is for the manager to establish a relationship with someone who is independent of a specific solution and who will be prepared to play a strategic role, taking a long-term perspective. It is incumbent upon the manager to review the relationship to ensure that the recommendations being proffered are appropriately contributing to the long-term success of the firm.

Also, managers should take a proactive approach toward the adoption of information systems. This would involve actively seeking out ways to leverage information systems to create or improve products or services offered to customers. However, the manager should avoid being an early adopter of new hardware and/or software applications.

Consultant

It is important for consultants to recognize that in regard to the nature, timing and acquisition of resources, the small business manager generally aims to minimize the amount of resources used at each stage of the firm's growth. Generally, consultants need to be able to provide opportunities for small businesses to "phase in" information systems in stages. Doing so will accommodate small business practice and form the foundation for a mutually beneficial ongoing relationship.

Vendor

Vendors should make a visible commitment to small business through the establishment of an entity specifically directed at small business. The small business sector is a large and important one; thus target marketing this sector makes good business sense. Also, software vendors must ensure that an application performs the necessary functions for small business. It is incumbent upon the vendor to ensure the hardware or software addresses the appropriate functionality of the small business.

Government

Government can help overcome resource poverty by providing advice and financial incentives to small business. By initiating relationships with small business managers, individuals representing government services can more effectively support these managers by tapping into their informal networks to exchange required information.

The role of tax and other financial incentives may be employed to encourage the expanded use of information systems.

CONCLUSION

Information systems have increased the efficiency of daily operations for small business.

Generally, evidence suggests that information systems expenditures are being made in reaction to needs or problems, rather than as a result of a long-term coordinated plan. The suggestions included here should contribute to more effective use of information systems by small business.

KEY TERMS

Dependency: The requirement to rely upon another individual or organization.

Effectiveness: The ability to accomplish a task with fewer errors.

Efficiency: The ability to accomplish a task with few resources.

Information Systems: Interrelated components working together to collect, process, store, and disseminate information to support decision-making, coordination, control, analysis, and visualization in an organization.

Internal Champion: Highly respected individual within the organization who possesses expertise in a specific area, specifically information systems.

Resource Poverty: The lack of time, finances, and human resources.

Sales/Revenue: Receipt of income for the exchange of goods or services.

Small Business: Various categories may be employed to define this term. Some examples are as follows:

Employees:

- Micro business: 0 – 10 employees
- Small business: 10 – 50 employees
- Medium business: 50 – 250 employees

Stakeholder: An independent party who may have the ability to impact another party.

Strategy: A business plan of action.

INTRODUCTION

The information systems (IS) field has been recognized as a scientific discipline since the 80's, as indicated by: (i) the existence of an intellectual community related with doctoral programs and research centers around the world that generates scientific knowledge and solves practical problems using standard scientific procedures accepted and regulated by this community, and (ii) the diffusion of scientific knowledge related with IS through research outlets and research conferences under a rigorous peer-based review process.

Nonetheless, the discipline of information systems has been critiqued by: (i) the lack of formal theories (Farhoomand, 1987, p.55); (ii) the scarce utilization of deductive and formal (e.g., logical-mathematical) research models and methods (idem, p.55); and (iii) the lack of a formal and standard set of fundamental core well-defined concepts associated with the central object of study in this discipline (Alter, 2001, p.3; Banville & Landry, 1989, p.56; Wand & Weber; 1990, p.1282). Consequently, a common-sense language based on informal, conflicting and ambiguous concepts is used as the communicational system in this discipline (Banville & Landry, 1989), and this approach hinders the development of a cumulative research tradition and delays the maturation of the field (Farhoomand, 1987; Wand & Weber, 1990). Furthermore, a deep examination (Mora, Gelman, Cervantes, Mejia, & Weitzenfeld, 2002) of definitions of the term information system, reveals that fundamental concepts are based on few and misused core concepts from the theory of systems (Ackoff, 1960, 1971) and the few formalization proposals (Alter, 2001; Mentzas, 1994; Wand & Weber, 1990) are incomplete.Therefore, the reduction of the lack of formalization of the core concepts used in the IS discipline becomes a relevant and mandatory research purpose. This article contributes to the IS literature with the adaptation and extension of previous formal definitions reported of the terms *system* (Ackoff, 1971; Gelman & Garcia, 1989) and *organization* (Mora, Gelman, Cervantes, Mejia, & Weitzenfeld, 2002) based on the core principles from the Theory of Systems and with the proposal of a formal definition of the term *information systems*. The article also examines the implications for IS research and practice.

BACKGROUND

The term *information system (IS)* has been widely defined in textbooks. Table 1 shows a sample of the main definitions posed in the literature. An examination of these definitions suggests that the IS notion: (i) lacks fundamental standardized and formal concepts (Alter, 2001); (ii) lacks competitive formal macro-structures to cumulate

Table 1. A sample of informal definitions of "what is an information system"

Definition	Reference
"An IS is a system composed of subsystems of hardware, programs, files and procedures to get a shared goal."	(Senn, 1989, p.23)
"An IS is a system composed of application software, support software, hardware, documents and training materials, controls, job roles and people that uses the software application".	(Hoffer, George & Valacich, 1996, p.8)
"An IS is a system composed of inputs, models, outputs, technology, data bases and controls."	(Burch & Grudnitski, 1989, p.58)

theories (Farhoomand & Drury, 2001, p. 14); and (iii) has an excessive variety of micro-theories (Barkhi & Sheetz, 2001).

There have been few, if any, efforts to formalize the discipline. Despite attempts to reduce ambiguity, the proposals (Alter, 2001; Wand & Weber, 1990) have been underpinned on partial views – e.g., syntactical and structural perspectives that hide core semantic information – of what is a *system* (Mora, Gelman, Cervantes, Mejia, & Weitzenfeld, 2002; Sachs, 1976). Others (Mentzas, 1994) offer a more articulated definition than exhibited on Table 1 – by the identification of five subsystems and their functional properties – still lack formalization due to they were developed using a common-sense language critiqued in the IS literature (Banville & Landry, 1989). Therefore, the concept *information system* has still multiple meanings. A systems-based research stream (Alter, 2001; Mora, Gelman, Cervantes, Mejia, & Weitzenfeld, 2002; Paton, 1997) combined with an ontological perspective (Wand & Weber, 1990) suggest that formal foundations from the Theory of Systems (Xu, 2000, pp.113) can reduce this ambiguity and strengthen the rigor that a scientific discipline requires to mature and simultaneously to be relevant and useful for practitioners.

MAIN THRUST OF THE ARTICLE

Formalization reported in this article is adapted and extended from previous work by the authors on the formal concepts of *system* (Gelman & Garcia, 1989) and *organization* and *business process* (Mora, Gelman, Cervantes, Mejia, & Weitzenfeld, 2002). This conceptual development follows a ontological path to define primitive concepts and postulates to derive updated definitions of the constructs *system-I, system-II, general-system, organization, business process* and finally *information system*. A similar approach was used by Wand and Weber (1990) and Wand and Woo (1991) to define what is an *information system* and what is an *organization*.

Formal Definition of System-I. An object of study **X,** formalized as ***system-I*** and denoted as $\mathbf{S_I(X)=<B(X),RB(X),E(X)>}$, is a whole **X** that fulfills the following conditions: (I.1) it has a *conceptual structure* **§(X)** that defines its set of *attributes* **B(X)**, its set of *events* **E(X)** and its set of *range of attributes* **RB(X)**; (I.2) for any subset **B'(X)** of *attributes* of **B(X)**, the set of *events* **E(X)** associated with **B(X)** differs in at least one element from the set of *events* **E'(X)** associated with **B'(X).**

Therefore, to define a situation of study as a *system-I* implies to specify $\mathbf{S_I(X) = <§(X)> =<B(X), E(X), RB(X)>}$ and to fulfill the condition (I.2).

Formal Definition of System-II. An object of study **X,** formalized as ***system-II*** and denoted as $\mathbf{S_{II}(X)=<C_X, \Re_S(C_X')>}$ is a whole **X** that fulfills the following conditions: (II.1) the whole **X** is a set $\mathbf{C_X}$ of elements $\mathbf{X_1, X_2, ..., X_k}$, called *subsystems*, where each $\mathbf{X_i}$ for i=1,2,..., k can be formalized as $\mathbf{S_I(X_i)}$ or $\mathbf{S_{II}(X_i)}$; (II.2) there is a collection finite $\mathbf{\Re_S(C_X')}$ of *set-relations* where $\mathbf{\Re_S(C_X')=\{\Re_1(C_X'), \Re_2(C_X'),\ldots\}}$ on the set $\mathbf{C_X'=\{C, S_I(X)\}}$ and where each *set-relation* $\mathbf{\Re_p(C_X')=\{ {}_p\Re_1, {}_p\Re_2, \ldots \mid {}_p\Re_n = < X_i, {}_ia_j, X_j > or\ {}_p\Re_n = < X_i, {}_ia_X, S_I(X)> or\ {}_p\Re_n = < S_I(X), {}_Xa_j, S_j>}$ and ${}_i\mathbf{a}_j$ stands by the output-input parameters or acts between the two elements}; and (II.3) exists at least a *non-directed-path* among two any items X_i and X_j in the *set-relation* $\mathbf{\Re_S(C_X')}$.

It must be noted that: (i) condition II.3 assures that for any two elements X_i and X_j in the multi-digraph **X**, X_i is reachable from X_j and vice versa; (ii) it is a recursive definition to let a *subsystem* has *subsystems;* and (iii) this definition updates previously reported by authors to consider the output/input relationships between any *subsystem* and the whole *system*. Therefore, to define a situation of study as a *system-II* implies to specify: $\mathbf{S_{II}(X)=<C_X, \Re_S(C_X')>}$ where $\mathbf{C_X=\{ S_I(X_i)\ or\ S_{II}(X_i) \}}$ for i = 1,2, .., k; $\mathbf{\Re_S(C_X')=\{\Re_1(C_X'), \Re_2(C_X'), \ldots\}}$ and the fulfillment of the condition II.3.

Formal Definition of System as General-System. An object of study **X,** formalized as ***general-system*** and denoted as $\mathbf{S_G(X)}$, is a whole **X** that can be defined simultaneously as a *system-I* $\mathbf{S_I(X)}$ and as a *system-II* $\mathbf{S_{II}(X)}$.

Postulate 1. Any *general-system* $\mathbf{S_G(X)}$ defined as *system-I* $\mathbf{S_I(X)}$ can be mapped to a *system-II* $\mathbf{S_{II}(X)}$ and vice versa.

Auxiliary Definition 1. Suprasystem. A whole **SX** is called the ***suprasystem of a system X*** and it is denoted as **SS(X)** if (IV.1) the whole **X** is a *subsystem* of **SX**; and (IV.2) **SX** can be formalized as $\mathbf{S_I(SX)}$ or $\mathbf{S_{II}(SX)}$.

Auxiliary Definition 2. Envelope. A whole **EX** is called the ***envelope of a system X*** and it is denoted as **EE(X)**, if (V.1) the whole **EX** is the *suprasystem* of the *suprasystem* of **X**; and (V.2) **EX** can be formalized as $\mathbf{S_I(SX)}$ or $\mathbf{S_{II}(SX)}$.

Auxiliary Definition 3. Environment. A whole **WX** is called the ***environment of a system X*** and it is denoted as **W(X)**, if (VI.1) **WX** can be formalized as $\mathbf{S_I(WX)}$ or $\mathbf{S_{II}(WX)}$ and (VI.2) **W(X)={SS(X), EE(X)}.**

Postulate 2. Any *general-system* $\mathbf{S_G(X)}$ has a *suprasystem* **SS(X)** and an *envelope* **EE(X)**.

The first formal definition of the concept *system* – for example, *system-I* – accounts for the conception of an external view that sees the *system* as a single-unit with special characteristics – called, *attributes* – and potential acts to execute – called, *events*. In turn, the second formal definition – for example, *system-II* – represents the more usual view – for example, the internal view – that sees the system as a digraph. Furthermore, the definitions of the *set-relations* $\mathbf{\Re_1(C_X'), \Re_2(C_X'), ..., \Re_m(C_X')}$ consider the *system* as a multi-digraph instead of digraph and therefore eliminates some limitations of classic digraph-alike definitions critiqued in the systems theory's literature (Sachs, 1976). Auxiliary definitions and the second postulate help to support the expansionist systemic perspective that indicates that every system always belongs to other larger system (Ackoff, 1971).

Formal Definition of Business Process as System. An object of study **X** is called a ***business process*** and denoted as **BP(X)** if satisfies the following conditions: (VII.1) **X** can be defined as a *system-II* $\mathbf{S_{II}(X)=<C_X, \mathfrak{R}_S(C_X')>}$ where $\mathbf{C_X =\{S_G(CSS), S_G(OSS), S_G(ISS)\}}$ are respectively called the control, operational and information subsystems; and $\mathbf{\mathfrak{R}_S(C_X')= \mathfrak{R}_S(X, S_I(X)) =\{\mathfrak{R}_1(C_X'), \mathfrak{R}_2(C_X'), \ldots, \mathfrak{R}_{12}(C_X') \mid \mathfrak{R}_1(C_X')=\{ {}_1\mathfrak{R}_1 = < X_{CSS}, {}_{CSS}a_{OSS}, X_{OSS}>\}, \ldots, \mathfrak{R}_{12}(C_X')=\{ {}_{12}\mathfrak{R}_1 = <X_{CSS}, {}_{CSS}a_X, S_I(X)> \} \}}$; and (VII.2) $\mathbf{\mathfrak{R}_S(X, S_I(X))}$ satisfies condition (II.3).

It must be noted that the *item-relations* $\mathfrak{R}_{S1}$ to $\mathfrak{R}_{S12}$ take into account at least all possible interrelationships between any two subsystems and of them with the whole system **BP(X)**.

Formal Definition of Organization as a System. An object of study **X** is called an ***organization*** and denoted as **O(X)** if satisfies the following conditions: (VIII.1) **X** can be defined as a *system-II* $\mathbf{S_{II}(X)=<C_X, \mathfrak{R}_S(C_X')>}$ where $\mathbf{C_X =\{S_G(X.1), S_G(X.2), \ldots S_G(X.k)\}}$ and $\mathbf{\mathfrak{R}_S(C_X')= \mathfrak{R}_S(X, S_I(X))}=\{\mathfrak{R}_1(\mathbf{C_X}'), \mathfrak{R}_2(\mathbf{C_X}'), \ldots, \mathfrak{R}_P(\mathbf{C_X}') \mid$ for N=1,2, … , p, each set-relation $\mathfrak{R}_N(\mathbf{C_X}')$ has item-relations ${}_N\mathfrak{R}_1$, ${}_N\mathfrak{R}_2$, ${}_N\mathfrak{R}_3$… of the format $< X.i, {}_{.i}a_j, X.j>$ or $< X.i, {}_{.i}a_X, S_I(X)>$ or $< S_I(X), {}_{.X}a_j, X_j>$ and ${}_\mathbf{i}\mathbf{a}_\mathbf{j}$ stands by the output-input parameters or acts between the two elements X.i and X.j }; (VIII.2) $\mathbf{\mathfrak{R}_S(X, S_I(X))}$ satisfies condition (II.3); and (VIII.3) for j=1,2, … , k either $\mathbf{S_G(X.j)= BP(X.j)}$ or $\mathbf{S_G(X.j)= S_{II}(X.j)=<C_{X.j}, \mathfrak{R}_S(C_{X.j}')>}$ where $\mathbf{C_{X.j} =\{BP(X.j.1), BP(X.j.2), \ldots BP(X.j.n)\}}$ and $\mathbf{\mathfrak{R}_S(C_{X.j}')}$ exists.

Therefore, a *business process* can be considered a *system* with three *subsystems*: control, operational and informational. In turn, an *organization* is a *system* composed of at least two *general-systems* that in turn can be either a *business process* or a *system-II* composed by *business process*. This general definition offers modeling freedom according to the scope of a specific research. In this article, we will use a cybernetic management perspective of organizations that suggests that any organization is composed by two *subsystems* called the *driving* or *management* and the *driven* or *productive subsystems*, respectively (Gelman & Negroe, 1981, 1982). *Management subsystem* can be composed of the planning, decision-making, financial and controlling subsystems, and the *productive subsystems* in turn can be composed by manufacturing, logistic, marketing, and sales/post-sales *subsystems*. However, it must be noted that general definitions of what is an *organization* can adopt other management perspectives such as Porter's added-value chain. In that case, it would be necessary to consider three *subsystems*: of the primary activities, of the support activities and of the top management activities. With these previous antecedents, the formalization of what is an *information system* is straightforward.

Formal Definition of *Information System* as System. An object of study **X** is called an ***Information Systems*** and is denoted as **IS(X)** if fulfills the following conditions: (IX.1) **X** is a *system-II* $\mathbf{S_{II}(X)=<C_X, \mathfrak{R}_S(C_X')>}$ where **$\mathbf{C_X}$={$\mathbf{S_G}$(IT="Information Technology"), $\mathbf{S_G}$(IR=" Information Resources"), $\mathbf{S_G}$(IW="Information Workers"), $\mathbf{S_G}$(IP="Information Procedures") }** and $\mathbf{\mathfrak{R}_S(C_X')= \mathfrak{R}_S(X, S_I(X))=\{\mathfrak{R}_1(C_X'), \mathfrak{R}_2(C_X'), \ldots, \mathfrak{R}_{32}(C_X') \mid \mathfrak{R}_1(C_X')=\{ {}_1\mathfrak{R}_1 = < IT, {}_{IT}a_{IR}, IR> \}, \ldots, {}_{32}\mathfrak{R}_1(C_X')= <IR, {}_{IR}a_X, S_I(X)> \} \}}$; (IX.2) $\mathbf{\mathfrak{R}_S(X,S_I(X))}$ satisfies the condition (II.3); and (IX.3) the *suprasystem* **SS(IS(X))** is a *business process* **BP(Y)** and the **IS(X)** corresponds to the information *subsystem* $\mathbf{S_G}$**(ISS)** of the *business process* **BP(Y).**

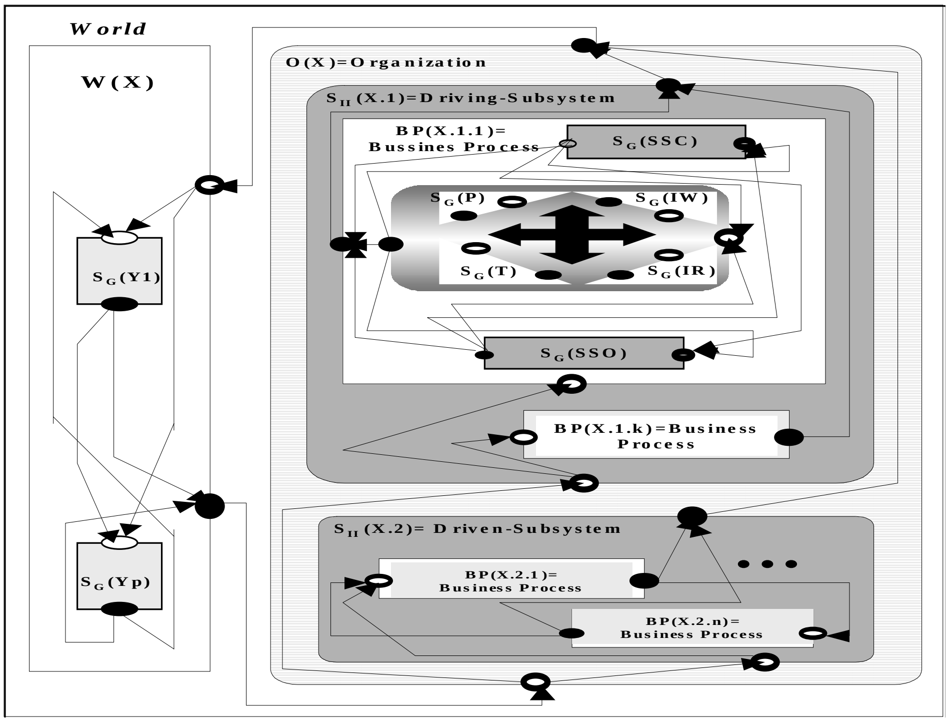
Figure 1 presents a visualization of all formal concepts reported. Due to space limitations, all notation of the *item-relations* of all *systems-II* are hidden. Also, all *item-relations* into the *subsystems* of the *information system* are represented by the four arrows grouped in a single shape. The formal definition posed indicates that an *information system*, as a *system*, is a part of a larger *system*, that is, a *business process system*, that in turn, is the *suprasystem* of the *IS* denoted as SS(IS). Full dots represent the concentration of the subsystems' outputs towards the environment of the system. In turn, clear dots represent the concentration of the environment's inputs into the system. Therefore full and clear dots are useful to take into account the dual specification of any system either as *system*-I – for example, a monolithic view – or as *system-II* – for example, a multi-digraph view.

FUTURE TRENDS

We claim that the proffered formal definition offers a flexible framework to model and specify an *information system* in the level of detailed demanded by the researchers or practitioners. Four possible applications are briefly presented under a theoretical and practice perspective: (i) formal integration of the common-sense concepts used into the informal definitions of what is an *information system*; (ii) elimination of the ambiguity caused by the "Siamese Twin Problem" (Alter, 2001, pp. 30-31); (iii) analysis of failures on information systems through the systemic classification of problems; and (iv) generation of conceptual and dynamic simulation models of information systems.

(i) The formal approach offers a flexible framework consistent with previous definitions of an *IS*. For example, Table 2 exhibits a straightforward way to

Figure 1. Diagram of the overall and systemic perspective of "what is an information system"



formalize the informal definition from Hoffer et al. (1996). Consider for instance the specification of the <job roles> potentially performed by <people> in an *IS*. In this case, the S_G(IW) can be modeled as a *system-I* and the <job roles> can be specified as a system's attribute B(IW)={ $_{IW}b_1$=<job roles>} and specify all possible <job roles> by the definition of the range of attributes RB(IW)={ $_{IW}Rb_1$={operational-user; staff-user; executive-user; etc } }. Another modeling alternative is the representation through system's events E(IW)={ $_{IW}e_1$, $_{IW}e2$, ... }, depending on the interest of the researcher or practitioner. Furthermore, some *item-relations* from the formal definition can be useful to model *subsystem's* acts between the subsystems, the whole *IS*, and its environment. Hoffer et al.'s definition of *IS*, does not account for the information component per se, even though such a component could be considered as the main output of the Hoffer et al.'s IS. Using the formal construct, this component can be modeled as a *subsystem* S_G(IR). In turn, S_G(IR) can be modeled as a *system-I* with system*'s attributes* B(IR)={ $_{IR}b_1$, $_{IR}b_2$, ...}, such as quality, clarity, accuracy, accessibility, appropriateness, among others (Burch, Strater, & Grudnitski, 1979).

(ii) Systemic properties of *organization* and *hierarchy* mapped into the concept of *IS* are useful to resolve the "Siamese Twin Problem". This problem involves the fallacy of studying *IS* without studying the *work system*. The *hierarchy* property of *systems* and the *expansionism approach* suggest that *IS* should not be studied in isolation. Instead, an *IS* should be viewed as part of a larger *system*, that is, the *business process system* or Alter's *work system* concept. Moreover, our formal definition is in agreement with the synthetic thinking view that the behavior of every system can be best understood when studied in relationship to its *suprasystem*, as established by the condition (IX.3).

(iii) Potential deep explanations of failures of *IS* implementations or studies of effectiveness of IS can be theoretically supported through the classification of problems according to the theory of systems. Ackoff (1973, p.666) suggests that failures on *systems* are caused by the conflicts between the system's purpose and the environment's purpose, the system's purpose and the subsystems' purposes and the systems with itself, called respectively the environmentalization, humanization and self-control problems. Formal constructs of *systems* and *IS*, and with conceptual simple tools such Figure 1 and Table 2, can help researchers and practitioners to acquire a holistic perspective of the situation under study and to recognize the influence of the interaction between the systems' parts and the whole

Table 2. Example of formalization of Hoffer et al.'s (1996) definition of information systems

</table>

within its environment. Furthermore, since the formalisms posed can be extended through the addition of parameters in the set of *a-actions* in the *item-relations*, it is possible to model social, technical and political features through the specification of *attributes* and *events* assigned to *subsystems* in the *system's environment* W(BP(X)), where BP(X) represents the *suprasystem* of the *IS* under study. For example, soft features as <top management support>, <environmental hostility>, <environmental dynamism> and <organizational climate>, once specified and measured, can be easily assigned as subsystems' *attributes* of W(BP(X)).

(iv) Complex conceptual and dynamic-based simulations models of *IS* can be specified. A case in point is the recent development of a conceptual and system dynamic-based simulation model of the implementation process of Decision-Making Support Systems (Mora, Cervantes, Gelman, & Forgionne, 2003, 2004) that generated satisfactory predictive results from several well-known reports in the literature.

In short, this article suggests that the formal definition of the term *information system*, developed from the formal principles of *theory of systems*, enables researchers and practitioners to: (i) avoid ambiguity from informal definitions; (ii) account for practically all informal definitions; (iii) specify and customize a structure of the concept *IS* with the level of detail demanded by the modelers; and (iv) help to build complex systemic models of organizations that use *IS*. However, since formalisms in the information systems field have been scarcely reported, it is strongly recommended that further research be conducted to deploy their benefits and cope their limitations.

CONCLUSION

This article supports the thesis that formalisms – from the theory of systems – are required in the field of information systems to reach the rigor and maturation needed for a respectable scientific discipline. However, gains will not be free since researchers and practitioners could be required to add to his/her conceptual tools the utilization of logical-mathematical models. Perhaps, then, the information systems discipline will no longer be a "fragmented adhocracy" (Banville & Landry, 1989, p.56). Formalisms posed offer a non-trivial way to understand and model an *information systems* and therefore contribute toward the maturation of our field.

KEY TERMS

Attribute (Informal Definition): A substantial feature of a whole that is perceived by an observer with the potential to produce or cause a product or effect.

Event (Informal Definition): An act performed by a whole or to the whole that is perceived by an observer directly or through its consequences on other(s) whole(s).

Subsystem: Any immediate inner system that is subsumed to the system.

Suprasystem: The immediate outer system that subsumes any system.

System (Informal Definition): A whole composed of subsystems, and at the same time included in a suprasystem in such way that some particular properties of the whole and of the subsystems are getting lost when they are considered analytically, for example, by separation of the parts of the whole.

Theory of Systems: A research inquiry paradigm based on an expansionist world view, a synthetic and holistic thought and teleological principles, which makes it suitable and effective for studying complex phenomena.

Information Systems and Technology in South Africa

Anesh Maniraj Singh
University of Kwazulu Natal, South Africa

INTRODUCTION

South Africa, like most of its African neighbors, has a dual economy that sees formal and informal trading taking place side by side. Walking down many of the main streets of South African cities, one can immediately see the informal traders conducting their trade on the doorsteps of established retailers. Many of the formal traders complain about the informal activity and its impact on their businesses. However, there seems to be a symbiotic relationship that ensures their peaceful coexistence. For many foreigners, there is the perception that South Africa is a jungle with lions and tigers running around the streets and wind-up telephones as a means of communication. This is, however, far from the reality. Technology in the formal economy is almost as good as and sometimes better than it is in the United States and other first-world countries. Cellular telephone technology is one generation ahead of the United States. However, like the economy, a technology divide exists, where some parts of the population have access to technology, while others do not. This article will examine the trends in technology, outlining the use of technology in South African industry. The digital divide will also be discussed, looking at the problems and how the State in partnership with the private sector can bridge the gap.

BACKGROUND

Technology has always been existent in South Africa. However, it has never kept pace with the developments in first-world countries. During the apartheid era, trade sanctions resulted in extremely high costs in acquiring technology, and as such, South African organisations were unable to keep pace with the latest developments in technology in developed countries. However, at present, organisations are capable of implementing the latest systems and technologies as they roll off the production line, as is evidenced by the following scenarios.

The Private Sector

Manufacturing

According to Hodge and Miller (1997), the manufacturing sector spent about R900 million on hardware and a billion Rand on software. In order to improve productivity and manage costs more effectively, manufacturers rely heavily on MRP (materials requirements planning) software (Faull, 1995). Toyota South Africa has one of the most technologically advanced production lines in the country. SAPREF (South African Petroleum Refiners) monitors and controls the entire petroleum refining process from a centralized control room.

Retail

The retail industry has seen an evolution of systems from the basic adding machine to the latest in scanning and optical character recognition systems. Companies such as Pick ’n Pay use their point-of-sale systems not only for calculating and receiving payments but also for EFTPOS (electronic funds transfer at point of sale). Pick ’n Pay is linked electronically to almost all South African banks, allowing customers to draw cash and make account payments to third parties at the supermarket cashier.

Banking

According to the Reserve Bank, the banks and financial services sector spends almost as much on technology as the manufacturing sector. SASWITCH was introduced in the 1980s and linked the various institutions’ ATMs (automated teller machines) on a single network, allowing customers to use any bank’s ATM to access their accounts at another bank. Standard banks were among the pioneers to offer electronic account payments from an ATM. They also formed a relationship with MTN (a cellphone network operator) to allow customers to top up their cell phone airtime from an ATM. All the banks offer Internet banking facilities. Investment houses such as Old Mutual, Sanlam, and Liberty have Web sites where the customer can view his or her investment portfolios, check exchange rates, and conduct secure transactions.

Banks have been moving steadily in developing their offerings electronically, with a long-term vision of reducing branches and services by developing self-service centres. Reducing branches and staff would lower overheads, allowing the banks to become lower-cost providers and enabling them to become more profitable and competitive.

Telephony

Telkom is South Africa's sole provider of fixed-line telecommunications. Most of South Africa was connected via copper wire. However, in 1981, fibre optic was introduced in the then Transvaal. Beltel, a text-based service, was introduced in 1986, allowing subscribers to gain access to banks, entertainment, adult entertainment, and static text-based advertisements. ISDN was introduced in 1994, and the first cellular phone networks were introduced (Highlights of the…, 2004). MTN, Vodacom, and Cell-C are the only cellular service providers. Apart from providing voice communications, they also offer WAP (wireless application protocol), GPRS (general packet radio service), SMS (short message service), and MMS (multimedia messaging service). The cellular phone industry is extremely advanced and also offers value-added services, such as mobile banking. The advances in telephony have come about due to the lifting of trade sanctions imposed during the apartheid era. Accessing the latest technologies from foreign developers as they unfold is much easier than in the past. South African companies have also chosen, in some spheres, to leapfrog certain intermediate developments in technology rather than gradually evolve from one technology to the next. This is why, in certain areas of technology, South Africa is ahead of some Western countries.

However, according to Weidemann (2004a), South Africa is losing its role as Africa's technology leader due to its restrictive information and communications technology (ICT) legislation. He goes on further to state that legislation is affecting new technologies, such as voiceover Internet protocol (VOIP) and wireless fidelity (WIFI). South Africa has been active in attracting international call centres to its shores. However, according to Jones (2004), because of the prohibitively high costs of fibre optic based communication, providers want to use VOIP, which would drive tariffs down and allow South Africa to compete with call centre hubs in India.

Videoconferencing came into being in 1991, and today, 80% of the top 500 companies in the country use it (Weidemann, 2004b). Videoconferencing is being used extensively for meetings across provinces, e-learning and training, and, more recently, for conducting interviews, saving on travel and accommodation costs. The University of Kwazulu Natal uses videoconferencing to conduct meetings across its five campuses.

The Public Sector

Unlike the private sector, the public sector has trailed significantly behind with regard to technology implementation and technology usage. According to Hodge and Miller (1997), it was estimated that seven in 100 government employees had access to computers; this figure has hardly changed, with approximately 16 in 100 employees having access to a PC (Source Withheld). The Home Affairs department that handles birth, identification, travel, and death documents does not have PCs at the counters. Information is recorded manually in books, causing long delays in the event of a query. Furthermore, there is no document management system to track documents sent from regional offices to national offices and vice versa.

In order to improve IT skills, usage, and backup service, SITA, the State Information Technology Agency, was set up as an "outsource" organisation to ensure that proper procedures were developed and implemented in procuring IT, providing end user support, and training, developing, and maintaining information systems. However, there are departments that believe that SITA has not delivered on its mandate due to its being an organ of the State. It is believed that SITA has only benefited central government officers and offices, whereas provincial departments do not enjoy the same service delivery, and local and municipal governments are totally excluded.

Although there are departments that have inadequate information technology (IT) and information systems (IS), there are others that have very sophisticated systems. NATIS (national traffic information system) is a database of all driver details and records of road offences. Traffic officers on the street, armed with laptops can access the database and determine if someone who has been stopped has previous unpaid fines or active warrants of arrest. The Prince Alfred Luthuli Hospital in Durban is the first paperless hospital in the country. All records are stored electronically and can be easily accessed, ensuring proper patient care and administration of medication. The Prince Alfred Luthuli project will be used as a case study and benchmark for the conversion of other state hospitals to paperless institutions.

The use of technology in education displays a digital divide of its own. Public primary and secondary schools use outdated technologies for administration and teaching, such as pentium® 1 computers and software such as

Windows® 95. Pupils taking computer education classes in secondary school are taught Turbo Pascal® which is totally outdated. Private schools, on the other hand, have computerised administrative systems and use the latest technology and programs for teaching purposes. Tertiary institutions are well ahead of schools and use specialized software, such as Integrated Tertiary Software, that tracks a student's progress, fees, and related academic activities from the date of first registration.

University and Technikon academics use IT extensively for research. The Internet is used daily to search for information, university libraries are linked to some of the leading international electronic journals and databases. Database packages are used for capturing research data, and analysis is conducted using some of the latest statistical packages such as SPSS.

Many of the tertiary institutions are partnering with big brands, such as Microsoft, IBM, SAP, Oracle, 3Com, Novell and Cisco among others, creating specialist training academies to provide stand-alone courses and to incorporate some modules into the academic curriculum.

The Internet in South Africa

The Internet is growing rapidly in South Africa. Internet usage in 2001 was a mere 2.4% but has grown to 6.8% in 2003 (Internet usage statistics…, 2004). Initially, the Internet was used mainly by academics. However, this has been rapidly overtaken by e-commerce, both business-to-business (B2B) and business-to-consumer (B2C). B2B commerce was predicted to reach R28.3 billion and B2C to account for R2.5 billion (Goldstuck, 2001). All the retail banks in South Africa have a Web presence, while a number of large retailers have extended their services online. Pick 'n Pay and Woolworths have shopping Web sites and offer deliveries to customers. Pick 'n Pay has not shown a profit from its online store. However, in line with its 5 year strategy, the online losses have been decreasing each year (Mercury, 2004).

Kulula.com, South Africa's first online airline, allows passengers to purchase tickets online in three easy steps. The airline has shown a profit from day one (Scholtz, 2003). The Government has also embraced the Internet by developing an online presence where information in the form of articles, green papers, and white papers are made available for public scrutiny. The South African Revenue Services (SARS) has an interactive site that allows citizens to file taxes online and to effect online payments.

It is evident from the discussion that South Africa is on par with first-world countries in terms of private-sector usage of technology. However, it has also surfaced that a divide exists between public- and private-sector usage of technology.

The Digital Divide in South Africa

The digital divide separates those who have access to technology from those who do not. The term "digital divide" stems from the global information society (GIS), where it is intimated that those people, countries, or organizations that do not have access to the GIS will become marginalised and will not share in the benefits that the Internet brings with it. More than 80% of people around the world have never heard a dial tone, let alone surfed the Web. The gap between the information haves and have-nots is widening (Bridging the Digital Divide, 1999). Developing countries only account for 4.25% of Internet users worldwide. Poverty, illiteracy, lack of infrastructure, and inadequate government interest or intervention has led to the information have-not situation. According to Stillkind (1996), those countries that are lagging behind in access to the Internet are bound to fall further behind to the point of exclusion. Research pertaining to the digital divide attributes its existence to developed and developing countries, but is this truly the case?

Factors that Contribute to the Digital Divide

The digital divide is not only the product of the difference between first and third world standards. The digital divide also exists, among others, gender, physical disability, racial segregation and age.

- *Gender*: In some countries and organisations, females have less access to the Internet than males, but in some instances, males tend to be marginalised as well. In a survey by Lake (1997), it was found that fewer males (38%) had limited access to the Internet than females (41%). This indicates that gender creates a divide between the information haves and the have-nots; however, the context may differ from place to place.
- *Racial segregation*: According to a study by Novak and Hoffman (1998), African Americans differ significantly from whites in their access to computers and web usage. The study revealed that 44% of White Americans had home PCs, whereas only 29% of Blacks had home PCs. This limited the access that Blacks had to the Internet. Similarly, in South Africa, Blacks up to the age of 35, have the least access to computers and the Internet (Saner, 2003).
- *Age*: According to a study carried out by Singh (2001), persons aged 15–24 (45%) used the Internet

daily. Older respondents, especially those in the 45–54-year-old category (27%), used the Internet once a month. It is clear from this study that a digital divide exists between age groups, because youth are more exposed to technology and are willing to use it, whereas older people are resistant to change and avoid the use of technology.

- *Literacy*: A major problem in South Africa is illiteracy (Aitchison, 1998). Due to the low levels of literacy and poor schooling infrastructure, many South Africans are excluded from the world of technology and the Internet.

The digital divide in South Africa is extremely pronounced in that only 4.5% of the total population comprises information haves and 95.5% comprises information have-nots (South African Web Usage Behavior, 2000). The main reason for the digital divide in South Africa is the apartheid legacy that promoted separate development, which provided inferior education and poor or no access to learning opportunities for nonwhites. The existence of the digital divide is also attributed to high levels of poverty, a lack of telecommunications infrastructure, and high costs of connectivity. The foregoing illustrates that a digital divide exists in any situation where there are information haves and have-nots, and it is not limited exclusively to a divide between first- and third-world nations.

Solutions to the Digital Divide

The solutions to the digital divide range from micro interventions to overarching policy developments and investment by the government.

- *Computer recycling*: Many large corporations and institutions upgrade their hardware at least once in 3 years. The old machines should be refurbished and donated to schools for use in the classroom and by administrators.
- *Training and development*: There are many sector education and training authorities (SETAs) that have funds available for training. These funds could be utilized to train the masses of unemployed into computer end users.
- *IT incubators*: The Cape IT Initiative (CITI) is aimed at promoting Cape Town as the hub into Africa (About Citi, 2004). In creating jobs within the IT sector, CITI has developed a number of linkages, both locally and internationally. According to Annecke (2004), Microsoft is helping to develop "digital villages," where locals teach themselves computing and then transmit these skills among the community. Many entrepreneurs have emerged from this initiative. One man opened up a CV writing business based on the skills learned from the village.
- *Public–private partnerships*: The Government does not have the funds or the skills to bridge the digital divide. Therefore, they need to partner with the private sector in order to obtain funding and skills to bridge the gap between the technology haves and the have nots. With the introduction of The Digital Partnership, South Africa has seen the development of over 20 partnerships to deliver e-learning centres to disadvantaged schools (The Government of…, 2002). However, public–private partnerships need not only be for the development of citizens but should also seek to develop the IT skills within Government. Specialists from industry could be engaged to help the Government make strategic IT plans and help them implement these plans.

The Legal Environment

IT law is becoming very competitive and is growing into a discipline of its own, due to the increase in white collar crime, especially those perpetrated using technology (Vecchiatto, 2004). The legal fraternity is becoming more involved in issues such as intellectual property law, privacy, spam, and online contracts.

In order to balance the rights of consumers, employers, and employees using the Internet, the Electronic Communications and Transactions Act (ECTA) was promulgated in 2002. ECTA was developed to establish a formal structure to define, develop, regulate, and govern e-commerce in South Africa (Michaelson, 2003). The Act also covers issues unique to electronic environments, such as domain name registration, cryptography standards, and authentication service providers. Other supporting legislation includes the following: The Access to Information Act that determines what information can and must be kept private, and what can and must be made easily available to people requesting it; The Interception and Monitoring Prohibition Act that determines who is allowed to intercept communications; and The Interception and Monitoring Prohibition Act that makes it illegal for employers to monitor employee usage of Internet facilities at work. However, due to the increase in employee abuse of Internet facilities and electronic industrial espionage, representation has been made to have the Act amended to allow employers to monitor and intercept employee's electronic communications.

It is evident that ICTs are playing a major role in South Africa, hence the interest and commitment to developing standards to regulate electronic activity.

FUTURE TRENDS

As previously mentioned, information systems and technology play a mixed role in South Africa, with the private sector using cutting-edge technology and the public sector lagging behind in the technology and the systems used. Public schools have a major role to play in spreading IT skills and knowledge to the masses, which will require investment and support from Government and the private sector. Apart from the contribution made by Mark Shuttleworth and a few others, South Africans tend to be adopters rather than innovators of information systems and technology; hence, there are no new "killer applications" or products that have emanated from the country. However, most organizations are quick to adopt the best systems and technology from the East and West and implement them very effectively.

Cellular telephony seems poised for great success in the event of a breakthrough business application being developed. SMS is a very profitable application for the cellular networks; however, this platform needs further development for transaction purposes. Wireless technology is finding its way into large corporations, which will make wired LANs obsolete. Hot spots are finding their way in public arenas, such as in the country's international airports and Mugg & Bean Coffee Shops, making Internet connections available to traveling businesspeople among others. Community centres, Internet café's public information terminals (PITS), and digital villages will make technology available even in the most remote rural areas. Bank branches will become smaller, offering limited personal service as customers embrace Internet banking and the use of ATMs.

CONCLUSION

It is evident that like most developing countries, South Africa has a first- and third-world approach to information systems and technology. This has created a digital divide that can only be bridged due to Government intervention in reducing poverty, improving literacy, and providing access to ICT. Furthermore, Government has to develop policies and provide guidelines for the ethical use of technology in society and also provide protection for businesses and individuals engaging in e-commerce. Furthermore, private-sector investment is needed to boost telecommunications and to bridge the digital divide. It is evident that although South Africa is not a technology innovator, the effective implementation of technology strategies has enabled certain sectors, such as banking and telephony, to dominate in the effective use of technology. Mass access and usage of technology, especially computer technology, will only take place when technology becomes more affordable to the masses. Democratic South Africa is undergoing rapid change, and perhaps all that is needed to get information systems and technology up to first-world standards, is time.

KEY TERMS

Digital Divide: Refers to the gap between those who have access to the Internet and those who do not.

Electronic Commerce: Refers to the use of electronic technologies, especially the Internet, to conduct buying and selling.

Global Information Society (GIS): Refers to the linking of people using the Internet to share information for the benefit of all societies around the globe.

Information Systems: Refers to a set of people, procedures, and resources used to collect, process/transform, and disseminate information in an organisation.

Information Technology: Refers to the physical components that are needed to create information products; normally refers to the hardware, such as computers, monitors, printers, and other computer components.

Private Sector: The private sector refers to businesses that are engaged in commerce for the sole purpose of making a profit and increasing shareholder wealth.

Public Sector: This refers to the government and its various departments that serve the citizens of a country. These departments are nonprofit-making organs of the State.

Information Technology Strategic Alignment

Fernando José Barbin Laurindo

INTRODUCTION

Information technology (IT) has assumed an important position in the strategic functioning of leading companies in competitive markets (Porter, 2001). Particularly, e-commerce and e-business have been highlighted among IT applications (Porter, 2001). Two basic points of view can be used for understanding the role of IT: the acquisition of a competitive advantage at the value chain and the creation and enhancement of core competencies (Porter & Millar, 1985; Duhan et al., 2001).

Several problems have been discussed concerning IT project results and effectiveness of their management. Effectiveness, in the context of this article, is the measurement of the capacity of the outputs of an information system (IS) or of an IT application to fulfill the requirements of the company and to achieve its goals, making this company more competitive (Laurindo & Shimizu, 2000; Walrad & Moss, 1993; Maggiolini, 1981; Drucker, 1963).

There is a general consensus about the difficulty in finding evidence of returns over the investments in IT (the "productivity paradox"), even though this problem can be satisfactorily explained (Brynjolfsson, 1998). In order to better use these investments, organizations should evaluate IT effectiveness that allows for the strategic alignment of objectives of implemented IT applications and their results with the company business vision (Laurindo et al., 2003; Laurindo, 2002; Smithson & Hirscheim, 1998).

The comparison and evaluation of business and IT strategies and between business and IT structures must be a continuous process, because the company situation is constantly changing to meet market realities and dynamics.

FINDING STRATEGIC IT APPLICATIONS

Critical success factors (CSF) is a widespread method used for linking IT applications to business goals, and for planning and prioritizing IS projects. This method was proposed by Rockart (1979), although King and Cleland (1977) had suggested a similar idea (critical decision areas) before.

According to this method, the information systems, especially executive and management information systems, are based on the current needs of the top executives. These information needs should focus on the CSF. Rockart defined CSF as the areas where satisfactory results "ensure successful competitive performance for the organization." This author states that CSF prime sources are the structure of the industry, competitive strategy, industry position, geographic location, and environment and temporal factors.

Basically, the CSF method includes the analysis of the structure of the particular industry and the strategy and the goals of the organization and its competitors. This analysis is followed by two or three sessions of interviews with the executives, in order to identify the CSF related to business goals, define respective measures (quantitative or qualitative) for the CSF, and define information systems for controlling CSF and their measures (Carvalho & Laurindo, 2003).

For Rockart, this process can be useful at each level of the company and should be repeated periodically, because CSF can change through the time and also can differ from one individual executive from another.

The CSF method had an important impact on managerial and strategic planning practices, even though it was primarily conceived for information systems design, especially management and executive information systems. Besides the utilization in information systems planning and information systems project management, it has been used in strategic planning and strategy implementation, for management of change, and as a competitive analysis technique (Pollalis & Frieze, 1993). This method leads to a policy-oriented approach by focusing on the essential issues of companies. Furthermore, the continuous measurement of the CSF allows companies to identify strengths and weaknesses in their core areas, processes, and functions (Rockart, 1979; Sullivan, 1985).

More details of the process of implementation of the CSF method can be found in Rockart and Crescenzi (1984) and Martin (1982).

McFarlan (1984) proposed the strategic grid that allows the visualization of the relationship between IT strategy and business strategy and operations. This model analyzes the impacts of IT existent applications (present) and of applications portfolio (future), defining four boxes, with each representing one possible role for IT in the enterprise: "Support," "Factory," "Turnaround," and "Strategic" (Figure 1):

- *Support*: IT has little influence in present and future company strategies.
- *Factory*: Existent IT applications are important for a company's operations success, but there is no new strategic IT application planned for the future.
- *Turnaround*: IT is changing from one situation of little importance ("support" box) to a more important situation in business strategy.
- *Strategic*: IT is very important in business strategy in the present, and new planned applications will maintain this strategic importance of IT in the future.

In order to assess the strategic impact of IT, McFarlan proposed the analysis of five basic questions about IT applications, related to the competitive forces (Porter, 1979):

- Can IT applications build barriers to the entry of new competitors in the industry?
- Can IT applications build switching costs for suppliers?
- Can IT applications change the basis of competition?
- Can IT applications change the balance of power in supplier relationships?
- Can IT applications create new products?

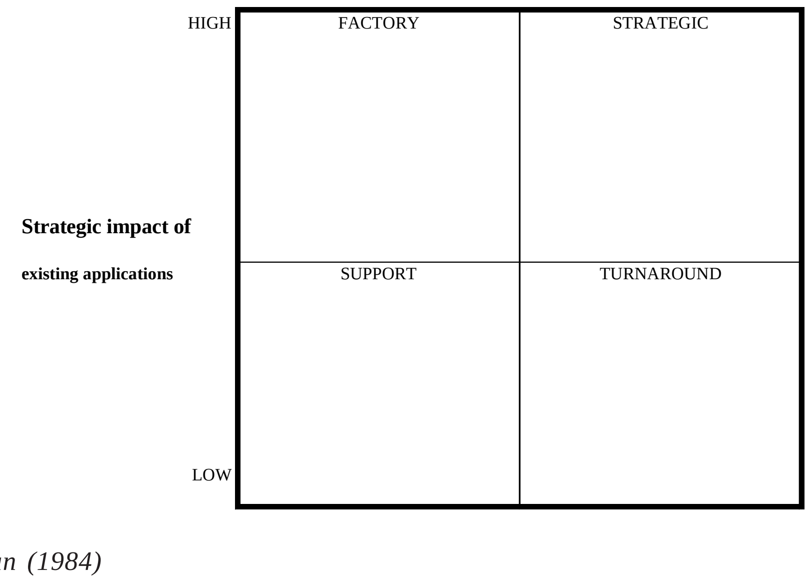
These questions should be answered considering both present and planned future situations.

Thus, IT may present a smaller or greater importance, according to the kind of company and industry operations. In a traditional manufacturing company, IT supports the operations, because the enterprise would keep on operating even when it could not count on its IS. However, in a bank, IT is strategic for business operations, because it is a source of competitive advantage, and a bank cannot operate without their computerized IS.

Henderson and Venkatraman (1993) proposed the Strategic Alignment Model that analyzes and emphasizes the strategic importance of IT in the enterprises. This model is based on both internal (company) and external (market) factors.

Two fundamental concepts in this model are strategic fit (interrelationships between strategy and infrastructure) and functional integration (integration between

Figure 1. Strategic grid of impacts of IT applications



Source: McFarlan (1984)

business and IT, in the strategic and infrastructure aspects). The authors emphasize that strategy should consider both internal and external domains of the company. The internal domain is concerned with the administrative structure of the company. The external domain is concerned with the market and the respective decisions of the company. Thus, according to this model, four factors (that the authors called domains) should be considered for planning IT:

1. Business strategy
2. IT strategy
3. Organizational infrastructure and processes
4. IS infrastructure and processes

The Strategic Alignment Model brings the premise that the effective management of IT demands a balance among the decisions about those four domains above.

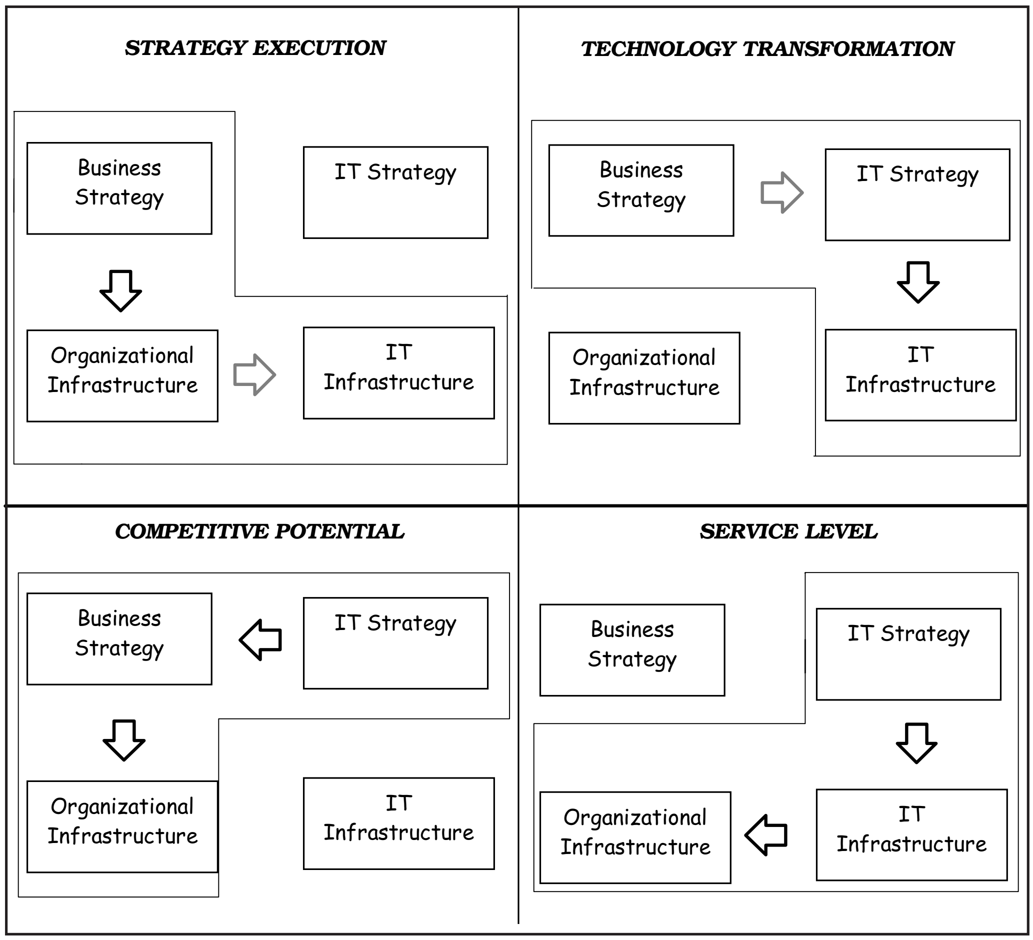
According to Henderson and Venkatraman, there are four main perspectives of strategic alignment, through the combination of the four factors, starting from business strategy or from IT strategy, as shown in Figure 2.

One important innovation of this model is that IT strategy could come first and change business strategy, instead of the usually general belief that business strategy come before IT planning.

This planning should be a continuous process, because external factors are in permanent changing situations. If the company does not follow these changes, it will be at a serious disadvantage in the fiercely competitive market. This is particularly true when a new technology is adopted by almost all companies in an industry, passing from a competitive advantage for those that have it to a disadvantage to those that do not use it.

Thus, in this sense, the strategic alignment differs from the classic vision of strategic plan, which does not present the same dynamic approach.

Figure 2. Perspectives of strategic alignment (Henderson &Venkatraman, 1993)



After the proposal of these four perspectives above, Luftman (1996) described four new perspectives that start in the infrastructure domains, instead of the strategies domains:

- Organizational IT infrastructure perspective: Organizational infrastructure → IT infrastructure → IT strategy
- IT infrastructure perspective: IT infrastructure → IT strategy → Business strategy
- IT organizational infrastructure perspective: IT infrastructure → Organizational infrastructure → Business strategy
- Organizational infrastructure perspective: Organizational infrastructure → Business strategy → IT strategy

Luftman (1996) also proposed that in some situations, a fusion of two perspectives might occur. In these cases, two perspectives can be simultaneously assessed and can impact the same domain: IT infrastructure fusion, organizational infrastructure fusion, business strategy fusion, and IT strategy fusion.

Research was developed in order to find the enablers of strategic alignment. Luftman (2001) listed five of them: senior executive support for IT, IT involved in strategy development, IT understands the business, business–IT partnership, well-prioritized IT projects, and IT demonstrates leadership. The absence or poor performance of these same factors is considered an inhibitor of strategic alignment.

Some authors, like Ciborra (1998), state that the strategic success of IT applications might be achieved through a tentative approach, rather than through structured methods of strategic IT planning. These authors argue that frequently the drivers of strategic IT applications are efficiency issues, instead of a result of a strategic IT plan. Some important and well-known successful information systems, with clear strategic impacts, do not present evidence of being previously planned, which seems to be in agreement with this kind of thinking (Eardley et al., 1996).

CONCLUSION

The concepts described above show the importance of a broad view for analyzing IT strategic alignment. Each of the described models (CSF, strategic grid, and strategic alignment) focuses on specific aspects of this issue.

These three widespread known models, in fact, have complementary characteristics, and concomitant use of them allows for better comprehension of the IT role in an organization.

On the other hand, even the use of the three models does not solve the complexity of IT alignment in organizations. As highlighted by several authors, sometimes a tentative and evolutionary approach can be successfully adopted in circumstances in which structured methods do not work properly.

Further studies would be necessary for a better and deeper understanding of the importance of IT effectiveness for the success of competitive companies. However, the intent of this article was to help find a way to reach this understanding.

KEY TERMS

Competitive Forces: According to Porter and Millar (1985), the state of the competition in a particular industry depends on five basic forces: new competitors, bargaining power of suppliers, bargaining power of customers, rivalry among current competitors, and substitute products or services.

Critical Success Factors (CSF): The areas where satisfactory results, according to Rockart (1979), "ensure successful competitive performance for the organization."

Effectiveness: In the context of IT, this is the measurement of the capacity of the outputs of an information system or of an IT application to fulfill the requirements of the company and to achieve its goals, making this company more competitive. In a few words, effectiveness can be understood as the ability to "do the right thing."

Productivity Paradox: The discussion about the lack of evidence about the return of investments on IT in the economy productivity indicators.

Strategic Alignment: The IT Strategic Alignment Model was proposed by Henderson and Venkatraman (1993) and consists of a framework for studying IT impacts on business and understanding how these impacts influence IT organization and strategy, as well as it enables us to analyze the market availabilities of new information technologies.

Strategic Grid: McFarlan (1984) proposed the Strategic Grid that allows the visualization of the relationship between IT strategy and business strategy and operations. This model analyzes the impacts of IT existent applications (present) and of the applications portfolio (future), defining four boxes, with each representing one possible role for IT in the enterprise: *Support*, *Factory*, *Turnaround*, and *Strategic*.

Value Chain: According to Porter and Millar (1985), this is the set of technologically and economically distinct activities a company performs in order to do business.

Information Technology Usage in Nigeria

Isola Ajiferuke
University of Western Ontario, Canada

Wole Olatokun
University of Ibadan, Nigeria

INTRODUCTION

The term information technology (IT) came into common use in the late 1980s, supplanting earlier terms such as electronic data processing systems (EDP), management information systems (MIS), and office systems (IS). Oliver, E. C., Chapman, R. J. and French, C. S. (1990) defined IT as the technology which supports activities involving the creation, storage, manipulation and communication of information (principally computing, electronics and electronic communications) together with their related methods, management and applications. Such an all-embracing term is clearly open to a number of interpretations depending on in which context it is used. In some contexts, the term "information technology" means computers, ancillary equipment, software and firmware (hardware) and similar procedures, services (including support services) and related resources. Also, it includes any equipment or interconnected system or subsystem of equipment that is used in the automatic acquisition, storage, manipulation, management, movement, control, display, switching, interchange, transmission or reception of data or information.

The emergence, development and diffusion of information technology has changed the society dramatically into what is now sometimes called an information society. IT makes it possible to collect, process and transmit information much faster and much cheaper than before. The use of IT has had profound effects on the economy, production, services and the society as a whole, and its areas of application include education, health care, commerce, publishing, manufacturing, finance, and banking (Hanna, N., Guy, K. & Arnold, E,1995).

BACKGROUND

Even though the use of IT is spreading fast, most of the market remains geographically concentrated in the advanced industrialised countries, notably the United States, Western Europe and Japan. There are great differences between industrial and developing countries: Hanna, Guy and Arnold (1995) concluded that developing countries are poor in the infrastructure that is the key to IT diffusion. Lack of trained manpower, the high cost of telecommunications and document delivery, and the cost of information itself are other barriers developing countries are struggling with (Conceicão Calomon Arruda, 1997).

Apart from the problems identified above, the other major impediment to the successful adoption of IT in developing countries is the non-availability of a well-articulated information technology policy. According to Shila (1994), such policies are needed to:

(i) solve coordination problems in IT such as haphazard development or importation of systems without regard for nationwide concerns and priorities;
(ii) create a critical mass of expertise in the public sector;
(iii) raise general awareness about the social and economic consequences of IT;
(iv) increase the efficiency of government computerization; and
(v) launch specific projects that cut across agency lines in the fields of infrastructure development, standardization, human capital formation, and technology support for the private sector.

Shila's view is corroborated by Mulira (1995), who states that the purpose of having an appropriate national IT policy is to create an environment where economic and social benefits may be achieved; where utilization of resources may be optimized; where domestic technological capabilities may be encouraged; and where procurement decisions can be taken rationally. Hence, the objectives of this chapter are to review the IT usage in a typical developing country, Nigeria, and to evaluate the appropriateness of its recently formulated IT policy.

MAIN THRUST OF THE ARTICLE

The Federal Republic of Nigeria is situated on the West African coast, and shares common borders with the Benin Republic in the West, Niger to the North, Chad Republic to the North-East, and Cameroon Republic to the East. Nigeria is the most populous country in Africa, with an estimated population of about 123 million people (Encyclopedia4u, 2000). The climate is wholly tropical, and even though more than 75% of the people live in rural areas, agriculture is not the mainstay of the Nigerian economy. The expansion in the oil sector in the 1970s and early 1980s has led to a considerable decline in agriculture.

IT usage in Nigeria cuts across the major sectors of the economy but with varying degrees of applications. The use of computers in manufacturing - with the exception of certain high-technology process industries in which the process computer is essentially a part of the process machinery (e.g. petroleum refining and the steel mill) - is only a recent phenomenon. It is in the area of coordination, or management, which the greatest advance has been made. In fact, computerization has been most widespread in the area of financial management, including payroll, accounts, general ledger, sales, and invoicing. More than 80 per cent of computer installations are used in this way. There are also many instances of companies that have not installed computers but have their accounts and payroll batch-processed on a bureau computer owned by a vendor or an agency.

In the banking and financial industry, computerization is still limited to ledgers, communication, and current account management (Ugwu, L.O., Oyebisi, T.O., Ilori, M.O., & Adagunodo, E.R., 2000; Idowu, P.A., Alu, A.O., & Adagunodo, E.R., 2002; Uche, 2003). There are no automated telling machines, nor are multi-branching facilities available. However, the service to the customer is improving in many respects, including "quick service" cash counters, and prompt and regular monthly statements of account. In general, the thrust of computerization in banks is in the direction of more automation and networking, but the rate of progress is limited by the ineffective telecommunications infrastructure in the country. Other service industries, such as advertising, also use IT mainly for word processing and accounting functions (Ehikhamenor, 2002; Odesanya and Ajiferuke, 2000; Adetayo, J.O., Sanni, S.A., & Ilori, M.O., 1999).

In the communications field, the Nigerian Telecommunications Limited (NITEL), the national carrier, is heavily computerized, with a huge installed capacity including mainframes, minis, and micros. These computers are located in four regional headquarters as well as in the national headquarters in Lagos. The machines are used for administrative purposes and for the management of the telephone network. At present, they function on a stand-alone basis, but it is known that NITEL is interested in interconnecting these machines in both local and wide area networks for greater efficiency and increased flexibility. The National Television Authority (NTA) is computerized, and so are the leading telecommunications outfits represented in Nigeria. However, the postal agencies are yet to adopt the use of IT in sorting mails.

Government departments are rapidly computerizing (Tiamiyu, 2000). As many as 13 federal ministries have computers; the Ministry of Defence alone has 9 installations. The Ministry of Works operates a computerized maintenance system. The Federal Office of Statistics, the national body responsible for the gathering and compilation of statistical data ranging from trade statistics to commodity prices and population data, is fully computerized. Among the state governments, it is usual to install a central computer facility in the Ministry of Finance for financial administration. In almost all the 25 federal universities there are well-staffed computing centres equipped with time-shared multi-user mainframe computers used for teaching and research (Ehikhamenor, 2003). In addition, several departments and faculties have their own computer facilities, consisting mainly of micros. Many university computing centres also provide computer services for the administrative departments, such as the bursary, the registry, and the library.

For the general public, only a few homes have computers but IT training centres and cybercafés are spread across Nigeria, especially in the major cities (Adomi, E.E., Okiy, R.B., & Ruteyan, J.O., 2003). These centres provide IT training as well as allow people to do word processing, send e-mails, and browse the Internet.

Overall, IT usage in Nigeria is widespread but the depth is very shallow. The reasons for these, which are similar to those in other developing countries, include: very low literacy level; extremely low density of telecommunications facilities and services; underdeveloped computing infrastructures and culture; government regulations; corruption in both public and private organizations; and lack of a coordinated national IT policy (Eze, 2002, Oyebisi & Agboola, 2003).

FUTURE TRENDS

To increase the depth and effective usage of IT in Nigeria in the future, solutions would have to be found to the problems identified above. Telecommunications is probably the first critical requirement because it provides the network through which various people, organizations and regions of Nigeria can be linked together, and to the rest of the world. Telecommunications facilitates not only Internet connectivity, but also interpersonal voice, radio and TV communications. However, investors in the sector must be ready to focus on investing in the short and medium terms, and recovering their investments in the long run. They must also be willing to popularize the telephone culture through appropriate pricing.

Computing infrastructure must also become more widespread in order for people to use computers to exploit Internet-based information service opportunities. But computers are still relatively expensive to acquire for most people and organizations. Nevertheless, an area requiring urgent attention is the educational sector - primary, secondary and tertiary institutions, because graduates from such institutions would eventually constitute the future work force. Hence, we should begin by introducing and expanding computing laboratories and networks in educational institutions. Indeed, the development of these laboratories and centres in schools, colleges, organizations, and shopping plazas will quickly popularize computing culture among students, employees, and the masses in general.

The presently low literacy level in Nigeria will take time to improve. Related to the low literacy level are the two other underdeveloped aspects of the Nigerian socio-economy: restriction of universal access to public information, and inadequate appreciation and application of science and technology. A high literacy level will empower the masses to request for intellectually nourishing information as well as demand for their citizenship right of access to public information. Also, a high literacy level will enable the masses to appreciate science and technology better.

In response to the lack of an enabling national IT policy, the Nigerian Government, in February 2001, put together a national IT Policy for Nigeria (Federal Government of Nigeria, 2001). This policy is in the early stages of implementation, and we shall evaluate its adequacy below under the following broad headings: scope and coverage, relevance of the policy to the IT needs of Nigeria, acceptability among stakeholders, the realism of the objectives and strategies set out in the policy, and the implementation strategy.

(i) **Scope and coverage**: Based on the content analysis of the Nigerian IT policy, the policy was found to be very comprehensive in scope. The policy gave recognition to fifteen sectoral areas; these are human resource development, infrastructure, governance, research and development, health, agriculture, trade and commerce, fiscal measures, government and private sector partnerships, arts, culture and tourism, national security and law enforcement, legislation, global considerations, and IT popularization and awareness. However, as comprehensive and all-embracing as the policy is in terms of scope, there are still some gaps. For instance, a strategic sector like education was glaringly omitted. The role of education, as producer and user of IT products and systems, was mentioned in connection with the human development sector. But one finds it difficult to believe that education can be so relegated to the background in a national IT policy for Nigeria where illiteracy rate is still pretty high.

(ii) **Acceptability among stakeholders**: The policy is far from being acceptable to some of the stakeholders. For instance, prior to the formulation of the policy, both the Information Technology Association of Nigeria (ITAN) and the Computer Association of Nigeria (COAN) submitted proposals on what the content of an IT policy for Nigeria should look like. In the final document, some of the suggestions made by these two associations were ignored. Thus, the present IT policy is far from being acceptable to all the stakeholders. This is why National Information Technology Development Agency (NITDA) has been finding means of reviewing the policy both for meeting new challenges, and also to make it more acceptable to the different stakeholders.

(iii) **The realism of the objectives and strategies set out in the policy:** The vision statement of the policy was "*to make Nigeria an IT capable country in Africa and a key player in the information society by the year 2006, using IT as the engine for sustainable development and global competitiveness.*" The question is how realizable is this vision statement in a country where computer illiteracy rate is still pretty high, and the information and telecommunications infrastructures are very poor. Also, the mission statement identified four key areas for the use of IT: creation of wealth, poverty eradication, job creation, and global competitiveness. It neglects education as a key area in which IT could be applied. For instance, how can IT be used in creating jobs and eradicate poverty when the majority of the population is still not knowledgeable about IT?

On governance, one of the objectives is "*to replace traditional governance with electronic governance*". The state of the telecommunications infrastructure and the level of computer literacy among Nigerians create serious doubts about the capability to achieve this objective. E-governance, at best, will distance government from the people and neglect the generality of Nigerians owing to the low levels of literacy and computer literacy among Nigerians.

(iv) **Policy Implementation strategy:** One of the important strategies set out for the implementation of the IT policy is contained under policy implementation sub-section 16.3 (i) as follows:

"Establishing a coordinated program for the development of a National, State and Local Informa-

tion Infrastructure (NII, SII, LII) backbone by providing emerging technologies, such as satellite (including VSAT), fibre optic networks, high-speed gateways and broad bandwidth/multimedia within the next eighteen months but not later than the fourth quarter of 2002"

The above strategy is well thought out and of great import. But one would have thought that the policy would have been patterned after that of India by promoting state-owned enterprises in such a way that each state in the country will be made to have its own IT policy and thus develop the aspect of the State Information Infrastructure (SII) while the local governments will be made to develop the aspect of the Local Information Infrastructure (LII). This pattern, if adopted will be with a view to integrating SII and LII with the National Information Infrastructure (NII). It is believed that with this approach, there will be a rapid progress in the development of the National Information Infrastructure (NII). This perception applies to other aspects of the policy, such as IT popularization and awareness, governance, IT human resource development, national security and law enforcement as well as other sectoral applications.

CONCLUSION

In this chapter, we have provided an overview of IT usage in Nigeria as well as discuss the national IT policy. It is our view that Nigeria needs to modify its national IT policy in such a way that technology is put at the centre of the developmental planning. Along this line, we submit that policy implementation requires an institutional framework without which any planning effort may be futile, no matter how elaborate or well intentioned. Thus, we conclude by saying that the future of IT and related technologies in Nigeria cannot but be bright provided public and private sector initiatives and policies are implemented to remove the obstacles identified above.

KEY TERMS

Cybercafé: A café that makes available a number of personal computers that are connected to the Internet for the use of the general public.

Developing Country: A country with a relatively low per capital gross national product (GNP).

Information Economy: An economy which is dominated by information-related activities.

Information Society: A society in which information is used heavily in everyday life of most citizens.

Information Technology: Encompasses all forms of technology used in processing and disseminating information.

Policy: A course of action developed for the achievement of a set of goals.

Strategy: A plan or method for obtaining a specific result.

I

Informationbase – A New Information System Layer

Kovach Dragan
SUPER-King, Inc., Croatia

INTRODUCTION

Information is a set of data purposefully organized into a report. In the database of an information system, only the raw material for the information is stored, that is, the data. To get the information one needs:

- To find an adequate option in the information system menu.
- To understand the possibilities of the option and to enter appropriate values for the parameters required.
- Execute the option and …
- … wait to get the report.

The concept of the informationbase eliminates these steps and enables the user to get the information directly and instantly.

Informationbase is a top layer of the information system that uses information systems database and information system reporting options to automatically maintain set of reports and graphs, permanently available to the user. Hence, it acts as an information manager that:

- enables free design of the informationbase contents and structure,
- automatically activates predefined information system options ...
- ... and delivers parameters for those options to produce up to date reports,
- reports produced automatically and/or manually stored in an informationbase, where they could be easily accessed by authorized users, and
- manages authorization of informationbase usage.

The rationale for the informationbase concept is the following:

Instead of being repeatedly and randomly produced by individual users, information could be once generated by the editor and/or automatically generated and stored in the informationbase, that is, be permanently available to all potential users.

Thus, the final product of the information system - information - could be available as up to date reports, rather than as a vague potential possibility, hidden in the complexity of the information system.

One of advantages of the informationbase is that it solves the problem of computer capacity overload, so commonly present and caused by simultaneous information retrieval of many users.

As Zygmont (1999) states: “The usual lifecycle goes like this: The user first accepts the reporting tools and templates provided by the ERP vendor. The honeymoon ends shortly after implementation, when workers become comfortable enough with a new system to begin making demands”.

“Structure of data within ERP systems generaly prevents efficient reporting. Data tables are very normalized, containing minimal cross references, so that transactions move rapidly. But that means to get reports, you have to hit up against many different tables. That eats a lot of CPU cycles.”

But even more important is that it makes easy to grasp what are the most important deliveries of the information system to the user organization. Namely, the scope of information system coverage is carefully structured and clearely presented in the informationbase. Thus, the user gets the understanding of the system far faster, more completely and with less effort than studying system manuals. The cognitive and organizational learning dimensions of the information system are recognized and considered as important issues in the literature (van Stijn, 2001, p. 502).

BACKGROUND

Informationbase concept is developed by the author of this paper, working for SUPER-KING Inc., Zagreb, Croatia, and implemented in TOMAS (**TO**tal **MA**nagement **S**ystem) ERP (enterprise resource planning) software. In the Croatian version, the name of software is SUPER (**S**ustav **U**pravljanja **P**oslovanjem **E**lektronickim **R**acunalom). The first version of informationbase was implemented in 1994 (Kovach, 1996). SUPER has been implemented in an organization with a multimilion transactions database. This caused problems with computer overload during the day, for many users had been making reports that required handling large database. First, we tried to solve that so that computer operators were producing the most frequently needed reports after normal working hours and during the night, so that the next day printed reports were distributed to users. The first version of informationbase was a report management system that enabled storage of generated reports and retrieval at will.

In this article the second version, developed in 1996, is presented, to describe the concept first presented in Kovach (2001, 2004). In this version, capabilities of informationbase have been extended to the limits of our imagination and remain to the present time unchanged.

PROPERTIES OF THE INFORMATIONBASE

Informationbase is a structured set of reports and/or graphs ready to use. TOMAS' informationbase offers the following capabilities:

- Informationbase is built for the user organization and a calendar year, but any number of informationbases could be kept simultaneously.
- Each informationbase could have:
    - up to 99 chapters,
    - up to 34 reports/chapter, and
    - unlimited number of pages/report.
- Structure of chapters and reports could be defined by the user. The default structure of the informationbase is available, but the user could modify or change it completely.
- Access to the informationbase is controlled by an authorization system. User password determines what chapters and/or reports are available to the user and whether the user is allowed to change informationbase structure.
- Reports in the informationbase could be updated automatically and/or manually. For each informationbase entry to be updated automatically, there should be stored parameters that are described next.

  Based on these parameters, informationbase is automatically updated, using standard information system options for report generation, which are used apart from the informationbase as well.

Hence, informationbase is a new layer of an information system for maintaining a permanently available and up to date set of reports and graphs predefined by the user.

CREATING THE STRUCTURE OF THE INFORMATIONBASE

Informationbase structure is created in the following way:

- Chapter is defined by the chapter number and the chapter title.
- Chapter entry, that is, report or graph, is defined by entry number and entry title.
- For each chapter entry (report or graph) to be generated automatically, the following parameters are to be stored:
    - Number of the option from the information system menu that makes the report. These options are used to produce reports normally, apart from informationbase, but also could be used for automatic report generation for the the informationbase. This requires additional considerations in information system development.
    - Option template number, with specified values of parameters. Options for report generation in TOMAS have usually 15 - 20 parameters and the capability of producing billions of report variations, depending on user chosen values of parameters. Combinations of parameters values could be stored as option templates.
    - Type of date interval – reports are always made for some period of time. This period is defined by several parameters. Type of date interval is one of parameters and refers to one of the following:
        - date of data entry
        - document date
        - payment due date
        - financial month/year
        - planned due date
        - order delivery date, and so forth
    - Relative report time period – defines the period for which the report is to be made in relative terms, which could be:
        - yesterday
        - today
        - previous month
        - current month
        - current year up to today
        - current year up to the end of previous month, and so forth
        - to previous could be added +/- N days, where N is defined by the user

This makes it possible that time cycle for each report in the informationbase could be defined. Also, this parameter is needed because in the program unit for making report, one must specify the date interval for which report is to be made. Hence, when the option is used for the informationbase, the informationbase driver has to determine actual time limits for "yesterday," "previous month" and so forth and insert them into option parameters so that the report could be produced.

- Time activator, that is, trigger for automatic update of the report in the information base, could be:
  - calendar day
  - calendar month
  - calendar year
  - financial (booking) month and so forth

So, if the trigger is calendar day, the report is produced automatically each day. If the trigger is booking month, the report is produced whenever the booking month is changed in the database.

UPDATING THE INFORMATIONBASE

There are three ways to update the informationbase:

- Manually, that is, any report could be stored in any of the chapters of the informationbase,
- Semiautomatic – the user starts the option for automatic updating of the whole informationbase or only part of it, for example some chapters and/or reports.
- Fully automatic – the option for updating the informationbase is set to start every day at a specified time.

When the informationbase update is started, the system scans time activators and checks what reports are to be updated, starts appropriate options, that is, application programs for report generation with predefined option templates, and updates the informationbase.

ADVANTAGES OF THE INFORMATIONBASE

The informationbase concept brings the following advantages:

- Information is comprehensive and well structured: in 10 – 15 chapters and 150 – 200 reports carefully defined, all aspects of business are covered:
  - In typical time segments (yesterday, today, current month, current year, etc.)
  - Summarized by relevant entities (materials, vendors, etc.)
  - Presented as ABC analysis, that is, sorted by relevant value, with cumulative percentages
  - Due dates approaching in next period, for example orders to be delivered in the next 5 days
  - Due dates that are already late, for example undelivered orders or unpaid invoices
  - Exceptions to the rules, for example inventories below minimum and so forth

The user could acquire information by normal use of an information system, as well, using system options in a standard way, but the major part of information needs should be covered by the informationbase.

What is going to be in the informationbase depends upon the potential of the information system and user judgment as to what is relevant. Still, whatever the quality of the information system is, the informationbase concept makes possible that full potential of information system output repertoire is carefully structured, completely transparent and permanently available to the user.

- Information system is much easier to grasp: Full potential of information system output repertoire that is relevant to the organization is transparently presented by the informationbase structure and contents. Hence, it is easy to grasp what most important information system capabilities are.
- Information is always up to date - updating is done automatically.
- Full availability and direct use of information – the user immediately gets the information, without intermediates, at any time, from any place (remote access and/or via INTERNET), and no computer literacy is required.
  Therefore, users can forget about all intricacies of the information system – all one needs to do is to enter the informationbase menu and choose the information.
- Directs attention – titles of chapters and reports indicate aspects to be scrutinized, even if the user has no idea what to look for.
- Efforts and costs minimized – information is made once, automatically and used by many, so human and computer resources required are minimized.
- Resultant effect of informationbase is that all users, especially management, are better informed, with less total costs and effort.

STANDARD (DEFAULT) INFORMATIONBASE

To help the user, information system offers standard, that is, default informationbase, with all parameters ready made. As has been mentioned already, the user could change it or define a completely different structure, without programming. The structure of chapters and content of some chapters for standard TOMAS informationbase is shown as follows.

FUTURE TRENDS

As far as TOMAS, that is, SUPER is concerned, there are no plans for further development of the informationbase software engine. Rather, we work on informationbase content, that is, structure of the informationbase chapters for various business functions (e.g., sales, production control, etc.) and types of organizations (e.g., retail, manufacturing, etc.); that is, we study the morphology of logical informationbase. Still, if the concept of informationbase would be accepted, it is conceivable that informationbase software could be developed for existing ERP packages and/or information systems of large organizations.

CONCLUSION

The informationbase is a new layer of the information system, which uses information systems database and application programs to automatically maintain the final product of the information system, that is, information. Information produced in this manner is comprehensive, carefully structured, permanently up to date and available to the user, without the need for users to run any programs. Hence, informationbase is a sort of information system management that permanently keeps available full potential of the information system, ensuring maximum efficiency in getting information and minimum of human and computer resources required.

KEY TERMS

Authorization for Informationbase: Regulates access to informationbase, that is, what chapters and entries are available to a particular person, authority to initiate informationbase updating and to change informationbase structure.

Informationbase: Set of reports and graphs, structured by means of chapters, updated automatically and/ or manually.

Informationbase Chapter: Part of informationbase, group of reports or graphs.

Informationbase Entry: Part of an informationbase chapter, single report or graph,

Relative Time Period: Informationbase parameter that defines relative time period for which the report is to be produced, for example yesterday, today, previous month and so forth. Informationbase driver translates this into actual dates for data processing.

Time Activator: Trigger for initiating automatic update of the report in the informationbase. Could be calendar day, month or year, financial (booking) month and so forth. So, if the trigger is calendar day, the report is produced automatically each day. If the trigger is booking month, the report is produced whenever booking month is changed in the database.

Type of Date Interval: Informationbase parameter that defines the relative time period. This could be document date, delivery due date, payment due date and so forth.

InfoSec Policy – The Basis for Effective Security Programs

Herbert J. Mattord
Kennesaw State University, USA

Michael E. Whitman
Kennesaw State University, USA

INTRODUCTION

The success of any information security program lies in policy development. The lack of success in any particular program can often be attributed to this unmet need to build the foundation for success. In 1989, the National Institute of Standards and Technology addressed this point in *Special Publication SP 500-169: Executive Guide to the Protection of Information Resources* (1989):

The success of an information resources protection program depends on the policy generated, and on the attitude of management toward securing information on automated systems. You, the policy maker, set the tone and the emphasis on how important a role information security will have within your agency. Your primary responsibility is to set the information resource security policy for the organization with the objectives of reduced risk, compliance with laws and regulations and assurance of operational continuity, information integrity, and confidentiality (p.1).

Policy is the essential foundation of an effective information security program. As stated here by Charles Cresson Wood, in his widely referenced book *Information Security Policies Made Easy* (2003),

The centrality of information security policies to virtually everything that happens in the information security field is increasingly evident. These policies will stipulate the type of services that should be permitted, how to authenticate the identities of users, and how to log security-relevant events. An effective information security training and awareness effort cannot be initiated without writing information security policies because policies provide the essential content that can be utilized in training and awareness material (p.1).

Policy is essential because it is the primary mechanism an organization possesses to inform and enforce expected behaviors in employees. Policy has the effect of law within the confines of the institutions. However, while *ignorantia legis neminem excusat* (ignorance of the law is no excuse) is prevalent in the public domain, ignorance of policy is legally defensible.

Although information security policies are among the least expensive information security controls to create, they are often the most difficult to implement. Policy-based controls typically cost only the time and effort the management teams spends to create, approve, and communicate them, and the time and effort employees spend integrating the policies into their daily activities. Even when the management team hires an outside consultant to assist in the development of policy, the costs are minimal compared to the other forms of control, especially technical controls (Whitman & Mattord, 2004).

BACKGROUND

Policy is "a plan or course of action, as of a government, political party, or business, intended to influence and determine decisions, actions, and other matters" (Merriam-Webster, 2002). In other words, policies are a set of rules that dictate acceptable and unacceptable behavior within an organization. Policies must also specify the penalties for unacceptable behavior, and define an appeal process. An example of a policy would be an organization's prohibiting the viewing of pornographic Web sites at the workplace.

To execute this policy, the organization must implement a set of standards. A standard is a more detailed statement of what must be done to comply with policy. In the implementation of the anti-pornography policy, the organization may create a standard that the network will block access to pornographic Web sites. Practices (i.e., procedures and guidelines) explain how employees will comply with policy.

For policies to be effective they must be properly disseminated, via personnel manuals, organizational intranets, periodic supplements, staff meetings and/or training (to name a few). All members of the organization must read, understand, and agree to abide by the organization's policies. Failure to ensure each of these requirements can negate the regulatory effect of policy. Policies require constant modification and maintenance. As the needs of the organization evolve, so must its policies.

Some basic rules must be followed when shaping any policy, including information security policy:

- Policy should never conflict with law.
- Policy must be able to stand up in court, if challenged.
- Policy must be properly supported and administered.

Since policy is often difficult to implement, Bergeron and Bérubé (1990) have proposed guidelines for the formulation of computer policy, which are also directly applicable to information security policy:

1. "All policies must contribute to the success of the organization.
2. Management must ensure the adequate sharing of responsibility for proper use of information systems.
3. End users of information systems should be involved in the steps of policy formulation" (p. 16).

Bergeron and Bérubé further note that while it is an admirable goal for policies to be complete and comprehensive, too many policies or policies that are too complex can lower end-user satisfaction.

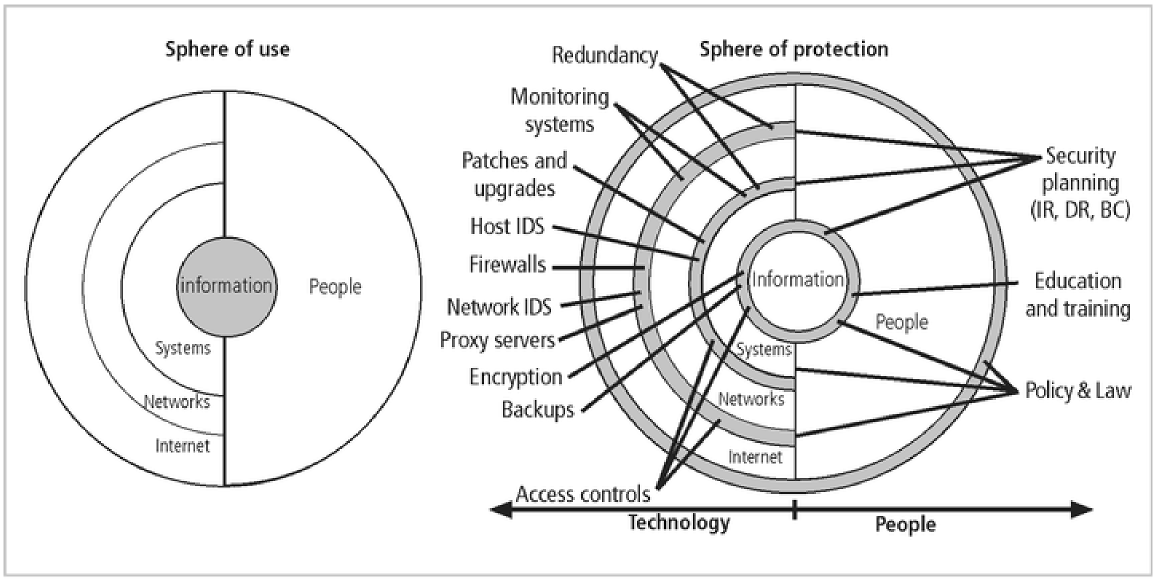
As is evidenced in Figure 1, in order to secure information an organization must place protection mechanisms at multiple points. This is easily done in the electronic arena, where most threats come through the Internet, to the internal network, to the systems that house information, and finally to the information itself. However, inside an organization you may only have a few opportunities to protect information from those that use it. These opportunities include security education, training and awareness programs (SETA) and policy.

The use of multiple layers of protection is a concept called defense-in-depth, whereby security components at multiple layers serve to back each other up in the event that one layer's controls fail. Until sound and useable IT and information security policy is developed, communicated, and enforced, no additional resources should be spent on controls other than policy.

EFFECTIVE INFORMATION SECURITY POLICIES

To produce complete information security policy in the organization, management must use three types of information security policies. These three types are based on National Institute of Standards and Technology Special Publication 800-14 (1996), which outlines the requirements of writing policy for senior managers. This document is recommended for professionals involved in creat-

Figure 1. Spheres of use and protection of information (Whitman & Mattord, 2003)



ing policy, and can be found at http://csrc.nist.gov/publications/nistpubs/800-14/800-14.pdf. The three types of policy are:

- Enterprise information security program policy (EISP)
- Issue-specific information security policies (ISSP)
- Systems-specific information security policies (SysSP)

Enterprise Information Security Policy

An enterprise information security policy (EISP)—also known as a security program policy, general security policy, IT security policy, high-level information security policy or information security policy—sets the strategic direction, scope, and tone for all of an organization's security efforts. The EISP assigns responsibilities for the various areas of information security, including maintenance of information security policies, and the practices and responsibilities of end users. In particular, the EISP guides the development, implementation, and management requirements of the information security program, which must be met by information security management, IT development, IT operations and other specific security functions.

The EISP is an executive-level document, drafted by the Chief Information Security Officer (CISO) in consultation with the Chief Information Officer (CIO), and shapes the security philosophy in the IT environment. The EISP usually does not require repeated or routine modification, unless there is a change in the strategic direction of the organization.

The EISP plays a number of vital roles, not the least of which is to state the importance of information security in support of the organization's mission and objectives. Information security strategic planning derives from the IT strategic policy (if the Information Security department is placed under the control of the CIO), which is derived from the organization's strategic planning. Unless the EISP directly reflects this association, the policy will likely become confusing and counter-productive.

Though specifics of EISPs vary from organization to organization, most EISP documents should provide the following:

- An overview of the corporate philosophy on security
- Information on the structure of the information security organization and individuals that fulfill the information security role
- Fully articulated responsibilities for security that are *shared by all members* of the organization (employees, contractors, consultants, partners and visitors)
- Fully articulated responsibilities for security that are *unique to each role* within the organization

The formulation of program policy in the EISP establishes the overall information security environment. As noted earlier, there are any number of specific issues that require policy guidance beyond what can be offered in the EISP. The next level of policy document, the issue-specific policy, delivers the specificity. The components of a good EISP are as follows:

1. Statement of Purpose - Answers the question "What is this policy for?" Provides a framework for the helps the reader to understand the intent of the document, that is, "This document will:

- Identify the elements of a good security policy
- Explain the need for information security
- Specify the various categories of information security
- Identify the information security responsibilities and roles
- Identify appropriate levels of security through standards and guidelines" (WUSTL, 2002).

2. Information Security Elements - Defines information security. It can also lay out security definitions or philosophies in order to clarify the policy. For example - "Protecting the confidentiality integrity and availability of information while in processing, transmission and storage, through the use of policy, education & training, and technology…" (WUSTL, 2002).

3. Need for Information Security - Provides information on the importance of information security in the organization and the obligation (legal and ethical) to protect critical information whether regarding customers, employees, or markets.

4. Responsibilities and Roles - Defines the organizational structure designed to support information security within the organization. Includes identification of categories of individuals with responsibility for information security (IT dept, management, users) and their information security responsibilities, including maintenance of this document.

5. Reference to Other Standards and Guidelines - Outlines lists of other standards that influence and are influenced by this policy document. These could include relevant laws, federal and state, as well as other polices in place in the organization. (Note: this outline was derived from a number of sources, the most notable of which is WUSTL, 2002.)

Issue-Specific Security Policy (ISSP)

A sound issue-specific security policy provides detailed, targeted guidance to instruct all members of the organization in the use of technology-based systems. The ISSP should begin with an introduction of the fundamental technological philosophy of the organization. It should assure the members of the organization that the purpose of the policy is not to provide a legal foundation for persecution or prosecution, but to provide a common understanding of the purposes for which an employee can and cannot use the technology. Once this understanding is established, employees are free to use the technology without seeking approval for each type of use. This serves to protect both the employee and the organization from inefficiency and ambiguity. According to Whitman et al., (1999) an effective ISSP:

- Articulates the organization's expectations about how the technology-based system in question should be used
- Documents how the technology-based system is controlled and identifies the processes and authorities that provide this control
- Serves to indemnify the organization against liability for an employee's inappropriate or illegal system use

An effective ISSP is a binding agreement between parties (the organization and its members) and shows that the organization has made a good faith effort to ensure that its technology is not used in an inappropriate manner. An ISSP may be drafted to cover many topics, including e-mail, use of the Internet and World Wide Web, office computing equipment, and a host of other fair and responsible use areas. The specific situation of any particular organization dictates the exact wording of the security procedures as well as issues not covered within these general guidelines. There are seven major sections of a good ISSP (Whitman, 2003). These are described here in detail.

1. Statement of Purpose - a clear statement of purpose that outlines the scope and applicability of the policy, addressing the purpose of this policy, who is responsible and accountable for policy implementation and what technologies and issues the policy document addresses.
2. Authorize Access and Usage of Equipment - who can use the technology governed by the policy, and for what purposes. This section defines "fair and responsible use" of equipment and other organizational assets, as well as addressing key legal issues, such as protection of personal information and privacy.
3. Prohibited Usage of Equipment - what the issue or technology cannot be used for, that is, personal use, disruptive use or misuse, criminal use, offensive or harassing materials, and infringement of copyrighted, licensed, or other intellectual property. Unless a particular use is clearly prohibited, the organization cannot penalize employees for such usage.
4. Systems Management - the users' relationships to systems management, including systems maintenance and storage authorization and restriction. The Systems Management section should specify users' and systems administrators' responsibilities.
5. Violations of Policy - the penalties and repercussions of violating the usage and systems management policies, as well as instructions on how to report observed or suspected violations, either openly or anonymously.
6. Policy Review and Modification - procedures and a timetable for periodic review. This section should contain a specific methodology for the review and modification of the ISSP, to ensure that users always have guidelines that reflect the organization's current technologies and needs.
7. Limitations of Liability - a general statement of liability or set of disclaimers. If an individual employee is caught conducting illegal activities with organizational equipment or assets, management does not want the organization held liable. Therefore, if employees violate a company policy or any law using company technologies, the company will not protect them, and is not liable for their actions, assuming that the violation is not known or sanctioned by management.

Systems-Specific Policy (SysSP)

While issue-specific policies are formalized as written documents, distributed to users, and agreed to in writing, systems-specific policies (SysSPs) are frequently codified as standards and procedures used when configuring or maintaining systems. One example of a SysSP is a document describing the configuration and operation of a network firewall. This document could include a statement of managerial intent, guidance to network engineers on selecting, configuring, and operating firewalls, and an access control list that defines levels of access for each authorized user. Systems-specific policies can be organized into two general groups, management guidance and technical specifications.

Management Guidance SysSPs

A management guidance SysSP is created by management to guide the implementation and configuration of technology intended to support the security of information. For example, while the specific configuration of a firewall belongs in the technical specifications SysSP, the general construction and implementation of the firewall must follow guidelines established by management. For example, an organization may not want its employees to have access to the Internet via the organization's network; the firewall would have to be implemented according to this rule.

Systems-specific policies can be developed at the same time as ISSPs, or they can be prepared in advance of their related ISSPs. Before management can craft a policy informing users what they can do with the technology and how they may do it, it might be necessary for system administrators to configure and operate the system. Some organizations may prefer to develop ISSPs and SysSPs in tandem, so that operational procedures and user outcomes are developed at the same time.

Technical Specifications SysSPs

While a manager may work with a systems administrator to create managerial policy as specified previously, the system administrator may need to create a different type of policy to implement the managerial policy. Each type of equipment has its own type of policies, which are used to translate the management intent for the technical control into an enforceable technical approach. For example, an ISSP may require that user passwords be changed quarterly; a systems administrator can implement a technical control within a specific application to enforce this policy. There are two general methods of implementing such technical controls, access control lists – which include the user access lists, matrices, and capability tables that govern the rights and privileges of users, and configuration rules - the specific configuration codes entered into security systems to guide the execution of the system when information is passing through it.

FUTURE TRENDS

In order to deal with the complexities of developing and implementing policies, organizations are increasingly turning to alternate solutions. These alternate solutions provide options ranging from templates based on established experts in the field (i.e., Charles Cresson Wood), to automated policy approval and distribution systems like Security Policy Management from NetIQ (Security Policy Management, 2004). These systems simplify the onerous task of drafting policy, obtaining management approval, distributing to end users, and documenting compliance with policy but creating a structure in which the draft policy is placed. Control and approval is passed from author to reviewer, and eventually published to end users. Once users have read the policy, the system documents their activities and eventually can provide quizzes on policy content. Use of systems like these greatly improves the organization's ability to issue and manage policy as an effective tool in supporting ongoing operations.

CONCLUSION

The early years of the 21st century have seen the emergence of information security as both a practical area of specialization in information technology and as an academic discipline in post-secondary education. As many new members join the information security community, it is important that the primary role of policy as the mechanism whereby an organization defines what is to be secured is clearly understood. Without sound policy as a foundation, policy constructed with the same care and attention to detail required by all parts of the information security mission, an organization is less likely to be successful in its mission to protect information assets.

KEY TERMS

Access Control List (ACL): A list of people or other entities permitted to access a computer resource.

Capability Table: Synonymous with capabilities table. A list that specifies data items or physical devices (for example printers) that users are authorized to access.

Defense in Depth: The multiple levels of security controls and safeguards that an intruder faces.

Enterprise Information Security Policy (EISP): A policy that sets the strategic direction, scope, and tone for all of an organization's security efforts.

Issue-Specific Security Policy (ISSP): Policies that provides detailed, targeted guidance to instruct all members of the organization in the use of technology-based systems.

Policy: A body of expectations that describe acceptable and unacceptable behaviors of employees in the workplace.

Standards: Detailed statements of actions that comply with policy.

Systems-Specific Security Policy: Policies codified as standards and procedures used when configuring or maintaining systems.

Innovation Link Between Organization Knowledge and Customer Knowledge

Helen Mitchell
Unitec, Auckland, New Zealand

INTRODUCTION

In 1959 Penrose referred to the importance of knowledge for using resources more innovatively and profitably, and in the same year Drucker indicated greater value should be placed on knowledge workers. An article by Nonaka (1991) suggested that the source of lasting competitive advantage is knowledge. Since then there has been a growing interest in knowledge, and an emerging view that the sharing of knowledge and creation of new knowledge leading to innovations is the key to providing future economic growth. In 1998, Amidon referred to the survey in 1996 produced by *The Economist* describing how rich economies will increasingly depend upon "their ability to innovate" (p. 24).

THE ORGANIZATION

At the corporate level it is important for organizations to recognize the value of knowledge. An environment accepting that knowledge sharing is the norm provides a conduit for the generation of innovations. Continuous innovation is necessary for survival in what is now a highly competitive global environment. Innovation springs from the knowledge within the organization. Corporate knowledge is accumulated through its systems and procedures, its databases and its technology, and from its employees sharing and applying their knowledge to the operational requirements of the business. The interaction of employees with external parties such as customers, suppliers, industry contacts and those residing in the wider community also provides a considerable source of knowledge for the organization.

Employees bring to an organization their individual knowledge bank gathered as a result of their education and experience of life. The longer they work in an organization, the more knowledge they accumulate about its operations, products and customers. Nonaka (1991) refers to the spiral of knowledge in the organization and says that knowledge begins with the individual. Taking this further, Inkpen (1996), when referring to the spiral of organizational knowledge creation, indicates the importance of moving knowledge from the level of the individual to group level and on upwards to organizational level.

It is perhaps worth taking cognizance of Davenport and Prusak (1998, p.108), who say, "Despite the corporate mantra that employee knowledge is a valuable resource, most firms do not make concerted efforts to cultivate the knowledge oriented activities of their personnel". Although knowledge comes from employees, Teece (1998, p. 62) indicates it is the organization that provides "the physical, social, and resource allocation structure so that knowledge can be shaped into competences". It is worth remembering that Drucker (1994, p. 71) said it is the knowledge workers who own the tools of production. Previously, "The industrial workers needed the capitalist infinitely more than the capitalist needed the industrial worker," but in the knowledge society organizations "…need knowledge workers far more than knowledge workers need them". It should be kept in mind that employees take their knowledge home with them each evening, and in some situations they may not return, thus depriving the organization of valuable knowledge. However, if it is recognized that employees have knowledge of value, then organizations need to maximize the benefit of that knowledge, and determine how to harness it to the advantage of the organization and the individual (Mitchell, 2002a).

When assessing the potential of knowledge, Carneiro (2000, p. 87) suggests organizations "…need to look for the knowledge that is able to add value. Value adding knowledge is very different to an information-mix." Lester (2001) also advises, "Managing knowledge is not like managing information, it involves focusing on, nurturing and winning the trust of the professional knowledge workers and the confidence of customers and suppliers" (p. 172). This means organizations need to look closely at encouraging a culture involving the development of good relationships based around trust, and in which knowledge is readily shared. Sharing knowledge increases the knowledge among those who share and adds value to the organization while at the same time making it difficult for competitors to copy.

It is, therefore, important for organizations to try to move the tacit knowledge of its employees into explicit knowledge to be embedded in the organization's knowledge repository for all to share. Codifying tacit knowledge is not easy, and all the knowledge the employee holds will never be captured. However, knowledge that can be codified becomes available for sharing with others in the organization. Knowledge sharing and creation of new knowledge emerges as a result of working in teams where problems that arise need to be resolved. Opportunities for social interaction should be encouraged – it is not unknown for useful knowledge to be exchanged in such an environment. While sharing knowledge for the benefit of the organization involves everyone, knowledge is also shared, wittingly, or unwittingly, with those external to it. This can present a two-edged sword. While knowledge can be lost, it can also be gained. However, from the knowledge of all those involved in the knowledge sharing process, along with the knowledge held within the structure of the organization, there emerges collective knowledge. Whether it is focused within the organization, or encompassing knowledge external to it, collective knowledge provides a catalyst for the development of innovations (Mitchell, 2002b).

THE ORGANIZATION AND INNOVATION

According to Kanter (1996, p. 94), "Structures and practices that may work well for the perpetuation of the known tend to be at odds with innovation." Creativity is a product of knowledge, and shared knowledge provides opportunities for organizations to be innovative – an important element for moving ahead (Mitchell, 2002b). Innovative organizations are growing organizations, with 3M being a classic example; therefore the organizational environment is important if innovation is to occur.

Amidon (1997) refers to Japanese firms placing customers at the heart of the innovation process. She goes on to say that innovation should be a strategic focus and to make a commitment to work with customers. Amidon provides a framework to assess the ability for organizations to develop ideas and take them to market. The innovation assessment encompasses 10 modules, identified as: collaborative process; performance measures; education/development; learning network; market positioning; products/services; market penetration; market image, leadership/leverage; technology/internet. For each module there are questions to be asked, and answered, and the model used views the organization from both an internal and external perspective. According to Amidon, executives who have followed the process have found creative ways of improving efficiency and effectiveness. Innovation is not solely dependent on new knowledge. Ideas emerge from unexpected sources and applying knowledge, recognizing potential and seeing opportunities is what brings innovative ideas to fruition (Mitchell, 2002d). As Drucker (1998) indicated, innovation needs knowledge, ingenuity and focus.

The view put forward by Johannessen, Olaisen, and Olsen (1999, p. 116) is that "Managers need to focus their attention on innovation. …create commitment…initiate change. To enhance innovation managers also need a high level of integrity. This means the ability to create trust …". Johannessen et al. identified the characteristics of people who manage the innovation process as being proactive in creating opportunities; willing to take risks; and goal setting. It is also necessary for managers to recognize the importance of innovation and its relationship with the knowledge of employees, its customers, suppliers and other external parties, and the need to promote an innovative culture.

However, management must thoroughly understand the level of knowledge, expertise, skills and competencies resident within the organization, and be able to identify what additional capabilities are needed if it is to successfully work for the development of innovations in a collaborative environment. Organizations that are aiming for success will maximize the benefit, for example, of cross-functional teams from which a montage of knowledge provides the opportunity for the creation of new knowledge from which new innovations can emerge. It may, therefore, be necessary for organizations to be prepared for changes arising from introducing an innovative environment that encourages closer working relationships with customers. No organization stands in isolation. Every organization is dependent upon and has responsibilities for its customers, suppliers, stakeholders and the wider community. There are real opportunities for organizations to effectively work together to become more innovative

The Organization, Innovation and Customer Relationships

"Customer loyalty is an asset" (Brooking, 1996, p. 26). Getting to know about customers – their needs, wants, expectations – is critical to the ongoing success of the company. Brooking identifies what she terms "Customer Audit Questions" that include: who are we selling to, why do those customers buy from us, who are repeat buyers, how do we monitor such events, and how often are customers contacted. Armed with such a knowledge base, the organization is in the position of being not only informed about its customers but also in a positive situation when interacting with them.

Research carried out in 1999 by Mitchell (2002c) found that organizations routinely increase their knowledge of customers in many ways, for example through the salesperson, credit cards, sales analysis, warranty cards, customer databases, surveys, and customer focus groups. However, many organizations do not give sufficient recognition to the importance of mining those sources for hidden gems of knowledge that could provide the means through which to enhance the potential of the business and at the same time more effectively meeting the needs of its customers. While knowledge about customers can be obtained through the organization's resources, more importantly it will come from associating closely with customers (Amidon, 1997; Byrne, 1993; Evans & Wurster, 1997; Fahey & Prusak, 1998; Kanter, 1996; Jordan & Jones, 1997; Teece, 1998).

Working collaboratively with a customer to jointly develop a product, or for the introduction of a new technology, brings benefits to both parties and there is a likely spin-off for other customers (Tidd, Bessant & Pavitt, 2002). Tidd et al. make reference to the approach taken by international energy and construction firms of having "policies of collaboration with customers overseas and source technologies from countries in which they wish to sell products" (p.178). Actively promoting a collaborative approach opens the way to being able to respond positively to opportunities as they arise.

Organizations working alongside customers on new products, or process innovation, or designing innovative solutions to meet specific needs, adds value to both the organization and its customers (Grant, 1997). Rowley (2002, p. 500) also supports the employee/customer connection: "Another rich seam of customer knowledge resides with the people who interact with the customer, whether they be the promoters of small business in B2B interacts or the service agent or retail assistant in B2C interactions." Suppliers to organizations must not be forgotten; after all, the organization is the suppliers' customer and there is much to gain from working collaboratively.

Research being undertaken by Mitchell in 2002/3 indicates that businesses are reaping benefits through working closely with customers. Some of those businesses have produced a number of innovative products, increased their intellectual property portfolio, and as a result of commercialization of those products have created increased wealth. Their customers are benefiting by gaining new and enhanced products. The following are some examples found by Mitchell of organizations successfully working collaboratively with customers:

A food manufacturing company that generates a number of ideas works closely with its customers and suppliers for all new products. A customer with an idea will put it to the company to assess its feasibility. One product the company is involved with was the result of such an approach and it has triggered a revolutionary method of production by the food company, resulting in a new product. The technological development was hailed as a breakthrough at an international trade fair, and has been welcomed by other companies involved in making similar products. An additional service provided by the company was the development of a document of agreement for its clients to protect their rights.

A packaging company worked alongside a customer to design a sophisticated system of packaging to prevent damage to a very delicate, perishable product. The success of the packaging has resulted in reducing damage claims to virtually zero. The customer is very satisfied, as are the customer's customers, and the packaging company developed technology that can be transferred to other products in its range.

Sales representatives working for an electronic products distributor keep a weekly log on feedback and suggestions and all suggestions are reviewed and followed up. A Web site has been developed for customer feedback. It was found that children, because of their interest in electronic games, give very good feedback and provide very good ideas. On the commercial side, customers will suggest specific types of software be developed to complement a product, or ask for the package to be designed as a mobile system.

Other benefits of working with customers are that they have considerable knowledge not only about an organization's products and how they are used, but also about the products of other suppliers. Observing how products are used provides valuable feedback that may instigate modifications, new customer solutions, or the customizing of products. It is also important to know what customers are thinking, and their rationale for changing to another supplier (Fahey & Prusak, 1998), and this is another reason to keep in close contact. Kanter (1996) suggests focusing on demanding customers. Difficult as these customers may be, it is a sensible approach as it is those customers who are likely to produce the greatest and most valuable knowledge, which may well lead to new innovations.

CONCLUSION

Without customers, organizations will not survive. As competition in the global market increases, the value of knowledge will become more important and working collaboratively with customers more critical. The future of organizations is dependent upon knowledge and the directing of it towards innovation. Organizations need to satisfy their customers, and their customers' customers. Linking the knowledge of the organization with the knowledge of the customer has the potential to lead to innovative activity opening up an avenue through which to combat competition while at the same time providing a sense of achievement and satisfaction to those involved.

KEY TERMS

Collective Knowledge: The knowledge of the organization, including the knowledge of its employees, customer/supplier and industry knowledge that can be actioned to bring about innovation.

Corporate Knowledge: The knowledge owned by an organization – its databases, technology, beliefs, culture, structure, processes and procedures. The organization has access to, but does not own, the knowledge of employees, and through research acquires knowledge of the external environment.

Explicit/Codified Knowledge: Knowledge that can be written down, for example a formula, policies and procedures, or a recipe, and readily available for sharing with others.

Innovation: Something new. It can be a product or a process and must provide benefit to the organization and to the advancement of society. An invention only becomes an innovation when it has become commercially successful.

Knowledge Sharing: Involves giving people some of the knowledge you have. It may be about how to do a particular job, where to find information, knowledge of a customer's products, and of industry developments.

Tacit Knowledge: Knowledge owned by the individual. It is personal and is developed through life experiences and education and is not readily shared or made explicit.

Innovations for Online Collaborative Learning in Mathematics

Rodney Nason
Queensland University of Technology, Australia

Earl Woodruff
OISE - University of Toronto, Canada

INTRODUCTION

The field of computer-supported collaborative learning (CSCL) has been growing in a number of areas and across a number of subjects (Koschmann, 1996; Koschmann, Hall, & Miyake, 2002; Wasson, Baggetun, Hoppe, & Ludvigsen, 2003). One of the most promising pedagogical advances, however, for online collaborative learning that has emerged in recent years is Scardamalia and Bereiter's (1996) notion of knowledge-building communities. Unfortunately, establishing and maintaining knowledge-building communities in CSCL environments such as Knowledge Forum® in the domain of mathematics has been found to be a rather intractable problem (Bereiter, 2002b; Nason, Brett, & Woodruff, 1996). In this chapter, we begin by identifying two major reasons why computer-supported knowledge-building communities in mathematics have been difficult to establish and maintain.

1. The inability of most "textbook" math problems to elicit ongoing discourse and other knowledge-building activity
2. Limitations inherent in most CSCL environments' math representational tools

Therefore, in this chapter, we argue that if mathematics education is to exploit the potentially powerful new ways of learning mathematics being provided by online knowledge-building communities, then the following innovations need to be designed and integrated into CSCL environments:

1. authentic mathematical problems that involve students in the production of mathematical models that can be discussed, critiqued, and improved, and
2. comprehension-modeling tools that (a) enable students to adequately represent mathematical problems and to translate within and across representation modes during problem solving, and (b) facilitate online student-student and teacher-student hypermedia-mediated discourse.

Both of the above innovations are directed at promoting and sustaining mathematical discourse. The requirement that the mathematical problems need to be authentic ensures that the students will have the contextual understanding necessary to promote a discussion about the mathematical models. Comprehension-modeling (Woodruff & Nason, 2003) further promotes the discourse by making student understanding yet an additional object for discussion.

Most textbook math problems do not require multiple cycles of designing, testing, and refining (Lesh & Doerr, in press), and therefore do not elicit the collaboration between people with special abilities that most authentic math problems elicit (Nason & Woodruff, 2004). Another factor that limits the potential of most textbook math problems for eliciting knowledge-building discourse is that the answers generated from textbook math problems do not provide students with much worth discussing (Bereiter, 2002b).

Another factor that has prevented most students from engaging in ongoing discourse and other mathematical knowledge-building activity within CSCL environments is the limitations inherent in their mathematical representational tools (Nason et al., 1996). Most of these tools are unable to carry out the crucial knowledge-building functions of (a) generating multiple representations of mathematical concepts, (b) linking the different representations, and (c) transmitting meaning, sense, and understanding.

Two clear implications can be derived from this review of the previous research. First is that different types of mathematical problems that have more in common with the authentic types of mathematical problems investigated by mathematics practitioners than most existing types of textbook math problems need to be designed and integrated into CSCL environments. Second, a new generation of iconic mathematical representation tools also needs to be designed and integrated into CSCL environments. In order to differentiate these tools from previous iconic math representation tools, we have labeled our new generation of tools as comprehension-modeling tools.

Each of these two issues will be discussed in the next two sections of this chapter.

AUTHENTIC MATH PROBLEMS

Credence for the viewpoint that the integration of more authentic types of mathematical problems into CSCL environments may lead to conditions necessary for the establishment and maintenance of knowledge-building activity is provided by the findings from two recent research studies conducted by the coauthors. Although both of these studies were situated within elementary schools, it should be noted that the same math problems used in these research studies could also be used within online CSCL environments to facilitate the development of mathematical subject-matter knowledge in high school students and preservice teacher-education students. Therefore, we believe that the findings from these two studies have much relevance for the establishment and maintenance of math knowledge-building communities not only in elementary schools, but also in secondary school and higher education institutions, too.

In a series of research studies, Nason, Woodruff, and Lesh have been investigating whether having students engage in model-eliciting mathematical problems with collective discourse mediated by Knowledge Forum would achieve authentic, sustained, and progressive online knowledge-building activity. In this section, we focus on two of these research studies.

In the first of the research studies (Nason & Woodruff, 2004), 21 students in a Grade-6 class at a private urban Canadian school for girls were asked to devise an alternative model that could be used for ranking nations' performance at the Olympic games that de-emphasized the mind-set of "gold or nothing." In the second research study (Nason, Woodruff, & Lesh, 2002), 22 students in another Grade-6 class at the same school were asked to build a model that could help rank Canadian cities in terms of quality of life.

In both studies, the students were initially presented with an article setting the scene for the model-eliciting activity and a set of focus questions based on the article. After this 45-minute warm-up activity, the students went through the phases of (a) initial model building (Phase 1, one session of 45 minutes), (b) sharing of initial models (Phase 2, one session of 45 minutes), and (c) iterative online critiquing and revision of models within Knowledge Forum (Phase 3, four sessions of 45 minutes). The sharing of the initial models in Phase 2 was done face to face within the classroom. After the face-to-face sharing of the initial models had been completed, each group attached their math model to a Knowledge Forum note where it could be viewed and evaluated by other participants within the online CSCL community. During the online critiquing and revision of models in Phase 3, Knowledge Forum provided the contexts and scaffolds for intergroup online discourse.

Five important elements of activity consistent with Scardamalia's (2002) principles of knowledge building were observed during the course of these two studies.

1. Redefinition of the problems, which highlights Scardamalia's principles of improvable ideas and rising above
2. Inventive use of mathematical tools, which highlights Scardamalia's principle of improvable ideas
3. Posing and exploration of conjectures, which highlights Scardamalia's principles of idea diversity and knowledge-building discourse
4. Collective pursuit of the understanding of key mathematical concepts, highlighting Scardamalia's principles of community knowledge and collective responsibility
5. Incremental improvement of mathematical models, which highlights Scardamalia's principle of improvable ideas

Much of the success in establishing and maintaining the online mathematics knowledge-building communities in these two studies can be attributed to the rich context for mathematical knowledge-building discourse provided by the model-eliciting problems. In both problems, students were required to produce a mathematical model for issues that the students found meaningful and relevant. Therefore, they were willing to proceed through multiple cycles of developing, evaluating, and revising their models. This process of proceeding through multiple cycles encouraged much online discourse between the groups in each classroom. The model-eliciting problems also had many different possible solutions. Because of this, there was much heterogeneity in the initial models produced by the groups of students. In order to understand other groups' models and also to explain their own model to other groups, each group had to engage in much iterative online discourse with other groups. During this discourse, they had to ask good questions, propose how other groups' models could be improved, and elaborate on and/or modify their explanations. Finally, the models themselves provided students with artifacts that could be discussed, evaluated, compared, and improved (just like the artifacts built by mathematics practitioners). Unlike the answers produced in most textbook problems that tend to only enable discourse about correctness (or incorrectness), the models produced from the model-eliciting problems were artifacts that could be evaluated

and discussed in terms of not only correct usage of mathematical concepts and processes, but also in terms of subjective, nonmathematical factors.

COMPREHENSION MODELING

Evidence to support the notion that the inclusion within a CSCL learning environment of comprehension-modeling tools can do much to facilitate knowledge-building discourse has been provided by research during the development of CHiLE (constructivist hypermedia interactive learning environment; Charles & Nason, 2000). CHiLE situates the learning of fractions in the context of a restaurant in which the children play the role of a waiter and are asked to partition and share out equal objects such as pizza and apple pies to customers sitting at the restaurant table (see Figure 1). The number of customers sitting at the table and the number of objects to be partitioned and shared can be varied. CHiLE provides the children with five different slicers (a knife-like tool) that enable objects to be cut in halves, thirds, fifths, sevenths, and ninths. With these slicers, the children can also create other fractions such as quarters (by halving the halves) and sixths (by halving the thirds).

CHiLE enables children to generate multiple representations of fraction problems and provides the iconic tools for facilitating synchronous hypermedia-mediated, knowledge-building, child-child and teacher-child discourse. CHiLE, however, has an added facility that enables teachers and children to also engage in online asynchronous knowledge-building discourse. With CHiLE, children are able to make an animated sequence of slides with accompanying text that not only enables them to communicate the solution to a fraction problem, but also the process (or model) that was used to generate the solution. CHiLE thus uses hypermedia as a way to animate and promote mathematical discourse: The strategy (or model) is reified on the screen via the iconic representation, the animation shows the “story,” and everything is recorded, thus promoting reflection and revisitation. This is illustrated below in a series of figures (see Figures 1 to 4) generated by two 8-year-old children who had been asked to share one pizza fairly between three people.

Nason and Woodruff (2004) have found that online knowledge-building discourse facilitated by CHiLE operates on two different levels. First, the discourse can occur at the global level and focus on the overall strategy (or model). For example, another group of students, when given the same problem as in Figure 1, decided to slice the pizza into sixths and give two sixths to each person. After looking at one another’s models, the two groups of students engaged in robust online debate about which

Figure 2. Early screen shot of students’ initial steps toward a solution

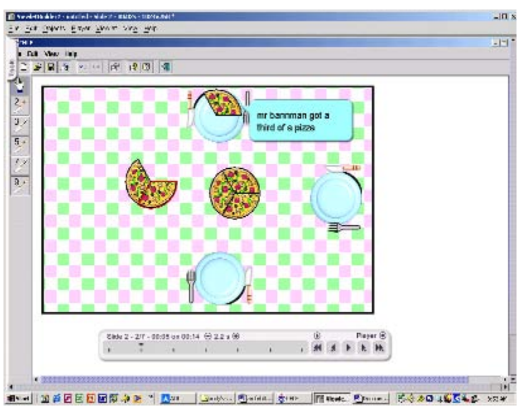

Figure 3. Screen shot midway toward a solution

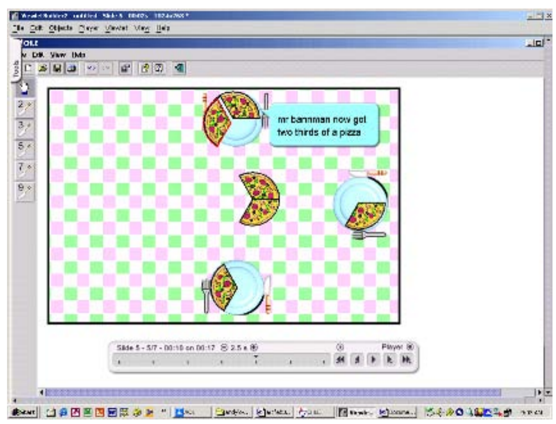

Figure 4. Screen shot of students' proposed solution

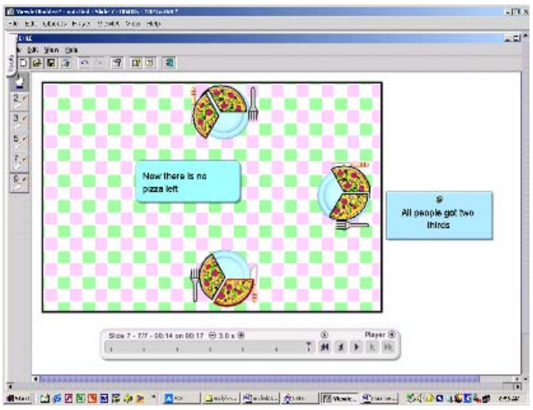

was the "better" strategy (and solution). During this debate, they were able to identify similarities and differences between the strategies, but more importantly, build conceptual links between thirds and sixths. Second, the discourse can occur at the language level. For example, there can be discourse about the best language to insert in a sequence of slides. This discourse often provides the contexts for the introduction of formal mathematical language as a more precise way of communicating meaning within mathematical contexts than natural language.

The hypermedia facilities provided by CHiLE enabled children to engage in online knowledge-building discourse synchronously and asynchronously via iconic, natural language, and/or mathematical language representations. CHiLE thus provided one of the most important dynamics that Scardamalia (2002) identified as being a technical determinant of knowledge building and knowledge advancement within online CSCL environments.

CHiLE also provided two other dynamics that Scardamalia indicated were technological determinants of knowledge building and knowledge advancement. First, there is her notion that computer technology should include facilities for bringing together different ideas in such a way that productive use can be made of diversity. The iconic tools provided by CHiLE met this criterion by enabling children to readily

1. generate diverse solutions and solution processes to the same mathematics problem, and
2. communicate both synchronously and asynchronously via the iconic models, natural and mathematical language, and mathematical symbols their diverse solutions and solution processes to others within the online learning community.
