Preface

The information technology revolution is for all practical purposes a second industrial revolution in the history of mankind, impacting every facet of business, society, and life worldwide with a speed beyond imagination. As in the case of the industrial revolution, the growth and expansion of information technology began during the early 1950s but continued on through the following decades. During the 1960s and ‘70s, computer technology was mainly utilized in business data processing and scientific applications of a mostly number crunching nature. As a result, the use of this technology was limited to those who had a good command of these systems and computer programming languages. With the merge of computers and telecommunications in the 1980s, a new information technology was born with a strong focus on the management and dissemination of information by both information providers and users. However, the advent of personal computers and the ability of users to communicate with each other regardless of their locations directed information technology into the lives of all society.

The most noticeable explosion in the information technology revolution was the creation of the World Wide Web (WWW) and its potential in the early 1990s. During the past two decades, WWW technologies have become the driving force in allowing people worldwide to communicate and exchange information in ways that have created a totally new dimension known as a virtual world. In recent years, through the use of web-enabled technologies, organizations of all types and sizes around the world have managed to utilize these technologies to conduct both information processing and dissemination with their prospective customers, suppliers, students, and governments. These technologies, now allowing readily available information for everyone regardless of their geographic location, bring the true meaning of the information age to its full realization.

In recent years, the science of understanding the nature of information processing and management combined with computer and telecommunication technologies to process, disseminate, and manage information has become known as “Information Science and Technology.” This new science includes many resources and components, including: 1) Type of Information; 2) Computer Hardware Technologies; 3) Computer Software Technologies; 4) Telecommunication Technologies; 5) Technology Applications; 7) Information Processing Systems Structures; 8) Systems Personnel and Management; 8) End Users; and 9) Management Skills and Programs (Khosrow-Pour & Yaverbaum, 1990).

Because information science and technology has profoundly impacted science, business, society, and every other aspect of life on our planet, numerous researchers around the world have focused on accumulating knowledge on this discipline. The volume and intensity of research in the field of information science and technology has by far exceeded many other fields of science, and the sheer impact of research discoveries in this area has become the driving force of many emerging technologies and applications. No longer is this discipline limited to a few technology-related areas, but, similar to the field of medicine, the field of information science and technology today is a collection of many specific disciplines researchers have created. This collection process has been accomplished by producing research results to understand the potentials, problems, and challenges of each individual discipline and by trying to expand the body of literature related to the topics of that discipline.

To access the latest research related to the many disciplines of the information science and technology field, I decided several years ago to launch an encyclopedia project where researchers from all over the world would assist me in providing the necessary coverage of each respective discipline in information science and technology. The primary objective of this project was to assemble as much research coverage related to the disciplines selected for this encyclopedia by defining the technologies, terms, and acronyms related to each discipline, and providing the most comprehensive list of research references related to each discipline. I had hopes of creating a single comprehensive reference source on all related discipline topics of information science and technology.

To provide the most comprehensive, in-depth, and recent coverage of information science and technology, disciplines carefully selected for this encyclopedia project included: Accounting Information Systems, Computing History, Database Management and Technologies, Data Warehousing and Mining, Decision Support Systems Technologies, Distance Education Technologies, E-collaboration, Electronic Commerce Technologies Management, End User Computing, Enterprise Resource Planning, Expert Systems, Geographical Information Systems, Global IT Management, Human Computer Interaction, Human Side of IT, Information Resources Management, Information Security Management, Information Systems Research, Information Technology Education, IT Evaluation Methods and Management, IT Management in Libraries, IT Management in Healthcare, IT in Small Business, IT Personnel, Professional IT Association, Intelligent Information Systems, Knowledge Management, Minorities in Information Technology, Mobile Computing and Commerce, Multimedia Information Management, Objected Oriented Technologies, Open Source Technologies and Systems, Social Responsibility in the Information Age, Software Engineering, Strategic IT Management, Telecommunications and Networking Technologies, Unified Modeling Languages and Unified Process, and Virtual Communities and IT.

In order to provide the best balanced coverage of concepts and issues related to the selected topics of this encyclopedia, researchers from around the world were asked to submit proposals describing their proposed coverage and the contribution of such coverage to the encyclopedia. All proposals were carefully reviewed by the editor-in-chief in light of their suitability, researcher's records of similar work in the area of the proposed topics, and the best proposal for topics with multiple proposals. The goal was to assemble the best minds in the information science and technology field from all over the world to contribute entries to the encyclopedia. Upon the receipt of full entry submissions, each submission was forwarded to at least three expert external reviewers on a double-blind, peer review basis. Only submissions with strong and favorable reviews were chosen as entries for this encyclopedia. In many cases submissions were sent back for several revisions prior to final acceptance.

As a result, this five-volume encyclopedia includes more than 550 entries highlighting current concepts, issues and emerging technologies. All entries are written by knowledgeable, distinguished scholars from many prominent research institutions around the world. Five thousand technical and managerial terms enhance these entries. These terms each have a 5-50 word description that allows the readers of this extensive research source to learn the language and terminology of the field. In addition, this five-volume set offers a thorough reference section with over 11,500 sources of additional information for scholars, students, and researchers in the field of information science and technology to access.

To assist readers in navigating and identifying needed information, this five-volume encyclopedia has been organized by listing all entries in alphabetical order by title throughout the five volumes, and by including the title in the regular "Table of Contents" in the beginning of each volume. Furthermore, all entries are organized under their prospective discipline/area and placed in a separate table of contents at the beginning of each volume. In addition, a comprehensive glossary of all terms will direct readers to the short definition on the subject. A keyword index is also available, listing important keywords included throughout all entries.

To keep up with emerging technologies and research discoveries, regular entry additions will be made to the online version of the encyclopedia. I am pleased to add that complimentary online access to this encyclopedia for the life of the edition will be provided to any library with the purchase of the print copy. This complimentary online availability will allow students, faculty, researchers, and corporate managers to access the latest contents of this comprehensive and in-depth encyclopedia regardless of their location. This particular feature will prove to be an extremely valuable resource for distance learning educational programs worldwide.

The diverse and comprehensive coverage of multiple disciplines in the field of information science and technology in this five-volume authoritative encyclopedia will contribute to a better understanding all topics, research, and discoveries in this evolving, significant field of study. Furthermore, the contributions included in this encyclopedia will be instrumental in the expansion of the body of knowledge in this vast field. The coverage of this five-volume encyclopedia provides strength to this reference resource for both information science and technology researchers and also decision makers in obtaining a greater understanding of the concepts, issues, problems, trends, challenges and opportunities related to this field of study. It is my sincere hope that this publication and its vast amount of information and research will assist my research colleagues, all faculty, their students, and our organizational decision makers in enhancing their understanding of this discipline. Perhaps this publication will even inspire its readers to contribute to the current discoveries in this immense field, tapping possibilities to assist humankind in making the world a better place to live for all inhabitants of this universe.

Acknowledgements

Putting together a comprehensive publication of this magnitude requires a tremendous contribution and much assistance from everyone involved. The most important goal of editing this encyclopedia, as with most publications, was identifying and selecting quality contributions. This goal could not have been achieved without the valuable contributions of more than 1,000 external reviewers who have provided me with their expert, rigorous, unbiased blind review and assessment of the manuscripts assigned to them. I am extremely grateful for their contribution to this publication. I am also indebted to all the authors for their excellent contributions. I would also like to express my gratitude and deep appreciation to the members of the Editorial Advisory Board of this publication for their wisdom, guidance, and assistance in deciding on different issues of this publication.

In terms of editorial assistance, I would like to convey my deep appreciation and gratefulness to Idea Group Reference Senior Managing Editor, Ms. Jan Travers, for all her wisdom and encouragement, Ms. Mandy Appicello, Managing Editor, for her countless attention to detail and keeping this project on schedule, and Ms. Renee Davies, Assistant Acquisitions Editor, for her immeasurable assistance during the review process. I would like to express my many thanks to Ms. Sara Reed, Editorial Assistant, Ms. Michelle Potter, Editorial Assistant, Ms. Rachel Shepherd, Editorial Assistant, numerous copy editors, particularly Ms. Ingrid Widitz, and Ms. Lisa Tosheff, Graphic Artist, for their involvement and assistance with this publication. My warmest thanks go to my wife, Beth Peiffer, for her support, wisdom, encouragement, understanding, patience, and love. My heart also goes to my two young girls, Basha and Anar, for the joys that they have brought to my life. Finally, much gratitude goes to all those who have taught me immeasurable amounts during the past three decades.

Mehdi Khosrow-Pour, D.B.A.
Editor-In-Chief

About the Editor

Mehdi Khosrow-Pour, D.B.A. is currently the Executive Director of the Information Resources Management Association (IRMA) and Senior Academic Editor for Idea Group Reference. Previously, he served on the faculty of the Pennsylvania State University as an Associate Professor of Information Systems for twenty years. He has written or edited over twenty books in Information Technology Management, and he is also the editor of the Information Resources Management Journal, Journal of Electronic Commerce in Organizations, Journal of Cases on Information Technology, and International Journal of Cases on Electronic Commerce.

A Duplicate Chinese Document Image Retrieval System

INTRODUCTION

An optical character recognition (OCR) system enables a user to feed an article directly into an electronic computer file and translate the optically scanned bitmaps of text characters into machine-readable codes; that is, ASCII, Chinese GB, as well as Big5 codes, and then edits it by using a word processor. OCR is hence being employed by libraries to digitize and preserve their holdings. Billions of letters are sorted every day by OCR machines, which can considerably speed up mail delivery.

The techniques of OCR can be divided into two approaches: template matching and structure analysis (Mori, Suen & Yamamoto, 1992). The template matching approach is to reduce the complexity of matching by projecting from two-dimensional information onto one; the structure analysis approach is to analyze the variation of shapes of characters. The template matching approach is only suitable for recognizing printed characters; however, the structure analysis approach can be applied to recognize handwritten characters.

Several OCR techniques have been proposed, based on statistical, matching, transform and shape features (Abdelazim & Hashish, 1989; Papamarkos, Spilioties & Zoumadakis, 1994). Recently, integrated OCR systems have been proposed, and they take advantage of specific character-driven hardware implementations (Pereira & Bourbakis, 1995). OCR generally involves four discrete processes (Khoubyari & Hull, 1996; Liu, Tang & Suen, 1997; Wang, Fan & Wu, 1997):

1. separate the text and the image blocks; then finds columns, paragraphs, text lines, words, and characters;
2. extract the features of characters, and compare their features with a set of rules that can distinguish each character/font from others;
3. correct the incorrect words by using spell checking tools; and
4. translate each symbol into a machine-readable code.

The duplicate document image retrieval (DDIR) system transforms document formatted data into document images, then stores these images and their corresponding features in a database for the purpose of data backup. The document images are called duplicate document images. When retrieving a duplicate document image from the database, users input the first several text lines of the original document into the system to create a query document image. Then the system figures out the features of the image, and transmits to the users the duplicate document image whose image features are similar to those of the query document image (Nagy & Xu, 1997).

Some approaches have been proposed for the DDIR system. Doermann, Li, and Kia (1997) classified and encoded character types according to the condition that four base lines cross each text line, and uses the codes as the feature of the document image. Caprari (2000) extracted a small region from one document, assigned this region to the template (signature generation), and then scanned this template over a search area in another document. If the template also appears in the second document (signature matching), the two documents are classified as duplicates. Angelina, Yasser, and Essam (2000) transformed a scanned form into a frameset composed of a number of cells. The maximal grid encompassing all of the horizontal and vertical lines in the form is generated; meanwhile, the number of cells in the frameset, where each cell was created by the maximal grid, was calculated. Additionally, an algorithm for similarity matching of document framesets based on their grid representations is proposed too. Peng, Long, Chi, and Siu (2001) used the size of each component block containing a paragraph text image in a duplicate document image and its relative location as the features of the duplicate document image.

The approaches mentioned previously are only suitable for stating the characteristics of an English document image. The characteristics of Chinese characters are quite different from those of English ones, and the strokes and shapes of Chinese characters are much more complicated than those of English characters. Chan, Chen, and Ho (2003) provided a line segment feature to represent a character image block and presented a duplicate Chinese document image retrieval (DCDIR) system based on this feature. The purpose of this short article is to give a brief overview of the duplicate Chinese DDIR systems.

BACKGROUND

Traditional information retrieval methods use keywords for textual databases. However, it is difficult to describe an image using exact information, and defining manually keywords is tedious or even impossible for a large image database. Moreover, some non-text components cannot be represented in a converted form without sufficient accuracy. One solution is to convert a document into digital images; meanwhile, some methods are applied to extract the features of the images. Based on the feature, some document images with database satisfying query requirements are returned.

A duplicate document image retrieval (DDIR) system has to own the following properties (Doermann, Li, & Kia, 1997):

- **Robust:** The features should be reliably extracted even when the document becomes degraded.
- **Unique:** The extracted features can distinguish each document image from others.
- **Compact:** The storage capacity required to hold the features should be as small as possible.
- **Fast:** The system needs a quick response with an answer to the query.
- **Scalable:** As more documents are processed, the size of the database could grow to tens of millions.
- **Accurate:** The system should accurately response with an answer, which satisfies the query requirement.

Unfortunately, many DDIR systems are vulnerable to poor qualities of document images, such as the scale, translation, rotation, and noise variants. Because of different resolution setup of a scanner, the same image may be scanned to become two images with different sizes. We call this phenomenon the scale variant. When an image is added with a great amount of noises, it may be regarded as a different image from the original one. It is named a noise variant image of the original one. In a particular document, images with rotation and translation variants may be generated owing to placing the document on different orientation angles or on different positions on a scanner. The variants mentioned previously will cause many troubles in feature extracting and image matching stages. They should be removed in advance.

A CHINESE DDIR SYSTEM

Many techniques about the DDIR system have been proposed (Caprari, 2000; Doermann, Li, & Kia, 1997; Peng, Chi, Siu, & Long, 2000; Peng, Long, Chi, & Siu, 2001). Since an English document mostly consists of approximately **70** commonly-used characters which contain **52** uppercase as well as lowercase English letters and punctuation marks, the classification and encoding procedure based on the feature of these characters' font types are possible. However, these techniques are only suitable for duplicate English document images, but not for duplicate Chinese document image retrieval (DCDIR) because the number of different Chinese characters is about **45,000**. What is more, the shapes of Chinese characters are complex, and many different characters have similar shapes to each other. Hence, there are several major problems with Chinese character recognition, that is, Chinese characters are distinct and ideographic, the size of a character is large, and there exist many structurally similar characters (Amin & Singh, 1996; Chan, Chen, & Ho, 2003).

It is necessary to develop a feature offering an excellent identification capability to classify Chinese characters by only using a little extra memory space. To reduce the extra memory space, it is feasible to segment a duplicate document image into blocks, each of which contains a set of adjacent characters, and then to extract the features from the blocks. Since the number of the blocks in a duplicate document image is much smaller than that of the characters in an identical duplicate document image, the feature dimensions are reduced greatly; however, its identification capability is lessened.

I. DCDIR System

The proposed duplicate document image retrieval system approximately includes three parts — image preprocessing, database creation, and document retrieval. This section will introduce these three parts in details.

A. Image Preprocessing

When scanning a document to generate a duplicate document binary image, the position of the document on the scanner may be misplaced so that the duplicate document image may become inclined. Figure 1(a) shows an original image and Figure 1(b) is its duplicate document image that appears inclined. The inclined condition of a document image may lead to inconvenience to users and cause the errors in extracting its image features. Peng et al. (2000) used a correlation-based method to detect the inclination of an image, and then applied an interpolation technique to turn the image back according to the detected inclination. The DCDIR system will use this technique to turn the inclined document image back. Figure 1(c) is the duplicate document image after adjusting the inclination.

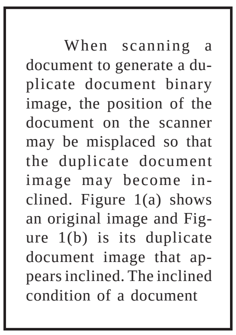
As in Figure 1(c), after turning back the duplicate document image, the frame of the duplicate document image will become inclined. It is necessary to cut off the border blank of the document image. While removing the border blank, the system starts scanning the duplicate document image from the left-top pixel. Then, in the order from left to right and top to bottom, each pixel is scanned until one certain black pixel ***P*** is found. Finally, all pixels locating on the lines, which are prior to the line containing ***P*** are removed to cut off the top border blank of the document image. By using the same method, the bottom, left, and right border blanks of the document image are removed as well. Figure 1(d) demonstrates the final duplicate document image after cutting off the border blanks of the document image as illustrated in Figure 1(c).

B. Database Creation

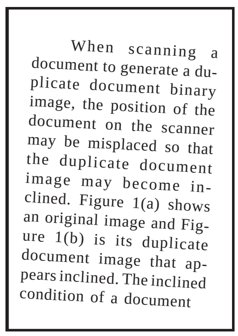
After that, the DCDIR system extracts the character image features from the duplicate document image ***I*** in which its border blanks have been cut off and the system stores the features in the database. Before extracting the character image features of ***I***, the system first performs the text line segmentation on ***I*** to make every line image

Figure 1. Normalization of an inclined document image

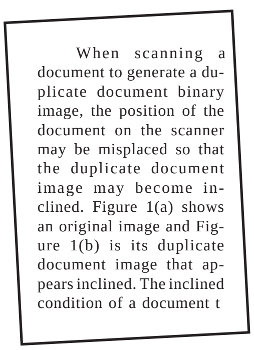
(a) Original document



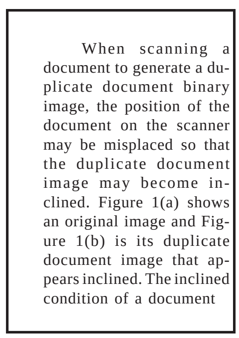
(b) Duplicate document image after scanning



(c) Duplicate document image after inclination adjusting



(d) Duplicate document image after cutting off the border blanks



block contain only the complete image of one certain line text in the original document. Then, the system segments out all character image blocks from each previously segmented line image block so that every character image block contains only one Chinese character. Finally, the feature of each character image block is then extracted.

Concerning the steps of segmenting line image blocks from a duplicate document image, first, all of the black pixels in the duplicate document image are projected in horizontal direction onto a projection vertical axis. The length of a black section on the projection vertical axis is just the height of the corresponding text line containing those character images whose black pixels are projected onto the black section.

Next, all of the black pixels in every line image block is projected in vertical direction onto a certain projection horizontal axis. In this case, the distribution borders of the black pixels and the white pixels on the projection horizontal axis are the locations of the left and the right boundaries of the character image blocks. On the projection horizontal axis, the length of a black section is just the width of the corresponding character image block whose black pixels are projected onto the black section.

The sizes of most Chinese characters are close. When the height of a certain character image block ***CB*** is smaller than three-fourths of the average height of all character image blocks in the document image, and the width of ***CB*** is also smaller than three-fourths of the average width of all character image blocks, the system will then regard the character in ***CB*** as a noise, and then remove it.

After that, three horizontal scanning lines are drawn on each character image block. These three horizontal scanning lines are respectively located at $1/4\times H$, $2/4\times H$ and $3/4\times H$ character heights in the block. Here H represents the height of the character image block. According to the ratio of the total number of the black pixels to that of the white pixels, which the scanning line goes through, an encoding process is executed to reduce the memory space required to store the feature of the character image block. The way of encoding is shown as follows:

$$X_i = \begin{cases} 0, \text{ if } D_{i,b} \times m > D_{i,w} \\ 1, \text{ if } D_{i,b} \times m \le D_{i,w} \end{cases}, \text{ for } i = 0, 1, \text{ and } 2.$$

In this equation, $D_{i,w}$ and $D_{i,b}$ are respectively the total numbers of the white pixels and the black pixels that the i-th scanning line passes through, and m is the weight (a given constant value) for the ratio from the total numbers of the black pixels and the white pixels on the scanning line. Thus, each character image block can be represented by a three-bit ($X_0X_1X_2$) code; we name the code the feature code of the character image block. There are ***8*** different binary codes ***000***, ***001***, ***010***, ***011***, ***100***, ***101***, ***110***, and ***111*** corresponding to decimal feature codes ***0, 1, …,*** and ***7*** respectively.

Because the resolution setup of a scanner may be different, the same original document may be scanned to become duplicate document images of different sizes. This proposed feature adopts the ratio from the number of black pixels and white pixels, so the feature encoding will not be affected due to the scale variant of images. Moreover, the desired duplicate document image and the query document image are both from the same original document. Therefore, the problem that the font type and style of the characters in the query document are different from those in the desired duplicate document image will not occur in this system.

C. Document Retrieval

Let $Q = q_1q_2\ldots q_l$ be the feature code of query document image I_q, and the length of the feature code be l. Next, the system extracts the first feature codes with the length l from every duplicate document image I_d in the database. Let the extracted feature codes be $D = d_1d_2\ldots d_l$. Then, the system compares the corresponding bit pair q_i and d_i between Q and D from left to right, respectively. When $q_i = d_i$, the system adds ***1*** to the value of S. The final value of S is the similarity between I_q and I_d. Finally, the duplicate document image with the largest similarity value is found out.

II. Experiments

Experiment 1 is to explore the constant weight m. As for different values of m, the character image blocks of ***5401*** in commonly used Chinese characters among Big5 codes, are categorized into eight groups each of which corresponds to one feature code. Table 1 shows the number of members in each group for $m = 2, 3$, and 4, where σ_c^2 is the variance of the number of members of the eight groups. The experimental results shows that when $m = 3$, σ_c^2 is minimal. This means, when $m = 3$, all Chinese character image blocks are most uniformly mapped to various kinds of feature codes. The next experiment will set $m = 3$.

Experiment 2 is to investigate the performance of the DCDIR system. This experiment scans each page of the book "朝花夕拾、吶喊" with ***336*** sheets to become images by a scanner. This experiment rescans ***101*** sheets of the book to generate the query document images. Here, the first L text lines of the ***101*** document sheets are respectively used as the contents of the query document images. Table 2 shows the experimental results. The average searching time is approximately ***8*** seconds for each query.

Table 1. Results of the first experiment

Feature code \ m	2	3	4
000	372	1253	2266
001	596	773	763
010	262	387	402
011	813	525	312
100	337	564	628
101	817	591	324
110	390	374	262
111	1798	918	428
σ_c^2	220549	74523	387785

FUTURE TRENDS

After a paper document is used over a long period, the document may be stained or worn out, so that its contents may be indistinct. How to develop an effective image feature insensitive to the rotation, scale, translation, and noise variations is an important task in the future. Many documents are printed or handwritten texts, are multilingual, or are composed of basic composition style and font for text. A future document image indexing method should own the robustness of the above variants.

Moreover, the following topics have been explored, and will continue to be researched. The first is to find or to match the instances of a document image with known content in a database. The techniques can be applied to maintaining database integrity by eliminating duplicates and retrieval itself. The second is to index image captions and to establish a relationship between the content and the images they describe. Then the caption can be a valuable tool of their duplicate document images. Ideally, a duplicate detection algorithm can find both exact duplicates which have just the same content, and partial duplicates, which have a large percentage of their text in common. Locating exact duplicates could reduce the storage required for a large database. Finding partial duplicates will allow users to easily find other versions of a given document.

KEY TERMS

Character Segmentation: The technique that partitions images of lines or words into individual characters.

Content-Based Image Retrieval (CBIR): The technique of image retrieval based on the features automatically extracted from the images themselves.

Duplicate Document Detection: The technique to find the exact duplicates, which have exactly the same content, or partial duplicates which have a large percentage of their text in common.

Duplicate Document Image Retrieval (DDIR): A system for finding the image-formatted duplicate of documents from a database.

MFU: Most frequently used characters in a character set with enormous members.

Optical Character Recognition (OCR): The technique of automatically translating the content of an image formatted document into text-formatted materials.

Skew Correction: The technology detects and compensates for the inclination angle of a document image.

Template Matching: The approach involves designing template masks, which are capable of detecting incidences of the relevant feature at different orientations.

A Language/Action Based Approach to Information Modelling

Paul Johannesson
Stockholm University/Royal Institute of Technology, Sweden

INTRODUCTION

There are several different views of the role of information systems. Two of the most important are the data view and the communicative view. According to the data view, the primary purpose of an information system is to provide a model of a domain, thereby enabling people to obtain information about reality by studying the model. In this respect, an information system works as a repository of data that reflects the structure and behaviour of an enterprise, and the system provides data that can be used for decisions about the enterprise. In contrast, the communicative view states that the major role of an information system is to support communication within and between organisations by structuring and coordinating the actions performed by organisational agents. The system is seen as a medium through which people can perform social actions, such as stating facts, making promises, and giving orders.

The data and communicative views of information systems are mirrored by two different views of organisations: the functional view and the constructional view (Dietz, 2003a). The functional view focuses on the functions of an organisation with respect to its environment, in particular, the resources that the organisation consumes and produces. A model of an organisation from a functional perspective is a black-box model, as it shows the interactions with the environment but not the internal mechanisms. The constructional view, on the other hand, focuses on how behaviour and function are brought about by the operations and structure of an organisation. A model of an organisation from a constructional perspective is a white-box model as it shows the inner workings of the organisation.

In information systems design, the starting point has often been based on the data view and the functional view, though frequently augmented by concepts like reasoning and monitoring. However, these views easily lead to a computer- and technology-biased management of the communication taking place in an organisation, and they benefit from being complemented by the communicative and constructional views. A promising theoretical foundation for these views is the language/action approach, which is based on theories from linguistics and the philosophy of language. In the language/action approach, business actions are modelled on the notions of speech acts and discourses, which provide a basis for distinguishing between different communication phases, such as preparation, negotiation, and acceptance. The purpose of this chapter is to outline how the language/action approach can be used as a basis for the information modelling of communicative aspects in organisations.

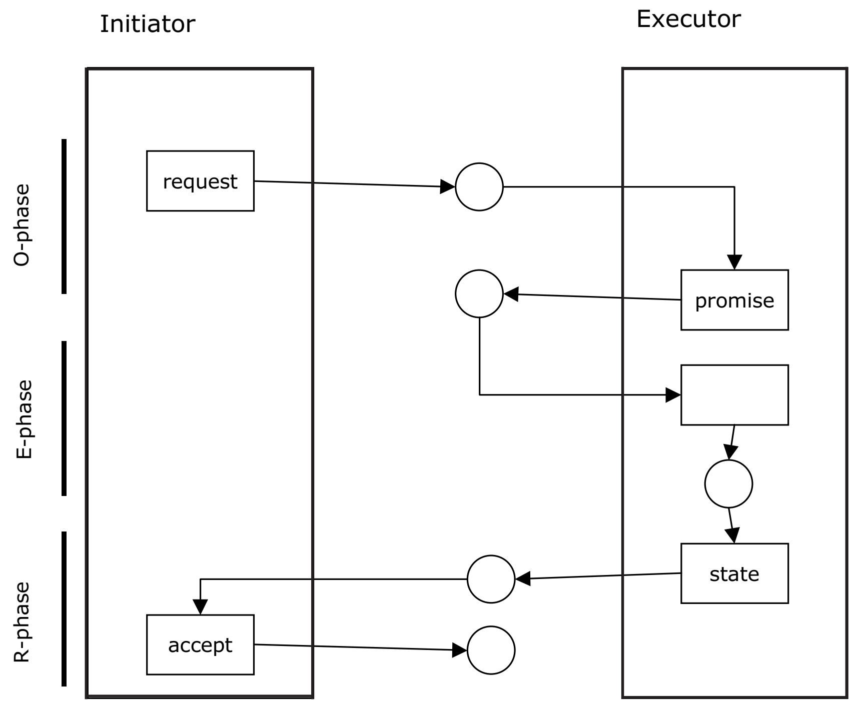
BACKGROUND

One important foundation of the language/action approach is speech act theory (Austin, 1962; Searle, 1969). The basic insight of speech act theory is that language can serve purposes other than that of representing the states of affairs of the world. Certain statements are equivalent to actions. For example, when someone says "I apologise," "I promise…," or "I name this ship…," the utterance changes the psychological or social reality. Statements such as these are called *speech acts*, and they enable people to use language as a means for acting as well as coordinating action.

In Searle (1969), a classification of speech acts is proposed based upon the way in which a speech act affects the social world. Searle identified five classes: assertive, commissive, directive, declarative, and expressive. An *assertive* is a speech act, the purpose of which is to convey information from a speaker to a hearer, e.g., "the cat is on the mat." A *commissive* is a speech act, the purpose of which is to commit the speaker to carry out some action or bring about some state of affairs, e.g., "I promise to bring it back." A *directive* is a speech act, where the speaker requests that the hearer carry out some action or bring about some state of affairs, e.g., "Please bring me the salt." A *declarative* is a speech act, where the speaker brings about some state of affairs by the mere performance of the speech act, e.g., "I hereby baptise you Samuel." An *expressive* is a speech act, the purpose of which is to express the speaker's attitude, e.g., "I like coffee."

In order to understand the role of speech acts, it is helpful to view human communication as taking place in three different worlds:

Figure 1. OER pattern



- The physical world—In this world, people carry out message actions. They utter sounds, wave their hands, send electronic messages, etc. Furthermore, other instrumental acts may take place in the physical world, such as repairing equipment.
- The communicative world—In this world, people express their intentions and feelings. They tell other people what they know and try to influence the behaviour of others through communication, i.e., they perform speech acts. These speech acts are brought about by means of message actions in the physical world. Note that a message action does not need to be verbal, as it can also be expressed by body language.
- The social world—In this world, people change the social and institutional relationships among them. For example, people become married or acquire possession of property. People perform such social actions by performing speech acts in the communicative world.

LANGUAGE/ACTION FOR BUSINESS PROCESS MANAGEMENT

The most important applications of the language/action approach have been made in the area of business process management (Lehtinen, 1986; Weigand, 2003). A language/action perspective provides a clear and well-founded basis for identifying and modelling recurring patterns in business processes. One such pattern is the order–execution–result (OER) pattern (Dietz, 2003b), which models a basic form of interaction that occurs in every business process (Figure 1). The interaction takes place between two parties—the initiator and the executor—and governs how they coordinate their actions. The interaction starts in the order phase by the initiator making a directive speech act, namely, a request to carry out some action (shown by a rectangle), which results in a state (shown by a circle in Figure 1), where there is an order from the initiator to the executor. The executor accepts the order by performing a commissive speech act (a rectangle labelled "promise" in Figure 1), resulting in a state where there is a commitment for the executor to carry out the action. This concludes the order phase, which is followed by the execution phase, where the executor actually performs the action (shown by an unlabelled rectangle in Figure 1) he or she is committed to. This action may be an instrumental action, e.g., delivering a package, or a declarative speech act, e.g., grading an exam. However, the execution phase is always concluded by a declarative speech act, where the executor states that he or she has carried out the committed action. The final phase is the result phase, where the initiator performs a declarative speech act and acknowledges that the executor has carried out the requested action in a satisfactory way.

The pattern introduced above shows the success path, where the initiator and executor agree to each other's actions. However, the pattern needs to be extended to handle cases where the parties do not agree, e.g., when the initiator does not accept the result of the execution phase. Larger business processes are typically built up by combinations of the OER pattern, e.g., when three or more parties are involved in a process or when reciprocal commitments are created in the process. The latter case occurs, for example, in e-commerce, as discussed in Lind (1997, 2003). Several variants of the OER pattern have been proposed in the literature, e.g., the conversation for basic action in Winograd (1986).

FUTURE TRENDS

The language action approach influenced another recent trend in the information systems community, agent-oriented information systems (AOIS Workshops, 2004). The language/action approach can be seen as one of the most active traditions within agent-oriented information systems. Agent concepts offer high-level abstractions addressing issues such as knowledge representation, communication, coordination, and cooperation among heterogeneous and autonomous parties. One precursor of agent-oriented information systems was the REA framework (McCarthy, 1982), which was designed for representing and reasoning about economic exchanges. The basic REA pattern models an exchange by three components: the *events* of the exchange, the *resources* that are exchanged, and the participating *agents*. In order to obtain a resource, an agent must give up some other resource. Therefore, an economic exchange always consists of two corresponding events, e.g., a purchase and a payment. Extended versions of the REA pattern also include commitments that are established, where a commitment is an obligation to perform a resource transfer some time in the future. These commitments are created through applications of the OER patterns.

One of the most comprehensive approaches to agent-oriented information systems is agent-object-relationship (AOR; Wagner, 2003), which is based on the notions of agents, events, actions, claims, and commitments. These notions form the basis for a general meta-model that can be used as a foundation for any information system. Another related work is that by Weigand et al. (1998), which proposes a layered architecture for information systems. At the lowest layer, we find the elementary acts—speech acts as well as instrumental acts. The next layer contains the business transactions. A business transaction is the smallest sequence of speech acts that results in a new deontic state, i.e., a state in which an obligation to carry out some action has been created, or a state where an authorisation for certain actions has been established, or a state where some action has been accomplished so that a previous obligation has become fulfilled. A single speech act is, in most cases, not sufficient to achieve a deontic effect. In general, at least two messages are required. For example, a customer requests that a supplier deliver a product, and the supplier promises to do so. These speech acts will result in two obligations: one for the supplier to deliver and one for the customer to pay upon delivery. The top layer is the workflow level, where a workflow is a set of linked business transactions that realise a business objective within an organisational structure.

CONCLUSION

The language/action approach to information modelling and systems provides a solid theoretical framework for analysing and designing communicative action in organisations. One foundation of the language/action approach is speech act theory, which investigates how language can be used to perform actions. The main application of the language/action approach has been in the area of business process design and management, where the approach can assist in creating complete and well-functioning processes. A recent trend is to apply the language/action approach for agent-oriented information systems, including applications to e-commerce and e-business (Bergholtz, 2003).

KEY TERMS

Business Process: This is comprised of business transactions that realise a business objective.

Business Transaction: This consists of speech acts that result in a deontic effect.

Deontic Effect: This is the establishment of an obligation or the fulfilment of an obligation.

Information System: This is a system for supporting communication within and between organisations.

Instrumental Act: This is an act performed in order to change the physical world.

OER Pattern: This is a basic pattern for business interaction based on order–execution–result phases.

Speech Act: This is a linguistic act performed with the intention of changing the social relationships between agents, in particular, creating deontic effects.

A Primer on E-Government

Shannon Howle Schelin
University of North Carolina at Chapel Hill, USA

OVERVIEW

E-government (electronic government) has become a mainstay in local, state, and federal government. The era of e-commerce and e-business began with the widespread adoption of the Internet in the mid-1990s and today many citizens expect the same responsiveness and access to government services as found in the private sector. According to the 2002 International City/County Managers Association e-government survey, over 73 percent of municipalities with populations larger than 2,500 have Web sites. The 2002 Pew Internet and American Life Project indicates that 58 percent (68 million people) of American Internet users have accessed at least one governmental Web site (Larson and Rainie, 2002).

Although there is widespread interest in the topic, e-government lacks a consistent, widely accepted definition. It is often related to revolutionizing the business of government through the use of information technology (IT), particularly Web-based technologies, which improve internal and external processes, efficiencies, and service delivery. The American Society for Public Administration (ASPA) and United Nations Division for Public Economics and Public Administration (UNDPEPA) have defined e-government as "utilizing the Internet and the World Wide Web for delivering government information and services to citizens" (UN & ASPA, 2001, p. 1). Based on this working definition of e-government, this article seeks to examine the historical premises and typologies of e-government.

HISTORICAL PREMISES

E-government has evolved from the information technology revolution. Information technology enables new methods of production, increases the flow and accuracy of information, and even may replace traditional standard operating procedures (Landsbergen & Wolken, 2001). Information technology in government has long been acknowledged as a method for improving efficiency and communication (Kraemer & King, 1977; Norris & Kraemer, 1996). Now, IT developments such as electronic mail (e-mail) have changed interpersonal communications to eliminate the constraints of geography, space, and time with profound organizational consequences (Rahm, 1999). The ability to buy and sell goods and services via the Internet has led to new private sector industries, constituting a new business model that the public sector now seeks to emulate. In addition, IT has promoted globalization, which also changes the environment within which public agencies function (Kettl, 2001).

The main concerns of e-government focus not only on the electronic dissemination of public information arising from traditional agency functions, but even more on reinventing agency processes to fully exploit the potential of information technology. As Fountain (2001) has noted, the reinvention process requires overcoming the rigidities and limits of traditional bureaucratic forms. Specific objectives may include the centralization of public data and the improvement of internal processes and communications (Alexander & Grubbs, 1998).

One of the first comprehensive visions of e-government is found in the 1993 National Performance Review report, *Creating a Government that Works Better and Costs Less: Reengineering Through Information Technology* (Gore, 1993; Kim & Wolff, 1994). This report laid the groundwork for new customer- and client-oriented ways for agencies to engage citizens via technology, involving both improved agency processes and improved methods of delivery. Most reinventing government literature has cited the need to rely on information technology to improve citizen-centric government services (Gore, 1993; Osborne & Gaebler, 1992). Although the reinventing government and e-government movements are related, the prospects are that the focus of public administration on e-government will endure for the foreseeable future, outlasting the reinventing government movement.

The 1995 amendment of the 1980 Paperwork Reduction Act (PRA) was another important milestone in the history of e-government. This amendment offered specific policies on issues associated with managing electronic information, including the establishment of standards, mandates for cross-agency information technology initiatives, and technology investment guidelines (Relyea, 2001). By outlining guidelines for information technology, the amended PRA solidified the government's commitment to improving citizen services via new channels based on technology.

The 1996 Electronic Freedom of Information Act (EFOIA) amendments added a new level of clarity to the issue of electronic records. This amendment extended the right of citizens to access executive agency records to include access to electronic formats and online information (Relyea, 2001). EFOIA also extended the time limits from 10 to 20 days to prohibit the use of agency backlogs as an excuse for noncompliance with information requests (Hammitt, 1999).

The 1996 Clinger-Cohen Act further heightened the role of information technology in government. It established a chief information officer (CIO) in every agency, making agencies responsible for developing an IT plan. Later, as the e-government movement gained momentum, the existence of the CIO strategic planning structure was an important element facilitating e-government implementation at the federal level.

Also in 1996, Congress passed the Personal Responsibility and Work Opportunity Reconciliation Act (PRWORA). This act, also known as the Welfare Reform Act, represented one of the first national pushes to incorporate the rhetoric of e-government with the routine services of agencies, specifically the administration of Temporary Aid to Needy Families (TANF). The act required interagency, interstate, and intergovernmental coordination of information technology systems to ensure that no individual exceeded the allotted five-year lifetime cap on assistance (Scavo & Shi, 2000).

In July 1996, President Clinton issued Executive Order 13011, which sought to improve management of information technology at the federal level. It also provided broad support for coordinated approaches to technology application in the executive office (Relyea, 2001). Although this executive order mandated implementation of and adherence to the PRA Act and the Clinger-Cohen Act, it also focused on the alignment of technology goals with strategic organizational goals. The support for interagency coordination of technology is codified in Executive Order 13011. Mandated goal-alignment and technology-investment reviews are included in the directive as a method for reducing the failure rates and cost overruns associated with federal technology initiatives.

More recently, in 2001 the E-Government Act was offered for consideration in the U.S. Senate. This act, approved by the Senate in June 2002, mandated the establishment of an e-government administrator in the Office of Management and Budget, and also provided for considerable financial assistance to spur interagency e-government initiatives. Each of these legislative actions has strengthened the federal government's commitment to e-government.

One of the most significant information technology developments at the federal level occurred after the tragedies of September 11. The attacks against America forced government officials to reexamine their information technology policies, infrastructure, and systems. The newly established Office of Homeland Security and its associated directives comprise the largest centralization and consolidation effort involving governmental databases in the history of the US. A recent General Accounting Office report (2002) highlights this effort and its challenges by examining the types of necessary data, the amount of data, and the transmission format of the data across vertical and horizontal governmental lines. The report also notes the challenges associated with traditional agency "stovepipes" and the need to move beyond this approach toward a centralized enterprise initiative (p. 8). The lack of connectivity and interoperability between databases and agency technologies is another crucial challenge that must be overcome, it is argued, in order to create a comprehensive infrastructure to deal with issues of terrorism.

Another example of the critical need to centralize and consolidate government information in order to mitigate future terrorist attacks is found in the Chambliss-Harman Homeland Security Information Sharing Act (HR 4598), passed by the U.S. House of Representatives in June 2002. This act mandates the dissemination of critical intelligence information from federal agencies, such as the CIA and FBI, to state and local governments (GCN, 2002). The goal of this act is to further reduce the vertical stovepipes that exist between federal, state, and local governments with respect to information access, and to encourage data sharing across all branches and levels of government in order to foster coordination and collaboration.

Although the effects of September 11 have impacted the use of information technology in the public sector in a variety of ways, there is little doubt that citizen demand for electronic information and services is likely to continue the trend of e-government adoption and expansion. According to the 2002 Pew Internet and American Life Project, Americans continue to use the Internet to access government information, research policy issues, contact elected officials, and participate in e-democracy in increasing numbers (Larson & Rainie, 2002). The number of Americans who have accessed government information online was 68 million in January 2002, compared with 40 million in March 2000. This marked increase further supports the idea that citizen demand for and use of e-government will continue to expand in the future.

E-GOVERNMENT TYPOLOGIES

Although several typologies have been developed to explain the progression of e-government (Layne & Lee, 2001; Moon, 2002), the UN and ASPA definition of the stages of e-government maintains continuity with the working definition set forth at the outset of this essay. It is also important to note that the stages to be discussed do not represent a true linear progression, nor are they specific block steps. Rather, the stages are a continuum in which governments can be within the same stage with very different functionalities and service offerings.

According to the UN and ASPA (2001), there are five main stages of e-government. Figure 1 offers a side-by-side comparison of the major components of the five stages of e-government. Each of the stages is discussed in further detail below.

The lack of an organizational Web site is not defined by a stage, but may be considered Stage 0. Stage 1 is the emerging Web presence, which involves static information presented as a type of online brochure (UN & ASPA, 2001). The main goal of the emerging Web stage is to provide an online mechanism for communicating key general information about the government to interested citizens and entities. The Web site lacks information about services and is not organized in a citizen-focused manner. Typically, the government has used a “go it alone” approach, which visually represents the stovepipes that exist within agencies—there is little coordination across agencies and levels of government in Stage-1 Web sites.

In Stage 2, enhanced Web presence, the role of the Web site becomes associated with information on services, although it is still organized by departments rather than by user groups. Enhanced-Web-presence sites typically have e-mail as a means of two-way communication. However, rarely are there available forms for download. Stage 2 offers limited communication and greater information about the services of the government, but it does not meet the citizen-centric approach that has been advocated for e-government (UN & ASPA, 2001).

Stage 3, interactive Web presence, begins to move into the citizen-centric realm of e-government (UN & ASPA, 2001). Typically, the information is portrayed by intuitive groupings that cross agency lines. For example, the Web site might use a portal as the single point of entry into various departments and service areas. The portal would offer major groupings like business, new-resident, seniors, children, or other standard groups. Then, the end user would select the grouping that applies and be launched into a new section of the portal where the most common services requested for the group are located. The services would not be listed by departmental areas, but rather by functional areas. Stage-3 sites have downloadable forms with online submissions, e-mail contacts for various governmental employees, and links to other governmental Web sites.

Stage 4, transactional Web presence, offers the ability to conduct secure online transactions (UN & ASPA, 2001). This stage is also organized by user needs and contains dynamic information. The Web site may offer a variety of transactions, including paying for services, paying bills, and paying taxes. Transactional Web presence includes online submission of forms, many downloads, e-mail contacts, and several links to other government sites. The use of digital signatures also falls under Stage 4.

The final stage, Stage 5, involves seamless government. Although this stage represents an ideal, there is no real example of its application. Stage 5 involves a cross-agency, intergovernmental approach that only displays one front, regardless of service area (UN & ASPA, 2001). For example, a seamless Web site would offer local, state, and federal government services via the state portal without the end user recognizing what level of government provides the service. A Stage-5 site would offer vertical and horizontal integration and would require true organizational transformation with respect to adminis-

Figure 1. E-government typology

Stage	Orientation	Services	Technology	Citizens
Stage 1: Emerging Web Presence	Administrative	Few, if any	Only Web	Going it alone
Stage 2: Enhanced Web Presence	Administrative, Information	Few forms, no transactions	Web, e-mail	Links to local agencies
Stage 3: Interactive Web Presence	Information, Users, Administrative	Number of forms, online submissions	Web, e-mail, portal	Some links to state and federal sites
Stage 4: Transactional Web Presence	Information, Users	Many forms and transactions	Web, e-mail, digital signatures, PKI, portals, SSL	Some links to state and federal sites
Stage 5: Seamless Web Presence	Users	Mirror all services provided in person, by mail, and by telephone	Web, e-mail, PKI, digital signatures, portal, SSL, other available technologies	Crosses departments and layers of government

trative boundaries (UN & ASPA). The closest example to seamless government is the FirstGov Web site created by the federal government of the United States. However, even this site lacks the coordination and cooperation required to make seamless government a reality.

With a working knowledge of the typology associated with e-government, it is easy to assess the current status of the concept. Much of the literature indicates that Stage 2, enhanced Web presence, is the typical placement of an American local government on the continuum. Alexander and Grubbs (1998, p. 3) note, "Few sites capitalized on the interactive nature of the Internet to conduct public discussions, maintain bulletin boards, or provide data and information available for download."

In his analysis of the 2000 International City/County Managers Association's (ICMA) E-Government Survey, Moon (2002) finds that a majority of municipalities with populations over 10,000 are not offering transactional Web sites. Furthermore, based on the 2002 ICMA E-Government Survey, only 62 (1.7 percent) municipalities offer online payment of taxes, 113 (3.1 percent) offer online payment of utility bills, and 91 (2.5 percent) offer online payment of fines and fees. The percentages for counties are only slightly higher, with 69 (16.3 percent) offering online payment of taxes, 17 (4.0 percent) offering online payment of utility bills, and 21 (5.0 percent) offering online payment of fines and fees. The state and federal governments offer more robust transactional services, which is to be expected based on information technology diffusion patterns.

CONCLUSION

The role of the Internet continues to increase as more citizens use it to find pertinent information, purchase goods and services, and to participate in virtual communities. By capitalizing on the Internet revolution, governments can create new channels of communication and new methods for participation via e-government. The changing information environment and the movement toward a knowledge economy, juxtaposed against citizen and business demands, mandate that government become involved in e-government initiatives and related uses of information technologies (Ho, 2002). Furthermore, success of existing e-government efforts provides increased legitimacy for further information technology adoption (Norris, 1999).

Although e-government has been offered as a panacea to the ills of the public sector, it has not yet achieved the massive reform and reorientation promised by its proponents. In fact, the e-government movement, similar to other management movements such as total quality management (TQM), new public management, and the reinventing government efforts, has not been successful in altering the core structures of government or avoiding its associated failures (Scavo & Shi, 2000). Given the documented lag time for technology adoption in the public sector, public sector realization of the power of the Internet and e-government must be seen as still nascent at best. By understanding the theoretical premises that underlie e-government and public information technology, programs and processes can be designed to assist government in reaping the benefits associated with the strategic use of information technology and e-government.

KEY TERMS

Citizen-Centric: A new approach to organization of government information and dissemination of government services that focuses on citizen needs and desires instead of traditional bureaucratic functions. For example, a citizen-centric Web site may combine various services, provided by different departments or agencies, under a common heading based on life events.

E- (Electronic) Democracy: A new method of engaging citizens in political participation, including e-rulemaking, e-voting, and various means of communication with elected and appointed government officials.

E-Government: A strategy for revolutionizing the business of government through the use of information technology (IT), particularly Web-based technologies, which improve internal and external processes, efficiencies, and service delivery.

E-Procurement: The online provision of goods and services by government agencies. E-procurement includes online requests for proposal (RFPs), online requests for bids (RFB), online bid acceptance, and online monitoring of contracts.

E-Services: The provision of government services via the Internet, including online information, online forms, online transactions, and online referral processes.

Portal: A one-stop, cross-department/business unit and cross-jurisdictional Web site that serves as an aggregation of government services in a given functional area or based on user needs.

"Stovepipe": The traditional orientation of government departments or business units, in which each department or business unit acts independently and autonomously. Lack of integration and interoperability and issues of duplication of efforts characterize stovepipe organizations.

A Socio–Technical Case Study of Bangladesh

Mahesh S. Raisinghani
University of Dallas, USA

Mahboobur Rahman
Gasmin Ltd., Bangladesh

EXECUTIVE SUMMARY

The revolutionary advent of IT has accelerated the pace of day-to-day office, personal and corporate communication. However, even now, Bangladesh, despite its natural resources and easily trainable workforce, cannot cope with the evolution of technology when compared to most of the developed and developing countries. Of course, there are reasons behind the slow growth of technology in Bangladesh. Despite this IT implementation here has begun, albeit a little slowly in different private and public sectors. In Bangladesh, IT use is still in a backward stage in terms of information generation, utilization and applications. In the absence of any private entrepreneur, the government initiates and funds as many of these projects as possible.

Constructing a case study on Bangladesh IT scenario is an impetus to depict the real picture of its obstacles and pitfalls, and success as well, if any.

INTRODUCTION

This write-up topic presents the IT scenario of Bangladesh as a whole, not an organization in particular. Readers will be interested in knowing facts like:

(1) Is there any historical background of computerization in Bangladesh?
(2) Was there any chronological follow-up to next generation of computerization?
(3) How did the private, autonomous and public agencies play roles in different periods of time for computerization?
(4) What are the hindrances that prevent Bangladesh from attaining a sufficient pace for IT advancement?
(5) What is the current status of IT as a whole in the country?

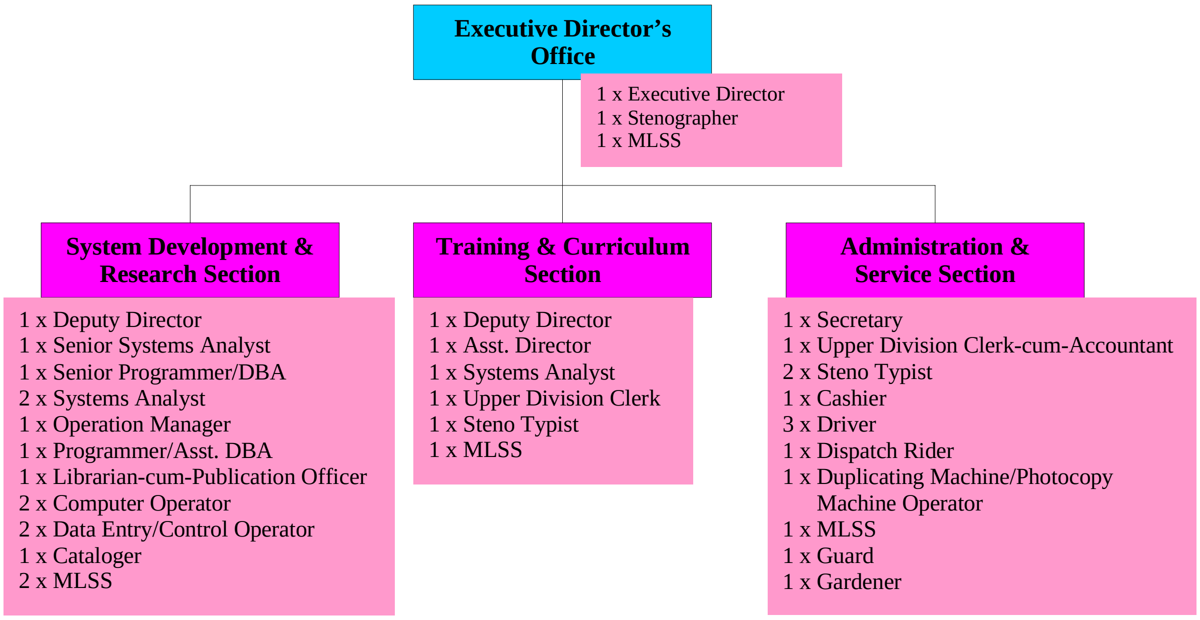
Readers will only get an organizational view as the spokesman for the IT organization (Bangladesh Computer Council) will offer his views during the case deliberations.

BACKGROUND

Bangladesh gained independence from Pakistan in 1971, missing out on much of technological wealth from its predecessor. To begin, the atomic energy commission acquired an IBM 1620 in 1964. This was the first computer in the country. Next, in line were Admajee Jute Mills (the biggest Jute mill in the world) and United Bank Limited (now Agrani Bank) acquiring an IBM 1400 and 1900 series. In early 1970s Bangladesh Bureau of Statistics (BBS) and Bangladesh University of Engineering and Technology (BUET) also acquired mainframe and mini computers. Until 1970s, use of computers was limited to research and calculations. As the boom of microcomputers occurred throughout the world, Bangladesh was merely touched by it. Gradually, the non-government sectors providing support to socio-economic development in the country took lead to accept the microprocessor-based standalone computers (XT and AT type) for their operations, research and office management. This revolution led to the slow but steady use of Microprocessors and Pentium series by government and non-government offices. Also, the installation of UNIX and CP/CMS operating systems on most Mainframe and mini computers in the 1970s made the punch cards and reading systems obsolete. This was followed by the quick adoption of operating systems such as DOS, OS/2, Windows NT, XENIX, AIX, and Mac.

Network technology in Bangladesh started in early 90s with banks and international organizations establishing LAN to meet business and office requirements. Very few government departments opted to have their computer under network environment. First Internet provider began in 1996 as opposed to the traditional dial-up Internet service provider from outside the country. There are more than 50 ISPs in the country, 8-10 more prominent than the others. Bangladesh had missed the opportunity to set up fiber optic infrastructure: first in 1992 when it passed up an almost free of cost opportunity to be connected with an underground cable SEAMEU-2; and second in 1998 when it passed up a minimum cost opportunity with SEAMEU-3. However, recently, there has been an initiation for a connection to the undersea cable

Figure 1. BCC's organizational structure



network APCN-2 and a tri-party contract agreement is under process.

However, very few firms are capable of customizing software; hence this is a small industry in Bangladesh. The necessary ingredients to become a potential exporter of computer software and data processing services do not currently exist in the required quantity in Bangladesh. If Bangladesh wants to enter into this market, it needs to cross a number of hurdles within a very short period. The National Computer Committee offered some ideas for the enhancement of the IT sector, and therefore the BCC designed an organizational structure to carry its functionalities with humanpower strength of 37 as shown in Figure 1.

BCC proposed a budget of US $5 million in their fourth 5-year plan (1990-1995) for the following five proposed IT development projects:

(1) BCC's Infrastructure Facilities
(2) National Information Technology Training Institute (NITI)
(3) National Data Network Authority (NDNA)
(4) National Software Export Bureau (NSEB)
(5) System Integrator Company Limited (SICOM)

Budget allocation was made for three of these projects for financial years 1991-92 and 1992-93. BCC also proposed a new project for establishment of a "data entry industry" in the country in 1992. However, none of the BCC's projects materialized due to some political controversy.

In fact, development of the IT sector and the role of BCC seemed to fade during the period between mid-1991 to mid-1996. In late 1996, a 14-member expert committee headed by a professor of BUET and members from different business and government bodies was formed by the government to study the feasibility of software export from Bangladesh. The committee submitted a report in September 2000 to the government with some very positive recommendations to boost the IT sector in order to create a favorable environment for software industry in the country and to export software. Following the recommendations of the expert committee, the government has taken some favorable decisions from 1998 and it is being continued to date, such as the following:

(1) Declaring IT industry as a thrust sector
(2) Patronizing of IT industry by different financial sectors, especially the banks
(3) Full exemption of import tax for all IT products (e.g., hardware, software, network, peripherals and accessories)
(4) Minimizing VSAT usage charge
(5) Increase of budget allocation for IT sector

In formulating an IT policy in the country, the government has formed a probe committee. The body is active and arranges workshops to draft policies on IT related HRD, procurement and usage guidelines, creating markets and developing infrastructure. The information age has also raised the importance of IT skills both in the workplace and civil society. A lack of such skills on a national level will pose a barrier to Bangladesh competing effectively in the global economy. Therefore, any IT human resource development policy will encourage widespread IT literacy and an adequate supply of IT professionals to support economic goals. The computer literacy rate in Bangladesh is very low due to lack of widespread IT education within the primary and secondary schools. The country needs to produce a large amount of skilled IT humanpower immediately to meet this challenge.

In the context of the world scenario of human resource, Bangladesh's strength is relatively poor. At the university level all national public universities and in particular new universities have started producing computer science graduates through opening computer science departments. Steps have been taken to implement computer education in the secondary and higher secondary levels. Since the last few years vigorous efforts have been made to improve the quality of IT education and research. The massive and strong participation by young people and their urge to become computer literate and develop professional competence is the most encouraging observation.

BCC conducts short-duration professional efficiency enhancement training program in IT. It has started a standard IT training program in Rajshahi division. The Bangladesh Institute of Communication and Information Technology (BICIT) has been included in the Annual Development Program in the 1999-2000 fiscal year. This institute will impart standard IT education, training, standardization and certification of IT related course curricula and products.

BCC, since its formation in 1990 to mid-1992, and some other private firms provided some training on few programming languages and databases, but not at a great extent. Taking this opportunity, several foreign franchisers started appointing their franchisees in Bangladesh. Presently approximately 20 foreign franchisers are operating their IT training centers in Bangladesh.

ANALYSIS

As mentioned, the computer revolution in Bangladesh began in 1960s. Mini (IBM 360, 370), mainframe (IBM 4300, 4361) and microprocessor-based computers were used and programming languages such as FORTRAN, COBOL and RPG remained popular till 1980s. Database management systems used here were SQL/DS, DB2 and earlier version of Oracle. Some organizations still follow the old system, while others have upgraded from mainframe and standalone environment. The current IT usage scenario at a glance can be viewed as shown in Table 1:

Compared to India or Malaysia the IT growth in the country still has a far way to travel. India has attained this tremendous achievement in the past two decades, with liberal policies, patronizing IT entrepreneurs and dependable infrastructure. Government changes neither dampen nor discourage the policies adopted by their predecessor.

Conversely in Bangladesh, government has the sole monopoly. Policy makers came into effect with NCC, NCB and BCC amidst controversy. Different governments modify the IT policies affecting the growth of the IT industry. During 1991-1996, the IT sector was totally ignored. With no follow-up, it may be a while before

Table 1. Current IT usage scenario in Bangladesh

Technology Usage Type		**Technology Product Model**
Computer	Server	IBM RS/4000 and RS/6000, Sun Enterprise, HP Netra, Compaq Proliant, Gateway ALR, Mac
	Client	Pentium (I, II & III), 486 processors, Mac
Operating Systems	Server	UNIX, AIX NT, LINUX, Mac OS, Novel Netware, OS/400
	Client	Windows 9x & NT, Mac OS (Client)
DBMS	Back Engine	Oracle, Sybase, SQL, Access, Informix
	Front Tools	Developer 2000/6i, Delphi, Power Builder, Power Designer
	Language	PL/SQL, T/SQL, Visual Basic
Programming Languages		Visual Basic, C, C++, Java, COBOL, RPG, OOP, J++
Web Design & Development Tools		FrontPage, Dream weaver, HTML Editor, XML, CSS, Java Script, ASP, Hot Dog
Drawing, Animation & Multimedia Tools		Adobe Photoshop, Visio Drawing, Illustrator, Freehand, Corel Draw, Quark Express, Macromedia Director/Flash, Auto Cad, Sound Forge
Back Office Mail Server		MS Exchange Server, Linux, IBM AX

Bangladesh can be at par with the rest of the world. Also, the acceptance attitude and capability to upgrade their knowledge and skills is always under question. There is no customized software due to thin response and lack of enthusiasm from the HRD and the entrepreneurs. The inherent bureaucratic and traditional attitude of the government has caused the major impediment in infrastructure.

DISCUSSION

The Committee formed by the Ministry of Commerce of the People's Republic of Bangladesh has identified a few major problems that threaten the growth of software industry:

- Fiscal
- Human Resource Development
- Infrastructure
- Marketing

In order to make Bangladesh a potential offshore source of software and data processing services, this case makes short-term and medium-term recommendations for each of the above category, depending on the priority and importance.

Short Term

Fiscal

a) To exempt computer hardware and software from import duty, VAT, infrastructure development surcharge, import license fee, and advance income tax.
b) To allow a tax holiday for the export-oriented software and data processing services industry, for 10 (ten) years.
c) To give a 15% price advantage to local software developers over import of the same products.
d) To allow export of software and data processing services through sales contract, instead of letters of credit.
e) To bring the bank interest rate on loans/advances/ overdraft down to the level applicable to other export-oriented thrust sectors.
f) To create a special fund to be administered by the Ministry of Science & Technology for giving interest-free loans to teachers and students for purchase of computers and related equipment.
g) To create a venture capital fund of at least Tk.10 Crore at eExport Promotion Bureau for equity participation in export-oriented software and data processing services companies.

Human Resource Development

a) To give BCC necessary authority to function as the primary facilitator to help growth of private sectors IT industry (such as National Computer Board of Singapore and Department of Electronics of India).
b) To introduce "basic computer skills as a mandatory subject and to set up Computer Science Department in all universities.
d) To ask BCC to update computer science course curriculum.
e) To empower BCC to develop IT related certification exams and to encourage employers of both government and private sectors to give preference to such certificate holders for jobs.

Infrastructure

a) To enact appropriate laws for the protection of intellectual property rights, as required under the WTO Charter.
b) To set up low-cost high-speed data and voice communication link with the USA and the UK, with a minimum speed of 2 MBPS. Private sector should be allowed to provide such service along with BTTB.
e) To make video conferencing facility available through VSAT.
f) To allow private sector to set up their own satellite communication links in order to obtain competitive price advantage and greater availability of communication facilities.
g) To create separate customs houses to handle all incoming and outgoing equipment/ documents so as to ensure clearance of such equipment/documents within 24 hours.
h) To create a central resource center at BCC with current books, magazines, periodicals, software, and user/system manuals on IT related subjects.
i) To encourage software firms to form an association primarily to protect the interest of the software and data processing services sectors, in line with NASSCOM, ASOCIO, WITSA, and JISA.

Marketing

a) To mobilize non-resident Bangladeshi IT professionals and inform them about the incentives being provided by GOB and encourage their support to help Bangladeshi entrepreneurs.

b) To ban use of all pirated software in all organizations, both in the public and private sectors.

c) To encourage all government, semi-government, autonomous organizations and private sector companies to replace the manual system of documentation and records by computerized system through the use of locally developed customized application software.

d) To send marketing missions to North America/E.U. consisting of members from IT Associations and EPB, on a regular basis, with a view to publicizing Bangladesh software and data processing services capabilities as well as establishing personal contacts with the prospective customers.

e) To create a database and a Web site of all major organizations/institutions engaged in out-sourcing of software and data processing services.

f) To explore the possibility of obtaining business on sub-contract basis from the suppliers of software and data processing services in India, Sri Lanka and the Philippines.

g) To ask the concerned trade associations to organize international exhibitions/fairs in Bangladesh for IT products and services, in collaboration with Export Promotion Bureau.

Medium Term

Fiscal

a) To create a market promotion fund to be administered by Export Promotion Bureau for meeting the expenses of promoting Bangladesh as a potential source of software and data processing services to the overseas markets.

b) To create a special fund for supporting industry oriented IT research and development activities, to be administered by BCC.

Human Resource Development

a) To strengthen BCC and make it responsible for imparting higher-level special need-based training to the IT professionals who are graduating from the universities.

b) To incorporate industry placement program in final year of a computer science degree program.

Infrastructure

a) To set up an Information Technology Village (ITV) and to equip the same with all necessary facilities, such as high-speed communication, special custom bonded warehouse, resource center (hardware, software, manuals, book), power and water supplies, and telecom facilities.

b) To ask BTTB to set up ISDN/HDSN/ADSL lines all over the country, and a fibre optic backbone.

c) To set up a communication hub in Bangladesh.

d) To form a standing committee to formulate and implement policies, strategies and action plans for promotion of export of software and data processing services.

Marketing

a) To ask Export Promotion Bureau to set up permanent liaison offices in the USA and the UK to be manned by professional marketers of IT field, who should perform and achieve definite quantified business objectives.

b) To ask BCC to create a database of Bangladesh IT professionals working at home and abroad, in order to obtain their help when needed.

d) To encourage IT industry members to take steps for ISO-9000 certifications and eventually ratings from Software Engineering Institute (SEI) of Carnegie-Mellon University of USA.

Other Recommendations

Bangladesh can also learn from the experience of its neighboring country – India, and can adopt the measures that helped India.

(1) Take advantage of the opportunities available in the conversion market of US $650 billion and the Euro-currency conversion.

(2) Focus on multimedia market that is experiencing the maximum growth.

(3) Influence Microsoft Corporation of USA to involve Bangladesh in their plan to introduce Bangla as a language for Windows NT 5.0.

CONCLUSION

The fact that Bangladesh is far behind local and global IT status is established. Currently, a lot of decisions and steps have been taken in favor to uphold and patronize IT sector. Many entrepreneurs and investors are attracted to the IT sector. The need for an IT policy for the development of the IT sector within the framework of overall national development is now well recognized. The massive and strong participation by young people and their urge to become computer literate and develop professional competence is the most encouraging.

KEY TERMS

Export-Oriented Software: A unit will be considered export-oriented if at least 70% of its revenue comes from export.

Long Term: Timeframe of three to four years to accomplish the recommendations.

Medium Term: Timeframe of two to three years to accomplish the recommendations.

NASSCOM: National Association of Software and Service Companies.

Short Term: Timeframe of a year to accomplish the recommendations.

Taka (Tk): Bangladesh currency is called Taka (1 US Dollar = 60.552 Bangladeshi Taka, 1 Bangladeshi Taka (BDT) = 0.01651 US Dollar (USD) as of March 14, 2004).

Tax Holiday: No taxes for export-oriented software and data processing services industry every 10 years.

A Systemic Approach for Information Systems Evaluation

Ala Abu-Samaha
Amman University, Jordan

INTRODUCTION

Traditionally, information technology (IT) evaluation, pre-implementation appraisals, and post-implementation reviews have been characterised as economical, tangible, and hard in nature. The literature review on IT evaluation shows a great bias towards using economical and tangible measures that represent the management's view of what is 'good' and 'bad', which had been described as narrow in scope and limited in use. Smithson and Hirschheim (1998) explain that "there has been an increasing concern that narrow cost benefit studies are too limited and there is a need to develop a wider view of the impact of a new system." Ezingeard (1998) emphasises the importance of looking at the impact of IS on both the overall system and the whole organisation.

The concern of IT evaluation is to measure whether the IT solution meets its technical objectives and to what extent. In such activity, instrumentation is highly appreciated and particularly chosen. Product oriented, instrument led, and unitary are the main characteristics of such a perception. Mainly evaluation was seen as a by-product of the decision-making process of information systems development and installation. Most of the evaluation tools and techniques used were economic based, geared to identifying possible alternatives, weighing the benefits against the costs, and then choosing the most appropriate alternative. St. Leger, Schnieden, and Walsworth-Bell (1992) explain that evaluation is "the critical assessment, on as objective a basis as possible, of the degree to which entire services or their component parts fulfil stated goals." Rossi and Freeman (1982) advocate that "evaluation research is the systematic application of the practice of social research procedures in assessing the conceptualisation and design, implementation, and utility of social intervention programs."

Post-implementation evaluation has been described by Ahituv, Even-Tsur, and Sadan (1986) as "probably the most neglected activity along the system life cycle." Avison and Horton (1993) report that "evaluation during the development of an information system, as an integral part of the information systems development process, is even more infrequently practised." In acknowledging all of the above concerns about the evaluation of IT interventions, the author presents in this article a measures identification method that aims at identifying those measures or indicators of performance that are relevant to all the stakeholders involved in such interventions.

POST IMPLEMENTATION REVIEW

Many researchers concerned with IT evaluation, mainly post-implementation reviews, have identified an urgent need to migrate from this 'traditional' and economical view towards using a mixed approach to IT evaluation. Such an approach will allow IT evaluators to mix between 'hard' and 'soft' measures, as well as economical and non-economical measures (Chan, 1998; Ezingeard, 1998; Bannister, 1998; Smithson & Hirschheim, 1998; Avison 7 Horton, 1993). Furthermore, there is a need to shift towards utilising an approach that reflects the concerns of all involved stakeholders rather than a Unitarian approach (Smithson & Hirschheim, 1998). Any systemic approach to IS evaluation must take into account two main issues regarding the collective nature of IS: choosing the relevant measures of performance, and equal account for economical as well as non-economical measures.

Choosing the Relevant Measures of Performance

Abu-Samaha and Wood (1999b) show that:

"the main methodological problem in evaluating any project is to choose the right indicators for the measurement of success, or lack of it. These indicators will obviously be linked to aims but will also be relevant to the objectives chosen to achieve these aims, since if the wrong objectives have been chosen for the achievement of an aim, then failure can be as much due to inappropriate objectives as to the wrong implementation of the right objectives."

Willcocks (1992), in a study of 50 organisations, gives 10 basic reasons for failure in evaluation practice; amongst these reasons are inappropriate measures and neglecting intangible benefits. Ezingeard (1998) shows that "…it is difficult to decide what performance measures should be used." On the other hand, a different set of indicators or measures of performance will be chosen at each level or layer of the IT intervention (product, project, and programme), which adds more to the relevance of the chosen measures.

Another important aspect of choosing indicators or measures of performance is to choose the relevant measures that add value to a particular person or group of persons. Smithson and Hirschheim (1998) explain:

"There are different stakeholders likely to have different views about what should be the outcome of IS, and how well these outcomes are met. Who the different stakeholders are similarly need[s] to be identified."

The measures identification method proposed by the author in this article provides such relevance through the identification of stakeholders and the subsequent 'human activity system' analysis. This is done by exploring the particular worldview, which is unique for each stakeholder, and the identification of the relevant criteria for *efficacy*, *efficiency*, and *effectiveness* of each stated transformation process. Such investigation would allow for the identification of the most relevant measures or indicators of performance for the stated stakeholder(s).

Equal Account for Economical as well as Non-Economical Measures

Post-implementation reviews have had a tendency to concentrate on 'hard', 'economical', and 'tangible' measures. Chan (1998) explains the importance of bridging the gap between 'hard' and 'soft' measures in IT evaluation, realising that "this in turn requires the examination of a variety of qualitative and quantitative measures, and the use of individual, group, process, and organisation-level measures." Avison and Horton (1993) warn against confining post-implementation reviews to monitoring cost and performance and feasibility studies on cost-justification, saying that "concentration on the economic and technical aspects of a system may cause organisational and social factors to be overlooked, yet these can have a significant impact on the effectiveness of the system." Fitzgerald (1993) suggests that a new approach to IS evaluation, which addresses both efficiency and effectiveness criteria, is required.

The approach described in this article gives an equal account to tangible as well as intangible benefits of IT intervention by identifying efficacy and effectiveness measures along with efficiency measures. The measures identification method proposed by the author provides a better understanding of the context of evaluation which would give a better account of the content of evaluation.

SOFT EVALUATION

The approach advocated here brings together formal work in evaluation (Patton, 1986; Rossi & Freeman, 1982) with a qualitative process of investigation based on Soft Systems Methodology (Checkland & Scholes, 1990) in order to allow us to make judgements about the outcomes of an implementation from a number of different viewpoints or perspectives. The performance measures identification method proposed in this article operates through three stages.

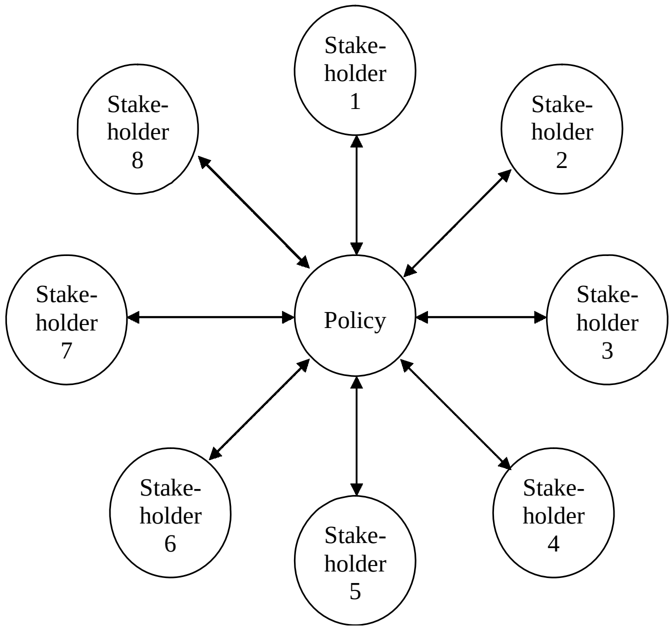
Stage One: Stakeholder Analysis

The first stage of the proposed method is to identify the intra- and inter-organisational stakeholders involved in the intervention. A stakeholder, as defined by Mitroff and Linstone (1993), is any "individual, group, organisation, or institution that can affect as well as be affected by an individual's, group's, organisation's, or institution's policy or policies." Mitroff and Linstone (1993) explain that an "organisation is not a physical 'thing' per se, but a series of social and institutional relationships between a wide series of parties. As these relationships change over time, the organisation itself changes." Mitroff and Linstone's view of an organisation is synonymous to Checkland and Howell's (1997), which negates the 'hard goal seeking machine' organisation.

Stakeholder analysis can be seen as a useful tool to shed some light on the subjective process of identifying relevant measures of performance for evaluation. A number of questions can be asked at this stage such as where to start, who to include, and who to leave out. The value of the investigation will be of greater importance if all relevant stakeholders are identified and included in the evaluation effort. It is obvious at this stage that some stakeholders will be of greater importance than others because of the power base that they operate from, and such stakeholders are to be acknowledged. At the same time, however, other relevant stakeholders should not be undermined for lack of such power.

While Mitroff and Linstone (1993) do not describe the process through which stakeholders may be identified, they recommend the use of a *stakeholder map*, as shown in Figure 1. They explain that "a double line of influence extends from each stakeholder to the organisation's policy or policies and back again-an organisation is the entire set of relationships it has with itself and its stakeholders." On

Figure 1. Generic stakeholder map (Adopted from Mitroff & Linstone, 1993, p. 141)



the other hand, Vidgen (1994) recommends the use of a rich picture, being a pictorial representation of the current status, to support this activity.

Stage Two: Human Activity Systems Analysis

The second stage of the proposed method constitutes the systemic organisational analysis of the problem situation or subject of evaluation. SSM is based upon systems theory, and provides an antidote to more conventional, 'reductionist' scientific enquiry. Systems approaches attempt to study the wider picture: the relation of component parts to each other, and to the whole of which they are a part ('holism') (Avison & Wood-Harper, 1990; Checkland, 1981; Checkland & Scholes, 1990; Lewis, 1994; Wilson, 1990). SSM uses systems not as representations of the real world, but as epistemological devices to provoke thinking about the real world. Hence SSM is not an information systems design methodology. It is rather a general problem-solving tool that provides us with the ability to cope with multiple, possibly conflicting, viewpoints.

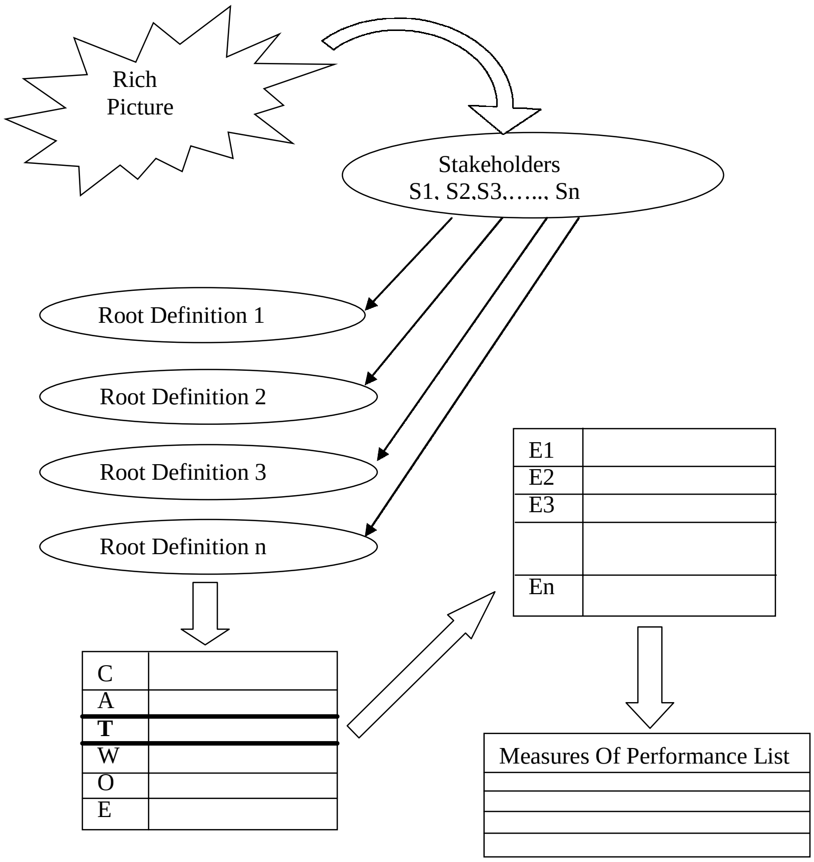
Within this stage the aim is to determine a *root definition* for each stakeholder, which includes their "worldview," a transformation process, together with the definition of the criteria for the efficacy, efficiency, and effectiveness of each stated transformation process (Wood-Harper, Corder, Wood & Watson, 1996). A root definition is a short textual definition of the aims and means of the relevant system to be modelled. The core purpose is expressed as a transformation process in which some entity 'input' is changed or transformed into some new form of that same entity 'output' (Checkland & Scholes, 1990). Besides identifying the world-view and the transformation process, there are the three E's to consider as stated by Checkland and Scholes (1990):

- *E1: Efficacy.* Does the system work? Is the transformation achieved?
- *E2: Efficiency.* A comparison of the value of the output of the system and the resources needed to achieve the output; in other words, is the system worthwhile?
- *E3: Effectiveness.* Does the system achieve its longer-term goals?

Stage Three: Measures of Performance Identification

According to Checkland's Formal Systems Model, every human activity system must have some ways of evaluating its performance, and ways of regulating itself when the desired performance is not being achieved. This final stage aims at identifying appropriate Measures of Performance related to the criteria identified in the earlier stage.

Figure 2. Generic process of soft evaluation



For each criterion of the three Es identified in the earlier stage, it is important to identify the measure of performance that would allow us to judge the extent to which the system has achieved its objectives.

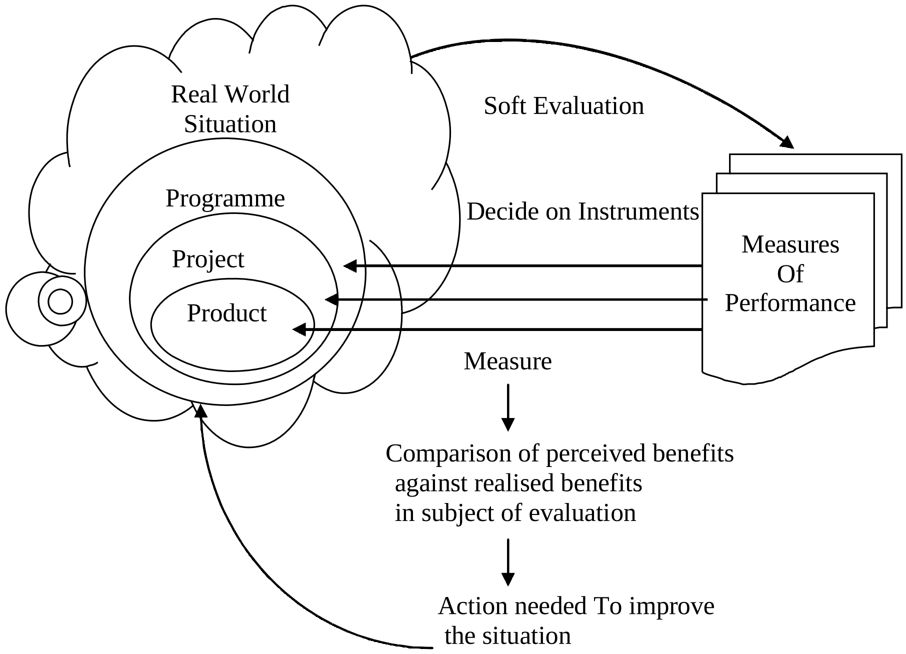
Figure (2) provides a diagrammatic representation of the generic process of soft evaluation, which shows the relationship between the different tools used to investigate the success/failure of an IT intervention.

CONCLUSION

This proposed IT evaluation framework is refined from an earlier work by Abu-Samaha and Wood (1999) to reflect the layered nature of IT interventions. The approach advocated here is founded on the interpretive paradigm (Burrell & Morgan, 1979) and brings together formal work in evaluation (Patton, 1986; Rossi & Freeman, 1982) with a qualitative process of investigation based on Soft Systems Methodology (Checkland & Scholes, 1990) in order to allow us to make judgements about the outcomes of an implementation from a number of different viewpoints or perspectives. The literature survey has revealed three levels of IS/IT intervention evaluation. Measures would differ at each level of analysis, prompting a different instrument as well as a different process of evaluation. Figures 3 and 4 provide a diagrammatic representation of the soft evaluation method and framework, where the three layers of IT intervention-product, project, and programme-have been included in the evaluation process.

Relevance is of paramount importance for IT and IS evaluation. The main methodological problem in evaluating any project is to choose the right indicators for the measurement of success, or lack of it. The earlier classification of product, project, and programme evaluation shows that a different set of indicators or measures of performance will be chosen at each level or layer of the IT

Figure 3. Soft evaluation framework in use



intervention which adds more to the relevance of the chosen measures. Another important aspect of choosing indicators or measures of performance is to choose the relevant measures that add value to a particular person or group of persons. Non-economic as well as economic measures are of equal importance. The proposed approach gives an equal consideration to the tangible as well as the intangible benefits of IT intervention by identifying both efficacy and effectiveness measures along with efficiency measures.

KEY TERMS

Effectiveness: A measure of performance that specifies whether the system achieves its longer-term goals or not.

Efficacy: A measure of performance that establishes whether the system works or not-if the transformation of an entity from an input stage to an output stage has been achieved?

Efficiency: A measure of performance based on comparison of the value of the output of the system and the resources needed to achieve the output; in other words, is the system worthwhile?

IS Success: The extent to which the system achieves the goals for which it was designed. In other words, IS success should be evaluated on the degree to which the original objectives of a system are accomplished (Oxford Dictionary).

Post-Implementation Evaluation: The critical assessment of the degree to which the original objectives of the technical system are accomplished through the systematic collection of information about the activities, characteristics, and outcomes of the system/technology for use by specific people to reduce uncertainties, improve effectiveness, and make decisions with regard to what those programs are doing and affecting (Patton, 1986).

Product Evaluation: The emphasis at this level is on the technical product, software, IT solution, or information system. The concern at this level is to measure to what extent the IT solution meets its technical objectives. The emphasis here is on efficacy: Does the chosen tool work? Does it deliver?

Programme Evaluation: The concern at this level is to measure whether the programme aims have been met and whether the correct aims have been identified.

Project Evaluation: The emphasis at this level is on the project, which represents the chosen objective(s) to achieve the aims of the programme. The concern at this level is to measure whether the project meets these objectives and to what extent it matches user expectations. The emphasis here is on efficiency. Does the project meet its objectives using minimal resources?

Soft Systems Methodology: A general problem-solving tool that provides us with the ability to cope with multiple, possibly conflicting viewpoints based on systems theory, which attempts to study the wider picture; the relation of component parts to each other. It uses systems as epistemological devices to provoke thinking about the real world.

Stakeholder: Any individual, group, organisation, or institution that can affect as well as be affected by an individual's, group's, organisation's, or institution's policy or policies (Mitroff & Linstone, 1993).

A University/Community Partnership to Bridge the Digital Divide

David Ruppel
The University of Toledo, USA

Cynthia Ruppel
The University of Alabama in Huntsville, USA

INTRODUCTION

Companies want employees with core values who ascribe to corporate values. Emotional intelligence (EQ) is used by companies in recruitment (Foote, 2001), and guides managers in dealing with team performance problems. Similarly, leadership requires refocusing on core values, which over time builds character (Badaracco, 1998). Thus, educational institutions should devote considerable attention to character building (Foote, 2001).

Service-learning is designed to help. Jacoby (1996a, p. 5) has defined service-learning as "…a form of experiential education in which students engage in activities that address human and community needs together with structured opportunities intentionally designed to promote student learning and development".

Service-learning is important in information technology where students need technical skills and experience, and a strong ethical foundation. Legal aspects of technology have not kept pace with technology; often IT people are confronted with complex ethical decisions. It has been argued that service-learning represents a "unique pedagogy…that enhances the ability of private sector managers to be effective stewards of society's moral authority" (Godfred, p. 364). Service-learning in colleges is tightly linked with K-12 education (Jacoby, 1996B) due to the growing number of at-risk children, a vested interest for colleges to improve the future students, and because students will view service-learning as an appropriate college activity if they benefited from it prior to college (Jacoby, 1996b).

A policy concern in the information age is the "digital divide," a gap between those who have easy access to technology and those who do not. References are made to information "haves" and "have-nots" in an age where information is equivalent to wealth (Holloway, 2000). The "have-nots" are in danger of exclusion from the new economy and marginalization into low-wage jobs (Dunham, 1999). In 2000, the President of the United States asked the IT community to help close this digital divide for moral reasons and to ensure that the economy flourishes with the availability of skilled workers (Shewmake, 2000).

This overview summarizes a five-phase service-learning project accomplished through a partnership between the University of Toledo and a local K-8 parochial/non-profit school. The students were primarily enrolled in a Systems Analysis, Design and Implementation course (SAD). This longitudinal project was undertaken to plan, design, and wire a network for the school and to assess and implement continuing and future computer needs. It allowed students to gain "real-life" experience while contributing to the growth of IT among children in a non-profit setting.

BACKGROUND

The school is a parochial school enrolling approximately 200-250 students. All grades have a dedicated classroom; a computer lab and library are also provided.

Existing computers consisted of a classroom set of older Macintosh computers in the 8th grade room. Each classroom had an older Macintosh computer for the teacher, all with unused LAN capability. The computer lab contained older Apple computers used in the primary grades for computer literacy and keyboarding skills.

Phase 1

The school had accumulated technology funds and hired a teacher with a Master's degree in Educational Technology. The teacher and principal agreed to participate in the project since an estimate from a local company exceeded the funds accumulated. While the teacher had pedagogic knowledge of computers, he did not possess the expertise to evaluate the quotation or analyze the technical aspects of the network. The school indicated that it hoped to apply for a grant, but needed technical information.

Students self-selected into the project: *The goal of the project was to educate themselves as to alternatives, costs and provide background information concerning networking to prepare a grant application.* They had the opportunity to examine the existing environment and interview stakeholders.

The instructor and students toured the building, including attic and closet locations where existing asbestos could not be disturbed. The stakeholders were asked to determine the number of “drops/connections” required in each room based on immediate and future use. Two drops were requested in each classroom — one for the teacher’s computer and another for a classroom network. The group submitted a plan to the school including alternatives, costs, and technical information for the design of the campus network to be used for grant preparation.

Phase 2

Phase 2 included completing a grant proposal and the physical networking of the building. The wiring project was popular among students and required instructor selection to participate. Two students had experience, while others were chosen based on enthusiasm and desire to learn the “hands-on” aspects of networking.

Using the plan, a grant proposal was submitted providing evidence of the school’s commitment and a plan for the educational use of the network. The university students’ involvement was documented, and the authors were listed as consultants.

The grant writing was divided among the authors, the teacher, and the principal. Guidelines required a technology plan and a specific grant request. The accumulated funds were sufficient to wire the building without grant funding. Subsequently the maximum grant was awarded for continuation of the project.

The wiring plan included an Ethernet LAN in the 8th grade room and a campus LAN with connections in all classrooms and offices. Microsoft Windows NT Server 4.0 with Services for Macintosh (SFM) was chosen as the network operating system (NOS) based on the requirements of the heterogeneous network. With SFM, the Windows server appears as an Apple server to Macintosh clients.

The NOS was installed on a computer with a dial-up Internet connection, a temporary arrangement until high-speed access was available. Proxy server and content-filtering services were installed, providing low-bandwidth Internet access to all clients in the 8th grade classroom. Secure storage for network users was provided.

In wiring the building, a storage closet was used as the wiring closet where hubs were installed and all building wiring runs terminated. Since the computers were regularly used, work was partitioned into elements that could be done over a weekend to maximize availability for students and teachers. A file server for administrative applications and intranet e-mail was installed in the wiring closet with a tape drive to provide network backup.

Phase 3

The next step was to install high-speed Internet access for which the school receives state funding. The authors recommended the installation of a T-1 line (1.544 Mbps).

In 2001 the network consisted of three servers, each running Microsoft NT Server 4.0. A laser printer was available to over 50 network clients running various operating systems.

Phase 4

We now needed to recommend replacements for outdated equipment and provide information for equipment grant applications. Students self-selected into this project, and met with the stakeholders. The main issue was whether the replacement equipment should be Apple or Windows-based. Pertinent factors were educational needs, existing equipment, and available expertise. The group analyzed these factors together with their survey of surrounding schools to determine local norms. Their recommendation was Apple equipment.

After network completion, it was obvious that the computers were outdated. An early goal was to minimize expenses by leveraging existing equipment. An obsolete Web browser was installed since the machines’ capabilities prohibited current versions. While slow, the clients provided Internet access where none existed before. In today’s world, fast access is a necessity. Revenaugh (2000) suggests that access does not equal equity; just connecting a wire to a school does not mean it will be used well. Also, the browser security certificates had expired, so secure Web sites could not be accessed.

Phase 5

Using this recommendation, a second grant proposal was prepared requesting the maximum award to purchase new computers for the teachers. The replaced computers will be placed in the classrooms in small networks for student use.

Another group of students worked on designing a Web site for the school. A preliminary school Web site, created 2 years earlier, was out-of-date and the students were asked to produce an up-to-date, easily maintainable Web site.

CONCLUSIONS AND LESSONS LEARNED

There must be a close working relationship between the community organization and the university faculty. Trust was necessary to order materials, remain in the building after-hours, and obtain quotations on behalf of the school.

Since this is a functioning organization, work cannot be left unfinished. Work must be analyzed and divided into tasks that can be completed within the available time. Student self-selection should be combined with faculty approval since the faculty member(s) have the ultimate responsibility for project completion.

Students appreciate being part of a project that benefits others. Food was provided on Saturdays, motivating the students and keeping them on site. The students had time to relax and discuss the project among themselves and with the instructors informally as recommended by the service-learning literature (Godfrey, 1999; Kenworthy-U'ren, 1999). During this time it was interesting to note their perceptions of how elementary education has changed since "their day". They even became attached to the classroom pets – feeding them, and so forth.

The school purchased materials on time and provided significant access to the building. They valued the students' work, since they had received a commercial bid. We recommend this procedure where applicable to eliminate the perception that free means valueless.

Choose the students both to ensure project completion and to make it a learning experience. From the volunteers, students were selected to ensure some students had necessary skills and also included inexperienced students. This facilitated a sharing of knowledge and maximized learning, giving the experienced students leadership opportunities.

Expect unanticipated problems. Since the building had been built in stages (to our surprise), we needed to wire through old exterior walls. Also, the 8th grade class rabbit ate through the cables and had to be sent to a new home. We recommend exploring insurance coverage for students involved in labor with the potential for injury.

It is important to seek knowledge from a variety of sources. Experience with Apple computers was limited among the students and the instructors. A student, not part of this project, was familiar with Apples and made relevant suggestions. Another former student, who works with Apple computers in his employment, supplied information, agreed to troubleshoot computers, and created a CD containing the software set-up for the computers. He showed the students how to install the set-up and was so impressed with one of the students that he arranged a job interview for the student, resulting in a job offer.

In the service-learning literature, one caveat is the time required of the instructor(s), particularly relative to the current faculty reward systems (Godfrey, 1999; Kenworthy-U'ren, 1999; Kolenko, Porter, Wheatley & Colby, 1996). The amount of instructor time and nature of instructor tasks varied according to the type of student projects undertaken. This is consistent with the findings of Bush-Bacelis (1998), who suggests that service-learning projects do not require more work, but a different type of work both for the students and the instructor. The wiring project required a significant amount of dedicated instructor time, as did the grant writing. However, students indicated they found the wiring project particularly fulfilling, especially since the feedback was a working network and a tangible skill set was learned.

Student Assessment

In group projects, students are asked to assess each member's contribution to the group. To assess the quality grade for those completing the physical wiring, the instructors were present in the building. For the more traditional projects, the instructor assessed quality and adherence to SAD principles after obtaining "perceived value and usefulness" feedback from stakeholders.

Benefits to the School

The age of the existing computers limited their usability, and the school did not have the funds to replace them. By placing them on a network, their useful life was extended. Due to limited funds and lack of technical knowledge the school was prevented from completing these projects.

Benefits to the Students

Kenworthy-U'ren (1999) suggests that service-learning projects should be grounded in experiential learning, not merely a service-related activity. These projects allowed the students' involvement in projects related to their career objectives. The students appeared determined to provide a quality product because it was being given to a "real" organization for decision making and to the next group who would use their work and attempt to "better it". These projects, if carefully planned, are win-win situations for the students and the community partner.

FUTURE TRENDS

The necessity of networking schools is becoming increasingly important and at lower levels such as primary school also. To continue to eliminate the digital divide, students, even grade school students, must be able to access and evaluate information to learn to make informed decisions. This project was designed to both give students "hands-on" experience and to provide access to young students so they can become familiar and comfortable with this access.

The technology in providing this access will continue to change. Many devices today are wireless devices (as schools can afford to purchase them), which would eliminate the need to wire the building and would use more current technology. However, in a school setting, due to cost constraints, the available technology appears to change more slowly than a business environment would. The issues involved in setting up a wireless network may seem less involved since no physical wiring must take place, but different complex issues arise, such as providing coverage to all areas and methods of extending the signal on large campuses. So the exercise for the students becomes no less important.

KEY TERMS

Bandwidth: A measure of the data transmission capacity of a communications link.

Digital Divide: The term digital divide describes the fact that the world can be divided into people who do and people who do not have access to - and the capability to use - modern information technology, such as the telephone, television, or the Internet.

Ethernet: A communications standard (IEEE 802.3) for Local Area Networks (LAN). When a device wishes to transmit, it waits until the link is empty and then transmits. In the event that two or more devices transmit simultaneously (collision), all devices stop transmitting and wait a random time period before attempting to re-transmit.

Heterogeneous Network: A network where network clients run a variety of operating systems. An example would be a network of machines running Windows, Unix, and Mac OS X.

Intranet: Computer network contained entirely within an organization.

LAN: Local Area Network. Group of computers and other devices sharing a single communications link. Typically, the longest distance between any two connections is a few kilometers. Usually owned by a single organization.

Network Operating System: An operating system for a computer designated as a server in a LAN. Manages network resources available to network clients such as printers, files and databases. Responsible for maintaining a database of names and addresses of clients attached to the network.

Service-Learning: A form of experiential education in which students engage in activities that address human and community needs together with structured opportunities intentionally designed to promote student learning and development.

Systems Analysis and Design Course (SAD): A course in which the student learns to understand how an information system can support organizational needs, how to design the system, build it and deliver it to users.

T-1 Line: A communications link that can be used for digital data transmission. Provides a data rate (bandwidth) of 1.544 million bits per second (Mbps).

A Web-Geographical Information System to Support Territorial Data Integration

INTRODUCTION

The design of a Web-geographical information system, Web-GIS (Worboys & Duckham, 2004; Zhong Ren & Ming Hsiang, 2003), strongly requires methodological and operational tools for dealing with information distributed in multiple, autonomous and heterogeneous data sources, and a uniform data publishing methodology and policy over Internet Web sites. In this article we describe the experience of the Politecnico di Milano group in the activities of requirement analysis and conceptual design of the DEAFIN Web-GIS (Schreiber et al., 2003), whose objective is to provide a common environment for comparison of information about available vacant industrial sites coming from different regional data sources. Heterogeneity and Web availability requirements have been taken into account in the system architecture design; the system is thus conceived as a federated Web-based information system, apt to manage and provide access to all the regional relevant information in an integrated and complete fashion. Furthermore, since the data available by a given region partner can be both spatial and alphanumeric, a Web-GIS is defined for each regional component system.

BACKGROUND

The DEAFIN (development agencies and their impact on foreign direct investments) project has been launched with the purpose of allowing companies and investors to get a comprehensive information framework about areas located in European regions suited for potential investments. The aim is to make the regional data about possible investment areas homogenous and comparable, and internationally accessible. Potential investors need both a survey and a detailed view of vacant sites in different locations in order to compare different opportunities and decide their convenience. Quite naturally, such requirements call for a federated information system (FIS), which grants local sites a great deal of autonomy while enabling interoperation by means of a global integrated conceptual schema, that is, the federated data schema. Furthermore, owing to the capillarity of the end-user locations and to the need of a simple and widely known interface, Web-based access is mandatory. To define the functional specification of the system, the following activities have been carried out:

- *analysis of the requirements* of a distributed Web-based information system relying on a common conceptual database schema of the regional information that was initially (almost completely) available on paper support;
- *conceptual design* of the DEAFIN FIS, centered on the conceptual design of the federated conceptual database schema. The regional databases must be built according to the federated schema and then made accessible via the Web. The availability of data on the Web allows potential investors to navigate in the DEAFIN site according to various and customizable criteria, based on a benchmarking model developed within the project.

INFORMATION REQUIREMENTS

Three regional administrations from Germany, Italy, and Sweden were involved. The project started with a data-gathering phase, aimed at collecting requirements about data and processes managed at the partner Public Administrations. A questionnaire-based tool was circulated to collect common information to be stored in the FIS.

The basis of the questionnaire is a set of the data categories managed in Public Administration information systems. The relevant data categories concern land use plans (master and regional or specific), territorial services, industrial vacant sites, mobility data, statistical and social-economic data, base cartography data, and information on cadastral units data. Information on vacant industrial sites is the main focus of the investigation. For each category, the questionnaire collected the data characteristics reported in Table 1.

In general, the data collected at the sites show uniformity with respect to the attention paid to cartographic availability, regulations and laws about reuse of vacant areas, and centralization of resources. In particular, the need exists at each regional site to introduce tools able to treat heterogeneous data, since these data more and more intensively are to come from various data sources, to be mapped into the federated schema. Also, the degree of automation is similar, since cartographic systems and basic data management tools are available at the three partners' sites.

Several ongoing local projects concern the digital acquisition of land use plans, the automation of document management, and the development of various thematic databases and Web sites. What is required is a unified common schema for the regional databases. Moreover, the need of a uniform data publishing methodology and policy over Internet Web sites emerges clearly from the participants and involves almost all data categories.

Table 1. Summary of data characteristics collected in the data-gathering phase

Data Characteristics
Availability of the data category
Location of the data source
Support technology and name of products/tools
Data format
Data owner
User roles involved in data access
Restrictions applying to data access
Performances
Maintenance policies
Availability on the Web

USAGE MODES

The data-gathering phase has also detailed a set of user profiles, which specify how different access demands can be supported by the system towards a variety of user groups. The design and implementation of profiles have obviously a deep impact on the usability of the system. Hence, a careful analysis of user typologies and profiles has been performed during the specification phase, while an enrichment of profiles and access modes has been planned in a post-implementation follow-up. The purpose is to have the system start with a set of pre-configured access typologies, and then tune the access modes and user profiles against the most typical uses observed for a fixed period on the DEAFIN pilot implementation. The first broad difference is between the profile of public administrations and that of private users, due to different data needs. Moreover, two basic interaction modes must be provided: browsing (using thematic areas and other refined search parameters) and querying (using simple and user-friendly interfaces). The system can be regarded as: a passive tool, when responding to user questions; an active tool, when used as a decision support system or when used as a standard application, allowing new European partners to join the DEAFIN consortium.

As a passive tool, the contents of the federated database can show the advantages and disadvantages of an area: the information provided can be related to the specific search needs of a specific user. These searches are different according to user types, but apart from the function of locating (or re-locating) business activities, the motivation probably exists to retrieve general information about a region.

SYSTEM ARCHITECTURE

In the literature, several approaches and tools for handling heterogeneous data sources have been developed, and standards for distributed information systems have been defined (Mylopoulos & Papazoglou, 1997; Wiederhold, 1992). For these systems, the use of multiple layer, mediator-based architectures, and of a common data model have been employed (Garcia Molina et al., 1997). Wrapper/extractor and mediator tools (see Key Terms section) are proposed to obtain a uniform data representation (abstracting from the formats of the original data sources) and to facilitate federated access. Following this direction, in order to handle heterogeneity at each regional site, an architecture has been defined where extractors translate data coming from local heterogeneous data sources to a common reference format defined at the mediator level (Schreiber et al., 2003).

The aspect of data publishing over Internet Web sites has emerged clearly as a need from the partner regions. The system is thus conceived as a Web-based federated information system, apt to manage and provide access to all the regional relevant information in an integrated and complete fashion, thus satisfying the Web availability need.

Generally, data made available by a given partner region can be both spatial and alphanumeric, requiring each regional component system to be a GIS. Each regional site is in charge of data publishing and certification over the system according to the common federated schema. Each regional Web site contains a specific interface and stores regional data in a database by means of a Web-GIS technology, and operates as a central server that contains the common interface and some aggregate data. The global system is composed of Web-interconnected sites: the central Web site is the reference site for aggregate data and for requirements about new regional sites to be added in the federation or new applications to be developed in the component systems.

FEDERATED DATABASE CONCEPTUAL DESIGN

The federated database conceptual schema provides an integrated high-level representation of all data to be handled by the FIS. In order to achieve the highest readability and the widest possible diffusion, a common set of terms is needed. We adopted the dictionary of terms as defined by the EuroDicAutom (EuroDicAutom, 2001) of the EU; the international system of measurements, and commonly agreed upon data categories were adopted.

The database conceptual design produced a set of conceptual views, represented in terms of ER diagrams (see Key Terms section), that provide schematic requirement representations, each related to a specific information set. The following views were defined: vacant site description view, land use plan view, administration view, eco/reclamation view, transportation view, service view, document view, procedure and task view; the global conceptual data schema is a merge of these different views.

The design identified 36 entities (including entities with spatial representation that describes their shape, extension and location on the earth surface, marked as geo-referenced), with a total number of about 200 attributes. The XML (eXtensible Markup Language) language was chosen for logical specification, providing a common reference format to facilitate data customization, translation and mediation.

The FIS should enable the user to dynamically query the databases and in particular the geographical data they contain; these requirements, as we discussed previously, are fulfilled by a Web-GIS system able to perform advanced operations guided by the client side.

THE WEB-GIS

The interface of the central Web site allows the users to access data in two search modes: direct search, which leads directly to the vacant area of interest, including also information about the surroundings; and navigation, which presents a list of vacant sites to be filtered progressively, according to various criteria. Indeed, a static benchmarking table presents a list of site features, along with the corresponding values for each partner: from this table the user can choose a partner and obtain pages that describe the partner's area, highlighting its most attractive features. Some aggregate data about the vacant sites of each region are also displayed for subsequent browsing operations, where the user can execute queries in order to filter the vacant sites on the basis of preferences or specific criteria, such as: the type of usage, area size, costs, surrounding services, and accessibility. Finally, links to the regional Web sites are provided.

The Web interfaces of regional sites support more specific functions: the exploration of the partner area by choosing a specific theme such as land planning, business and market activities, mobility system, services, demographic and macroeconomic data and development strategies; the access to business information such as contact offices and particular business opportunities that are currently available for some vacant sites of the area; the access to aggregated data about vacant sites of the area and to a benchmarking table where the user can apply some selection conditions based on the available comparison parameters; the search of vacant sites based on forms that guide the user in the specification of the query, including geography related conditions (SQL with geographic extensions) like "search the vacant sites with a railway station within a radius of <parameter value> km"; the selection of specific features of the chosen vacant site, for example, buildings, eco quality, themes presenting the characteristics technological networks, land planning, mobility system, territorial services, procedures and tasks and documents.

FUTURE TRENDS

Web-GIS applications are becoming more and more important to a growing number of activities. Geography, geology, environmental studies, business marketing, and other disciplines have gained benefits from GIS tools and methods. Continual improvements in GIS hardware and software will lead to a much wider application of this technology throughout government, business, and industry. In particular, integrated geodata services based on data format standardization will increasingly facilitate the exchange of information among users of different systems by allowing data sharing and improving cooperation and communication among the organizations involved in environmental protection, planning, and resource management.

CONCLUSION

The development of the DEAFIN Federated Information System started from an analysis of the requirements and of the locally available information, performed through a data-gathering phase. The federated database was modeled in the form of a set of conceptual views, both as ER diagrams and XML specifications. The architecture of the overall system is in the form of a federated Web-GIS: at the main Web site a high-level view over the entire federated system is allowed, while local specializations are allowed at the level of every regional Web site adhering to the recommendations for the entire database.

The proposed system offers a marketing and information platform in a European context based on advanced Web functions, integrating geographic information systems (GIS), decision support tools, and database federation features. Analogous projects in the European area have been developed, mainly in the field of tourism (Pühretmair & Wöß, 2001), where integration of data sources and access to GIS in a graphical context are needed.

Further details about the project can be found in Schreiber et al. (2003).

KEY TERMS

Conceptual Schema of a Database: A semi-formal high-level description of the database, independent of its implementation.

ER (Entity-Relationship) Diagrams: The most widely used model to express the database conceptual schema.

eXtensible Markup Language (XML): Markup language proposed by the World Wide Web Consortium [W3C] for data and documents interchange.

Federated Information System (FIS): An information system is named federated when it supports interoperation among several autonomous and possibly heterogeneous information systems, by means of a shared global data schema.

Geographical Information System (GIS): Information system storing geographical data along with alphanumeric and spatial components. GIS systems also provide the data structures and algorithms to represent and efficiently query a collection of geographical data.

Mediator: A software component providing a uniform integrated interface to process and execute queries over data stored in multiple, heterogeneous data sources.

Web-GIS: A GIS system empowered with a Web-based interface.

Wrapper: A software tool to extract content from data sources and perform data format translation.

Actor-Network Theory and Adoption of E-Commerce in SMEs

Arthur Tatnall
Victoria University, Australia

Stephen Burgess
Victoria University, Australia

INTRODUCTION

Just because e-commerce technologies seems like useful tools that may assist a small to medium enterprise (SME) in doing its business better, it does not necessarily follow that these technologies will be *adopted* by this business. The implementation of an e-commerce system in an SME necessitates change in the way the business operates, and so should be considered as an innovation and studied using innovation theory.

Electronic commerce (e-commerce) is concerned with how computers, information systems and communications technologies can be used by people to improve the ways in which they do business. As e-commerce necessarily involves interactions of people and technology, any study of how it is used by a small business[1] must be considered in a socio-technical context. Although there is no universal consensus on what constitutes e-commerce, we believe that it contains elements of information systems, business processes and communications technologies. The complexity of studies in e-commerce is due, to a considerable degree, to the interconnected parts played by human actors and by the multitude of non-human entities involved. Small business managers, sales people, staff involved in procurement and warehouse operations, computers, software, Web browsers, Internet service providers (ISP), modems and Web portals are only some of the many heterogeneous components of an e-commerce system.

BACKGROUND

Adoption of E-Commerce by SMEs

In this article we will argue that the decision to adopt, or not to adopt a new technology, has more to do with the interactions and associations of both human and non-human actors involved in the project than with the characteristics of the technology. Information systems are complex socio-technical entities and research into their implementation needs to take account of this complexity, which will only be seen if it is reported in all its "messy reality" (Hughes, 1983). Research into the implementation and operation of these systems needs to take this heterogeneity into account and to find a way to give due regard to both their human and non-human aspects.

One view of the adoption of an electronic commerce innovation by a small business suggests that decisions are made primarily based on their perceptions of the characteristics of the technology concerned. Innovation diffusion (Rogers, 1995) uses this approach, and is based on the following elements: characteristics of the innovation itself, the nature of the communications channels, the passage of time, and the social system. Using this sort of approach, the researcher would probably begin by looking for characteristics of the specific e-commerce technology to be adopted, and the advantages and problems associated with its use. The next step would be to suggest that the adoption, or rejection, of this technology by the small business was due largely to these characteristics. We contend that while there may be some validity in such an approach, it is unlikely to provide the complete explanation, as it would miss other influences due to interpersonal and inter-business interactions, and to the backgrounds of the people involved.

Innovation Translation

We argue that actor-network theory (ANT) has much to offer in a situation like this. A researcher using an actor-network approach to study innovation would concentrate on issues of network formation, investigating the human and non-human actors and the alliances and networks they build up. They would investigate how the strength of these alliances may have enticed the small business to make the adoption or, on the other hand, to have deterred them from doing so (Tatnall, 2000, 2002; Tatnall & Gilding, 1999). While some research approaches to technological innovation treat the social and the technical in entirely different ways, actor-network theory proposes instead a socio-technical account in which neither social nor technical positions are privileged.

Actor-network theory argues that interactions between actors are heterogeneous and denies that purely technical or purely social relations are possible. It considers the world to be full of hybrid entities (Latour, 1993) containing both human and non-human elements. Change, in the ANT view, results from decisions made by actors, and involves the exercise of power. Latour (1986) argues that the mere possession of power by an actor does not automatically lead to change unless other actors can also be *persuaded* to perform the appropriate actions for this to occur.

In our experience it is often the case that when a small business is considering a technological innovation it is interested in *only some aspects* of this innovation and not others (Tatnall, 2002; Tatnall & Burgess, 2002). In actor-network terms it needs to *translate* (Callon, 1986) this piece of technology into a form where it can be adopted, which may mean choosing some elements of the technology and leaving out others. What results is that the innovation finally adopted is not the innovation in its original form, but a translation of it into a form that is suitable for use by the recipient small business (Tatnall, 2002).

In many instances a small business proprietor will adopt e-commerce because a friend is using it, or because they know a competitor is using it, or because a son or daughter learned about it at school (Burgess, 2002; Tatnall, 2002). The nature and size of each small business, the inter-business interactions in which they engage, and the backgrounds and interests of particular individuals in each are also likely to have had an important effect that would, most likely, have been ignored by the essentialist approach offered by innovation diffusion. Actor-network theory, in examining alliances and networks of human and non-human actors, provides a good foundation from which small business adoption and use of e-commerce can be researched. The ANT approach will be further amplified in the case studies that follow, particularly in respect of the identification of actors and networks.

FUTURE TRENDS

Actor-Network Theory and E-Commerce Innovation

The theory of innovation diffusion (Rogers, 1995) is well established and has been used as the framework of many studies. In most cases, however, the success of the diffusion model has been in explanation of innovation "in the large," when the statistical effects of big numbers of organisations and individuals involved come into play. It has, typically, been less successful in explaining how particular individuals or specific organisations make their adoption decisions, and it is in situations like this that an innovation translation approach, using actor-network theory, is especially useful.

In offering a socio-technical approach to theorising innovation, ANT provides a particularly useful tool to the study of innovations in which people and machines are intimately involved with each other. The adoption of e-commerce technologies certainly involves a consideration of the technologies themselves, but also of business organisations, business processes, and the needs and likes of individual humans. ANT, we suggest, is especially useful in researching innovations like these, and in particular, when considering individual adoption decisions.

The main use made of any research approach such as ANT is in the study of past events, and ANT makes no claim to be able to predict what may happen in the future. We suggest, however, that ANT analysis can identify some pointers towards the successful introduction of an innovation, and the change management associated with this. ANT argues that it is not the characteristics of either the innovation itself or the potential adopter acting alone that are important, but rather the interactions of many actors. The key to successful change management, it would thus seem, involves allowing for these interactions and for the socio-technical nature of the process.

Case Studies

This article now offers several brief case studies in which actor-network theory has provided a means by which adoption (or non-adoption) of technology can be explained. In each case, data for the study were obtained through semi-structured interviews with the proprietors and personnel of the businesses involved, between September 2001 and August 2002.

1. *Adoption of a Portal by a Storage and Transport Company*

The business to be considered in this study is a medium-sized Melbourne company, with about 50 employees, that stores frozen food and transports it to supermarkets and other locations around the country. It became clear from the study that the transport company had "not really been into computers," and had only recently started coming to grips with this technology.

Although the manager had some idea of the benefits to his company of using the portal, he had no clear plan for using it. It was just "a really good idea". The reasons he adopted this innovation thus had little to do with the characteristics of this technology, and much more to do with his involvement with the local business community and because of his belief that the portal had the potential to improve business in the region.

2. *Adoption of Electronic Commerce by a Small Publishing Company*

The second case concerns a small publishing company where four people work on the production of textbooks and research publications. The company is a very small business with a relatively low turnover but a well-established market. The business has adopted some e-commerce technologies, but not others. Some time ago, it registered a domain name and set up its own Web page, but only for informational purposes. The site shows details of the company's products and indicates how orders can be placed, but does not support sales or other business-consumer (B-C) transactions.

When asked why the company had not considered instituting a B-B e-commerce system with the printer, the director replied that they would like to do so, but that the printer was not really interested or geared up to get into this type of order. Adoption decisions of the company thus had more to do with the technological status of their suppliers and their customers than with the e-commerce technology itself. The company was interested in using those e-commerce technologies that its business partners used and those it considered useful or timesaving. What was adopted could be seen as a translation of an e-commerce innovation to include just these things.

3. *Non-Adoption of E-Commerce by a Small Chartered Accountancy Firm*

The last case is of a small chartered accountancy firm which is a family business in the western suburbs of Melbourne. Employees of the business are the main accountant, who has a degree in accounting and is a Certified Practicing Accountant (CPA); the main accountant's father, who previously ran the business but, as he is not qualified, is limited these days mainly to supporting the taxation side of the business; another accountant (CPA); and a full-time secretary. The firm offers services that are typical of a small accounting business and its clients include both individuals and small businesses.

For some time members of the business had been debating whether to set up a Web site. The decision seemed to come down to two major opposing viewpoints. The first, held by the main accountant, was that a Web site was "the way of the future," that customers would expect it and that some competitors already had one. The opposite viewpoint, held by the father, was that it is a waste of time and money, that there was nothing you could put on a Web site that customers would want anyway, and "who is going to do it?" Other members of the business seemed quite apathetic about the whole matter.

The upshot was that the Web site could not be "translated" into a form where it could be adopted by this business. The main accountant was the prime motivator in attempting to define the problem and to discover the solution: he did not do this well enough, however, to gain acceptance of the innovation.

CONCLUSION

All of the situations described point to the fact that decisions on the adoption of electronic commerce technologies are often made on the basis of more than just the characteristics of the technology, and that in many cases these characteristics are not especially significant in the decision making process.

In each of these instances, the actor-network approach therefore offers a useful explanation of why a particular e-commerce initiative was or was not adopted. On the other hand, an innovation diffusion approach to investigating each of the potential adoptions would have looked for explanations for the uptake, or lack of uptake, primarily in the characteristics and properties of the technology in each case. It would not have considered, as particularly important, the human and non-human interactions described here. In our view, the decision to adopt, or not to adopt, has more to do with the interactions and associations of both human and non-human actors involved in the project than with characteristics of the technology.

KEY TERMS

Actor: An entity that can make its presence individually felt by other actors. Actors can be human or non-human, non-human actors including such things as computer programs, portals, companies and other entities that cannot be seen as individual people. An actor can be seen as an association of heterogeneous elements that constitute a network. This is especially important with non-human actors as there are always some human aspects within the network.

Actor-Network Theory (ANT): An approach to research in which networks associations and interactions between actors (both human and non-human) are the basis for investigation.

E-Commerce Studies: Contain elements of information systems, business processes and communications technologies.

Innovation Diffusion: A theory of innovation in which the main elements are: characteristics of the innovation itself, the nature of the communication channels, the passage of time, and the social system through which the innovation diffuses.

Innovation Translation: A theory of innovation in which, instead of using an innovation in the form it is proposed, potential adopters *translate* into a form that suits their needs.

Small to Medium Enterprise (SME): For the purpose of this article SMEs are considered to be those businesses that have from 1-20 employees – small, and 21-50 employees – medium.

Technological Innovation: The introduction or alteration of some form of technology (often information technology) into an organisation.

Technology Adoption: The decision, by an organisation or individual, to utilise and implement a technology.

Actor-Network Theory in Information Systems Research

Arthur Tatnall
Victoria University, Australia

INTRODUCTION

Building an information system is a difficult task, partly due to the problem of ascertaining the requirements of the intended users, but also because of the complexity of the large number of human-machine interactions (Banville, 1991). This complexity is reflected in the difficulty of building these systems to operate free from error and to perform as intended. The dictionary defines innovation as "the alteration of what is established; something newly introduced". As the introduction or improvement of an information system in an organisation *necessarily* involves change, information systems research often involves research into technological innovation.

BACKGROUND

Information Systems as a Socio-Technical Discipline

The discipline of information systems (IS) is concerned with the ways people build and use computer-based systems to produce useful information and so has to deal with issues involving both people and machines; with the multitude of human and non-human entities that comprise an information system (Checkland, 1981). Information systems is neither merely a technical discipline nor a social one, but one that is truly socio-technical. Researchers in information systems face the problem of how to handle complexities due to interconnected combinations of computers, peripherals, procedures, operating systems, programming languages, software, data and many other inanimate objects; how they all relate to humans and human organisations, and how humans relate to them (Longenecker, Feinstein, Couger, David & Gorgone, 1994).

This article will outline a socio-technical approach, based on actor-network theory (ANT), to researching how people interact with and use information systems (Tatnall & Gilding, 1999). In actor-network theory the key is in using an approach that is neither purely social nor purely technical, but socio-technical.

Qualitative Research Traditions in Information Systems

Each field of academic inquiry is characterised by its own preferred and commonly used research approaches and traditions. In information systems research, Myers (1997) outlines four qualitative traditions as being particularly significant: case study research, ethnography, grounded theory and action research.

Case study research is the most commonly used qualitative approach in information systems. As IS research topics commonly involve the study of organisational systems, a case study approach is often appropriate. Ethnography has grown in prominence as a suitable approach to information systems research after work such as that undertaken by Suchman (1987) and Zuboff (1988). It has been used especially in research where the emphasis is upon design, computer-supported cooperative work, studies of Internet and virtual communities, and information-related policies (Star, 1995). Grounded theory is an "an inductive, theory discovery methodology" (Martin & Turner, 1986) that seeks to develop theory that is grounded in data that are systematically gathered and analysed and involves "continuous interplay" between data and analysis (Myers, 1997). Orlikowski (1993) argues that in information systems research situations involving organisational change, a grounded theory approach can be useful as it allows a focus on "contextual and processual" elements as well as on the actions of key players.

Action research has been described as proceeding in a spiral of steps where each step consists of planning, action and evaluation of the result of the action. It is seen as aiming "... to contribute both to the practical concerns of people in an immediate problematic situation and to the goals of social science by joint collaboration within a mutually acceptable ethical framework" (Rapoport, 1970, p. 499). A variant of action research that is slowly gaining acceptance in information systems is soft systems methodology (SSM), developed by Peter Checkland (1991). SSM attempts to give due recognition to both the human and technological aspects of a system. It acknowledges both human and non-human aspects of IS, but considers these to be entirely separate types of entities.

FUTURE TRENDS

ANT and Socio-Technical Research

Actor-network theory considers both social and technical determinism to be flawed and proposes instead a socio-technical account (Latour, 1996) in which nothing is purely social and nothing is purely technical (Law, 1991). ANT deals with the social-technical divide by denying that purely technical or purely social relations are possible.

To see better how this works, suppose that an IS researcher was investigating the uptake of a business-to-business e-commerce portal developed by a local government authority for use within a regional area, with an Internet service provider (ISP) and a software company engaged to build the portal, and a bank to provide a payment gateway. ANT asserts that the world is full of hybrid entities (Latour, 1991) containing both human and non-human elements and offers the notion of heterogeneity to describe projects such as this. The project will involve not just these entities, but also non-human entities such as computers, computer programs, data storage devices, modems and telephone lines, and human entities including local business proprietors from small and large businesses, customers, programmers and local council staff. The utilisation of heterogeneous entities (Bijker, Hughes & Pinch, 1987) then avoids questions of: "is it social?" or "is it technical?" as missing the point, which should be: "is this association stronger or weaker than that one?" (Latour, 1991).

Information systems researchers using an ANT approach would concentrate on issues of network formation, investigating the human and non-human alliances and networks built up by the actors involved. They would concentrate on the negotiations that allow the network to be configured by the enrolment of both human and non-human allies. Interactions and associations between actors and networks are all important, and actors are seen simply as the sum of their interactions with other actors and networks.

In the case of the portal an actor-network researcher would begin by identifying some of the important actors, starting perhaps with the local government portal project manager. An interview with the project manager would reveal why the project was instigated and identify some of the other actors. The main advice on method suggested by the proponents of actor-network theory is to "follow the actors" (Latour, 1996) and let them set the framework and limits of the study themselves, and one line of inquiry resulting from the interview with the project manager might be to approach the portal software designer and programmers. Another set of actors is the proprietors of the local businesses themselves, and the project manager may suggest some "business champions" to interview first. At least some of these business people might then point to the influence exerted by the computer hardware or software as a significant factor, so identifying some non-human actors. Negotiations between actors must be carefully investigated. Apart from the obvious human-to-human kind of negotiation, also included must be human-to-non-human interactions such as the business people trying to work out how the portal operates, and how to adapt this technology to be most suitable for their own business purposes. The process of adopting and implementing the portal can now be seen as the complex set of interactions that it is, and not just the inevitable result of the innate characteristics of this technology.

How Actor-Network Theory Handles Complexity

Longenecker et al. (1994) suggest that computer-based information systems should be regarded as complex socio-technical entities, begging the question of how this complexity should be handled. A common method of handling complexity in all subject areas lies in simplification, but the danger with simplification is that it runs the risk of removing just those things that constitute a useful description of the phenomenon under investigation by concealing the parts played by many of the actors (Suchman, 1987). The question here is which details to include and which to leave out, and who is to decide. In this respect, an appropriate research approach needs to ensure that complexities are not lost "in the process of labelling" (Law, 1991).

In actor-network theory the extent of a network is determined by actors that are able to make their presence *individually felt* by other actors. The definition of an actor requires this and means that, in practice, actors limit their associations to affect only a relatively small number of entities whose attributes are well defined within the network. An actor is not just a point object but an association of heterogeneous elements, themselves constituting a network. An actor can, however, in many ways also be considered as a black box (Callon, 1986), and when we open the lid of the box to look inside it will be seen to constitute a whole network of other, perhaps complex, associations. In many cases details of what constitutes an actor - details of its network - are a complication we can avoid having to deal with all the time.

When investigating the e-commerce portal it might be convenient, most of the time, to consider both the ISP and the portal software to constitute a black box. This would mean that this aspect of the technology could then be considered as just a single actor; the portal, and its interactions with other actors investigated on this basis. At other times it might be necessary to lift the lid of the black box and investigate the enclosed network of the ISP, telephone lines, computers, data storage, programmers, and interface designers it contains. The advantage of black-boxing though is that most of the time, however, the portal can be regarded as just another actor. The important thing to note about the use of black-boxing for simplification is that the complexity is not just put into the black box and lost, as it is always possible, and indeed necessary, to periodically reopen the black box to investigate its contents.

The portal black box could be considered as shown in Figure 1. This black box itself also contains several other black boxes (portal software, portal hardware and payment gateway) that we do not need to consider in detail until such consideration becomes necessary. Figure 1 also shows some of the other main actors that interact with the portal. Until (and possibly after) the portal is fully operational, of course, these actors will also interact directly with each other.

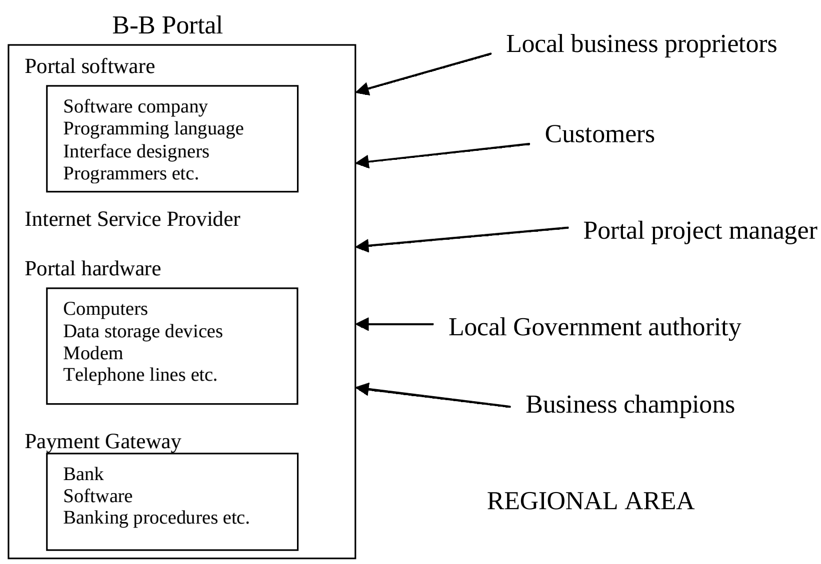
Limitations and Criticisms of Actor-Network Theory

There are several main criticisms of actor-network theory. To begin, there is the criticism by Grint and Woolgar (1997) that it is not always sufficiently clear where the boundaries of a network lie or whose account of a network is to be taken as definitive. They note that the analyst's story seems to depend on a description of the "actual" network, as if this was objectively available.

A second criticism relates to ANT's treatment of non-human actors. A critique by Collins and Yearley (1992) claims that in giving an autonomous voice to "things," ANT concedes too much to realist and technical accounts. In reply, Callon and Latour (1992) claim that technological artefacts are implicated in the very fabric of the social and are "social relations viewed in their durability and cohesion".

Thirdly, Grint and Woolgar (1997) argue that ANT retains a degree of residual technicism in its need to sometimes refer to "actual" technical capacities of a technology. They quote Callon's (1986) analysis of the attempts at building a French electric car, in which they claim that he makes reference to the "unfortunate tendency" of the catalysts to become quickly contaminated. They note that the anti-essentialist approach of actor-network theory would point to this "actual property" being treated as a construction. Despite these minor reservations, however, Grint and Woolgar note that actor-network theory points to the possibility of an understanding of technology that does not rely on the presence of a "god within the machine".

Figure 1. Actors, interactions and the portal black box



CONCLUSION

In this article I have argued that information systems is a socio-technical discipline involving both human and non-human entities, and that information systems implementations are complex activities inevitably involving some form of technological innovation. I have also argued that simplistic views of how information systems are built, implemented and used often conceal important interactions between human and non-human actors and so give a less than complete picture of what has happened.

An actor-network approach avoids the need to consider the social and the technical, and thus human and non-human actors, in different ways. Highlighting how the human and non-human actors involved in socio-technical situations, such as the building and use of information systems, interact with each other is an important benefit of adopting an ANT research framework. In showing how these interactions may lead to the formations of stable networks, actor-network theory offers a useful way to handle the complexity of such studies.

KEY TERMS

Actor: An entity that can make its presence individually felt by other actors. Actors can be human or non-human, non-human actors including such things as computer programs, portals, companies and other entities that cannot be seen as individual people. An actor can be seen as an association of heterogeneous elements that constitute a network. This is especially important with non-human actors, as there are always some human aspects within the network.

Actor-Network Theory (ANT): An approach to research in which networks associations and interactions between actors (both human and non-human) are the basis for investigation.

Black Boxing: A technique used for simplification. Multiple actors can be put into a black box so that it is not necessary to look at them in detail. The portal mentioned in this article could be considered as a black box containing the ISP, portal software, data storage devices, modems, telephone devices and so on. Black-boxing is done for convenience, as it means that an entity can then be seen as just another actor, and saves looking at the detail until necessary. The black box can later be reopened to investigate its contents.

Socio-Technical Research: Involving both social and technical interactions, occurring is such a way that it is not easily possible to disentangle them.

Technological Innovation: The introduction or alteration of some form of technology (often information technology) into an organisation.

A

Adaptive Mobile Applications

Thomas Kunz
Carleton University, Canada

Abdulbaset Gaddah
Carleton University, Canada

INTRODUCTION

The convergence of two technological developments has made mobile computing a reality. In the last few years, developed countries spent large amounts of money to install and deploy wireless communication facilities. Originally aimed at telephone services (which still account for the majority of usage), the same infrastructure is increasingly used to transfer data. In parallel, wireless LAN technologies are providing hotspot coverage in many high-traffic locations. The second development is the continuing reduction in size of computer hardware, leading to portable computation devices such as laptops, palmtops, or functionally enhanced cell phones. Given current technology, a user can run a set of applications on a portable device and communicate over a variety of communication links, depending on his/her current location.

As will be explained in more detail later on, the mobile computing environment is highly dynamic. Available bandwidth changes by orders of magnitudes, based on the selected wireless access technology. Also, portable devices differ in processing power, memory, display capabilities, and other characteristics. It is generally argued that applications should "adapt" to the current environment, for example by filtering and compressing data or by changing the functionality offered to the user. Some researchers even argue that all future applications, not just the ones intended for execution on mobile devices, will have to be able to adapt to changing requirements and changing implementation environments on time scales from microseconds to years (Kavi, 1999). This article reviews the work on adaptive mobile applications and provides an outlook on future trends.

The alternative to adaptive applications is to either implement a single application that is designed for the lowest common denominator (in terms of resource availability) or multiple functionally identical or similar binaries, tuned for specific environments. The former will needlessly sacrifice application features when running in more resource-rich environments. The latter approach is an inferior solution as well, for a number of reasons. The user of a portable device has to install and maintain multiple applications, which is a drain on the limited storage capabilities typically found on those devices. It also potentially results in different user interfaces and causes high software development overheads when developing the "same" mobile application multiple times. Finally, it forces the user to identify the current execution conditions and select the "right" application.

The next section will review the motivation for adaptive approaches towards mobile application design. We will then briefly review traditional approaches to adaptive mobile applications, followed by a discussion of mobile middleware that is intended to support adaptive mobile applications. The article finishes with a brief conclusion of the state-of-the-art and identifies areas of future work.

BACKGROUND

Wireless communication and portable devices make it possible for mobile users to have access to information anywhere and anytime. Designing, implementing and deploying applications that work well across all portable devices and across a wide range of wireless access networks is non-trivial.

There are at least three common factors that affect the design of mobile applications: portable devices, network connection, and mobility. *Portable devices* vary from one to another in term of resource availability. Devices like laptops can offer fast CPUs and large amount of RAM and disk space while others like pocket PCs and phones usually have scarce resources. It is either impossible or too expensive to augment the resource availability. Hence, applications should be designed to achieve optimal resource utilization. In general, the design of portable devices strives for properties such as size, weight, durability and long battery life. Different devices will emphasize different trade-offs between CPU speed, memory, I/O capabilities, and power consumption, providing very heterogeneous execution environments for mobile applications.

Network connection in mobile scenarios is characterized by limited bandwidth, high error rate, higher cost, and frequent disconnections due to power limitations, available spectrum, and mobility. Wireless communication is more difficult to achieve than wired communication because the surrounding environment interacts with the signal, blocking signal paths and introducing noise and echoes. Therefore, mobile application designs need to be more concerned about the network conditions than applications designed for fixed networks. Many wireless and mobile networks such as WaveLAN are organized into geographically defined cells, with a control point called a base station in each of the cells. Devices within the same cell share the network bandwidth; hence, the bandwidth rapidly decreases whenever a new device joins the cell. Portable devices may move around different areas with no coverage or high interference that cause a sudden drop in network bandwidth or a loss of connection entirely. Unpredictable disconnection is also a common issue that frequently occurs due to the handoff process or shadowed areas. Most wireless network services charge a flat fee for their service, which usually covers a fixed number of messages. Additional charges are levied on per packet or per message basis. In contrast, the cost for sending data over cellular networks is based on connection time instead. This forces mobile users to connect for short periods of time.

Physical device mobility can greatly affect network connection, which accordingly has to adapt to user mobility by reconnecting the user with respect to a new location. Portable devices may interact with different types of networks, services, and security policies as they move from one area to another. This requires applications to behave differently to cope with dynamic changes of the environment parameters. As a consequence, mobile applications also have to cope with a much greater variation in network bandwidth: bandwidth can shift from one to six orders of magnitude between being plugged into the wired network versus using (different) wireless access networks.

The constraints and limitations mobile applications face are not a product of current technology, but they are related naturally to mobility. Together, they complicate the design of mobile applications and require rethinking traditional approaches to application design. Any feasible approach to mobile computing must strike a balance between conflicting demands. This balance cannot be static, as the execution environment of mobile applications varies; it must react, or in other words, the applications must be adaptive.

ADAPTIVE MOBILE APPLICATIONS: TRADITIONAL APPROACHES

Designing adaptive applications is an active research area. Traditionally, most work focused on the wireless link(s). Early work provides general solutions that do not change the TCP semantics but focus on improving TCP throughput over wireless links; see for example Balakrishnan (1995). While this addresses issues such as high link error rates and spurious disconnections, it does not address the low and highly variable bandwidth characteristic of mobile computing.

A second group of approaches adapts to the scarce and varying wireless link bandwidth by filtering and compressing the data stream between a client application on a portable device and a server executing on a stationary host. Data compression is done at one of two places. Bolliger (1998) and Seshan (1997) enhance the server to generate a data stream that is suited for the currently available bandwidth. This typically represents an end-to-end approach, which is well known in the networking and system literature. Most other proposals (Angin, 1998; Fox, 1998) extend the client-server structure to a client-proxy-server structure, where a proxy executes in the wireless access network, close to the portable device. This proxy-based approach filters and compresses the data stream originating from the server to suit the current wireless bandwidth. Joshi (1997) incorporates both end-to-end and proxy-based approaches, using each as appropriate, to support Web access from mobile platforms. For example, tasks such as complex filtration, which require significant computational resources, are done in an end-to-end manner. The proxy-based approach, on the other hand, is used when the server is not able to generate the appropriate data stream.

A third, complementary approach, focuses on the computational effort (Kunz, 2000). Mobile applications, especially ones that require intensive computation (for example, video decoding), can be divided dynamically between the wired network and the portable device according to the mobile environment and to the availability of the resources on the portable device, the wireless link, and the wired network. The access network supports the mobile application by providing proxy servers that can execute parts of the application code. This may increase the performance of applications and reduce the power consumption on portable devices since offloading computation to the proxies in the wired network will reduce the CPU cycles and memory needed to achieve certain tasks at portable devices.

FUTURE TRENDS: MOBILE MIDDLEWARE

The early approaches reviewed in the previous section typically provide toolkits that support specific adaptation ideas. To generalize this effort, support for adaptive mobile applications should be embedded into appropriate mobile middleware. Traditional middleware systems, like CORBA and DCOM, have achieved great success in dealing with the heterogeneity in the underlying hardware and software platforms, offering portability, and facilitating development of distributed applications. However, these systems are based on the assumptions that the distributed applications will run in a static environment; hence, they fail to provide the appropriate support for mobile applications. Therefore, mobile applications need a middleware that facilitates adapting to environment variations.

Based on the mobile computing challenges reviewed previously, mobile middleware should meet the following requirements: *Asynchronous interaction* tackles the problems of high latency and disconnected operations. It allows mobile clients to issue a request for a service, disconnect from the network, and collect the result later on. This type of interaction model reduces bandwidth consumption, achieves decoupling of client and server, and elevates system scalability. *Reconfigurability* is the process of adding a new behavior or changing an existing one during system runtime. Dynamic reconfiguration of system behavior and operating context at runtime may require reevaluation and reallocation of resources. Reconfiguration could be based on context information. *Adaptivity* allows applications to modify their behavior instead of providing a uniform interface in all situations. The middleware needs to monitor the resource supply/demand, compute adaptation decisions, and notify applications about changes. *Context-awareness* of client capabilities, changes to network conditions, and the ability to change the behavior of the system as circumstances warrant are required to build an effective and efficient adaptive system. The context includes device characteristics, user's location, user's activities, and other resources. The system performance can be increased when information context is disclosed to the application to assist middleware in making the right decision. Finally, *lightweight load* should be considered when constructing middleware for mobile computing. Middleware should not increase the computational load on the most power-consuming components such as processor, network interface, and so forth. Middleware implementations often include a number of unused features that can be entirely omitted to reduce the computational load.

We identified four categories of mobile middleware: reflective, tuple space, context-aware, and event-based middleware. *Reflective middleware* like DynamicTAO (Kon, 2000) and Open-ORB (Blair, 2001) are built around the concept of component frameworks (CF). Components can be developed independently, distributed in binary form, and combined at run time. Reflection provides a *meta-interface* to inspect the internal behavior of the middleware and, if it is necessary, alter its behavior to better match the system's current operating environment. The main motivation of this approach is to make the middleware more adaptable to its environment and better able to cope with changes. Open problems are consistent dynamic reconfiguration and performance. There is some early work in this area that has focused on developing reconfiguration models and algorithms that enforce well-defined consistency rules while minimizing system disturbance (Kramer & Magee, 1990). In addition, all reflective systems impose a heavy computational load that causes significant performance degradation on portable devices.

Tuple-space systems such as LIME (Picco, 1999) and TSpaces (Wyckoff, 1998) exploit the decoupled nature of tuple spaces for supporting disconnected operations in a natural manner. A tuple space is a globally shared, associatively addressed memory space that is used by processes to communicate. Client processes create tuples and place them in the tuple space using a *write* operation. Also, they can concurrently access tuples using *read* or *take* operations. This communication paradigm fits well in a mobile setting where logical and physical mobility is involved. By default they offer an asynchronous interaction paradigm that appears to be more appropriate for dealing with intermittent connection of mobile devices, as is often the case when a server is not in reach or a mobile client requires to voluntary disconnect to save battery and bandwidth. Using a tuple-space approach, we can decouple the client and server components in time and space. In other words, they do not need to be connected at the same time and in the same place. Tuple-space systems support the concept of a space or spaces that offer the ability to join objects into appropriate spaces for ease of access. This opens up the possibility of constructing a dynamic super space environment to allow participating spaces to join or leave at arbitrary times. The ability to use multiple spaces will elevate the overall throughput of the system. One problem with tuple-space middleware systems is their excessive memory requirements, making them impractical for most portable devices available to-date.

Context-aware systems provide mobile applications with the necessary knowledge about the execution context in order to allow applications to adapt to dynamic changes in mobile host and network condition. The execution context includes but is not limited to: mobile user location, mobile device characteristics, network condition, and user activity (i.e., driving or sitting in a room). However, most context-aware applications are only focusing on a user's location. Nexus (Fritsch, 2000), for example, is designed to be a generic platform for location-aware applications. Reflective middleware may also improve the development of context-aware services and applications. For example, Capra (2003) has suggested the use of metadata and reflection to support context-aware applications. However, overall, limited attention has been given to contexts other than location. It is necessary to take into account other types of context awareness such as internal resources (i.e., memory size, battery and processor power) or external resources (i.e., network bandwidth and connectivity quality). More efforts need to be directed towards an easy context representation and simple interfaces that enable the applications to interact with the underlying middleware.

In *event-based systems*, clients first announce their interest in receiving specific events and then servers broadcast events to all interested clients. Hence, the event-based model achieves a highly decoupled system and many-to-many interaction style between clients and servers. Examples are JEDI (Cugalo, 2001) and STEAM (Meier, 2002). Most existing systems do not combine traditional middleware functionality (i.e., security, QoS, transactions, reliability, access control, etc.) with the event-based paradigm. In addition, the developers are responsible for handling the low-level event transmission issues. Current publish/subscribe systems are restricted to certain application scenarios such as instant messaging and stock quote dissemination. This indicates that such systems are not designed as general middleware platforms. The majority of event-based middleware architectures are based on a logically centralized component called event dispatcher or broker. This component acts as a gateway between interacting components and hence has global knowledge about all the generated events and subscription requests. However, this centralized design often results in performance bottlenecks. Furthermore, not all event brokers provide a persistent buffer that can store all events for the provision of a reliable event service. There is also no support for the notion of composite events. Composite-event services allow clients to sign up with several event sources and receive event notifications in form of composite events. A special mechanism is needed to model event arrival from different sources and to specify composite events. This however may complicate the system architecture and incur extra cost.

CONCLUSION

Mobile computing is a relatively new field. While the challenges arising from mobility and the limitations of the portable devices are relatively well understood, there is no consensus yet as to what should be done to address these challenges. A comprehensive solution has to address many different aspects, such as the issue of dynamically changing bandwidth, the power, computational, and other limitations of the portable devices, or the varying availability of services in different environments. Traditional approaches to these challenges involved the design and implementation of proxies to either transparently intercept the data stream or to cooperate with the client application in the portable device in offloading computational tasks. To generalize this work, such services are expected to be embedded in middleware for mobile applications. Traditional middleware systems, such as CORBA and Java RMI, are based on the assumption that applications in distributed systems will run in a static environment; hence, they fail to provide the appropriate support for mobile applications. This gives a strong incentive to many researchers to develop modern middleware that supports and facilitates the implementation of mobile applications. To date, there is no single middleware that can fully support the requirements for mobile applications. Several solutions have considered one aspect or another; however, the door for further research is still wide open.

Table 1 provides a simple comparison of mobile middleware solutions with respect to the identified requirements for mobile computing. As can be seen, no single middleware paradigm covers all requirements. Based on our analysis, an evolution of reflective mobile

Adaptivity	✓		✓	
Awareness	✓		✓	
Lightweight				✓

middleware appears most promising, however. The key challenges are to reduce the complexity and size of such middleware for thin clients and to efficiently support asynchronous interaction styles.

KEY TERMS

Context-Awareness: Makes applications aware of the dynamic changes in execution environment. The execution context includes but is not limited to: mobile user location, mobile device characteristics, network condition, and user activity.

Event-Based Systems: Systems in which clients (*subscribers*) have to express (*subscribe*) their interest in receiving particular events. Once clients have subscribed, servers (*publishers*) publish events, which will be sent to all interested subscribers.

Middleware: An enabling layer of software that resides between the application program and the networked layer of heterogeneous platforms and protocols. It decouples applications from any dependencies on the plumbing layer that consists of heterogeneous operating systems, hardware platforms and communication protocols.

Portable Device: Computational device that is small and can be carried by its user, such as smart cell phones, PDAs, and laptops. Unlike stationary devices, the design of portable devices typically trades-off CPU speed, memory, I/O facilities, and so forth for reduced power consumption and size.

Reflective Software: Computational process that reasons about itself, comprising an ingredient process (interpreter) formally manipulating representations of its own operations and structures.

Tuple Space: A globally shared, associatively addressed memory space that is used by processes to communicate asynchronously, based on the notion of tuples and tuple matching.

Wireless Communication: Data communication that does not require a wired connection between communicating peers, typically using radio or infrared transmissions.

Adaptive Playout Control Schemes for Speech over the Internet

Marco Roccetti
University of Bologna, Italy

Stefano Ferretti
University of Bologna, Italy

INTRODUCTION

The transmission of speech over the Internet is often dismissed as an impractical application because of the poor quality experienced by many users of Internet audio tools. In fact, while Internet audio services are required to operate in a bandwidth-, delay-, and packet loss-constrained environment, the actual best-effort service offered by the Internet architecture does not provide any guarantee on the delivery of data packets. Thus, it often occurs that very high packet delay, delay jitter and packet loss are experienced over many congested Internet links.

To ameliorate the effect of network delay, delay jitter and packet loss rate, novel protocol suites and networking technologies (e.g., RSVP, ATM networks) have been devised that provide users with quality of service (QoS) guarantees (Zhang, Deering, Estrin, Shenker & Zappala, 1993). However, these approaches are not yet widely used and, as a consequence, in the absence of network support to provide guarantees of QoS to users of Internet voice tools, an interesting alternative amounts to the use of adaptive playout control mechanisms at the receiver side. Those approaches are adopted by the majority of the existing Internet audio tools, such as *NeVot* (Schulzrinne, 1992), *vat* (Jacobson & McCanne, n.d.), *rat* (Hardman, Sasse & Kouvelas, 1998), *FreePhone* (Bolot & Vega Garcia, 1996) and *BoAT* (Roccetti, Ghini, Pau, Salomoni & Bonfigli, 2001).

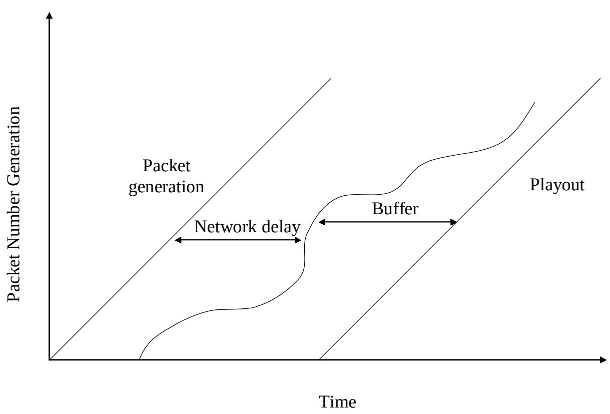
In essence, to compensate for variable network delays and remove jitter from audio packet streams, adaptive playout control mechanisms use a voice reconstruction buffer at the receiver and add artificial delay to the audio stream to smooth out the delay jitter. Simply put, received audio packets are first queued into the buffer and then the periodic playout of each packet is delayed for some quantity of time. This buffering policy must be adaptive, since jitter on the Internet may vary significantly with time. In this way, dynamic playout buffers can hide at the receiver packet delay variance at the cost of additional delay (see Figure 1).

It goes without saying that, even if this approach permits the removal of jitter from audio packet streams, and guarantees the speech intelligibility, a critical trade-off exists between the amount of delay that is introduced in the buffer and the percentage of late packets that are not received in time for playout (and are consequently lost). In fact, the longer the additional delay, the more likely it is that a packet will arrive before its scheduled playout time. Summing up, on one side, a too large percentage of audio packet loss may impair the intelligibility of an audio transmission, but, on the other side, too large playout delays (due to buffering) may disrupt the interactivity of an audio conversation (Kostas, Borella, Sidhu, Schuster, Grabiec & Mahler, 1998; Panzieri & Roccetti, 1997).

In conclusion, Internet playout control mechanisms adaptively adjust the playout delay of audio packets in order to keep this additional buffering delay as small as possible, while minimizing the number of packets delayed past the point at which they are scheduled to be played out (Boutremans & Le Boudec, 2003; Fujimoto, Ata & Murata, 2004; Liang, Farber & Girod, 2003; Sreenan, Chen, Agrawal & Narendran, 2000).

With this in view, in the remainder of this article we survey three different adaptive playout delay control mechanisms that have been designed to support speech

Figure 1. Smoothing out jitter delay at the receiver



transmission over the Internet. In particular, all three different approaches adopt adaptive control mechanisms that keep the same playout delay constant throughout a given talkspurt, but permit different playout delays in different talkspurts.

BACKGROUND

In this section we survey three different adaptive playout delay control schemes designed to transport speech over the Internet.

Playout Control Mechanism - #1

The adaptive playout delay adjustment algorithm proposed in Ramjee, Kurose, Towsley, and Schulzrinne (1994) is used in several Internet audio tools, such as *NeVoT* (Schulzrinne, 1992), *rat* (Hardman et al., 1998) and *FreePhone* (Bolot & Vega Garcia, 1996). This algorithm assumes that an external mechanism exists that keeps synchronized the two system clocks at both the sending and the receiving sites and that the delays experienced by audio packets on the network follow a Gaussian distribution. The mechanism works as follows.

The receiver buffers packets and delays their playout for a time quantity that is usually adaptively adjusted from one talkspurt to the next one. In essence, this mechanism works by calculating the playout time p_i for the first packet i of a given talkspurt as:

$$p_i = t_i + \underline{d}_i + k * \underline{v}_i,$$

where t_i is the time at which the audio packet i is generated at the sending site, d_i is the average value of the playout delay, $k \in [1, 2, 4]$ is a variation coefficient (whose effect can be enforced through shift operations) and v_i is the average variation of the playout delay. The playout point p_j for any subsequent packet j of that talkspurt is computed as an offset from the point in time when the first packet i in the talkspurt was played out:

$$p_j = p_i + t_j - t_i.$$

The estimation of both the average delay and the average delay variation are carried out using a stochastic gradient algorithm.

This strategy is also equipped with a delay spike detection and management mechanism. In essence, the algorithm works as described here, but when a spike is detected the mechanism uses the delay of the first packet of the talkspurt as the estimated playout delay for each packet in the talkspurt, in order to effectively react to very large change in transmission delays.

Playout Control Mechanism - #2

Another adaptive delay adjustment algorithm for speech transmission has been presented in Moon, Kurose, and Towsley (1998). The main idea behind this algorithm is to collect statistics on packets already arrived and then use them to calculate the playout delay.

In essence, the value of each packet delay is recorded and the distribution of packet delays is updated with each new arrival. When a new talkspurt starts, this mechanism calculates a given percentile point for an established amount of last arrived packets, and uses it as the playout delay for the new talkspurt.

In the presence of delay spikes the algorithm stops collecting packet delays as soon as a delay spike is detected, and starts following the spike by using as playout delay the delay value experienced by the packet that commenced that spike.

Playout Control Mechanism - #3

Another mechanism designed to dynamically adapt the talkspurt playout delays to the network traffic conditions has been proposed in Roccetti et al. (2001). This mechanism is at the basis of an Internet audio tool, called *BoAT*.

The mechanism is able to dynamically adjust the talkspurt playout delays to the network traffic conditions without assuming either the existence of an external mechanism for maintaining an accurate clock synchronization between the sender and the receiver, or a specific distribution of the end-to-end transmission delays experienced by the audio packets.

Succinctly, the technique for dynamically adjusting the talkspurt playout delay is based on obtaining, in periodic intervals, an estimation of the upper bound for the packet transmission delays experienced during an audio communication. Such an upper bound is periodically computed using round-trip time values obtained from packet exchanges of a three-way handshake protocol performed between the sender and the receiver of the audio communication. Then, the upper bound is used to dynamically adjust the playout delay from one talkspurt to the next, with the introduction of artificially elongated or reduced silence periods.

CRITICAL ISSUES

The need of silent intervals for allowing a playout delay control mechanism to adjust to the fluctuating network conditions is common to all three Internet audio mechanisms described in the previous section. This renders all the described control schemes particularly suitable for voice-based conversational audio with intervening silence periods between subsequent talkspurts. In fact, the presence of silent intervals permits to dynamically adjust the playout delay from one talkspurt to the next.

Thus, in order to assess the efficacy and the viability of these mechanisms, an accurate model of the talkspurt/silence characteristics of conversational speech is necessary for understanding whether sufficient (and sufficiently long) silent intervals occur in typical human conversations.

With this in view, Roccetti, Ghini and Pau (2001) conducted a simulation study showing that a sufficient total amount of silent intervals occur in human conversational speech to be used at the receiver to accommodate changes of the audio packet transmission delay, while maintaining speech intelligibility.

In particular, it is shown that the total quantity of silent intervals within a simulated two-party one-hour-long packetized conversation amounts to about 63-66%, depending on the voice packetization interval (see Figure 2).

Further, another important result obtained in that study is that the smaller the chosen packet voice size, the more the total number of silence periods increase and the average talkspurt length decreases. Instead, the larger the packet size, the larger the average duration of the talkspurt.

The main results concerning the quantity and the duration of the talkspurts are summarized in Figures 3 and 4 where, respectively, the total quantity of packetized talkspurts (with duration smaller than a fixed amount) and the percentage of talkspurts (with length smaller than a fixed amount) are reported.

As the duration of intervening silence periods in human speech may be artificially reduced or elongated to accommodate at the receiver changes of the audio packet transmission delays, another important question to be

Figure 2. Total amount of silence periods

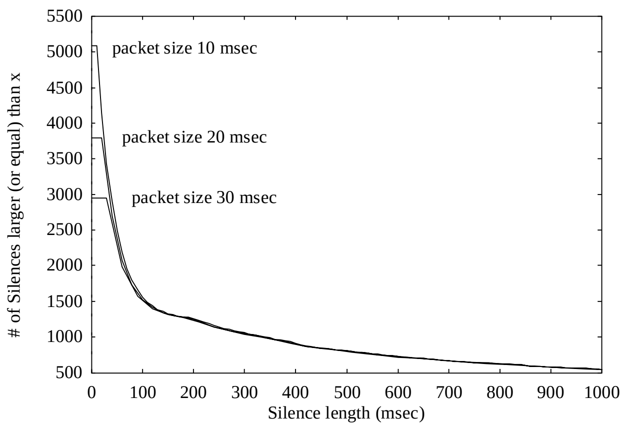


Figure 3. Total amount of talkspurts

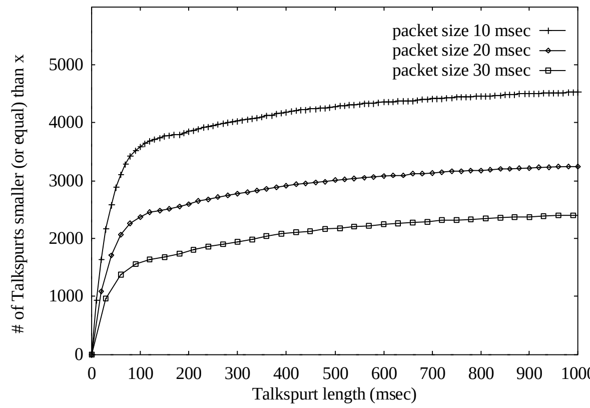

Figure 4. Percentage of talkspurts (with duration smaller than x) with regard to the total number of talkspurts

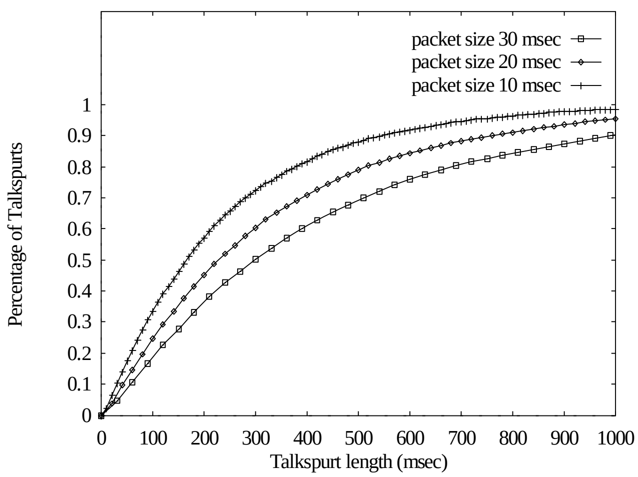

Figure 5. Percentage of silent intervals (with duration larger than x) with regard to the total number of silence periodsh

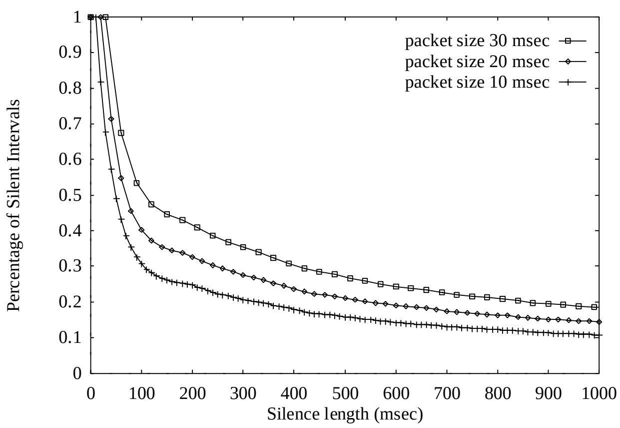

answered concerns the average length of the intervening silence periods in a human conversation. To this aim, in Figure 5 the percentage of silent periods (of length larger than a fixed amount) out of the total quantity of all the obtained silence periods are reported. Of particular interest is the fact that the larger the packet size, the larger the average silence duration.

In conclusion, the results we have reported show that there is room in human speech (i.e., silent intervals) to successfully exploit sophisticated Internet audio control mechanisms.

FUTURE TRENDS

A recent review on Internet telephony (Bradner, 2002) shows that despite important research, its actual deployment is really limited due to quality of service (QoS) concerns. Recent studies summarize the key issues relating to the design of adaptive receiver-based buffer strategies for Internet speech transmission as follows: i) Internet packet loss, delay jitter and speech distortion effects over best-effort networks remain a serious problem that needs deeper modeling efforts. To this aim, further analysis of Internet delay studies is being undertaken; ii) more investigation is needed on the optimal implementation of application delay or buffering delay within adaptive receivers and, finally, iii) more analysis is required of the uncertainties caused by hardware/software within Internet speech endpoints.

CONCLUSION

Delay adaptation in the presence of fluctuant network delays is a crucial issue in determining the audio quality for real-time speech transmission over the Internet. With this in view, the typical approach is that of dynamically adapting the audio application to the network conditions so as to minimize the trade-off between packet playout delay and packet playout loss. The performance figures illustrate the adequacy of those mechanisms for human speech transmission across the Internet.

KEY TERMS

Audio Packet: Packet encoding an audio sample in digital form. Each audio packet has a timestamp and a sequence number as additional information. Timestamps are used to measure the end-to-end delay (jitter) experienced during the communication, and sequence numbers are used to detect packet losses. Typically, during an audio communication, audio packets are transmitted over the network, received in a playout buffer, decoded in sequential order and, finally, played out by the audio device.

Audio Sample: The amplitude of a waveform is measured (sampled) at regular time intervals and converted into an integer value. Each of these instantaneous measurements is an audio sample.

Delay Jitter: Variance of the network delay computed over two subsequent audio packets.

Delay Spike: Sudden, large increase in the end-to-end network delay, followed by a series of audio packets arriving almost simultaneously.

Network Delay: Time needed for the transmission of a data packet from the source to the destination over the underlying transport network.

Playout Buffer: Buffer used at the receiver side to store received audio packets in interactive real-time applications in order to compensate for variable network delays.

Playout Control Mechanism: Adaptive mechanism that fetches audio packets from the playout buffer and sends them to the audio device for immediate playout.

Playout Delay: Total amount of time that is experienced by an audio packet from the time instant it is generated at the source and the time instant it is played out at the destination. Such a delay consists of: i) the collection time needed for the transmitter to collect an audio sample and to prepare it for transmission, ii) the network delay, and finally iii) the buffering time, which is the amount of time that a packet spends queued in the destination buffer before it is played out.

Talkspurt: Short burst of energy, in an audio communication, during which the audio activity is carried out. A packetized audio segment may be considered as being constituted of several talkspurts separated by silent periods (during which no audio packet is generated). During speech transmission activities over the Internet, in order for the receiving site to reconstruct the audio conversation, the audio packets constituting a talkspurt must be played out in the order they were emitted at the sending site.

Addressing the Central Problem in Cyber Ethics through Stories

John M. Artz
The George Washington University, USA

INTRODUCTION

The central problem in cyber ethics is not, as many might think, how to address the problems of protecting individual privacy, or preventing software piracy, or forcing computer programmers to take responsibility for the systems that they build. These are, of course, legitimate concerns of cyber ethics, but the central problem is how you decide what the right thing to do is with regard to these issues when the consequences of any responses cannot be known in advance. Stated more clearly, the central problem in cyber ethics is - how do you establish ethical standards in a professional field that is defined by a rapidly evolving technology where the consequences of the technology and the impact of any ethical standards cannot be known in the time frame in which the standards must be established? Stories play a very important role in addressing this issue. Specifically, stories provide a means of exploring ethical issues for which the full range of consequences is not currently known. But, in order to justify this claim, a few words of explanation are in order.

BACKGROUND

The word "story" means many different things to different people. For example, if one of your children tells you that your dog ate the neighbor's cat, you might challenge the veracity of this claim by asking – "Is that true, or is that just a story?" The implication is that there is truth and there are stories. And if it is a story, it cannot be true. But true versus fictitious is not the same as true versus false; and a story can contain important truths while still being wholly fictitious. If we are looking for precise intellectual truths, then perhaps stories are not the best medium for exploration. However, in areas where our understanding is unclear, either because we do not fully understand a phenomenon, or the phenomenon is not available for study because it exists in a possible world, stories play a very important role in advancing our understanding. To put a finer point on this argument, science and logic fail miserably at telling us what could be, or more importantly, what should be. In these two areas stories are powerful vehicles for intellectual explorations. A story, for the purposes of the current discussion, is a rendition or a telling of a series of true or fictitious events, connected by a narrative in which a set of characters experience and react to a set of actions or events and in doing so reveal something about the human character or condition. In order to see the value of stories for the exploration of issues in cyber ethics, three prior arguments must be made.

NARRATIVE VS. LOGICAL THINKING

Narrative and logical reasoning represent two distinct methods of making sense out of the world around us. They are both legitimate and both can be very rigorous (Bruner, 1986). Sometimes they provide alternative paths to truth and understanding. Sometimes one or the other provides the only path. Logical reasoning is general, context independent, objective and leads to a single conclusion. Narrative reasoning is specific, context dependent, open to subjective interpretation, and potentially leads to multiple conclusions. The characteristics of narrative reasoning are considered flaws when applied to logical reasoning. But the reverse applies also. A story that has only one interpretation and means the same to everyone is not much of a story. While narrative and logical reasoning are different kinds of reasoning, they are not mutually exclusive. A good narrative is also often quite logical in structure, and a good logical argument can often be better understood with a good narrative example. But for the most part, they are complimentary, alternative modes of thinking that provide different paths to truth and understanding.

To some extent, logical and narrative reasoning address different domains. Logic is well suited to mechanistic processes that can be reduced to logical description. Logic is good for articulating general principles and deductive reasons. Logic is useful for describing and explaining. While logic is good for describing "what is," narrative is good for exploring "what could be" and figuring out "what should be". Narratives are a useful means for understanding the complex and ambiguous issues in human affairs. They allow us to explore possibilities and experience situations vicariously. Narrative reasoning is particularly well suited to cyber ethics because many issues are not well understood and the goal of cyber ethics is not to discover truth about the physical world, but truth about human nature. Narrative fiction gives us a means to explore and discover truths about what could be and what should be. Through narratives we can explore possible consequences of technology, construct alternative worlds and select the one in which we would like to live.

Critics of the use of narrative in ethics point out that after exploring narratives you always have to come back to principles. Ethics, they argue, is too messy without principles and discussion of narratives does not lead to consistent conclusions. This view misses the point of narratives. First, principles are developed by extracting the principles from experience. Narratives provide some of these experiences vicariously. Hence, narratives can be used in the development of principles. Second, it is often unclear which principles apply in given situations. Narrative explorations provide insight into situations, allowing us to determine the governing principles. And narratives can be used to explore the consequences of principled decisions to determine if the outcomes are indeed what are intended. Finally, narrative reasoning does lead to conclusions - very specific conclusions about very specific situations. Narrative reasoning is lacking in generality, as was mentioned before, not lacking in conclusions.

THE ROLE OF EMOTION IN REASON

Most people believe that emotions have no role in logical reasoning. After all, reasoning should be dispassionate and free from emotional influences that may cloud our reasoning. And there is some basis for this. For example, if you lose your temper in the middle of an argument and start flinging personal insults at your opponent, rational people would not consider you as having advanced your position. Most would say that you lost the argument when you lost your temper. Yet emotions play an important role in reasoning and in order to understand this, we need to better understand exactly what emotions are.

There is considerable debate about the exact nature of emotions. The philosopher Robert Solomon (Solomon, 1994) offers one very useful observation that "emotions are judgments about the world". If you are walking down a path in the woods and it is getting dark, you might start to get a little nervous and walk a little faster. If you hear an unfamiliar noise or a rustling in the leaves your heart may begin to beat a little faster as you experience the emotional reaction of fear. This fear is a judgment about the world in which you have judged your current situation as unsafe. You did not arrive at this judgment through a rational process. Specifically, you did not think – "It is dark and hungry animals or possibly monsters come out when it is dark. I just heard a noise that I cannot identify and therefore there could be a hungry animal near me. If I walk a little faster, I might get away before the animal gets me. If I am wrong then all I have done is walked a little faster. If I am right, I might avoid being eaten. Hence, it is logical and reasonable for me to walk faster." In fact, you probably did not think at all. You just felt scared and increased your pace. If asked later why you were walking so quickly you might come up with a reasonable explanation. But that reasonable explanation is certainly constructed after the fact.

Perhaps we have conceded at this point that emotions are judgments about the world and that they can play an important role in reasoning. The obvious question is "So what?" Why do we care and why should we bother to make an effort to incorporate our emotional judgments into our reasoning? Damsio (1994) describes the case of a young man who after suffering damage to part of his brain was no longer able to feel emotions. The unexpected side effect of this malady was that he was also unable to make good decisions or assign importance to competing tasks. He seemed normal in every other way and seemed to have his intellectual facilities fully intact. Yet he seemed no longer able to feel emotions and as a result he was unable to function as a normal person. When we make a decision we evaluate alternatives. If we are unable to feel emotions we are unable to place values on the different alternatives. If we cannot place values on the different alternatives then there is no difference between the alternatives and decision-making becomes seriously flawed. Hence, without emotions rational decision-making may not be possible.

A good story about an ethical issue is much more likely to draw an emotional response that an intellectual one, whereas an abstract analysis is more likely to yield an intellectual response. Ultimately, ethical decisions are emotional decisions because they embody human values. For this reason, examining ethics from a purely rational perspective completely misses the point.

IMAGINATION AND POSSIBLE CONSEQUENTIALISM

One of the problems in establishing standards of ethical behavior in a field driven by technology is that the consequences of the technology and reactions to the technology often cannot be known. Looking to the past to provide guidance is ineffective because the past provides few clues. Marshall McLuhan is often attributed with the famous observation that looking to the past to provide guidance for the future is like driving by looking in the rear-view mirror. Although it is disputed as to whether he ever said that or not, it is a rich metaphor for understanding how we should think about the future in times of rapid technological change.

Imagination is the key to understanding the future. The problem though, in using imagination to understand the future, is that we have a cognitive bias against understanding the future. We feel quite comfortable that we understand the past, but the future is the domain of prophesies. Yet assertions about the past are never testable because the past is gone, never to return, while assertions about the future are testable. So one could argue, on the basis of the testability criterion, that the future is more knowable than the past. However, that discussion is for another time.

Consider imagination as the creative capacity to think of possibilities. Imagination lets us see the world not as it is, but as it could be. Seeing the world as it could be allows us to make choices about how it should be. It is this ability to see possibilities that drives us to build technologies to bring about, or implement our preferences about possible worlds. Stories are both a product and a tool of our imaginations. Using stories in moral reasoning provides a means for a slightly different view of ethics that could be called "possible consequentialism". Whereas the consequentialist evaluates actions based upon their consequences, the possible consequentialist evaluates actions based upon their possible outcomes. The possible outcomes are described in stories and the likelihood of the outcome is determined by the believability of the story given our understanding of current conditions and human nature. As the literary critic Northrop Frye points out, "The fundamental job of the imagination in ordinary life, then, is to produce, out of the society we have to live in, a vision of the society we want to live in" (Frye, 1964, p. 140).

When we examine issues in cyber ethics, we cannot examine them in terms of consequentialist ethics because the consequences are not known. However, through the use of stories we can construct imaginative scenarios and examine possible consequences. Possible consequentialism may be a preferable approach to computer ethics because we can look at possible outcomes, assess the likelihood of each, and select the outcome we prefer. Imagination provides us with a means of fully examining possible outcomes and stories provide us with the means of sharing our imaginings. By writing stories and sharing them we can explore possible consequences and, through social debate, derive imaginary truths. These imaginary truths allow us to choose the kind of world that we would like to live in.

FUTURE TRENDS

While stories play an important role in the exploration of problems in cyber ethics, there is still a serious barrier to using them. That barrier is the fact that precious few stories have been written. Current work is addressing that problem (Artz, 2004). As researchers and teachers in cyber ethics become more comfortable with writing stories, the value of stories for exploring possible worlds will make this approach increasingly more attractive. Further, as the implications of information technology and the ethical problems they bring move further into the future, the ability of stories to capture possible worlds will make them increasingly more compelling.

CONCLUSION

The central problem in cyber ethics is not, as many may suppose, how to prevent software piracy or how to protect privacy on the Internet. It is instead - how do you establish ethical standards in a professional field that is defined by a rapidly evolving technology where the consequences of the technology and the impact of any ethical standards cannot be known in the time frame in which the standards must be established? Stories play an important role in addressing this problem by providing a means of exploring ethical issues for which the full range of consequences are not known. Stories allow us to construct narrative arguments to explore issues that we do not fully understand. They allow us to explore the emotional as well as rational aspects of a situation. Stories allow us to explore worlds that do not currently exist, which, in turn, allows us to examine possible consequences and make choices about the world in which we would like to live.

KEY TERMS

Cyber Ethics: A branch of ethics that focuses on behaviors that are specifically related to information technology.

Ethics: A branch of moral philosophy that examines the standards for proper conduct.

Imagination: The creative capacity to think of possibilities.

Logical Reasoning: General, context independent, objective reasoning that leads to a single conclusion.

Narrative Reasoning: Specific, context dependent reasoning that is open to subjective interpretation, and potentially leads to multiple conclusions.

Possible Consequentialism: Evaluating an ethical position in terms of its possible consequences.

Story: A rendition or a telling of a series of true or fictitious events, connected by a narrative, in which a set of characters experience and react to a set of actions or events and in doing so reveal something about the human character or condition.

Adoption of E-Commerce in the Value Chain by SMEs

Judith Jeffcoate
University of Buckingham, UK

INTRODUCTION

This article describes an analytical framework to identify the triggers for value chain transformation that will encourage small and medium enterprises (SMEs) to adopt e-commerce. The framework was adopted in the KITS project as part of a qualitative approach, using multiple case studies of SMEs that were involved in business-to-business (B2B) e-commerce (Jeffcoate, Chappell & Feindt, 2004). Results from this project are used to illustrate the use of the framework.

According to Yin (1994), one of the areas in which case research is most useful is the relationship between information technology and corporate strategy—precisely the area that is crucial to the development of e-commerce. Earlier researchers also adopted multiple cases for studies of SMEs in e-commerce or related areas. For example, Poon and Swatman (1997) studied 23 small businesses in Australia that were active Internet users in order to establish the pre-conditions for success and the strategic effects from its use. Other researchers in this area have relied on much smaller numbers of case studies, typically fewer than 10. Iacovou, Benbasat and Dexter (1995) carried out interviews on the adoption of electronic data interchange (EDI) with the managers of seven SMEs that were suppliers to the British Columbia government. Another study of the effect of EDI on a sample of eight small businesses in the UK (Chen & Williams, 1998) was based on in-depth interviews with key personnel.

BACKGROUND: THE KITS PROJECT

Knowledge Information Transfer Systems (KITS) was designed as a support action for SMEs in Europe and funded by the European Commission. It included a research programme whose aim was to analyse the activities of SMEs engaged in industry value chain relationships with suppliers and customers in order to establish best practice. An SME in this context is a company that employs fewer than 250 people. The research programme for KITS included two main work packages: the first looked at individual companies, whilst the second looked at evaluation across the value chain. This article, which is based on the first of these packages, describes the analytical framework that was adopted by this project.

The KITS sample consisted of 43 European SMEs that were actively involved in B2B e-commerce across industry and country boundaries (Table 1). The research focussed primarily on traditional SMEs with some level of automation, with a secondary focus on e-commerce start-ups (the 'dot.coms'). The interview programme was car-

Table 1. Companies by sector and country

	Manufacturing	Transport and logistics	Retail/wholesale	Business services	Total
Germany	7	3	1	3	14
Austria		1			1
Switzerland				1	1
Belgium			1		1
Italy	12	1	1		14
Sweden	1				1
UK	5	1	3	2	11
Total	**25**	**6**	**6**	**6**	**43**

ried out between September 2000 and January 2001. All of the respondents had board-level responsibility. They varied from managing directors in the smaller companies to IT, operations, and marketing directors in the larger organisations. It was felt that, in an SME, only one point of view is necessary, providing it is at a high enough level within the organisation.

The interviews were conducted using a semi-structured questionnaire that included both open and closed questions. The initial conceptual framework was adapted from one proposed by Ward and Griffiths (1996) for determining the strategic potential of information systems and establishing priorities for investment. Their framework takes a structured analytical route through the upper levels of the organisation. It is closely linked to the industry value chain, as well as to the organisational value chain, and was thus particularly appropriate for KITS. The following topics were covered: company background; strategy, objectives, and critical success factors; value chain partnerships and activities; and use of technology.

THE ANALYTICAL FRAMEWORK

The framework adopted for the analysis of the KITS case studies draws on key concepts proposed by a number of authors. It consists of the following elements:

- Type of industry value chain
- Stability of position within industry value chain
- Level of penetration of electronic links with customers and suppliers
- Complexity of automation of the internal IT environment
- Key value activities and interactions between value activities
- Complexity of automation of value activity interactions
- Level of achievable impact on the industry value chain

These elements are discussed in turn in the following sections, with illustrations from the KITS project.

CURRENT POSITION: THE SME IN THE VALUE CHAIN

A key element in the process by which SMEs adopt e-commerce is through the automation of the value chain, defined by Porter (1984) as a collection of activities that are performed by a company to design, produce, market, deliver, and support its product. Other authors refer to this as the internal value chain of a company, or organisational value chain, in contrast to the industry value chain. The latter consists of the organisational value chain, together with the value chains of the organisation's competitors, suppliers, and customers. It represents the movement of goods and services from the source of raw materials through to the final customer (Benjamin & Wigand, 1995).

Porter identified nine value activities, the physically and technologically distinct activities that the company performs and which add value to a product or service. More recently Chu (1995) defined critical value activities as those activities that an organisation must execute satisfactorily to ensure successful performance.

Type of Value Chain

An SME's perception of its value chain is important because it influences the company's strategy and therefore its e-commerce strategy. Companies can be classified as participating in one of four types of industry value chain defined by Baldock (1999):

- *Customer-Centric Value Chain:* The seller tailors its products to meet fast-changing consumer needs.
- *Seller-Driven Value Chain:* The seller presumes toknow what the market might want to buy.
- *Buyer-Driven Value Chain:* The customer states what he or she wants and sets out the terms and conditions that the supplier should meet.
- *Fragmented Value Chain:* Neither the buyer nor the seller business model dominates.

The majority of the KITS SMEs, who were in customer-centric value chains, believed that they should become more customer focused to meet the needs of such a value chain. They wanted to understand customers' needs better and more quickly, and, if possible, be proactive in meeting them.

Stability of Position within Value Chain

SMEs have upstream and downstream links with their business partners in the industry value chain. The strength, intensity, and permanence of these links are important in determining how deeply these SMEs are embedded in their networks (Yli-Renko & Autio, 1998). The majority of the KITS SMEs reported stable relationships with customers that had lasted for a number of years. They supported similarly stable relationships with suppliers, to whom they were highly loyal. However, they typically had far fewer suppliers than customers.

Level of Penetration of Electronic Links

The SME may support the links with its business partners by using a variety of technologies including network connections, support for information exchange, the use of applications (e.g., messaging, marketing), and of external services (e.g., value-added network service suppliers, application service providers, or Web hosting companies).

The penetration of electronic links into the supplier and customer bases of the KITS companies was low. Where such links existed, they were typically with a fraction of an SME's customer base: with key resellers or distribution partners, with one or two IT-literate customers. The electronic links were also typically being developed to secure and strengthen these relationships. As they proliferate through the customer and supplier base, however, the opposite effect may be achieved, and more *ad hoc* relationships with value chain partners may develop.

Amongst the KITS companies, electronic links with customers were more common and more extensive than electronic links with suppliers, confirming that, in most cases, customers tend to be larger and more e-commerce literate than suppliers. This observation is also consistent with the experience of larger companies that are automating their value chain activities. Fawcett and Magan (2001) report that most large U.S. companies surveyed are dedicating more resources to building strong customer relationships than to selecting and developing a world-class supply base.

Complexity of Automation of IT Environment

It is widely agreed that SMEs are being held back from participating in B2B e-commerce by the fact that they lack suitable IT infrastructures to support it (Lockett & Brown, 2001). They may have Internet access for e-mail and hosted Web sites, but it is thought that few SMEs engage beyond this in B2B e-commerce and other more complex applications.

The complexity of the IT environment can be assessed, using the following factors:

- The type of applications and IT infrastructure the SME has in place, including legacy applications and network environment
- Whether applications are packages or proprietary developments
- The level of application complexity
- The nature of the links between applications (e-mail, intranet, extranet)

The level of complexity, as defined by Lockett and Brown (2001), may range from very low for simple communications (e.g., e-mail, Web access) to very high for collaborative enterprise applications such as supply chain management (SCM) and customer relationship management (CRM). Hawkins (2001) points out that "home-made systems appear not to damage the e-commerce prospects of firms and may even improve them by ensuring that technology investment and roll-out is linked to actual signals from the market."

More than a third of the KITS companies conform to the general perception that the lack of IT infrastructure is a barrier to SME e-commerce, with a complexity rating of very low. Most of these do not have any electronic links with customers or suppliers. A further third of the sample have a complexity ranking of low. These companies do not necessarily automate more activities, but there is generally more integration between their activities. At least a third of the KITS companies have an IT infrastructure that can support relatively complex B2B e-commerce. A number of companies with lower complexity rankings are moving quickly towards this position.

Key Value Activities and Value Activity Interactions

The electronic links discussed above can link critical value activities both internally and between partners in the industry value chain. The relative importance of these activities to the SMEs can be established by asking respondents to rank each activity on a scale from 1 to 5, where 1 is unimportant and 5 is critical to the success of the company. It may be assumed that if an SME ranks a value activity as critical, then inputs and/or outputs to this activity that involve value chain partners will be a priority for automation. E-commerce solutions automate value activity interactions (VAIs) between value chain partners—each SME's customers and suppliers. Most of the VAIs link an SME's primary value activities, such as logistics, operations, or sales and marketing, with customer/supplier primary activities.

In the KITS sample the most widely supported value activity interaction is sales and marketing to procurement. All the SMEs in the sample have implemented a Web site with details of the company and its products. The second most supported VAI is outbound logistics to (customer) procurement. The fact that so many companies have implemented online order processing suggests that they perceive this to be important to customers, and that they will be better regarded by customers if they invest in it.

Complexity of Automation of Value Activities

The two most complex e-commerce solutions described by KITS respondents (vendor-managed inventory between two Web-enabled enterprise resource management systems and e-marketplaces) were not fully operational at the time of interview. It may be expected that, over time, it will be possible to track the development and impact of the different types of e-commerce solution. It may also be assumed that there will be wider adoption of more complex solutions over time.

Impact on the Value Chain

The complexity of an e-commerce solution affects an SME's ability to increase its value and even transform its role within its value chain. High-complexity e-commerce solutions have more potential to support value chain transformation than low-complexity solutions. Position in the value chain does seem to affect the complexity of the e-commerce solution adopted. Some SMEs, most notably those in the middle tiers, such as wholesalers (including e-marketplaces) and logistics companies, are able to provide additional intangible value to their value chain partners through the embryonic creation of new, virtual value chains (Rayport & Sviokla, 1995).

Within the KITS sample there appear to be four ways in which automating VAIs has an impact on an SME's value chain. VAI automation may:

1. Streamline the supply chain, taking out risk and cost. The electronic channel to customers/suppliers replaces existing methods of carrying out the value activity interaction (e.g., online ordering replacing phone/fax).
2. Transform the way a value activity is carried out, removing cost and adding new value. The way in which a value activity is automated changes the roles of customer and supplier (e.g., suppliers carry out inbound logistics on behalf of their customers, matching information about their own capability to deliver with information about the customer's production plans and sales through vendor-managed inventory).
3. Capture information (intangible good/service) that adds value to internal processes. For example, a company may gather information on customers through its Web site and organise, select, and distribute it to improve internal processes, such as sales and marketing.
4. Extend new information (intangible good/service) to external value chain partners' processes. A small portion of this information is being used to generate a revenue stream in its own right (for example, by e-marketplaces, which are synthesising and distributing information on a subscription basis).

FUTURE TRENDS: TRANSFORMING THE VALUE CHAIN

The KITS project aimed to research and analyse the activities of SMEs engaged in industry value chain relationships with suppliers and customers, in order to identify the triggers for value chain transformation that will encourage them to adopt e-commerce. A number of conclusions were drawn from the application of the analytical framework described above to the case studies in this project.

Is the Type of Industry Value Chain a Factor in Encouraging SME E-Commerce?

The impetus for adopting e-commerce solutions does not seem to depend on the industry sector or type of value chain in which the SME is engaged. It is expected that, over time, more value chains will become buyer-driven; this would have an impact on SMEs' roles and e-commerce strategies.

How Does the Stability of the Value Chain Affect SME E-Commerce?

The value chains studied are relatively stable, and the penetration of electronic linkages up and down the chains is low. However, the low level of value chain automation is a brake to change. Early adopter SMEs cannot capitalise on their innovation and leadership until the whole value chain is at a critical point for change.

Is the Level of Penetration of Electronic Links with Customers and Suppliers Important?

Once SMEs have established the benefits of e-commerce in a few key relationships, they may be motivated to extend its deployment fairly rapidly, as they can achieve better return on investment when the solution is extended to a critical mass of value chain partners. Strength in the value chain comes from partnership. Two interlinked SMEs that have synchronised their e-commerce strategies and solutions are more powerful than two individual companies. Business partnerships and alliances are not new, but e-commerce solutions make them easier and less costly to manage and more likely, other factors being equal, to succeed.

Is Complexity of Automation a Barrier for SME E-Commerce?

It is clear that companies with a vision of how they would like to participate in their value chain in the future are more likely to adopt medium- or high-complexity e-commerce solutions. These companies have considerably more power to effect change in the value chain than might have been expected, even in value chains with powerful customers downstream or dominant suppliers upstream. SMEs can be equally as innovative at driving value chain change as larger companies, and they can be faster and more flexible in doing so. The factors holding them back are not e-commerce related (such companies have a great deal of competency in this area), but have to do with risk, timing, and lack of access to the 'visionaries' in suppliers and customers.

Are Value Activity Interactions Important for SME E-Commerce?

Those SMEs that are applying e-commerce to value activity interactions with most determination are those that are proactively creating new, intermediary roles in the value chain, such as marketplaces that would not exist without the Internet. Investing in transformation is a high-risk strategy for a small company. The development of new services, either as add-ons to or as a revenue-generating replacement for an existing physical value chain role, is expensive and the outcome is uncertain.

Which Value Activity Interactions Should SMEs Automate?

SMEs need to select for automation value activity interactions that will support their business strategy, support their e-commerce strategy, and are appropriate for the level of IT literacy in their value chains. They therefore need to understand the impact particular automated value activities interaction will have on their value chain relationships and the kind of information (intangible good/service) VAIs will yield. E-commerce solutions should be selected based on the complexity level of partners' IT environments and how critical the VAI is to the business.

Can SME E-Commerce Transform Industry Value Chains?

Where e-commerce solutions support the 'bundling' and/or interlinking of VAIs (very high-complexity solutions), a virtual value chain of information-driven intangible goods/services may emerge. In certain circumstances, SMEs can use such intangible goods/services to generate the benefit of a completely new revenue stream.

CONCLUSION

In summary, although the use of this framework has already produced interesting insights into the objectives and practice of SMEs introducing e-commerce in different types of value chains, more work is needed to extract benefits and verify best practices. Such validation can only be achieved over time, when the effects of e-commerce solutions can be compared with anticipated impacts and benefits.

KEY TERMS

Buyer-Driven Value Chain: The customer states what he or she wants and sets out the terms and conditions that the supplier should meet.

Critical Value Activities: The *value activities* that an organisation must execute satisfactorily to ensure successful performance.

Customer-Centric Value Chain: The seller tailors its products to meet fast-changing consumer needs.

Fragmented Value Chain: Neither the *buyer-driven* nor the *seller-driven* model of the *value chain* dominates.

Industry Value Chain: Consists of the *organisational value chain*, together with the *value chains* of the organisation's competitors, suppliers, and customers. It represents the movement of goods and services from the source of raw materials through to the final customer.

Organisational Value Chain: The internal *value chain* of a company.

Seller-Driven Value Chain: The seller presumes to know what the market might want to buy.

Value Activity: A physically and technologically distinct activity that the company performs and which adds value to a product or service.

Value Activity Interaction (VAI): Interaction between two value activities performed by partners in a value chain.

Value Chain: A collection of activities that are performed by a company to design, produce, market, deliver, and support its product.

Advanced Techniques for Object-Based Image Retrieval

Y. J. Zhang
Tsinghua University, Beijing, China

INTRODUCTION

Along with the progress of imaging modality and the wide utility of digital images (including video) in various fields, many potential content producers have emerged, and many image databases have been built. Because images require large amounts of storage space and processing time, how to quickly and efficiently access and manage these large, both in the sense of information contents and data volume, databases has become an urgent problem. The research solution for this problem, using content-based image retrieval (CBIR) techniques, was initiated in the last decade (Kato, 1992). An international standard for multimedia content descriptions, MPEG-7, was formed in 2001 (MPEG). With the advantages of comprehensive descriptions of image contents and consistence to human visual perception, research in this direction is considered as one of the hottest research points in the new century (Castelli, 2002; Zhang, 2003; Deb, 2004).

Many practical retrieval systems have been developed; a survey of near 40 systems can be found in Veltkamp (2000). Most of them mainly use low-level image features, such as color, texture, and shape, etc., to represent image contents. However, there is a considerable difference between the users' interest in reality and the image contents described by only using the above low-level image features. In other words, there is a wide gap between the image content description based on low-level features and that of human beings' understanding. As a result, these low-level feature-based systems often lead to unsatisfying querying results in practical applications.

To cope with this challenging task, many approaches have been proposed to represent and describe the content of images at a higher level, which should be more related to human beings' understanding. Three broad categories could be classified: synthetic, semantic, and semiotic (Bimbo, 1999; Djeraba, 2002). From the understanding point of view, the semantic approach is natural. Human beings often describe image content in terms of objects, which can be defined at different abstraction levels. In this article, objects are considered not only as carrying semantic information in images, but also as suitable building blocks for further image understanding.

The rest of the article is organized as follows: in "Background," early object-based techniques will be briefly reviewed, and the current research on object-based techniques will be surveyed. In "Main Techniques," a general paradigm for object-based image retrieval will be described; and different object-based techniques, such as techniques for extracting meaningful regions, for identifying objects, for matching semantics, and for conducting feedback are discussed. In "Future Trends," some potential directions for further research are pointed out. In "Conclusion," several final remarks are presented.

BACKGROUND

Early Object-Based Techniques in Content-Based Image Retrieval

CBIR techniques are distinguished from traditional retrieval techniques by many aspects. Two of the most pertinent are that CBIR is a somehow subjective process, as for a given image, its means may have different interpretations for different users; and image retrieval is often a computationally expensive process, as the image database is often large in size and contains heterogeneous information. Due to these particular aspects, the results of CBIR could not be judged objectively—human perception should be considered. In addition, performing an exhaustive search for finding optimal solutions in CBIR is not feasible, and therefore, some suboptimal solutions will be chosen.

Because of the unique aspects of CBIR, object-based representation and description must be used even in so-called low-level feature-based image retrieval, though in these works, object recognition is not evidently performed and semantic information is not explicitly searched.

One typical example is in shape-based retrieval, as the shape features are generally extracted from individual objects (Latecki, 2002). In contrast, color features and textural features are often obtained by taking the whole image as a unit. From this point of view, shape-based retrieval is already at some higher level than color-based retrieval and texture-based retrieval (Zhang, 2003).

Structural query model is another instance in which partial matches are allowed and outputs related to the score of similarity can be provided. This type of retrieval is based on the relations between the individual objects and components in images (Zhou, 2001). In query by visual sketch, users sketch a scene by drawing a collection of objects. (It is assumed that these objects could fully define a scene.) For example, the objects are first identified and then used in a search (Chang, 1998).

Current Object-Based Techniques in Content-Based Image Retrieval

Currently, researchers seek explicit semantics and use the high-level descriptions that are common to humans, such as articles, people, places, and things. It is generally accepted that high-level features are crucial to improve the performance of CBIR up to so-called semantic-based querying. For this purpose, object-based content analysis, especially segmentation that segments the semantically meaningful objects from images, is an essential step (Zhang, 2001).

Complete image understanding should start at interpreting image objects and their relationships. Objects can be further identified in line with appropriate knowledge. For example, some object grammars based on rules for concept inference have been proposed (Petkovic, 2003). When domain knowledge is available, objects can be classified even without the explicit determination of object regions (Li, 2002b).

To extract high-level descriptions from images and to fill the gap between the low-level features and human beings' understanding of image contents, techniques to describe the whole image with a hierarchical structure to reach progressive image analysis are proposed (Castelli, 1998; Jaimes, 1999; Hong, 1999). The contents of images can be represented in different levels (Amir, 1998), such as the three-level content representation, including feature level content, object level content, and scene level content (Hong, 1999); and the five-level representation, including region level, perceptual region level, object part level, object level, and scene level (Jaimes, 1999). The problem here is how to implement these levels efficiently and effectively.

Another direction for extracting semantics information from an image is to map low-level visual features to high-level semantics. In other words, to fill the semantic gap, one makes the retrieval system work with low-level features, while the user puts in more high-level knowledge (Zhou, 2002). Two typical methods are to optimize query requests by using relevance feedback and semantic visual templates (Chang, 1998) and to interpret progressively the content of images by using interactive interfaces (Castelli, 1998). In both approaches, relevance feedback plays an important role, as humans are much better than computers at extracting semantic information from images (Rui, 1998; Ciocca, 1999).

MAIN TECHNIQUES FOR OBJECT-BASED IMAGE RETRIEVAL

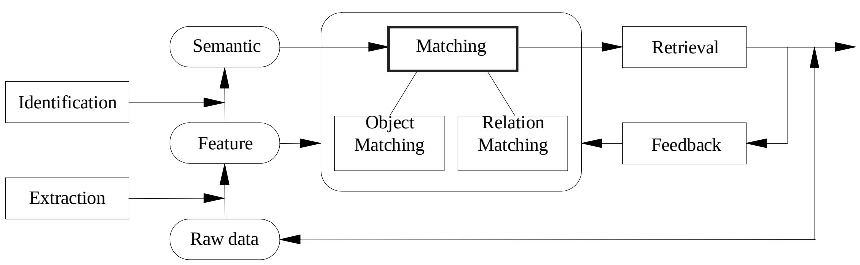
A General Paradigm

In general, people distinguish three levels of abstraction when talking about image databases: raw data level, feature level, and semantic level. The raw data are original images in the form of a pixel matrix. The feature level shows some significant characteristics of the pixel patterns of the image. The semantic level describes the meanings of identified objects in images. Note that the semantic level should also describe the meaning of an image as a whole. Such a meaning could be obtained by the analysis of objects and the understanding of images.

According to the above discussions, a multilayer approach should be used for efficiently treating image data. Though the number of layers and the definitions and functions of these layers could have some variations in different approaches, some principle steps are common for object-based image retrieval. A general paradigm is shown in Figure 1.

First, objects should be determined. Two important tasks are as follows:

Figure 1. A general paradigm for object-based image retrieval



1. Extract meaningful regions: To be able to base the image retrieval on objects, the interesting regions related to objects should be extracted first. This process relates the raw data level to the feature level.
2. Identify interesting objects: Based on the extracted regions, (perceptual) features should be taken out, and those required objects could be identified. This corresponds to the step from feature level to object level.

Once the objects in images are identified, further retrieval can be carried out by using objects as primitives. Two tasks are as follows:

1. Matching identified objects: For each identified object, suitable properties and attributes should be selected for proper description. The matching between images, such as object matching and relation matching, is then carried out.
2. Performing feedback in retrieval: This is to introduce human intelligence and to incorporate human semantics into the retrieval process.

The following sections introduce some techniques developed for each task.

Techniques for Extracting Region of Interest

Extraction of interesting regions from an image is, in general, called image segmentation (Zhang, 2001). Image segmentation is one of the most critical tasks in automatic analysis of image contents. A great variety of segmentation algorithms has been proposed in the literature. One should note that none of the proposed segmentation algorithms is generally applicable to all images, and different algorithms are not equally suitable for a particular application. This is the reason that though several thousands of algorithms have been developed, much attention and new efforts are continuously made on improving and perfecting them.

With the progress in segmentation techniques, people also realized that precise segmentation of objects in many cases is still beyond the capability of current computer techniques. On the other side, compared to some image analysis tasks that aim to obtain accurate measurements from the segmented objects, the requirement for precise segmentation of objects can be somehow relaxed in the context of image retrieval. Image retrieval is a subject-oriented process in which the precise object measurement is not the goal. In addition, for object-based image retrieval, the purpose of segmentation is for identifying the objects.

One idea derived from the above considerations is to extract approximately the so-called "meaningful region," instead of to segment the object accurately (Luo, 2001). The "meaningful region" provides an effective visual representation of objects from the point of view of object recognition. Though the "meaningful region" is not an exact representation of the objects, however, based on some domain knowledge, the semantic meaning of objects can still be recovered. On the other side, robust extraction of "meaningful regions" is easy to accomplish. This makes the object-based image retrieval with the extraction of "meaningful region" a feasible approach (Gao, 2000).

Another idea derived from the above considerations uses a particular matching procedure to reduce the requirement for precise object segmentation (Dai, 2004). The images are segmented both in a rough version and in a detailed version. The rough one is the merge result of several detailed ones and is less spatial-constrained by either oversegmentation or undersegmentation.

Techniques for Identifying Objects

From extracted regions, some perceptual features could be obtained. This can help to "recognize" what they represent in terms of human beings' perceptions. One iterative procedure uses this principle and transforms the recognition to a training-and-testing procedure (Gao, 2000). To make the problem simpler, it is assumed that there are finite types of interesting objects in a given image database. In fact, this requirement could often be satisfied in practice, as only limited image contents are considered in one application. The object recognition is then performed in an iterative way. Context-based information would be obtained during this process, helping to reach the correct recognition result.

To capture different aspects of images, multiple features are often used. The proportion of each feature in a description would be determined by training. Due to the lighting conditions and variety of object appearance, the objects belonging to the same category can have different visual aspects. To solve this problem, the most significant objects in the training set would be selected, and the trivial ones would be discarded. This recognition process can be iterated until the final recognition result is acceptable (in terms of the image composition, according to some *a priori* knowledge). With this iterative procedure, the context-based knowledge is gradually improved, and the correct recognition result is gradually approached.

Techniques for Matching Objects

Matching is one important task in image retrieval, which consists of comparison and judgment. As retrieval is a subjective process, so the decision is often made according to similarity (the distance to be reasonably small) but not according to equivalence (identical). Based on matching score, a database search can be carried out, and required images can be retrieved. Object match is more direct than feature match is in image retrieval.

One procedure is to describe the object in an image by an $M \times M$ matrix, where M is the number of all objects in the image database. It is a diagonal matrix, with each entry indicating the attribute of every meaningful region in the image. In addition, a relation matrix is also defined. It is a $K \times K$ matrix to indicate the spatial relationship between every two meaningful regions, with K representing the number of meaningful regions in the whole image. The object-matching procedure is dependent on a decision function. This decision function is determined based on the correlation among all content description matrices. It reflects whether all the relevant images have common contents, that is, the same objects. In the case that the relevant images have common objects, the match will be based on the objects of images. In the case that the relevant images do not have common objects, the match will be based on the features of images. For object matching, the similarity information from the common objects in all relevant images will be extracted to perform the matching between the relevant images and candidate images. Details can be found in Zhang (2004).

For compounded objects, matching might be accidentally performed among different parts. To solve this problem, a two-level matching is proposed (Dai, 2004). The principal idea is to describe the query images at a relatively rough scale and to describe the database images at some more detailed scales. As the rough description is based on the merging of detailed descriptions, the matching process will be carried on in an uneven way, and the minor errors caused by segmentation will be recompensed by the approximate matching procedure.

Techniques for (Interactive) Feedback

Feedback plays an important role, especially in high-level retrieval. As indicated above, retrieval is a subjective process, so feedback is required to combine the information from users, or in other words, to incorporate human knowledge and requirements. Retrieval is also a progressive process, so feedback is required to introduce interaction and to turn the search direction to follow the user's intention.

A self-adaptive relevance feedback technique has been used in an object-based image retrieval system (Gao, 2001). In such a system, objects are first identified, the relevance feedback relying on the high-level attributes could better catch image semantics, and the retrieval results are refined according to users' wishes in an explicit manner. In practice, to make the querying more convenient for the user, the procedure of feedback could be directed, also based on high-level information, without memory or with memory to make the feedback mechanism more flexible. In the former case, each feedback is an independent procedure, in which all of the relevant images selected in previous iterations would be ignored. In the latter case, the relevant image selected in previous iterations would be taken into account in the current iteration. A time-delay curve has also been proposed to simulate human beings' memory mechanisms in feedback with memory (Gao, 2001). The main idea of the proposed scheme is to analyze the fed-back relevant images marked by the user in different levels to reach comprehensive similarity analysis.

Another approach called association feedback has been proposed (Xu, 2001b). Feature elements are first defined that can be considered a type of perceptual primitives with abstraction levels located between that of raw images and that of objects in images (Xu, 2001a). These feature elements, different from commonly used feature vectors, have obvious intuitive visual senses and are relatively independent from each other physically. A selection mechanism called feature element evaluation is also proposed, which tries to find those feature elements that are closer to the interest of people by visual meaning. A group of feature elements can be used to represent compound objects. Based on feature elements, association feedback can be applied. In contrast to the weighting adjustment in relevance feedback, here the associated relations between different feature elements are counted. New sets of feature elements can thus be formed during the retrieval process, and this property is suitable for handling the so-called "interest switch" cases. In other words, the search for images can be controlled by users with the introduction of new feature elements according to the change of interest, and the search direction will be guided toward new goals.

FUTURE TRENDS

Further research can be considered in the concrete techniques for advanced image analysis and along the general research movements for image understanding.

To perform object-based image retrieval, different image analysis techniques are to be enhanced:

1. Improving the robustness of meaningful region extraction, especially with complicated images, by taking more characteristics of images into consideration

2. Describing objects as congruous to humans' sense as possible—as human beings are still far from knowing all the cognitive details from the real world, how to automatically form semantic objects is a challenging task
3. Using more efficient feedback procedures to make the search process fast following users' aspirations in the course of retrieval

In the "Background" section, two generations of object-based techniques are discussed. From the point of view of image understanding, the next stage would go beyond objects, though the third generation will still be based on objects. The actions and interactions of objects and thus generated events (or scenes) are important to fully understand the contents of images. The images would be, in this case, described by some metadata. The event detection and event retrieval have already played an important role in many applications (e.g., surveillance, war, etc.). However, only a few particular works are made now, and they are mainly based on audio and multiple frames (Li, 2002a). Further research in this direction, taking more advantage of human knowledge for constructing more intelligent image data would be promising.

CONCLUSION

Object-based techniques can fulfill many roles and tasks required by CBIR. Three generations of object-based techniques are reviewed and discussed in this article. Some of them have already made their contributions to the advancement of CBIR, and some of them need to be improved, and developing new object-based techniques for CBIR is even required.

The object-based techniques discussed here are mainly focused on CBIR. As content-based video retrieval (CBVR) appears like a natural combination of CBIR and content-based audio retrieval (CBAR), as well as some extensions along the temporal axis, many of these techniques would also be applicable for CBVR.

KEY TERMS

Content-Based Image Retrieval (CBIR): A process framework for efficiently retrieving images from a collection by similarity. The retrieval relies on extracting the appropriate characteristic quantities describing the desired contents of images. In addition, suitable querying, matching, indexing, and searching techniques are required.

Feature-Based Image Retrieval: A branch of CBIR that is based on specific visual characteristics called "features" and is considered at a low abstraction level. Features are commonly refereed to perceptive attributes of images, such as color, texture, shape, etc., of images.

Intelligent Image Data: A data format that embeds pixel information of images as well as higher-level information, such as indices and semantic information. This format is self-descriptive in the sense that data could explain by themselves what contents are inside and present and retrieve the related and interested portions for the users.

Metadata: A data format that may contain numerous information, including information obtained indirectly from the image, as well as information related to the actual description of the image content. At the highest level, images are often accompanied and associated by metadata.

MPEG-7: This is an international standard named "multimedia content description interface" (ISO/IEC 15938). It provides a set of audiovisual description tools, descriptors, and description schemes for effective and efficient access (search, filtering, and browsing) to multimedia content.

Query Model: An abstraction model for image querying in the context of CBIR. In this model, a submitted query would specify both a filter condition and a ranking expression, while the query result will be a rank of the images that satisfies the filter condition, according to grade of match for the ranking expression.

Semantic-Based Image Retrieval: A branch of CBIR based on descriptions with semantic meaning and considered at a high abstraction level. Semantic descriptions are more closely related to the human interpretation and understanding of images.

Semantic Gap (SG): The discrepancy between the perceptual property and semantic meaning of images in the context of CBIR. As the perceptual properties are usually described by low-level visual features that can be easily treated by computers, and the semantic meanings are commonly related to high-level object-based descriptions that are familiar to human beings, the semantic gap is also considered a gap between current techniques and human requirements.

Semiotics: The science that analyzes signs and sign systems and puts them in correspondence with particular meanings. It provides formal tools for image knowledge acquisition, generation, representation, organization, and utilization in the context of CBIR.

Agent- and Web-Based Employment Marketspaces in the U.S. Department of Defense

William R. Gates
Naval Postgraduate School, USA

Mark E. Nissen
Naval Postgraduate School, USA

INTRODUCTION

Two modes of matching people with jobs prevail at present: hierarchical planning and distributed markets. Patterned after centrally planned (e.g., former Soviet-style) economies, hierarchical planning remains prevalent for matching job candidates to jobs internally *within* an organization. With evolving information technology, the internal job-matching process could be accomplished far more equitably and efficiently using Web-based markets. Intelligent agents offer excellent potential to help both employees and employers find one another in a distributed electronic marketspace. But realizing this potential goes well beyond simply changing the rules of internal job matching or making agent technology available to job searchers. Rather, the corresponding markets and technologies must be designed together to mutually accomplish the desired results (e.g., efficient and effective matching) and conform to necessary properties (e.g., market clearing, employer policies).

BACKGROUND

As an example, the U.S. Navy currently uses a centralized, hierarchical labor market to match enlisted sailors to jobs (U.S. Navy, Bureau of Naval Personnel, 2000; U.S. Navy, Commander in Chief, United States Pacific Fleet, n.d.). Navy commands (e.g., ships, bases) identify open positions, and the Navy prioritizes job vacancies based on each command's mission, current staffing levels and several other relevant characteristics. Available sailors are categorized according to their qualifications, including skills (ratings), experience, education/training, career path, and so forth. Similar skill groups are arranged in "communities". Each community has a detailer charged with matching sailors to jobs. Sailors seeking job assignments express their personal preferences to the detailer. The detailer is responsive to job priority ratings, but there is some room for discretion to tailor job assignments to the sailors' personal preferences. This centralized detailing process reassigns approximately one-third of the enlisted force every year (i.e., 100,000 sailors). This labor-intensive process often leaves both sailors and commands dissatisfied.

Competitive labor markets can be used as the model to identify the desirable characteristics of internal labor markets. Competitive labor markets are both effective and efficient (Ehrenberg & Smith, 1997). They are effective because markets clear. The wage rate adjusts to its market clearing value, where the quantity of labor that employers hire willingly exactly equals the quantity of labor that employees supply willingly. Competitive labor markets are also efficient. On the demand side, markets allocate labor to its highest valued uses. As the market wage increases, lower valued uses drop out while higher valued uses remain filled. On the supply side, markets ensure that the employees hired are the most willing to work in the industry. As market wages decrease, individuals less willing to work voluntarily leave; those most attracted to the industry remain. Thus competitive labor markets balance labor supply and demand, and ensure that the most valuable jobs are filled with the most willing employees.

Unfortunately, the information requirements to ensure effectiveness and efficiency are extensive. To operate efficiently, the assignment process must have complete information regarding the employees' preferences over available jobs, and the employers' preferences over potential employees. To establish their preferences, employees must have complete information about all relevant job opportunities, including salary, benefits and job amenities (e.g., work environment and content, promotion potential, commute), and employers must have complete information about the employees' relevant job qualifications. If labor assignments do not factor in this information, the system wastes labor by applying it to less valuable jobs, and it reduces job satisfaction, morale and retention by assigning labor to jobs that are relatively less desirable. Clearly, some kind of technology could help people manage the required abundance of labor-market information.

INTELLIGENT AGENT TECHNOLOGY

Work in the area of software agents has been ongoing for some time, and it addresses a broad array of applications. Building upon research in the supply chain domain (Mehra & Nissen, 1998; Nissen & Mehra, 1998; Nissen, 2000), agent technology appears to have particular promise to automate and support electronic labor markets. As computational artifacts, they can help overcome human cognitive limitations (e.g., in terms of memory and processing speed), supporting rapid search and effective filtering through huge numbers of available jobs and potential employees. Further, agents possessing artificial intelligence (AI) can employ inferential mechanisms (e.g., rules, cases, scripts) to reflect and observe diverse individuals' preferences. In a domain with over a 100,000 available jobs and prospective employees (e.g., the Navy)—in which both employers and potential employees have specific, idiosyncratic needs and preferences—no other extant information technology offers the same level of automation and support capability as software agents. Here we discuss representative, extant agent technologies, and outline key capabilities of the Personnel Mall, a proof-of-concept multi-agent system developed to enact, automate and support an electronic employment market.

Extant Agent Applications

Following the literature survey and classification system of Nissen (2000), Table 1 summarizes extant agent applications into four classes: 1) information filtering agents, 2) information retrieval agents, 3) advisory agents, and 4) performative agents. Other groupings from the agents' literature could be used as well (e.g., Bradshaw, 1997; Franklin & Graesser, 1996; Nwana, 1996; White, 1997), but the classification scheme used here is useful to compare agent capabilities applicable to markets and matching processes.

Information filtering agents apply user-input preferences passively to screen and sort e-mail, network news groups, frequently asked questions and arbitrary text. Information retrieval agents collect information pertaining to commodities, such as compact disks and computer equipment, and services, such as advertising and insurance. This class also includes Web indexing robots and Web-based agents for report writing, publishing, assisted browsing, and so forth. Advisory agents provide intelligent advice and decision-support (e.g., CD and movie recommendations, electronic concierges, agent "hosts" for college campus visits, etc.). These agents also match buyers with sellers directly in market and matching domains. Agents in this third class decide what information is needed, and seek out and use this information to make recommendations. Finally, performative agents change the state of the external world through autonomous, deliberate action (e.g., binding commercial transactions). Performative agents include marketspaces in which agents conduct business transactions, auction environments in which agents buy and sell for their users, and several agent system designs for negotiation. Performative agents also automate knowledge work, such as scheduling, autonomously provide a cooperative-learning environment and provide digital library services.

The Personnel Mall

As noted above, the Personnel Mall is a proof-of-concept multi-agent system developed to enact, automate and support a Web-based marketspace for employee/job matching (Gates & Nissen, 2001). Like its predecessor system, the Intelligent Mall (which was developed for matching buyers with vendors in products and services markets), the Personnel Mall employs a shopping mall metaphor for employee-job matching. In a mall, shoppers are not expected to know in advance which shops exist or what products they offer for sale. Similarly, shops are not expected to know which other shops are selling like products or with which shoppers they will interact. But these agent-enabled marketspaces provide a qualitative contrast to their physical marketplace counterparts; that is, instead of *people* searching, matching, buying and selling within physical markets, such market and matching activities are performed by *software agents* representing people (i.e., the sailors and commands). The agents—implemented through software objects and methods—exchange messages with one another to communicate and coordinate their activities.

The Personnel Mall is probably categorized best as a performative agent. It can represent a variety of different users—on both the demand and supply sides—to find quickly, retrieve and organize large amounts of market information. Its conformance to market and organizational rules, established for a particular enterprise or circumstance, enables this multi-agent system to automate and support commerce in a broad diversity of electronic markets, including regulation-laden, hierarchical systems. Such ability suggests the Personnel Mall offers good potential to enact, automate and support the kinds of electronic labor markets addressed through this research.

In the Navy's assignment context, command agents can be specialized to reflect the preferences and priorities

Table 1. Agent taxonomy (Adapted from Nissen, 2000)

Information Filtering Agent Applications	
Filter e-mail messages	Maes, 1994; Malone et al., 1987
Filter network newsgroup postings	Sycara & Zeng, 1996
Filter frequently asked questions (FAQs)	Whitehead, 1994
Filter arbitrary text messages	Verity, 1997
Information Retrieval Agent Applications	
Collect product/service information	Krulwich, 1996; Insurance, 1997; PriceWatch, 1997; uVision, 1997
Web robots & publication tools	Amulet, 1997; Chen et al., 1998; Etzioni & Weld, 1995; InterAp, 1995
Assisted Web browsing	Burke et al., 1997
Advisory Agent Applications	
Recommend compact discs & movies	Maes, 1997; Nguyen & Haddawy, 1999
E-concierge services	Etzioni & Weld, 1995
Campus visit "host"	Zeng & Sycara, 1995
Planning support	Maturana & Norrie, 1997; Pinson et al., 1997
Project coordination advice	Johar, 1997

Performative Agent Applications	
Business marketspace	Chavez & Maes, 1996; Fox and Barbuceanu, 2000; Hu et al., 1999; Mehra & Nissen, 1998; Nissen & Mehra, 1998; Preece et al., 1999
Auction marketspace	Hu et al., 1999; Rodriguez-Aguilar et al., 1998; Sandholm, 1999
Agent negotiation	Bui, 1996; Collins et al., 1998; Guttman et al., 1998; Maes et al., 1999; Sun et al., 1999; Tesauro & Kephart, 2000
Scheduling	Sen, 1997; Walsh et al., 1998
Cooperative learning	Boy, 1997
Digital library services	Mullen & Wellman, 1996

of their principal (e.g., the Commanding Officer). For example, a command agent can be specialized to search and match based on one officer's preferences for education and training over rank and experience, whereas another agent can be specialized to reflect different (even opposing) preferences. Each command agent can be instantiated with a unique shopping list of job openings. Other knowledge and information—such as user preferences, budget restrictions, personnel requirements and need dates—can be formalized through rules for the agents.

Likewise, sailor agents can be designed by individual sailors to reflect their particular preferences. Like their command counterparts, sailor agents use messages to communicate individual sailors' attributes (e.g., rank, education, training, job skills, availability, community), and sailors can search the Mall to view a complete, current listing of job openings. Sailors use such listings to identify a specific subset of assignments in which they are particularly interested, and they use an input form to convey their relative preferences among this subset of job assignments.

With these capabilities, the Personnel Mall can be used at present to enact, automate and support search and matching in electronic labor markets, just as intelligent malls perform such functions for products and services along the supply chain. Relative to archaic centralized planning systems or crude information retrieval "bots" used in labor markets today, this innovative application of agent capability is expected to improve performance considerably (e.g., in terms of increased speed, greater information gathering, improved preference matching). For instance, the Personnel Mall can perform automatically most process activities required to match sailors with jobs—through its federation of intelligent agents—which eliminates the need for an organization of detailing personnel and associated staff. To provide a sense of magnitude, the Navy currently employs roughly 450 detailers and support personnel to perform distribution and assignment activities; some $30M could be saved by implementing a multi-agent application such as the Personnel Mall (Schlegel, 2000).

Additionally, Mall agents perform their search and matching tasks very quickly, gathering and considering substantial information in the process. Agents can also handle information overload, effectively processing much larger sets of job/sailor alternatives than their human counterparts. This suggests the lead-time required for assigning sailors to jobs can be reduced, perhaps to an interval so small it approaches just-in-time distribution and assignment. Alternatively, the period between assignments could be extended, simultaneously matching much larger groups of sailors and jobs, to improve the quality of fit. In either case, an intelligent multi-agent system eliminates many constraints currently limiting the detailing process (i.e., process time, information overload). Future analysis will determine the detailing process design that exploits these improvements best.

Redesigning the detailing process offers additional benefits. The Personnel Mall makes all job information available to sailors—and all sailor information available to commands—so personnel can search and rank alternatives from the complete listing of available Navy jobs. This addresses a common complaint from sailors: detailers fail to tell them about more than a handful of the job opportunities that the Navy needs filled. Exit interviews with sailors leaving the Navy suggest the distrust stemming from such behavior represents a significant factor in the decision not to re-enlist (Schlegel, 2000; Short, 2000).

Another putative benefit involves sailors' relative job preferences. Because the Personnel Mall matches sailors with job assignments explicitly based on preference information, personnel are more likely to be assigned to their preferred commands. Ostensibly this promotes better job performance than expected from sailors assigned to less-preferred jobs. Better sailor job matches also offer the potential for improved personnel retention, providing a better return on the Navy's investment in sailors' education and training and increasing the Navy's overall level of experience. Clearly, increased personnel retention decreases recruiting demands.

FUTURE TRENDS

The Personnel Mall—and any similar emerging agent technology—is still experimental in nature, and not yet mature or ready for "industrial strength" application (e.g., to Navy-wide distribution and assignment). One limitation, as currently designed, is that the Personnel Mall is effectively limited to *one-sided matching*; job assignments can reflect either the sailors' or commands' preferences, but do not consider both simultaneously. This suggests strong potential for incorporating within the Personnel Mall either an optimization algorithm or two-sided matching market (as used in the U.S. medical residency market (Demange et al., 1985; Gale & Shapley, 1962; Roth, 1984; Roth & Sotomayor, 1990).

Research comparing sailor and command social welfare for human detailers (the *status quo*) versus optimization or two-sided matching suggests significant increases in social welfare by moving to an algorithm-based assignment process (Gates & Nissen, 2002, 2004). Experimental results indicate that a shift away from unassisted matching can increase labor welfare by up to 20% and total welfare by 10 -14%. According to the U.S. Department of Defense (DoD) FY2002 budget, the U.S. Navy, which is currently moving from a hierarchical to a more automated assignment process, spent over $20 billion on labor in FY2002; the DoD spent over $82 billion (U.S. DoD, 2002). If these comparative results hold as we move from an experimental setting to application in the U.S. Navy or DoD, the absolute increase in welfare could be dramatic. This would represent a dramatic gain in employee morale and retention, and a significant improvement in the efficiency with which such public-sector enterprises use taxpayer dollars. Moreover, to the extent that the kinds of electronic employment market designs discussed here can be extended further to the private sector, the potential economic impact in terms of social welfare is staggering.

CONCLUSION

Two modes of matching people with jobs prevail at present: 1) hierarchical planning and 2) distributed markets. Each has strengths and limitations, but few systems have been designed to take advantage of strengths corresponding to both. With evolving information technology, however, the job-matching process could be accomplished far more equitably and efficiently using Web-based markets within the firm. Intelligent agents offer excellent potential to help both potential employees and employers find one another in a distributed electronic marketplace. But realizing this potential goes well beyond simply changing the rules of internal job matching, or making agent technology available to job searchers. Rather, the corresponding markets and technologies must be designed together to accomplish mutually the desired results (e.g., efficient and effective matching) and conform to necessary properties (e.g., market clearing). This article integrates the key economic and technological elements required to design robust electronic employment markets. The corresponding research provides new knowledge and insight into co-development of the requisite economic markets and agent technologies.

There is clearly much research yet to be accomplished before robust, electronic employment markets are ready for "industrial strength" implementation in the enterprise. Following the lead of this discussion, such research should necessarily be multi-disciplinary and integrative in nature. As noted in the introduction, economic and technological elements associated with labor-market design are inextricably intertwined, and a robust design cannot be achieved without addressing both in an integrated manner. The research described in this article has taken a first step along these lines and hopefully will stimulate further research.

KEY TERMS

Advisory Agents: Intelligent agents that provide intelligent advice and decision support autonomously. These agents decide what information is needed, seek it out, and use it to make recommendations.

Information Filtering Agents: Intelligent agents that apply user-input preferences autonomously to screen passively and sort information.

Information Retrieval Agents: Intelligent agents that search for and collect information autonomously based on user prescribed criteria.

Intelligent Agents: Computer software that employs artificial intelligence to make decisions and perform actions autonomously.

Performative Agents: Intelligent agents that change the state of the external world through autonomous, deliberate action (e.g., make binding market transactions). Performative agents seek out and act on information, according to user prescribed criteria.

Social Welfare: The amount by which the value society receives from an activity (e.g., product or service) exceeds the cost to society of providing that activity. Social welfare is used to measure the net benefit society receives from any activity.

Two-Sided Matching Markets: Markets involving two groups of participants, in which a member of one group is uniquely matched to one and only one member of the other group (e.g., two partners in a marriage). Matches are stable if no two participants, who are from opposite groups in the market and are not matched to one another, would prefer one another to their current partner.

Agent-Based Intelligence Infrastructure

INTRODUCTION

Today's enterprises must go beyond traditional goals of efficiency and effectiveness; they need to be intelligent in order to adapt and survive in a continuously changing environment (Liebowitz, 1999). An intelligent organization is a living organism, where all components and subsystems work coherently to enable the enterprise to maximize its potential in its goal-driven endeavors. Stonier (1991) suggested that intelligent organizations must have not only intelligent individuals, but also "collective intelligence" that is created through integration of intelligence from sub-units of the organization. Researchers have developed frameworks for building organizations around intelligence, as opposed to traditional approaches that focus on products, processes, or functions (e.g., McMaster, 1996; Liang, 2002). Analogous to intelligent biological life, an intelligent organization has a life of its own. An intelligent enterprise understands its internal structure and activities, as well as external forces such as market, competition, technology, and customers. It learns and adapts continuously to the changing environment. The learning and adaptation are achieved through real-time monitoring of operations, listening to customers, watching the markets, gathering and analyzing data, creating and disseminating knowledge, and making intelligent decisions.

Building an intelligent enterprise requires an intelligent foundation that supports intelligent reasoning and behavior at all levels of the organization. Modern information and communications technologies, combined with artificial intelligence (AI) research, provide necessary tools to create and sustain intelligence in the organizational infrastructure. Artificial intelligence has found wide applications in business, ranging from production planning and scheduling to data mining and customer relationship management. However, traditional AI systems have focused on domain-specific problem solving. Simple job shop scheduling and product malfunction diagnosis do not lend themselves well to enterprise-wide management. A more recent branch of artificial intelligence research is distributed artificial intelligence (DAI). DAI helps "far-flung, often stand-alone, application components work toward a common goal" (Chaib-draa, 1998, p. 31). Another development in AI research is the study of agent-based systems, in which autonomous software agents are deployed to carry out various tasks that are traditionally performed by humans (Jennings & Wooldridge, 1998). Recent advancements in distributed artificial intelligence, multi-agent systems, and networking technology have laid the foundation for real-world deployment of intelligent agents (Martin, Cheyer & Moran, 1999; Moukas, Zacharia & Maes, 2000).

BACKGROUND

Intelligent agents go by various names such as software agents, softbots, autonomous agents, or simply, agents (Huhns & Singh, 1998). Russell and Norvig (1995, p. 33) defined an agent as "anything that can be viewed as perceiving its environment through sensors and acting upon that environment through effectors." An intelligent agent is, according to Franklin and Graesser (1996), "a system situated within and a part of an environment that senses that environment and acts on it, over time, in pursuit of its own agenda and so as to effect what it senses in the future." In practical applications, intelligent agents are named according to their main functions. Examples include news agents, e-mail agents, shopping agents, search agents, information brokering agents, personal assistant agents, collaborative agents, negotiation agents, transaction agents, security agents, and so on.

Intelligence infrastructures have not been well studied. However, many successful businesses have already built intelligence infrastructures, enabling them to become intelligent enterprises. Broadly speaking, an intelligence infrastructure includes all basic facilities, services, and installations needed for the functioning of an intelligent enterprise. Intelligence infrastructure is defined as information technology-based facilities, systems, and services that support holistic intelligent behaviors throughout an organization. In the 1970s and 1980s, the information infrastructure of a business consisted of database and database management systems that supported various business processes. During the 1990s, businesses began the move from information age organizations to learning organizations, characterized by an information infrastructure based on data mining and knowledge management systems. Intelligent agents have emerged in recent years as key components in the organizational information infrastructure.

The evolution of modern organizations and their information infrastructure can be classified into three distinctive phases, as depicted in Figure 1. Information age organizations emphasize data and information processing. Transaction processing systems (TPSs), management information systems (MISs), decision support systems (DSSs), and executive information systems (EISs) are traditional business information systems used at different managerial levels. Database (DB) management and knowledge management (KM) provide the infrastructure support for learning organizations. A learning organization emphasizes knowledge creation, sharing, and dissemination. Supply chain management (SCM), enterprise resource planning (ERP), business process redesign (BPR), and total quality management (TQM) are commonly used in learning organizations. Multi-agent systems (MASs) can be designed to create dynamic connections to various information systems. MASs, DBs, and KM provide the foundation for distributed intelligence. Intelligence infrastructure (II), global resource management (GRM), and customer relationship management (CRM) are indispensable components of an intelligent enterprise.

Intelligent organizations require seamless integration of all systems in the organization through the intelligence infrastructure. Global resource management systems allow the intelligent organization to scan, analyze, and integrate global resources. The existence of advanced information and communication systems such as MASs, IIs, and GRMs does not automatically guarantee the success of the organization. It is a necessary condition for intelligent enterprises. Success of those enterprises depends on the assimilation of advanced information technologies into their organizational design.

A key feature of the intelligence infrastructure is the integration of all components and subsystems within the enterprise. Those components and subsystems include not only various information and knowledge systems, but also management control, human resource management, and environment management. Intelligent agents automate key operational processes, monitor operations, schedule activities, coordinate tasks, process data, anticipate needs, deliver proactive information and services, negotiate and collaborate with other agents, and intimate with their masters—the knowledge users. What distinguishes intelligence infrastructure from other types of systems is its ability to continuously capture and integrate business process knowledge, hence improving the organization's ability to learn and adapt while the changes occur, not after.

Although intelligent agents have found many successful applications, the research on integrating intelligent agents with traditional systems to create intelligence infrastructure is limited. Much of the research on intelligent agents has focused on technology issues and spe-

cific subsystems of intelligent enterprises. Zhu, Perietula, and Hsu (1997) explored building a link between information technology and organizational learning, focusing on creating business processes that can learn in a manufacturing environment. Peng et al. (1998) created a multi-agent framework that supports the integration of various types of expertise in an intelligent enterprise. Jain, Aparicio, and Singh (1999) introduced intelligent agents for streamlining processes in virtual organizations. Intelligent agents are particularly effective in providing a reliable and flexible foundation for virtual organizations through facilitating knowledge query and communications. Sikora and Shaw (1998) proposed a multi-agent framework for integrating various traditional information systems. In business-to-business e-commerce applications, Papazoglou (2001) advocated using intelligent business agents to support a natural merging of object orientation and knowledge-based technologies.

FUTURE TRENDS

A successful intelligence infrastructure not only provides support for intelligent decision making of the organization, but also evolves and improves autonomously. This kind of self-adaptation has been observed in complex adaptive systems (CASs), in which intelligent agents adapt by changing the rules that control their behaviors as the agents gain more knowledge and experience in the system. Sutherland and van den Heuvel (2002) termed those intelligent agent-based subsystems as *agentified enterprise components*. They also provided case studies of enterprise application integration with complex adaptive systems. Rather than relying on a few highly sophisticated intelligent agents to support decision making throughout the organization, intelligence at the infrastructure level arises from the interaction of a large number of heterogeneous intelligent agents. Those agents specialize in certain functional areas such as planning, information gathering, and process monitoring and control. Each agent may have a different level of learning and self-improvement capabilities at both infrastructure and application levels. Table 1 lists specialized intelligent agents that can be deployed in an intelligence infrastructure that supports organizational functions in various capacities.

As shown in Table 1, there is a wide spectrum of tasks that can be performed and/or assisted by intelligent agents. Furthermore, intelligent agents can be used as the next-generation software components or building blocks for creating intelligent subsystems for intelligent organizations (Griss, 2001). As part of the intelligence infrastructure, modern speech and vision technologies can be used to create an intelligent environment that supports natural human interactions and provides both proactive and reactive services to the knowledge users. With a semantic network for knowledge representation, organizational knowledge can be recorded and retrieved using complex queries. Hanssens, Kulkarni, Tuchinda, and Horton (2002) described agent-based intelligent workspaces that provide a multi-layered infrastructure capable of supporting an intelligent environment.

As intelligent organizations vary in size and structure—from project teams, to business entities, industries, and nations—so will the intelligence infrastructure. Although the capability of the intelligence infrastructure covers a wide spectrum, to allow intelligent enterprises to reap the desired benefits of an organic structure and spontaneity in responding to environmental changes, the intelligence infrastructure must meet the fundamental requirements summarized in Table 2.

In traditional systems, many of the functions and processes may not be autonomous. Furthermore, interoperability may be limited due to different platforms and standards used by various subsystems. Recent developments in standards-based networking and data communications, such as transactions based on SOAP (Simple Object Access Protocol) and XML (Extensible Markup Language) Web services, promise drastic improvements in machine-to-machine communications. These developments benefit standards-based intelligent agents' communications and the integration of intelligent agent systems with traditional systems. The inter-agent communication and negotiation can be facilitated by standard protocols such as the Knowledge Query and Manipulation Language (KQML). Although much progress has been made in recent years in creating intelligence infrastructure, there remain many open issues. Table 3 summaries some of the key research issues in designing and developing a successful agent-based intelligence infrastructure.

CONCLUSION

An intelligence infrastructure is created by integrating existing information/knowledge systems through the introduction of an encompassing, efficient, flexible, and intelligent communication system that greatly enhances the integration, coordination, and collaboration of people and resources in an organization. This built-in intelligence at the infrastructure level makes the organization agile and robust. Although traditional information systems infrastructure offers a certain degree of intelligence, it is in general limited, fractural, and static in nature. An intelligent organization needs an intelligence infrastructure that is integrated, comprehensive, dynamic, and adaptive.

The intelligence infrastructure supports and enhances the complex and dynamic functionalities of an intelligent organization. Through open standards and intelligent agents, traditional systems will be able to cooperate and provide coherent information and services to end users. Intelligent agents serve as intermediaries that not only

Table 2. Requirements for agent-supported intelligence infrastructure

• A distributed information/knowledge system with central coordination
• A distributed multi-agent system integrated with traditional systems
• Open standards-based technologies to ensure a high degree of interoperability
• A common ontology that enables agents to understand one another
• A high level of self-regulation in system operation, monitoring, and adoption
• A high degree of reliability and accessibility
• Secure and trusted agent-user and agent-agent relationships
• User-friendly interface and agent-supported learning
• Improved value to the end users
• Easy to develop, deploy, and maintain
• Integrating and updating existing assets
• Leveraging external resources
• Contingency management

Table 3. A summary of research issues in agent-based intelligence infrastructure

• Multi-agent communication and collaboration
• Intelligence infrastructure and knowledge management
• Agent and intelligence infrastructure standards
• Anthropomorphic agent (human-computer interface)
• Intelligence infrastructure and XML Web services
• Integration of intelligent agents with legacy systems
• Integration of heterogeneous systems
• Security of intelligence infrastructure
• Adaptation and diffusion of intelligence infrastructure
• Control and management of intelligence infrastructure
• Performance measures of intelligence infrastructure

make vast resources available to the users, but also empower the users by automating, consolidating, and simplifying routine tasks, and allowing the users to explore and perform tasks that were not possible in the past.

KEY TERMS

Distributed Artificial Intelligence (DAI): A subset of artificial intelligence that is concerned with the study of issues related to knowledge distribution and problem solving involving a society of decentralized but connected entities.

Intelligence Infrastructure: The organizational foundation that consists of information technology-based facilities, systems, and services that support holistic intelligent behaviors throughout an organization.

Intelligent Agent: An autonomous software program that performs certain tasks delegated to it by its master. The program is able to learn and adapt to its environment in order to perform the tasks better. Task-specific intelligent agents are given different names based on their functionalities, such as interface agent, information agent, e-commerce agent, and personal assistant agent.

Intelligent Organization: An organization is a living organism where all components and subsystems work coherently together to enable the organization to maximize its potential in its goal-driven endeavors. It is characterized by learning and adapting to the changing environment.

Multi-Agent Systems (MASs): Distributed systems with a group of intelligent agents that communicate, bargain, compete, and cooperate with other agents and the environment to achieve goals designated by their masters. Some MASs exhibit collective emerging behaviors that cannot be predicted from individual agent behaviors.

Organizational Intelligence: The collective organizational capacity of achieving goals and effectively responding to environmental changes.

Web Services: The programmatic interfaces that support application-to-application communication on the World Wide Web. Standards-based Web services use XML to interact with each other.

Agent-Based Negotiation in E-Marketing

V.K.Murthy

INTRODUCTION

This article describes in brief the design of agent-based negotiation system in e-marketing. Such a negotiation scheme requires the construction of a suitable set of rules, called protocol, among the participating agents. The construction of the protocol is carried out in two stages: first expressing a program into an object-based rule system and then converting the rule applications into a set of agent-based transactions on a database of active objects represented using high-level data structures.

BACKGROUND

An agent is a code-containing object, that along with data and execution context can migrate autonomously and purposefully within a computer network. Thus an agent knows what to do with the information obtained from its environment. Agents behave like actors and have intentions and actions. In addition, agents are flexible, proactive and have multithreaded control. In this overview, we describe in detail how a set of agents can be used for negotiation in e-marketing. For this purpose we need to have a model of the multi agent-based paradigm for executing the negotiation process analogous to what we humans do. Negotiation is an interactive process among a number of agents that results in varying degrees of cooperation, competition and ultimately to commitment that leads to a total agreement, consensus or a disagreement. It has many applications, including economics, psychology, sociology and computer science.

MAIN THRUST OF THE ARTICLE

The following subsections bring out the main thrust of this chapter, namely: what is a multi-agent system, what is planning, reasoning and negotiation, and how agents can be useful in modeling e-market and e-auction. Also we will briefly describe how a coalition among agents can cause a speculation bubble or a crash in e-share market.

A MULTI-AGENT SYSTEM

A simple model of an agent that is suitable for our purpose is shown in Figure 1. This is a unified model based on several important contributions made by the following authors: (Chen & Dayal, 2000; Dignum & Sierra, 2001; Fisher, 1995; Genesereth & Nilsson, 1987; Ishida, 1994; Murthy, 2002; Woolridge, 2002).

As shown in Figure 1, an agent consists of the following subsystems:

(1) Worldly states or environment U: Those states which completely describe the universe containing all the agents.

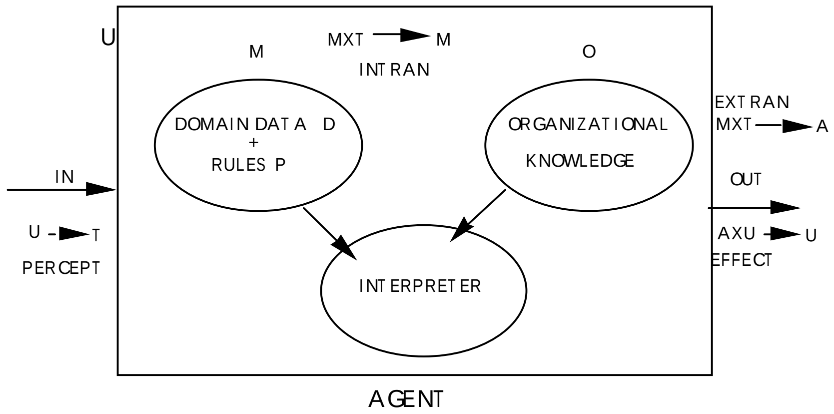
(2) Percept: Depending upon the sensory capabilities (input interface to the universe or environment), an agent can partition U into a standard set of messages T, using a sensory function Perception (PERCEPT): PERCEPT : $U \rightarrow T$.

PERCEPT can involve various types of perception: see, read, hear, smell. The messages are assumed to be of standard types based on an interaction language that is interpreted identically by all agents.

(3) Epistemic states or Mind M: We assume that the agent has a mind M (that is essentially a problem domain knowledge consisting of an internal database for the problem domain data and a set of problem domain rules) that can be clearly understood by the agent without involving any sensory function. The database D sentences are in first order predicate calculus (also known as extensional database) and agents' mental actions are viewed as inferences arising from the associated rules that result in an intentional database, whcih changes (revises or updates) D.

The agent's state of belief, or a representation of an agent's state of belief at a certain time, is represented by an ordered pair of elements (D, P). D is a set of beliefs about objects, their attributes and relationships stored as an internal database and P is a set of rules expressed as preconditions and consequences (conditions and actions). When T is input, if the conditions given in the left-hand side of

Figure 1.



P match T, the elements from D that correspond to the right-hand side are taken from D and suitable actions are carried out locally (in M) as well as on the environment.

(4) Organizational Knowledge (O): Since each agent needs to communicate with the external world or other agents, we assume that O contains all the information about the relationships among the different agents. For example, the connectivity relationship for communication, the data dependencies between agents, and interference among agents with respect to rules. Information about the location of different domain rules is in O.

(5) INTRAN: M is suitably revised or updated by the function called internal transaction (INTRAN).

Revision: Revision means acquisition of new information about the environment that requires a change in the rule system P. This may result in changes in the database D.

Example: The inclusion of a new tax rule in the tax system.

Update: Update means adding new entries to the database D; the rules P are not changed.

Example: Inclusion of a new tax-payer in the tax system.

Both revision and update can be denoted in set-theoretic notation by: INTRAN: $M \ X \ T \rightarrow M$

(6) EXTRAN: External action is defined through a function called global or external transaction (EXTRAN) that maps an epistemic state and a partition from an external state into an action performed by the agent. That is: EXTRAN: $M \ X \ T \rightarrow A$
This means that the current state of mind and a new input activates an external action from A.

(7) EFFECT: The agent also can affect U by performing an action from a set of actions A (ask, tell, hear, read, write, speak, send, smell, taste, receive, silent), or more complex actions. Such actions are carried out according to a particular agent's role and governed by an etiquette called protocols. The effect of these actions is defined by a function EFFECT, which modifies the world states through the actions of an agent:

EFFECT: $A \ X \ U \rightarrow U$; EFFECT can involve additions, deletions and modifications to U.

Thus an agent is defined by a set of nine entities, called a 9-tuple:

(U,T,M(P,D),O,A,PERCEPT,INTRAN,EXTRAN,EFFECT).

The interpreter repeatedly executes selected rules in P, until no rule can be fired.

We can interpret all the abstract machine models (such as a finite state machine or a Turing machine) and parallel computational models (such as classifier systems) as subclasses of the agents, by suitably formulating the definitions.

The nature of internal production rules P, their mode of application, and the action set A determines whether an agent is deterministic, nondeterministic, probabilistic or fuzzy. Rule application policy in a production system P can be modified by:

(1) Assigning probabilities/fuzziness for applying the rule
(2) Assigning strength to each rule by using a measure of its past success
(3) Introducing a support for each rule by using a measure of its likely relevance to the current situation

The preceding three factors provide for competition and cooperation among the different rules. Such a model is useful for negotiation in learning, as well as in e-marketing that involves interactions between many agents.

WHAT IS NEGOTIATION?

A negotiation protocol is viewed as a set of public rules that dictate the conduct of an agent with other agents to achieve a desired final outcome.

A negotiation protocol among agents involves the following actions or conversational states:

(1) Propose: one puts forward for consideration a set of intentions called a proposal.
(2) Accept: The proposal is accepted for execution into actions.
(3) Refuse: The proposal is rejected for execution into actions.
(4) Modify: This alters some of the intentions of the proposer and suggests a modified proposal that is at the worst, a refuse and a new proposal; or a partial acceptance and new additions.
(5) No proposal: No negotiation.
(6) Abort: Quit negotiation.
(7) Report agreement: This is the termination point for negotiation in order to begin executing actions.
(8) Report failure (agree to disagree): Negotiation breaks down.

Note that the previous actions are not simple exchange of messages but may involve some intelligent or smart computation.

Multiagents can cooperate to achieve a common goal to complete a transaction to aid the customer. The negotiation follows rule-based strategies that are computed locally by its host server. Here competing offers are to be considered; occasionally cooperation may be required. Special rules may be needed to take care of risk factors, domain knowledge dependencies between attributes, and positive and negative end conditions. When making a transaction several agents have to negotiate and converge to some final set of values that satisfies their common goal. Such a goal should also be cost effective so that it is in an agreed state at the minimum cost or a utility function. To choose an optimal strategy each agent must build a plan of action and communicate with other agents.

PLANNING, REASONING AND NEGOTIATION

The negotiation process is usually preceded by two cooperating interactive processes: planning and reasoning (Woolridge, 2000). The ability to plan ahead for solving a problem is the key aspect of intelligent behavior. To solve a problem through negotiation, we start with a set of desired properties and try to devise a plan that results in a final state with the desired properties. For this purpose, we define an initial state where we begin an operation and also define a desirable goal state or a set of goal states. Simultaneously, we use a reasoning scheme and define a set of intended actions that can convert a given initial state to a desired goal state or states. Such a set of intended actions called the plan exists if and only if it can achieve a goal state starting from an initial state and moving through a succession of states. Therefore to begin the negotiation process, we need to look for a precondition that is a negation of the goal state and look for actions that can achieve the goal. This strategy is used widely in AI and forms the basis to plan a negotiation (Genersereth & Nilsson, 1987). Such a planning is possible for clear-cut algorithmic problems. For general AI problems, however, we can only generate a plan that may or may not work; if the plan does not work we need to either modify the plan or devise a new plan. The same approach is used for devising a multi-agent negotiation protocol that is useful in e-auction, e-marketing and in other applications (Horlait et al., 2003; Marik et al., 2003; Schillo et al., 2003; Woolridge, 2000).

We now describe how to carry out distributed multi-agent negotiation by sending, receiving, handshaking and acknowledging messages and performing some local computations.

A multi-agent negotiation has the following features (Dignum & Sierra, 2001; Murthy, 2002):

(1) There is a seeding agent who initiates the negotiation and coordinates the negotiation.
(2) Each agent can be active or inactive.
(3) Initially all agents are inactive except for a specified seeding agent that initiates the computation.
(4) An active agent can do local computation, send and receive messages and can spontaneously become inactive.
(5) An inactive agent becomes active, if and only if it receives a message.
(6) Each agent may retain its current belief or revise its belief as a result of receiving a new message by performing a local computation. If it revises its belief, it communicates its revised state of belief to other concerned agents; else it does not revise its solution and remains silent.
(7) Finally, the negotiation terminates, or fails. If there is no consensus within a set time-out limit, the negotiation fails.

FUTURE TRENDS

Agent based systems will provide new approaches to modeling and simulation of complex business systems and also provide for new software engineering approaches (Lucena et al., 2004; Sichman et al., 2003). We will illustrate this by a simple example on modeling e-market and e-auction.

MODELING E-MARKET AND E-AUCTION

The agent negotiation system can model the e-market with many traders (agents), popularly known as buyers and sellers. These agents negotiate over the Internet to sell or buy shares or stocks in a stock market. In an e-market situation, it is possible that the negotiation ultimately leads to self-organization and criticality, causing crashes. That is, individual agents that correspond to a microscopic system can emerge as a self-organizing macroscopic system corresponding to a "percolation model" (Paul & Baschnagel, 1999).

In e-market situation (see Figure 1), to start with, the domain data D, rules P and organizational knowledge O can be based on three factors:

(1) the experience and economics knowledge of an agent deployed by a trader based totally on individualistic idiosyncratic criteria.
(2) the trader's acquired knowledge through communication with other selected agents; such a trader is called a fundamentalist.
(3) the trader's acquired knowledge by observing the trends on market from a collective opinion of other traders; such a trader is called a trend chaser.

The previous three factors play an important role in deciding the number of possible states that each agent will be in and his or her inclination to buy or sell or wait in an e-marketing decision.

In e-market, at every time instant a trader can adopt three possible states of action: buy, sell or wait, respectively represented by three states 1, -1 and 0. Each agent representing a trader can communicate with one another and this creates an imaginary bond or connectivity relationship among them, modifying the organizational knowledge O. This bond is created with a certain probability determined by a single parameter that characterizes the willingness of an agent to comply with others.

The three states of behavior are obviously a very complicated function of the behavioral property and personality of an individual and whether he or she uses elementary, derived or inferential beliefs. It is interesting to note that all the beliefs are again a function of the speed with which information is available to an agent, financial status, ability to reason and susceptibility to pressure from neighbors. Thus in a share market or auction situation we need to work out how the agents are linked in order to obtain information through communication, the personality factors such as age, financial status and the market trend. Using data mining techniques one can derive detailed information about the mechanism of bond formation among the agents. Based on this information, we can assume that any two agents are randomly connected with a certain probability. This will divide the agents into clusters of different sizes whose members are linked either directly or indirectly via a chain of intermediate agents. These groups are coalitions of market participants who share the same opinion about their activity. The decision of each group is independent of its size and the decision taken by other clusters. In this situation, using the random cluster model (Bak, 1996; Paul & Baschnagel, 1999) we can show that when every trader is on average connected to another, more and more traders join the spanning cluster, and the cluster begins to dominate the overall behavior of the system. This can give rise to "speculation bubble" (if the members all decide to buy), a crash (if the members all decide to sell) or a stagnation (if the members all decide to wait). These are cooperative phenomenon and depend upon trading rules, exchange of information- the speed and volume, and the connectivity relationship. For the three-state agents the critical probability $p(c) = 0.63$. That is, if an agent is even showing about 63% preference to the information from his or her neighbors, a crash or bubble is bound to happen. Crash is a highly cooperative phenomenon and depends upon trading rules, exchange of information- the speed and volume, and the connectivity relationship. Accordingly, an analogy exists between stock-market crashes and critical phenomena or phase transitions in physics. Thus a distributed agent system can eventually enter into a self-organized critical state or an emergent state. However, such a phenomenon is similar to an earthquake or epidemic, or fatigue in materials resulting in cracks and is hard to predict, since the cluster formation depends upon the various factors already mentioned.

CONCLUSION

This overview explained the use of multi-agent based planning, reasoning and negotiation in e-marketing. We explained how to use the techniques of AI planning to devise the multi-agent based negotiation protocol. We also explained how agents can reach a self-organized critical state that can result in crash, speculation bubble or stagnation in e-share market. The study of agent systems and their applications is a vastly expanding area for research; for more details, the following references may be consulted: (Horlait et al., 2003; Marik et al., 2003; Schillo et al., 2003; Woolridge, 2000).

KEY TERMS

Agent: A system that is capable of perceiving events in its environment, or representing information about the current state of affairs and of acting in its environment guided by perceptions and stored information (current definition by AOIS, agent oriented information system community).

Coordinator: An that acts as a coordinator among several agents to carry out the negotiation protocol.

E-Auction: This is a centralized protocol for redistributing resources among agents. Each agent attaches a value to each resource. The seller asks a price for a resource and buyer offers a price and they negotiate over the Internet to achieve a desired outcome satisfying to both; else the negotiation fails.

E-Market: An Internet based market with many traders (agents) popularly known as buyers and sellers. These agents negotiate over the Internet to sell or buy products in any market (e.g., shares or stocks in a stock market).

Negotiation: This is an interactive process among a number of agents that results in varying degrees of cooperation, competition and ultimately to commitment that leads to a total agreement, consensus governed by a voting policy, or a disagreement.

Negotiation Protocol: A negotiation protocol is viewed as a set of public rules that dictate the conduct of an agent with other agents to achieve a desired final outcome.

Protocols: A set of rules that dictate the behavior of objects for communication and interaction.

Self-Organized Critical State or Emergence: A group of interconnected communicating, interacting and negotiating agents reach a state of self-organization resulting in an unpredictable decision—such as a share-market crash, a stagnation or a speculation bubble.

Agents and Payment Systems in E-Commerce

Sheng-Uei Guan
National University of Singapore, Singapore

INTRODUCTION

An emerging outcome of the popularization of the Internet are electronic commerce and payment systems, which present great opportunities for businesses, reduce transaction costs, and provide faster transaction times. More research has been conducted with new technologies like mobile Internet used by business models (Baek & Hong, 2003). However, before using the Internet, it is essential to provide security in transferring monetary value over the Internet. A number of protocols have been proposed for these secure payment systems, including NetBill, NetCheque, Open Market, iKP, Millicent, SET (Sherift, 1998), E-Cash (Brands, 1995), NetCash, CAFÉ (Mjolsnes, 1997), EMV cards (Khu-Smith & Mitchell, 2002), etc. These systems are designed to meet diverse requirements, each with particular attributes.

Automation and intelligence is another issue that poses challenges in the development of e-commerce. Agent technology has been incorporated into the area of e-commerce to provide automation and intelligence for the e-trade process. An agent is a software program capable of accomplishing tasks autonomously on behalf of its user. Agents must provide trustworthy consistency and fault tolerance to avoid eavesdropping and fraud. Also, agents should have roaming capability so as to extend their capability well beyond the limitations of owners' computers. To meet these requirements, this chapter will discuss some related components under the SAFER (Secure Agent Fabrication, Evolution, and Roaming) architecture (Zhu & Guan, 2000) and propose an agent-based payment scheme for SAFER.

Different types of electronic payment systems have been developed to meet its diverse requirements, which generally include integrity, authorization, confidentiality, availability, and reliability for security requirements (Asokan, 1997). Payment systems can be classified in a variety of ways according to their characteristics (Dahab & Ferreira, 1998), such as the exchange model (cash-like, check-like, or hybrid), central authority contact (online or offline), hardware requirements (specific or general), payment amounts (micropayment), etc.

Among the available payment schemes in the market, E-Cash is one of the best in terms of security, flexibility, and full anonymity. E-Cash is a cash-like online system that uses electronic coins as tokens. E-Cash has unique advantages, such as flexibility, integrity, and full anonymity that cannot be found in electronic check and credit card based systems. It uses cryptographic techniques to provide full anonymity. The agent-based payment scheme for SAFER adopts some similar principles and concepts of E-Cash.

MAIN THRUST OF THE ARTICLE

This chapter presents a brief overview of agents and payment system attributes used in e-commerce. An agent-based e-payment scheme built for the SAFER e-commerce architecture is proposed, which is aimed at providing a flexible and secure financial infrastructure for Internet commerce.

Software Agents in Electronic Commerce

Attributes of Agent-Based Systems for Electronic Commerce

Agents are bits of software performing routine tasks, typically in the background, on behalf of the user. Gathering, filtering, and presenting information are some of the small and well-defined tasks given to simple agents. An agent distinguishes itself from any other software by its intelligence. Intelligent agents are capable of "thinking" and producing intelligent feedback (Guan & Yang, 1999). Agents are increasing in the degree and sophistication of automation, on both the buyer's and seller's sides, commerce becomes much more dynamic, personalized, and context sensitive. These changes can be beneficial to both buyers and sellers (He, Jennings, & Leung, 2003).

The requirement for continuity and autonomy derives from our desire that an agent be able to carry out activities in a manner that is responsive to changes in the environment without requiring constant human guidance or intervention. According to Bradshaw (1997), agents have the following attributes, as shown in Table 1.

There are several software agent prototypes under development that will be capable of doing even more on behalf of buyers and sellers. One is Kasbah, wherein agents would proactively seek potential sellers and nego-

Table 1. Attributes of software agents

Attribute	Description
Reactivity	The ability to selectively sense an act
Autonomy	Goal-directness, proactive and self-starting behavior
Collaborative behavior	Can work in concert with other agents to achieve a common goal
Communication ability	The ability to communicate with persons and other agents
Personality	The capability of manifesting the attributes of a believable character, such as emotion
Temporal continuity	Persistence of identity and state over long periods of time
Adaptivity	Being able to learn and improve with experience
Mobility	Being able to migrate in a self-directed way from one host platform to another

tiate with them on the buyer's behalf, making the best possible deal, based on a set of constraints specified by the buyer, including the highest acceptable price and a transaction completion date (Chavz, 1996). A disadvantage of this software agent is that it always accepts the first offer that can meet its asking price, when even better offers might exist. This disadvantage is resolved by AuctionBot, a general-purpose Internet auction server. *AGENTics* is another agent prototype that develops what is referred to as "*online catalog integration for e-commerce*." AGENTics products shield the user from the technicalities of "where" and "how" the information was gathered, while it synthesizes many information pieces into a coherent whole (Mougayar, 1997).

Some agents can select desired items based on preferences, search databases to look for selected pieces of information, and conduct transactions. An example of such an adaptive agent is the SAFER architecture for e-commerce.

SAFER (Secure Agent Fabrication, Evolution, and Roaming) is a Web-based distributed infrastructure to serve agents to query, buy, and sell goods in e-commerce.

Figure 1. Cooperating agents for the SAFER payment scheme

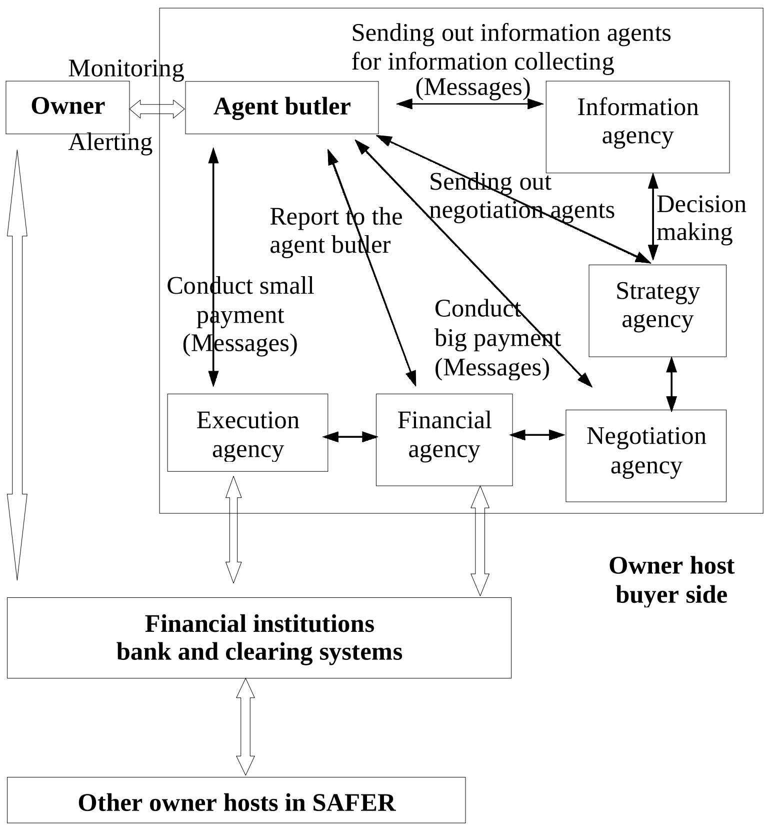

Figure 2. Prototype of agent butler

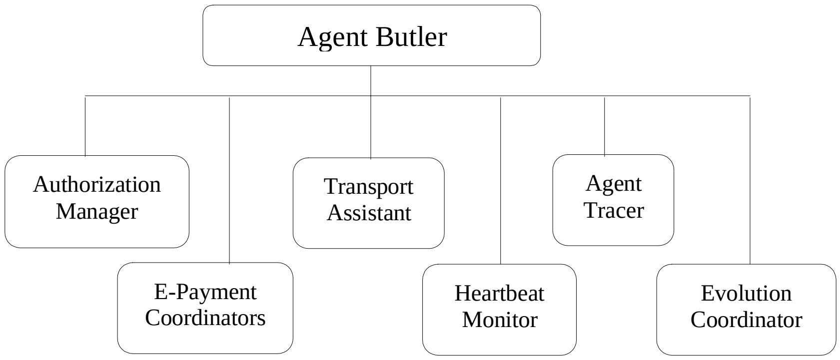


It establishes necessary mechanisms to transport, manufacture, and evolve all different types of agents. The goal of SAFER is to construct open, dynamic, and evolutionary agent systems for e-commerce (Zhu & Guan, 2000). There will be SAFER-compliant and noncompliant communities coexisting in the e-commerce network. Each SAFER community consists of several mandatory components: owner, butler, agent, agent factory, community administration center, agent charger, agent immigration, clearinghouse, and bank. Agent community is the basic unit in SAFER e-commerce, which offers virtual regions and vehicles to host and administrate mobile agents during roaming, transaction, and evolution. An owner is in charge of all his agents and of making respective authorizations to mobile agents and his agent butler, which is a 24-hour online watcher that would handle most of the tasks on behalf of the owner. When agents are sent roaming in the network, the butler has the responsibility of keeping track of agents' activities and locations by sending messages to agents and receiving messages from agents. At least one financial institution, usually a bank, that can link all value representations to real money, must also be involved. The payment scheme designed for SAFER is expected to fulfill flexibility and interoperability, which means that diverse representations of value will have the possibility of emerging in one framework for users' convenience. Given that, it is important that funds represented by one mechanism be easily converted into funds represented by others (Neuman, 1995).

An Agent-Based E-Payment Scheme for SAFER

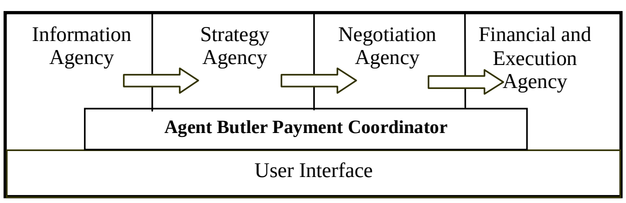
The payment module in the agent-mediated SAFER e-commerce architecture must contain several essential components: the marketplace, agents (including mobile agents, static agents, and agent butlers), financial institutions, and users. In SAFER, a community will offer virtual regions, factories, administration tools, vehicles to manipulate and administrate mobile agents during any activity, and provide security so that users can trust it.

Different types of agents fabricated by an agent factory of SAFER are running under the payment scheme for respective functions and tasks. They are briefly described in Figure 1.

In this scheme, a subsystem called agency is mentioned. Similar to the definition given by Dr. Larry Kerschberg in his Defense Personnel Support Center (DPSC) project, an agency can be thought of as a multi-layered agent group or a federation of agents with specific goals and functional roles in the architecture. It is also like a collection of cooperating intelligent agents with particular expertise (Kerschberg, 1997).

If the owner is interested in some items, he will assign tasks to his butler and agents. The agent butler will then send out information agents from the agency, taking note of the items of interest, and set parameters such as due date (by which the item should be purchased), desired

Figure 3. Payment coordinator



price, and highest acceptable price. The information agents used to sift, filter, and process information will roam in SAFER or even non-SAFER communities under a certain transport protocol, which is explained in the literature (Guan & Yang, 1999). It can help with dozens of purchasing decisions, thus lowering the cost and gaining efficiency. While roaming, agents are well tracked by the agent butler, by sending messages to report their activities and locations, which is described in detail in Zhu and Guan (2000). After gathering enough information, the information agent forwards all to the strategy agency, which will analyze the new data and settle on a decision for the user. All the recommendations will be reported to the agent butler first. Once a recommendation has been reported, the agent butler activates the negotiation agency that will send out negotiation agents to the shortlist merchant hosts. Negotiation is defined as follows in Green (1997), "negotiation is the communication process of a group of agents in order to reach a mutually accepted agreement on some matter" (21). If the negotiation agent and the receptionist agent reach an agreement, the result will be reported to the butler. The butler will inform the financial agency to initiate the contract for certain goods and make a transaction decision according to the amount of money involved, the distance from host to the destination vendor, etc. Financial agents will take charge of the goods reception and payment transaction under the authorization of the butler. They communicate with the merchant host, autonomously make a payment request, and sign a contract order against the right good.

Implementation

The implementation of SAFER is under way. The overall architecture consists of several closely related but separate modules: roaming, evolution, fabrication, negotiation, and electronic payment.

The implementation of the payment module began with the development of the agent butler, which is defined as a combination of several separate functions, as shown in Figure 2. They are authorization manager, e-payment coordinator, transport assistant, heartbeat monitor, agent tracer, and evolution coordinator.

In the e-payment coordinator module, communication channels are set up between agent butler and all agencies of diverse functionalities, each of which is running in a separate thread. User interfaces are designed so that the user can assign tasks, define needs and requirements, check records, and read alerting messages reported by his or her agent butler.

Making all types of agents and merchant hosts available to fit in the same framework will be difficult in the current research stage, because the attributes that agents require to communicate may differ. Given that, we have chosen to implement a limited number of typical agents to test the system functionality and will consider how the work could be generalized to e-commerce in the future.

FUTURE TRENDS

The foremost important feature of e-commerce is transaction security. If the system is not trustworthy, there will be no incentive for participants to cooperate. A prerequisite is the prevention of double spending of electronic cash or coins. Ensuring this is the crux of any system, and it will incur significant overhead. Electronic currency in the context of mobile-agent-based systems has one particular caveat: the credits that an agent may carry are essentially just data, to which the host potentially has access. To ensure system reliability and reduce overhead, there are still many open issues for further consideration and discussion in future work:

- Privacy issues in collecting data and negotiation, e.g., to prevent agents from divulging private information to other hosts and to protect agents from malicious hosts
- The extent that users will let agents make decisions for them (based on their preference)
- The agent's ability of negotiation (This should be protected to prevent a host from having access to the agent's negotiation function and then affect the agent's buying power.)
- Agent traceability (An agent butler keeps in contact with his mobile agents periodically.)
- Fault tolerance and credits recovery in case of sudden crash of remote systems or unexpected attack on mobile agents
- Protection of agent's public and secret key during agent roaming

CONCLUSION

The agent-based SAFER e-commerce payment scheme incorporated agent technologies and took advantage of some well-known secure payment transaction protocols. It aims to simulate and even enhance physical cash and is designed to support a multitude of currency types. By incorporating the concepts of agent, the system is expected to provide security, efficiency, flexibility, autonomy, and intelligence. It is designed to provide anonymity against other parties and audit ability (traceability) for the owner (or agent butler). At last, a number of potential improvements, practical aspects, and some open issues have been identified for future work.

KEY TERMS

Adaptability: The ease with which software satisfies differing system constraints and user needs (Evans, 1987).

Agents: A piece of software that acts to accomplish tasks on behalf of its user.

Anonymity: The degree to which a software system or component allows for or supports anonymous transactions.

Confidentiality: The nonoccurrence of the unauthorized disclosure of information (Barbacci, 1995).

Cryptography: The art of protecting information by transforming it (encrypting it) into an unreadable format, called cipher text. Only those who possess a secret key can decipher (or decrypt) the message into plain text.

Flexibility: The ease with which a system or component can be modified for use in applications or environments other than those for which it was specifically designed (IEEE, 1990).

Alignment of Business and Knowledge Management Strategies

El-Sayed Abou-Zeid
Concordia University, Canada

INTRODUCTION

The role of knowledge as a crucial asset for an enterprise's survival and advancement has been recognized by several researchers (e.g., von Krogh, Ichijo & Nonaka, 2000). Moreover, by having knowledge (intellectual resources), an organization can understand how to exploit and develop its traditional resources better than its competitors can, even if some or all of those traditional resources are not unique (Zack, 1999).

However, realizing the importance of organizational knowledge and its management in creating value and in gaining competitive advantage is only the first and the easiest step in any knowledge management (KM) initiative. The second and almost as important step is to answer how and where to begin questioning (Earl, 2001). In fact, "many executives are struggling to articulate the relationship between their organization's competitive strategy and its intellectual resources and capabilities (knowledge)" (Zack, 1999). As Zack (1999) argued, they need pragmatic yet theoretically sound model. It has been highly accepted that a pragmatic and theoretically sound model should meet at least two criteria. First, it should explicitly include the external domains (opportunities/threat) and internal domains (capabilities/arrangements) of both business (B-) and knowledge (K-) strategies and the relationships between them. Second, it should provide alternative strategic choices.

In order address this issue a KM strategic alignment model (KMSAM) is presented. It stems from the premise that the realization of business value gained from KM investment requires alignment between the business (B-) and knowledge (K-) strategies of the firm and is based on the Henderson-Venkatraman SAM for IT (Henderson & Venkatraman, 1993).

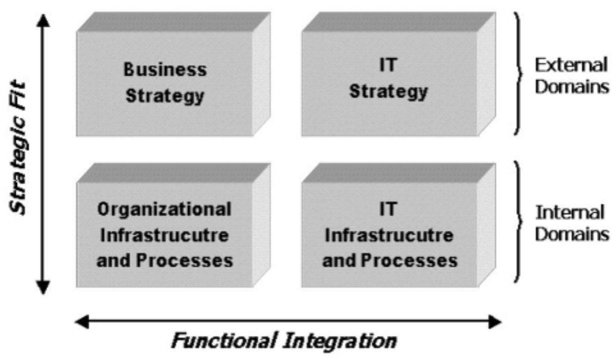
Overview of the Henderson-Venkatraman Strategic Alignment Model

The KM strategic alignment model is based on the theoretical construct developed by Henderson and Venkatraman (1993). In their model business success is viewed as the result of the synergy between four domains. The first two, the external domains, are business strategy and information technology (IT) strategy. The strategy domains are described in terms of (business/technology) scope, (distinctive business/IT systemic) competencies and (business/IT) governance. The second two, the internal domains, are organizational infrastructure and processes and IT infrastructure and processes. Both internal domains are described in terms of (administrative/IT) infrastructure, (business/IT) processes and (business/IT) skills. This synergy is achieved through two types of relationship:

- **Strategic fit** emphasizes the need for consistency between strategy (external domain) and its implementation (internal domain).
- **Functional integration,** which has two modes, extends the strategic fit across functional domains. The first mode, *strategic integration,* deals with the capability of IT functionality both to shape and to support business strategy. The second mode, *operation integration,* focuses on the criticality of ensuring internal coherence between organizational infrastructure and processes and IT infrastructure and processes.

Figure 1 shows the elements of the IT strategic alignment model (ITSAM).

Figure 1. IT strategic alignment model (Henderson & Venkatraman, 1993)



A

KM Strategic Alignment Model (KMSAM)

The premise of the original ITSAM is that ”the effective and efficient utilization of IT requires the alignment of IT strategies with business strategies” (Henderson & Venkatraman, 1993). In parallel way, the premise of KMSAM, in which knowledge strategy replaces IT strategy, is that “the effective and efficient use of organizational knowledge requires the alignment of knowledge strategies with business strategies”. Since strategy, whether business (B)-strategy or knowledge (K)-strategy, can be seen as a balancing act between the *external domain* (opportunities/threats) and the *internal domain* (capabilities/arrangements) of the firm (strengths and weaknesses) (Henderson & Venkatraman, 1993; Zack, 1999), the external and internal domains of K strategy have first to be defined.

K-Strategy External Domain

In the case of K-strategy, the *external domain* involves three dimensions: *K-scope* (what the firm must know), *K-systemic competencies* (what are the critical characteristics of the required knowledge) and *K-governance* (how to obtain the required K-competencies). The first dimension, K-scope, deals with the specific domains of knowledge that are critical to the firm’s survival and advancement strategies. Survival strategies aim at securing current enterprise profitability, while advancement strategies aim for future profitability (von Krogh et al., 2000).

Determining the K-scope can be achieved by constructing a business (B-) domain/ Knowledge (K-) thing matrix that documents the current and required state of organizational knowledge concerning some or all business domains. The first group of elements that constitute this matrix includes the list of B-domains (B_i). The second group of elements includes the K-things (K_j) that describe the current state of knowledge associated with each of the relevant B-domains. To relate this knowledge to enterprise business strategies, K-things are further classified according to the roles they play in such strategies. Von Krogh et al. (2000) have suggested that there are two types of strategies: survival and advancement. Survival strategies aim at securing current enterprise profitability, while advancement strategies aim for future profitability. Therefore, organizational knowledge, and consequently K-things, is classified into two categories: survival (K_S) and advancement (K_A). Figure (2) shows the generic form of this matrix.

The second dimension of the K-strategy external domain is K-systemic competencies. The focus of this dimension is the set of utilization-oriented characteristics of knowledge that could contribute positively to the creation of new business strategy or better support of existing business strategy. This set includes characteristics such as:

Figure 2. Generic form of B-things/K-things matrix (Abou-Zeid, 2002)

	Survival Knowledge			**Advancement Knowledge**		
B_1	K_{S11} (Current/Required States)	….	K_{S1n} (Current/Required States)	K_{A11} (Current/Required States)	….	K_{A1m} (Current/Required States)
B_2	K_{S21} (Current/Required States)	….	K_{S2k} (Current/Required States)	K_{A21} (Current/Required States)	….	K_{A2l} (Current/Required States)
….	….	….	….	….	….	….
B_N	K_{SN1} (Current/Required States)	….	K_{SNk} (Current/Required States)	K_{AN1} (Current/Required States)	….	K_{ANl} (Current/Required States)

- *Accessibility*, the extent to which organizational knowledge is made available to its members regardless of time or location (Buckman, 1998);
- *Transferability*, the extent to which the newly acquired knowledge can be applied in other contexts, for example organizational, cultural (Grant, 1996);
- *Appropriability*, the extent to which knowledge can be imitated. Things are said to have "strong" appropriability if they are difficult to reproduce by another organization. The converse is "weak" appropriability. A related concept is that of "sticky/slippery"; that is, sticky knowledge is such an integral part of a regime that it cannot be extracted in a meaningful whole (Grant, 1996; Narasimha, 2000);
- *Depth and breadth* (Narasimha, 2000);
- *Compositionality*, the amenability of knowledge to be synthesized from existing knowledge; and
- *Integrateability*, the extent to which the newly acquired knowledge can be integrated with existing knowledge.

Finally, K-governance dimension deals with the selection and use of mechanisms for obtaining the required K-competencies. The following are examples of some "acquisition mechanisms" (Probst, Raub & Romhardt, 2000):

- Bringing experts to the firm by recruiting specialists as full-time or temporary staff. Temporary hiring is becoming an increasingly interesting alternative.
- Tapping knowledge held by other firms through different inter-organizational co-operation forms such as joint ventures or strategic alliances.
- Utilizing the knowledge of stakeholders, for example, customers, suppliers, employees and owners. For example, involving customers early in the product-development process could generate valuable information about their needs.
- Acquiring knowledge products such as software, patents, and CD-ROMs.

K-Strategy Internal Domain

In the case of K-strategy, the internal domain involves three dimensions: *knowledge (K)- processes, knowledge (K)-infrastructures,* and *knowledge (K)-skills.*

Knowledge (K)-processes, the first dimension of the K-strategy internal domain, can be classified into two main categories: K-manipulating processes and K-enabling processes. The first category, K-manipulating processes, includes all the organizational processes needed to change the state of organizational knowledge such as K-generation, K-mobilization and K-application (Abou-Zeid, 2003). The second category, K-enabling processes, includes organizational processes that support K-manipulating processes such as managing conversation, mobilizing knowledge activists, creating the right context, and globalizing local knowledge (von Krogh et al., 2000).

Organizational knowledge processes are socially interaction-intensive. They involve social interactions and direct communication and contact among individuals and among members of "communities of practice". Therefore, they require the presence of social capital. Social capital is "the sum of actual and potential resources embedded within, available through, and derived from the network of relationships possessed by a social unit" (Nahapier & Ghoshal, 1998). Recognizing the importance of social capital, Gold et al. (2001) have identified three key K-infrastructures, the second dimension of the K-strategy internal domain, that is, technical, structural and cultural, that enable social capital. The *K-technical infrastructure* includes IT-enabled technologies that support KM activities such as business intelligence, collaboration and distributed learning, K-discovery, K-mapping, opportunity generation and security. The *K-structural infrastructure* refers to the presence of enabling formal organization structures and the organization's system of rewards and incentives. Finally, the *K-cultural infrastructure* involves elements such as corporate vision and the organization's system of values (Gold et al., 2001).

The last dimension of the K-strategy internal domain is K-skills. KM processes are by their very nature multifaceted. They involve many dimensions such as technical, organizational and human. This characteristic of KM processes reflects on the nature of skills required to perform them. For example, Malhotra (1997) defines a senior knowledge executive, such as a chief knowledge officer (CKO) or an organizational knowledge architect, as the person who should have the combined capabilities of a business strategist, technology analyst, and a human resource professional. The ability to facilitate the ongoing process of knowledge sharing and knowledge renewal, the ability to develop the human and cultural infrastructure that facilitates information sharing, and the ability to utilize the available technologies for serving the creation, sharing and documentation of knowledge are some examples of the required skills.

The Dynamics of KM Strategic Alignment Model (KMSAM)

Effecting a change in any single domain may require the use of three out of the four domains to assure that both strategic fit and functional integration are properly addressed. Therefore, applying KMSAM requires the identification of three domains: pivot, anchor and impacted

Figure 3. The dynamics of the strategic alignment process

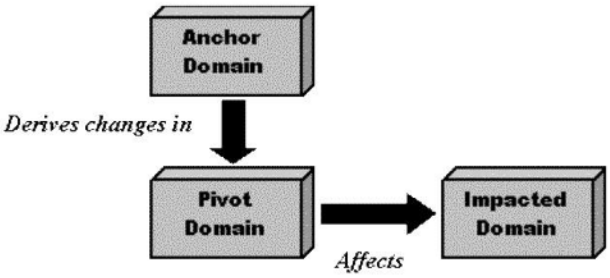


Figure 4. Knowledge potential perspective

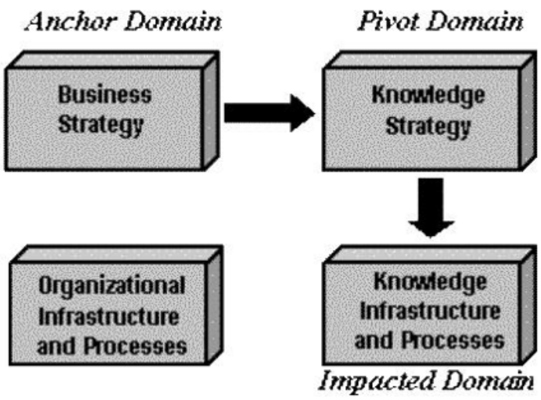
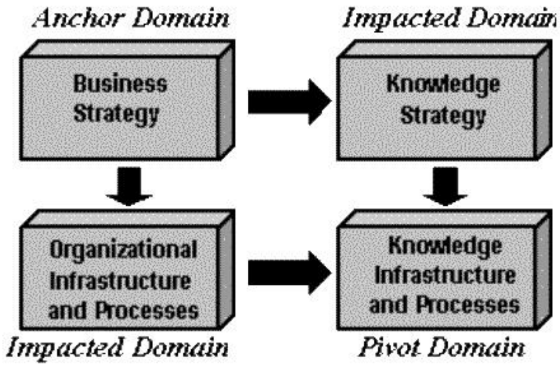


(Luftman, 1996). The pivot domain is the weakest and offers the greatest opportunity for improvement. The anchor domain is the strongest and will be the driver of change. Finally, the impacted domain is the area affected by a change to the pivot domain. Figure 3 shows the dynamics of the strategic alignment process.

Based on this distinction, different perspectives of strategic alignment can be identified. Each perspective represents a pattern of linkages between at least three elements of the four elements of KMSAM, that is, the two external domains (business strategy and knowledge strategy) and the two internal domains (organizational infrastructure and processes and knowledge infrastructure and processes). By identifying the strongest (anchor) domain and the *adjacent* weakest (pivot) domain, it becomes possible to identify the area that will be affected by the changes (the impacted domain). The direction the perspective flows is based on which domain is the strongest and which is the weakest.

For example, Figure 4 shows knowledge potential perspective in which business strategy, the strongest domain, derives changes to the adjacent weakest domain, knowledge strategy, and these changes will impact knowledge infrastructure and processes. In general, each alignment perspective has to include two types of relationships. The first is between external and internal domains of its business and knowledge components, that is, strategic fit. The second is the functional integration between business and knowledge domains. Eight single-path alignment perspectives can be then identified, namely: from anchor domain to adjacent pivot domain to impacted domain.

Figure 5. K-infrastructure fusion perspective



When the pivot and the anchor domains are not adjacent to one another, but rather across from each other on the diagonal, there will be two possible "paths" from the anchor domain to the pivot domain. This yields four fusion perspectives that result from fusing two of the eight single-path perspectives (Luftman, 1996). For example, Figure 5 shows K-infrastructure fusion perspective in which business strategy derives changes to the K-infrastructure and processes domain through organizational infrastructure and processes, and K- strategy domains.

Table 1 summarizes the 12 alignment perspectives.

CONCLUSION

Based on the premise that the realization of business value from KM investments requires alignment between the business and knowledge strategies and on the IT strategic alignment model (SAM) developed by Henderson and Venkatraman (1993), a KM strategic alignment model (KMSAM) is developed. Moreover, it provides executives with a logical framework for analyzing and assessing alternative strategic choices with regard to aligning K-strategy and B-strategy.

Extension of this work would move in two directions. The first would be to use KMSAM in cross-sectional

Table 1. KM strategic alignment perspectives

	Strategic Perspective \ Domain	Anchor Domain	Pivot Domain	Impacted Domain
1	**Strategy Execution**	Business Strategy	Organizational Infrastructure and processes	K-Infrastructure and processes
2	**Knowledge Potential**	Business Strategy	K-Strategy	K-Infrastructure and processes
3	**Competitive Potential**	K-Strategy	Business Strategy	Organizational Infrastructure and processes
4	**Service Level**	K-Strategy	K-Infrastructure and processes	Organizational Infrastructure and processes
5	**K-/Organizational Infrastructure**	K-Infrastructure and processes	Organizational Infrastructure and processes	Business Strategy
6	**K-Infrastructure/ K-Strategy**	K-Infrastructure and processes	K-Strategy	Business Strategy
7	**Organizational/ K-Infrastructure**	Organizational Infrastructure and processes	K-Infrastructure	K-Strategy
8	**Organizational Infrastructure/ Business Strategy**	Organizational Infrastructure and processes	Business Strategy	K-Strategy
9	**K-Infrastructure Fusion** (Perspectives 4 + 7)	Business Strategy	K-Infrastructure and processes	▪ Organizational Infrastructure and processes ▪ K-Strategy
10	**Organizational Infrastructure Fusion** (Perspectives 1 + 5)	K-Strategy	Organizational Infrastructure and processes	▪ Business Strategy ▪ K-Infrastructure and processes
11	**Business Strategy Fusion** (Perspectives 3 + 8)	K-Infrastructure and processes	Business Strategy	▪ Organizational Infrastructure ▪ K-Strategy
12	**K-Strategy Fusion** (Perspectives 2 + 6)	Organizational Infrastructure and processes	K-Strategy	▪ Business Strategy ▪ K-Infrastructure and processes

study of KM initiatives in order to identify the dominant patterns of K-strategy and B-strategy alignment. As "strategic alignment is not an event but a process of continuous adaptation and change" (Henderson & Venkatraman, 1993), the second direction would be a longitudinal study of each enterprise cycle around the alignment perspectives and how the adopted perspective is related to the degree of maturity of the KM initiative.

KEY TERMS

Anchor Domain: The area that provides (drives, catalyzes, or enables) the change forces applied to the pivot domain.

Impacted Domain: The area affected by a change to the pivot domain.

K-Systemic Competencies: The set of utilization-oriented characteristics of knowledge that could contribute positively to the creation of new business strategy or better support of existing business strategy.

Pivot Domain: The problem or opportunity being addressed.

Alignment of Information Technology and Human Resources Strategies

K.F. Dery
University of Sydney, Australia

D.A. Samson
University of Melbourne, Australia

INTRODUCTION

Increased productivity within modern organizations over the past two decades has largely been generated by more effective use of information technology. However, the increase in technological capability has necessitated a wide range of organisational changes. These changes to process and work structure have implications for the recruitment, remuneration, reward, skill levels and general management of people. Therefore some of the greatest challenges have been associated with integrating and aligning information systems with the appropriate human resources management strategies.

While it is widely accepted that new information systems will have an impact on the management of human resources there is a significant lack of conceptual frameworks and practical guidelines to integrate all aspects of human resources policy with those of information systems strategy. HR and IT strategies should ideally be aligned in their competitive goals in order to maximise technology investment effectiveness.

This article provides a framework to:

(1) identify and analyse the degree of alignment between HR and IT and
(2) identify the enablers and inhibitors to the alignment process.

BACKGROUND

There is recognition in both academic and business practitioner literature that Human Resource (HR) management issues play a major part in the realization of improved business performance from Information Technology (IT) investment (Zuboff, 1988; Peters, 1988; Keen, 1991). While there is significant evidence of intent to align HR and IT activities, firms experience difficulties in the implementation process. There is therefore a need to better understand the relationship between the strategic planning and implementation of IT and the associated management of HR, to ensure that the firm has the capacity to maximize the opportunities enabled by technology innovations.

As contingency views of the role and activities of the HR and IT functions gained momentum, many management theories recognized the importance of aligning IT and HR with organization strategy to change work practices and increase productivity (Becker, Huselid, & Ulrich, 2001). New theories of management and organization process re-designs suggested by Business Process Redesign (Hammer & Champy, 1993; Davenport & Short, 1990), Knowledge Management (Nonaka, 1991; Ambrosio, 2000; Pfeffer & Sutton, 2000), and Virtual organizations (Ashkenas, Ulrich, Jick, & Kerr, 1995), were technology driven but required significant organizational change to implement successfully. People management was frequently cited as the reason for failures in the implementation of these management theories (Ambrosio, 2000), yet to date little is known about the issues that surround gaining alignment between the organizational demands of the technology and the strategic management of people.

CASE RESULTS AND ANALYSIS

A series of four Australian companies were examined in detail using case studies that described an IT project. While the unit of analysis was the firm for comparative purposes, the IT project was used as a lens to gain more specific insight into the minds and actions of executives' as the project was instigated, planned and implemented.

Each of these projects had significant implications for the HR strategy and therefore in each case we might expect to see some evidence of alignment in the planning activities and implementation programs between the IT and HR executives. Table 1 below summarizes the cases, the IT projects and implications for HR strategies.

A

Table 1. IT project selection for each company

	Mbank	PFS	WxPress	Snax Ltd
IT Project	On-line mortgage application system	On-line superannuation fund management system enhancement	On-line retail ordering system	R&D system to co-ordinate recipe development, ingredient sourcing and labeling
Implications for HR	Processes previously dominated by data entry and validating, now restructured with a greater focus on analysis and assessment skills. Additional opportunities to restructure jobs with part-time /job sharing rosters.	Organization built on corporate relationships moving to longer term relationships with individual policy holders. Increased complexity of consumer demands. Current bias favouring administrative skills moving to financial advisory skill requirements.	Customer contact staff initially employed for ability to communicate by telephone with customers, now required to move to a written medium and provide the same degree of advice and information.	Specialist operators detailing, proofing and checking compliance on labeling and recipe development will no longer be required in their current form. Potential for significant job redesign based on more co-operative, process driven systems.

(i) Identification and Analysis of the Degree of HR/IT Alignment

A series of unstructured interviews with executives in each company from IT, HR, user groups and senior executives were conducted. These were analyzed in conjunction with written evidence to create indicators that we might expect to observe in an organisation where HR and IT was aligned. The indicators included factors that suggested that (a) the organization intended to align the activities of HR and IT and (b) the behaviours that contributed to an organizational state of realized alignment. These two views of alignment are consistent with Reich and Benbasat's (1996, 2000) work that examined the intellectual (intended) and social (realized) perspectives of alignment, and will be further discussed in this paper.

Indicators of alignment were identified as:

a. Evidence of intellectual (intended) alignment between HR and IT strategies as evidenced by:

- written plans,
- internal consulting processes,
- reporting structures,
- regular meeting arrangements,
- other regular activities that suggest that the company's strategic requirements were being considered in the activities of the HR and IT functions.

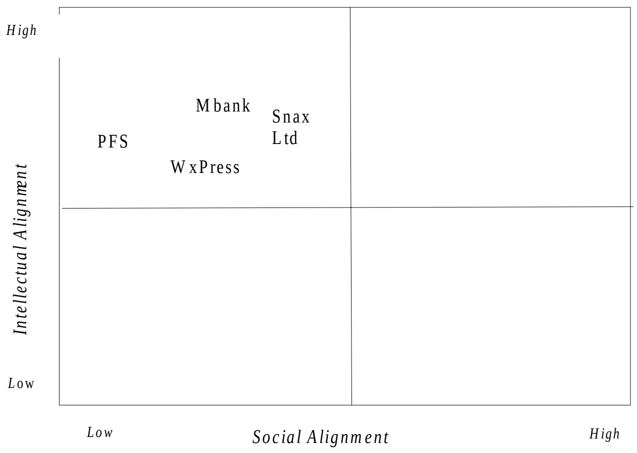
b. Evidence of social alignment (executive understanding and actions) as evidenced in the following factors:

- Regular communication between IT and HR executives.
- Company requirements that a representative from HR be included in all IT project teams.
- Written and verbal evidence that the CIO understood the importance of HR strategies to effectively implement the IT strategy.
- Understanding by the HR manager of the IT strategy and the implications of that strategy for the management of people in the organization.
- Recognition by the senior executives that having HR strategies built around the requirements generated by changes in IT was critical to realizing the rewards from the investment in the IT strategy.

Each case was assessed according to the alignment indicators identified above using both self assessments and documentary evidence. The findings were used to position each company on a spectrum of intellectual and social alignment (Figure 1).

Despite some indicators in written documents and discussion that alignment was intended between HR and IT, there was no evidence in the cases of systemic processes that ensured HR input into IT strategies and projects. Any social alignment observed was based on

Figure 1. Intellectual and social alignment ratings



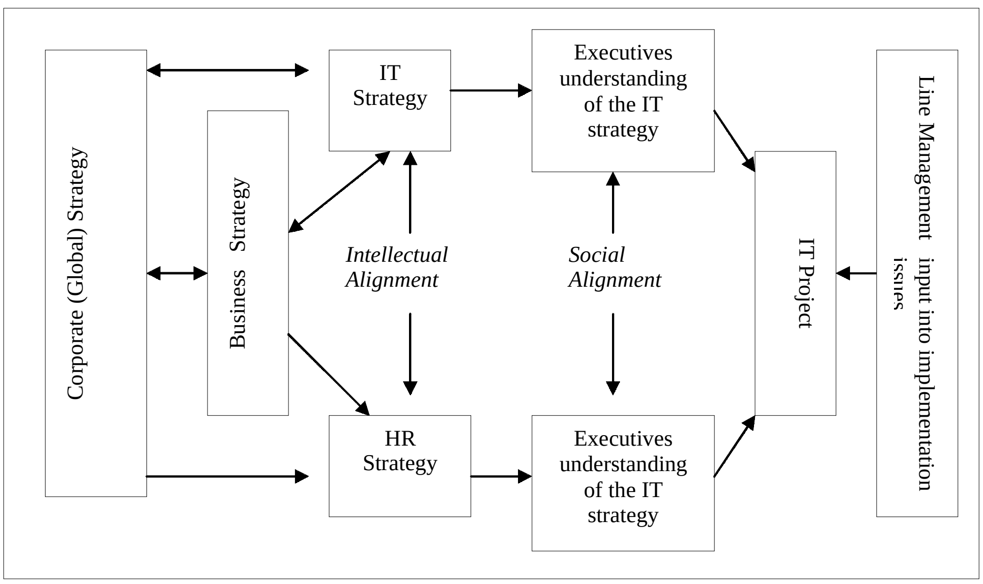
personal views of the HR managers' competencies and ability to add value. In three out of the four cases the HR manager was replaced (either during the research period or soon after) with a more experienced executive who not only had more strategic HR experience, but also a greater working knowledge of both the business and the industry. In Wxpress and Snax Ltd the stimulus for the new HR manager came from the acknowledged need for a well managed change management program in association with pending ERP implementations. Mbank's decision was a reactionary move to attempt to rescue their failing e-mortgage project.

While moves were in place in three of the cases to increase connectivity and effective communication between IT and HR, the smallest of the companies was progressing more slowly. It was recognized by the CEO of PFS that a lack of alignment was impeding their ability to maximize the returns from the IT investment, however, the size of the company made it difficult to employ an HR manager with the experience needed to have effective strategic input.

People management issues were typically devolved to line management (Figure 2) where the overwhelming response to the introduction of new technology was a training schedule. While training processes assisted in the short term implementation, there was little evidence of longer term strategic HR planning based on the expected impact of the IT strategy. In three of the companies the IT systems had not realised their expected returns and the fourth, Snax Ltd, dramatically changed its approach replacing both IT and HR managers as they embarked on a major strategic change program facilitated by new IT opportunities. As the CIO of Snax Ltd commented:

"It is no good assigning the responsibility for the people management issues and change process to the line manager because more often than not, it is the activities and responsibilities of that very person that have to change the most. The hardest thing for line management to let go of, is the power that comes with having more experience and knowledge than their staff. When everyone has access to the knowledge and the system takes over much of the processing, the line

Figure 2. Input and alignment indicators



manager is left searching for a new role and more often than not, they will hold on to the existing one."

(ii) Enablers and Inhibitors to the Social Alignment between HR and IT

Once a picture existed that indicated the nature of alignment between IT and HR, the Reich and Benbasat (1996, 2000) framework of social alignment, originally produced to examine the linkage between IT and business strategy, provided a valuable lens through which to examine the factors that influenced the understanding of executives' in the strategic alignment process. The framework was adapted to examine the inter-functional alignment between IT and HR and extended to reflect the research results.

The notion of social alignment was designed to focus on executives' understanding of each other's objectives and plans, as distinct from the intellectual intent of written documents (Figure 2). Given the nature of functional strategies, which are not necessarily deliberate and expressed in detailed, written plans (Lederer & Mendelow, 1989) but may emerge out of the collective actions of executives' (Mintzberg, 1987), and also may not necessarily be performed by a designated department that is readily observable (Ohmae,1982), the study of beliefs and behavior was important .

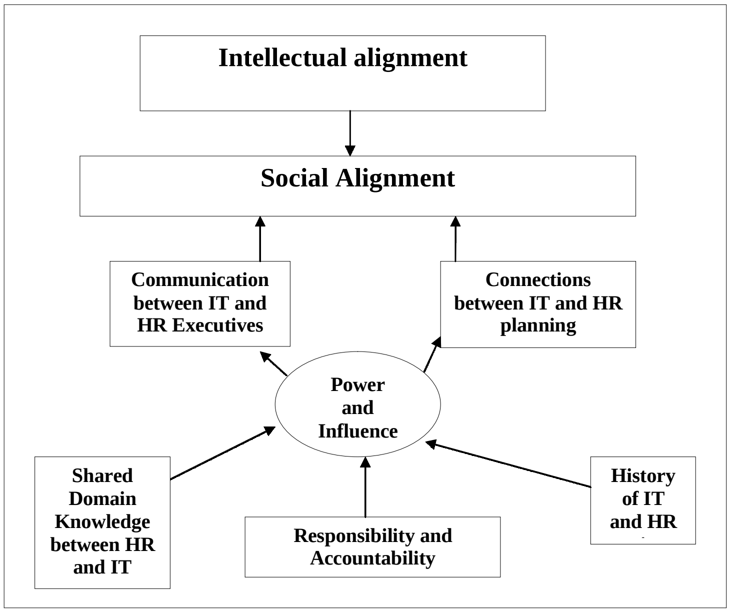
Reich and Benbasat (1996) defined the construct of alignment on two dimensions (adapted to examine the relationship between IT and HR):

- The intellectual dimension exists when the content of information technology and human resource strategies are consistent and externally valid.
- The social dimension exists when IT and HR executives understand and are committed to each others plans.

In order to examine the notion of social alignment in a meaningful and relevant manner a series of enabling factors were explored. These were all found to be significant in creating executives' understanding of each others strategies and therefore the necessary actions required in order to align their activities. Communication and planning connections supported by shared domain knowledge and a history of implementation success were identified as critical factors determining the degree of social alignment.

The revised map in Figure 3 (Dery, 2003) bears a close resemblance to that proposed by Reich and Benbasat (2000) but provides insight into factors that make the roads impassable at times and provide directions to help HR and IT work more closely together to reach their common goal.

Figure 3. Proposed framework of analysis to create a greater understanding of the alignment process between HR and IT (Dery, 2003)



Shared knowledge was the most powerful factor that had the potential to clear road blocks and help executives to visualise a way forward together. The HR executives initially involved in the IT projects examined had a limited knowledge of the business and their knowledge of IT was restricted to personal computing at best. New HR management in Mbank, Snax Ltd and Wxpress were significantly more experienced in the business processes and, with the exception of Wxpress, could contribute knowledgably to IT discussions. These new HR recruits were significantly more active in IT projects than their predecessors.

Both shared knowledge and past history are recognised bases for influence in the literature. Bacharach and Lawler (1980) identified these bases as expertise and personal characteristics. Specialist knowledge, or expertise, is a source of powerful influence as others turn to the specialist for knowledge that they do not possess. Thus specialist knowledge generates power based on dependence. Personal characteristics enhance the credibility of the executive's input and enables perspectives to be swayed in the desirable direction. The characteristics connected with reputation (Bacharach & Lawler, 1980) based on past experiences are recognized as important bases for influence.

Evidence suggested that the balance of power was generally tipped in favor of IT in the cases analyzed. The HR managers in all cases entered the "power and influence round- about" low on IT and business knowledge which reduced their ability to apply their specialist HR knowledge in an influential way. Past experiences of HR in IT departments had not been positive in all but one case (PFS). These experiences had a negative impact on the HR executives' personal credibility with the CIO and further reduced their ability to influence discussions. The paths to further communication and participation in planning activity were thus difficult to negotiate. In the three cases where HR management had been more recently replaced the evidence suggests that their increased knowledge had enabled them to exert more specialist power and thus smooth the road to improved communication and planning input. The HR managers in Mbank and Snax Ltd had moved into their new positions with proven track records with the CEO's of those companies and reputations as experienced and business-savvy executives.

When line management were charged with the task of assessing and managing the people issues, the power bases appear to adjust in their favor as they leveraged off specialist operations knowledge and, in most cases, had more IT knowledge than the HR manager. The CIO in all cases, except Snax Ltd, felt comfortable with referring people issues to line management who were generally more integrally involved with the IT project and had significantly more influence in project discussions than the HR Manager. The danger as documented in Mbank, and recognized by the CIO at Snax Ltd, is that old practices may simply be automated and anticipated benefits from the IT investment are inhibited by a lack of strategic HR thinking.

"It is very hard for line managers to envisage how the new order might look when they themselves are likely to be facing the most significant change. Most line managers source their power from their specialist operations knowledge so when all their employees can access the same information they tend to feel very threatened. CIO Snax Ltd."

When HR managers abrogated full responsibility to the line or project managers they offered little specialist support other than advice on compliance or redundancy programs. There was no link evident that suggested that the line or project manager was managing the people issues under the umbrella of the HR strategy. In fact, it was apparent that the only strategic input from HR, when a line or project manager took full responsibility for an IT project, was by default from the general managerial planning processes. This level of input was at best unreliable and at worst non-existent.

Responsibility and accountability were also recognized as important contributing factors. There was no evidence in the cases that indicated that CIO's were held accountable for an IT project beyond the development, technical implementation and support for the system itself. IT had no responsibility or accountability for the people management factors that were critical to implementation. Nor was there any evidence to suggest that HR were held accountable beyond the delivery of compliance advice. Line management were ultimately responsible and accountable for effective implementation but this was a short term response to ensuring that users accepted and could use the system effectively. Expectations were regularly revised and there was little attention paid to longer term strategic opportunities.

FUTURE TRENDS

The focus for IT research has moved to large, integrating systems such as ERP's which have significant implications for organisational change. People management challenges are increasingly creating obstacles to successful implementations and organisations are searching for new ways to enable greater alignment between the IT strategies and the organisational change process. The findings of this research add value to these discussions and provide a practical framework to more closely integrate the strategic planning and activities between HR and IT.

CONCLUSION

The evidence from these cases suggests a non-systemic approach to aligning IT and HR leaves the relationship vulnerable and often abrogated to line management. There is significant evidence to suggest that HR management is frequently unwilling to take a management role in IT projects and IT management seldom sees their role extending beyond system development. Organizations that invest in educating both the HR manager and the CIO and support them to maximize opportunities to align their activities are more likely to gain competitive leverage from their IT investment than those who assume that alignment will occur as a result of the general planning process and who abrogate strategic HR input for IT projects to the line.

KEY TERMS

Alignment: An orientation based on a series of ongoing processes based on the will to achieve a common goal. For the purposes of this research alignment is distinguished from the more static concept of fit. Alignment is conceptualized as an outcome with determinant factors that affect the degree to which one set of objectives and mutually consistent and supportive of the other.

Connections in Planning: Refers to the degree of contact between HR and IT executives in their respective planning processes.

History of Implementation Success: Describes the track record of IT projects in HR and the effectiveness of HR into IT people management issues.

Human Resources (HR): All activities of planning, staffing, appraisal and remunerating, improving employees and the working environment and establishing and maintaining working relationships.

Information Technology (IT): All hardware, software, communications, telephones, facsimiles, all personnel and resources dedicated to the delivery of information and processes via computerised mediums.

Intellectual Alignment: Describes a state where the content of IT and HR business plans are consistent and externally valid.

Shared Domain Knowledge: Refers to IT and HR executives' understanding of the business and of the knowledge in HR of the IT strategies and vice versa.

Social Alignment: Describes a state where IT and HR business executives understand and are committed to each others plans.

An ERP Life-Cycle Cost Model

A

José Esteves
Instituto de Empresa, Spain

Joan Pastor
Universidad Politécnica de Catalunya, Spain

INTRODUCTION

Nowadays, the enterprise resource planning (ERP) products and services industry is one of the most promising. Through the usage of ERP systems such as SAP, BAAN, Peoplesoft and Oracle, organizations try to integrate the information flow of the different business areas and, at the same time, improve efficiency and reduce costs. Theoretically, these integrated systems provide large functionality in terms of problem solving associated with data flow when they are integrated with different software systems.

Some critiques of ERP systems focus essentially on the high costs of ERP projects, the high failure rates and their complexity, which makes it difficult for users to perceive the benefits and the opportunities of these systems. ERP systems demand a large investment at the economic, human resource and organizational levels. This investment is made not only in the initial phase but also throughout their life-cycle. Thus, this study is intended to analyze the necessary investment to integrate an ERP system during its life.

BACKGROUND

One of the issues in the ERP systems area is that of determining if the investment made will be compensated in the future. A survey of Meta Group Inc. (Craig, 1999) shows that in financial terms, ERP projects cost more than the expected benefits. This is close to academic studies on this object. But there are some suggestions that financial terms and other strategic benefits should be considered. This issue is included in broader discussions about investment in information systems (IS) and their performance (Bender, 1986; Brynjolfsson & Hitt, 1994; Harris & Katz, 1988). Some authors found no or little relationship between them (Strassmann, 1990, 1999; Turner, 1985), while others concluded that the investment in IS has been detrimental to organizations (Roach, 1988).

A study conducted by Meta Group (2000) showed that only 20% of companies that have implemented ERP solutions actually know the total cost of ownership (TCO) of their deployments. The other 80% do not fully understand the magnitude of on-going support and infrastructure-related costs. Our study analyzes the necessary investments for the integration of an ERP system during its existence, along with an analysis of the costs associated with each phase.

ERP SYSTEMS LIFE-CYCLE

To define the ERP life-cycle model we use a simplified version of the model proposed by Esteves and Pastor (1999). Other authors have proposed models for ERP systems but focusing on the ERP implementation phase. However, there is a misunderstanding in relation to the concept of implementation. Our model is structured in phases and dimensions. Here, we only make reference to the phases as the different stages of the life-cycle of an ERP system in an organization. Next, we describe each phase, that is, adoption, acquisition, implementation, usage and maintenance, evolution and retirement.

- **Adoption decision phase:** During this phase managers examine the need for a new ERP system while selecting the general IS approach that will best address the critical business challenges and improve the organizational strategy. The decision phase includes the definition of system requirements, its goals and benefits, and an analysis of the impact of adoption at a business and organizational level.
- **Acquisition phase:** This phase consists of the product selection that best fits the requirements of the organization, thus minimizing the need for customization. A consulting company is also selected to help in the next phases of the ERP lifecycle, especially in the implementation phase. Factors such as price, training and maintenance services are analyzed and the contractual agreement is defined. In this phase, it is also important to make an analysis of the return on investment of the selected product.
- **Implementation phase:** This phase consists of the customization or parameterization and adaptation of the ERP package acquired according to the needs

of the organization. Usually this task is done with the help of consultants who provide implementation methodologies, know-how and training.

- **Use and maintenance phase:** This phase consists of the use of the product in a way that returns expected benefits and minimizes disruption. During this phase, one must be aware of the aspects related to functionality, usability and adequacy to the organizational and business processes. Once a system is implemented, it must be maintained, because malfunctions have to be corrected, special optimization requests have to be met, and general systems improvements have to be made.
- **Evolution phase:** This phase corresponds to the integration of more capabilities into the ERP system, providing new benefits, such as advanced planning and scheduling, supply-chain management, customer relationship management, workflow, and expanding the frontiers to external collaboration with other partners.
- **Retirement phase:** This phase corresponds to the stage when with the appearance of new technologies or the inadequacy of the ERP system or approach to the business needs, managers decide if they will replace the ERP software with other information system approaches more adequate to the organizational needs of the moment.

COSTS ALONG THE ERP LIFE-CYCLE

The literature on ERP research shows a lack of studies on ERP system costs and investments (Esteves & Pastor, 2001). Based on published case studies and literature review related to the cost analysis of IS, we developed a structure of costs along the ERP life-cycle. Next, we conduct an exploratory case study to validate this structure of costs (for more details see Esteves et al., 2001).

Table 1 summarizes the cost items, where costs are classified as tangible or intangible. Thus, tangible costs are the costs that can be measured in a direct way, taking always into account that, sometimes, tangible costs cannot be measured in monetary terms. Intangible costs are those costs that are difficult to be measured in a direct way, since they refer to vague concepts, as illustrated in Table 1. Next, we describe in detail each phase and related costs.

ADOPTION PHASE

Tangible Costs

- **Decision-making costs:** This phase is perhaps the phase that has the least associated costs, because it represents only the decision to adopt or not an ERP system. The associated cost is essentially the time spent by managers in the decision-making task. In the context of the decision-making process, the concept of avoidable costs is used to define the costs that can be eliminated when we opt for a specific choice or solution. The unavoidable costs refer to the costs that we cannot eliminate.
- **Consultancy costs:** Consultants help with knowledge and experience in the evaluation of the existent IS architecture and the definition of the new IS strategy.

Table 1. Cost items along the ERP life-cycle

Phase	Tangible Costs	Intangible Costs
Adoption	Consultancy	Decision-making costs
Acquisition	Consultancy Hardware Software licenses	Decision-making costs Opportunity costs
Implementation	Consultancy Training Human resources System specification	Customization, conversion and data analysis Time dedicated by staff Business process reengineering
Usage and Maintenance	System reconfiguration System adaptation Cost of system failure	Indirect costs of system failure Lost of competitiveness
Evolution	Cost of new applications Consultancy	
Retirement		Opportunity costs Decision=making costs

ACQUISITION PHASE

Tangible Costs

- **Consultancy costs:** Again, consultants help with knowledge and experience in the selection of the ERP system most adequate to the organizational needs, and they help in the implementation phase. They also act as mediators between the ERP provider and the organization. Analysts are unanimous in stating that the costs related to consultancy are the highest for an ERP system.
- **Hardware costs:** Acquisition of an ERP system implies changes in the existing hardware infrastructure. These changes can vary from a change and/or actualization of the actual hardware infrastructure to the complete installation of a new hardware infrastructure. Hardware needs must not be forgotten due to the fact that the new hardware infrastructure must have the maximal performance to provide access in real time to databases and the ERP system modules. Aspects such as network-communication capacity, servers and processing-speed rates are important.
- **Software licenses:** After the selection of ERP software, there is the need to make an agreement contract. The cost of this contract can be calculated in several ways. Some contracts consider the number of licenses and the number of users, while others include factors such as organization benefits and number of employees. Usually, providers offer price reductions depending on the number of modules acquired and the acquisition of extended applications and the purchase of maintenance services and upgrades of software.

Intangible Costs

- **Decision-making costs:** In the acquisition phase, decision-making costs must be analyzed again. The main decision consists of the selection of the ERP system that best addresses the organization needs.
- **Opportunity costs:** These costs measure the opportunity that is lost or is sacrificed when an option is abandoned. The analysis of the several ERP systems that exist in the market should take into account these costs.

Analysts recommend that at this point a return on investment (ROI) study should be done. The ROI has two important elements: the “how much” and the “when”. The “how much” element represents the benefits created by the investment, and the “when” represents the period of investment return.

IMPLEMENTATION PHASE

Tangible Costs

- **Consultancy costs:** Most organizations use consultants to implement the ERP system, due to the fact that they do not have the technical knowledge in-house to complete this process. Consultants incorporate knowledge, experience, implementation methodologies, and training programs for users. They also help re-engineering the organization and its business processes.
- **Training costs:** Here, we include the training of a project team and the end users. These costs are usually high because users need to learn a set of new processes and not just the usage of a new software application. To minimize these training costs, there presently exist Internet-based tools or videoconference tools that reduce the number of trainers and have a larger scope of training.
- **Human-resources costs:** The costs associated with the project team have a high weight. They are expert professionals and their price per hour is high and must be quantified. Sometimes there is the need to recruit these human resources from outside.
- **System-specification costs:** These costs refer not only to the number of human resource hours spent on this task but also the acquisition of tools and instruments (denominated enterprise modeling tools) that help to make specific the necessary business vision.

Intangible Costs

- **Customization, conversion and data analysis:** The effort made in the software customization and adaptation to organization needs is usually not measured, except in terms of time. The data to be inserted in the new system constitute a heavy burden to the project costs. The data converted from other systems and the new ones have to be verified due to inconsistencies, because usually they are not adequate to the new formats. Usually, there is the need to insert new data in the new system.
- **Time of dedicated staff:** The project team and staff have to keep many times their work and make the tasks related with the project. The costs associated with this effort and the respective loss of efficiency

are not usually measured. The option of keeping them totally dedicated to the project could result in the recruitment of personnel, whose costs are measurable.

- **Business-process re-engineering cost:** Forrester Research Inc. (Koch, 1997) estimated in 1997 that in a typical SAP installation, more than 50% of the implementation budget is spent in business process re-engineering. The implementation of an ERP system means in many cases a radical change in the organization business processes, forcing changes in organizational flows and in organizational structures.

USAGE AND MAINTENANCE PHASE

Tangible Costs

- **System reconfiguration:** Usually, after ERP system implementation, some inefficiency appears in its operation, which requires an adjustment to the ERP configuration. Reporting functions are particularly sensitive to reconfiguration needs.
- **System adaptations:** Organizations change over time, so there is always therefore the need to adapt the systems to whatever changes have been made. The introduction of new information flows and new business processes influence the ERP system usage and performance.
- **System-failure costs:** Failure costs refer to the costs arising from ERP system breakdowns. In big organizations the direct costs are very high, because orders cannot be satisfied, stocks cannot be updated, and in certain cases these failures cause a total disruption of the organization's business.

Intangible Costs

- **Indirect costs of system failure:** System failures cause many indirect costs, such as loss of access to vital information, loss of customer loyalty, or the ability to survive in the business (Uram, 1999).
- **Loss of competitiveness.** A common criticism of ERP systems is the standardization of business models through the imposition of ERP models. Most organizations adopt these business models to facilitate the software implementation and they may thereby lose competitive advantages over other organizations. These changes should be measured in economic terms.

EVOLUTION PHASE

Tangible Costs

- **Cost of new applications:** In this phase the main costs are related to the purchase and implementation of new applications, such as advanced planning and scheduling, customer relationship and management, workflow, e-commerce, and so forth.
- **Consultancy costs:** Most organizations use consultants to implement these new applications, due to the fact that they do not have the technical knowledge in-house to complete this process.

RETIREMENT PHASE

Here, the opportunity and decision-making costs repeat, along with all the tangible costs related with software. When this phase is reached, it is expected that the original investment would be recovered. In cases of abandonment (in implementation phase, for instance), the associated costs can constitute high losses, as happened to the FoxMeyer company (Scott, 1999). The company imputed its bankruptcy to the investment made in an ERP system.

CONCLUSION

This study attempts to analyze the costs associated with ERP systems along the typical ERP life-cycle phases. The article presents a list of costs that demonstrate that this type of system has a strong organizational perspective, and therefore the costs associated with this perspective should be taken into account and measured. The list does not intend to be exhaustive but attempts to give a general view of the whole ERP life-cycle. As for future research, we plan to validate this model with case studies and surveys to different organizations. We attempt to analyze the differences among industry sectors, size of companies, and countries. Another issue is the return on investment (ROI). With regard to this issue we attempt to study the reasons to measure ROI, how companies measure it, and the ROI results.

KEY TERMS

Business Process Reengineering (BPR): This is related with the alignment between business processes and the ERP business model and related best practices. This process will allow the improvement of the software functionality according to the current and future organization needs. Managers have to decide if they do business process reengineering before, during or after ERP implementation.

Consultancy: The process of helping organizations to better understand complex processes through their knowledge and experience and provide solutions to achieve the objectives. Consultants may help organizations in the whole ERP life-cycle. The usage of external consultants will depend on the internal know-how that the organization has at the moment.

Data Conversion: This process involves moving the existing data from the legacy systems, performing an integrity check and then transporting them to the ERP system that has been implemented. There are diverse tools available to reduce the effort on conversion process. In some occasions, there is the need to introduce manually the data into the system. Due to this effort, the conversion process must be planned at the beginning of the ERP project in order to avoid delays.

Enterprise Resource Planning (ERP): Typically, ERP systems are software packages composed of several modules, such as human resources, sales, finance and production, and providing cross-organization integration of transaction-based data throughout imbedded business processes. These software packages can be customized to the specific needs of each organization.

ERP Life-Cycle: Consists of the several stages that an ERP system goes through during its whole life within the hosting organization.

Intangible Costs: Those costs that are difficult to be measured in a direct way, since they refer to vague concepts.

Return on Investment (ROI): A technique for measuring the return on investment. It is calculated by the earnings produced by the assets compared to the money invested in the asset. This technique is used in ERP contexts to justify ERP adoptions and also to measure how well an ERP was implemented.

Tangible Costs: Those costs that can be measured in a direct way, taking always into account that sometimes tangible costs cannot be measured in monetary terms.

Total Cost of Ownership (TCO): Accounts for all of the costs associated with procuring, deploying and operating an existing asset like an ERP system at a given point in time. Microsoft defines TCO as: "refers to the administrative costs associated with computer hardware and software purchases, deployment and configuration, hardware and software updates, training, maintenance, and technical support" (Microsoft glossary: www.microsoft.com/windows2000/techinfo/howitworks/management/glossary.asp).

Analyzing the Quality of Virtual Teams

Robert M. Verburg
Delft University of Technology, The Netherlands

J.H. Erik Andriessen
Delft University of Technology, The Netherlands

Joris P.G. de Rooij
Delft University of Technology, The Netherlands

INTRODUCTION

Global market developments and the large-scale use of diverse applications in the area of information and communication technology (ICT) have been key factors in the emergence of distributed teams. Such teams are often referred to as virtual teams. Virtual teams enable collaboration between people across traditional boundaries and offer tremendous opportunities for various achievements. Businesses are no longer tied to a single time zone and are, for example, able to develop software around the 24-hour clock. The Internet—as the almost universal medium for interaction across boundaries—has created an infrastructure that enables many organizations to launch virtual teams. Hardly any technical obstacle for communication and collaboration across geographic boundaries remains, as these processes are supported by high-tech collaboration solutions such as groupware and other collaborative applications (e.g., videoconferencing, electronic blackboards). Virtual teams have a number of opportunities that are not found with co-located teams, such as involving rare expertise.

For example, a group of eight scientists from different organizations rapidly developed a revolutionary rocket engine design by working under geographically dispersed conditions and without prior work relationships (Majchrzak, Rice, Malhotra, King & Ba , 2000). The complex and innovative design could not have been developed without the expertise of the eight highly specialized scientists. However, the design was not only a result of a careful combination of expertise, but required a number of interdependent iterative 'virtual' brainstorming sessions among the team of rocket scientists. All these activities were performed through a collaboration tool called "the Internet notebook," whereby the specialists spend no more than 15% of their time on the project.

As the above example illustrates, virtual teams have the advantage of bringing people together without the obvious constraints with regard to travel time, workspace, and socialization. Virtual teams perform a variety of tasks and are also defined in various ways. The term generally implies groups of geographically and culturally dispersed co-workers using a combination of communication and information technologies to accomplish an organizational task (Townsend, DeMarie & Hendrickson, 1998; Jarvenpaa, Knoll & Leidner, 1998). Hutchinson (1999) distinguishes three types of virtual teams: intra-organizational teams, inter-organizational teams, and inter-organizational distributed teams. In this overview we will have all three types in mind when discussing our approach.

BACKGROUND

Being 'virtual' is a matter of degree and refers, according to various authors, to dimensions such as spatial distance, time, cultural diversity, temporality, organizational contract, and mode of interaction (Mowshowitz, 1997; Jarvenpaa & Leidner, 1998; DeSanctis, Staudenmayer & Wong, 1999; Vartiainen, 2003). Mode of interaction is an important dimension. Some teams meet regularly face to face, but may also have some e-mail-based interaction, while other teams interact intensively and almost exclusively via various media and sophisticated groupware tools. Geographical distance and different timeframes may obviously be important reasons for groups to communicate electronically.

'Virtuality' refers to the extent to which a group is geographically distributed, is organizationally and culturally diverse, has different timeframes for work, communicates electronically ('mode of interaction'), and whose members are freelance or have fixed contracts with an organization. The degree of reliance on ICT, its availability, and the proficiency of the users are very important for virtual teams (Dubé & Paré, 2004). The more of the above, the more a team is considered to be a virtual group. 'Virtuality' is the highest in globally dispersed teams of culturally diverse members of different organizations (or freelancers) that interact temporarily and communicate exclusively via electronic means.

A useful definition of a team (or work group) is a collection of individuals who see themselves and who are seen by others as a social entity, who are interdependent because of the tasks they perform as members of a group, who are embedded in one or more larger social systems (e.g., community, organization), and who perform tasks that affect others (Guzzo & Dickson, 1996). Although often not defined, a number of implicit characteristics of conventional teams seems to include that members are often permanent employees of one organization, are often co-located, and the main form of interaction consists of face-to-face contact.

Virtual teams may not seem to be crucially different from co-located teams. There are comparable levels of responsibility for adequately performing basic processes of groups, such as information sharing, cooperation, coordination, and team building. Virtual teams also have to mobilize the necessary resources, and need to develop a cohesive team with clear goals. However virtual teams have to care for these processes under conditions of less-than-optimal communicative channels, of higher distance in time, space, and culture than face-to-face teams. Inadequate ICT tools or infrastructures and the incompatibility of technology will result in barriers for cooperation. But with sufficient attention to team building and adequate ICT tools, these problems may be overcome. The process of team building can be difficult in the virtual context, specifically when the 'life cycle' of a team is short, the stability of membership is limited, and face-to-face meetings are scarce.

Global virtual teams have to deal with the additional issues of communicating across different time zones, languages, and cultures (e.g., Dubé & Paré, 2001; Montoya-Weiss, 2001).

Other problems may include missing non-verbal cues in communication and a lack of unplanned social encounters, resulting in problems with 'awareness' of availability and state of others, of progress of the work, or of the setting in which others work (see, e.g., Steinfield, 2002). These barriers may result in a lack of trust and cohesion, which often may lead to lower performance levels. Jarvenpaa and Leidner (1998) confirmed that global virtual teams might start with a form of 'swift' trust (Meyerson, Weick & Kramer, 1996), but that such trust appears to be fragile and temporal. Cramton (1997) illustrates, for instance, the multiple interpretations members of virtual teams may give to the meaning of silence of their distant team members. Additionally, virtual team membership can be highly fluid, demanding continuous adaptation processes between the existing team and new members, who bring their own beliefs and frame of reference. It is this system of shared views and beliefs people hold that is often considered very important for team functioning. The specific situation of a virtual team hinders the development of such a system.

TEAM PERFORMANCE

A crucial difference between co-located and virtual teams is the fact that virtual teams have the opportunity to combine and integrate both co-located and distributed interaction. Virtual teams may combine the better of two worlds and may therefore have an advantage over conventional teams. Virtual teams require certain tools in the area of information and communication technology to support interaction. Some modern tools have sophisticated functionalities that provide such teams with opportunities that conventional teams do not have. One of the major effects of the introduction of collaboration technology has been that certain types of meetings can now be held with a large number of participants. Moreover, some tools allow for easy storage and retrieval of information and for collaborative editing of documents.

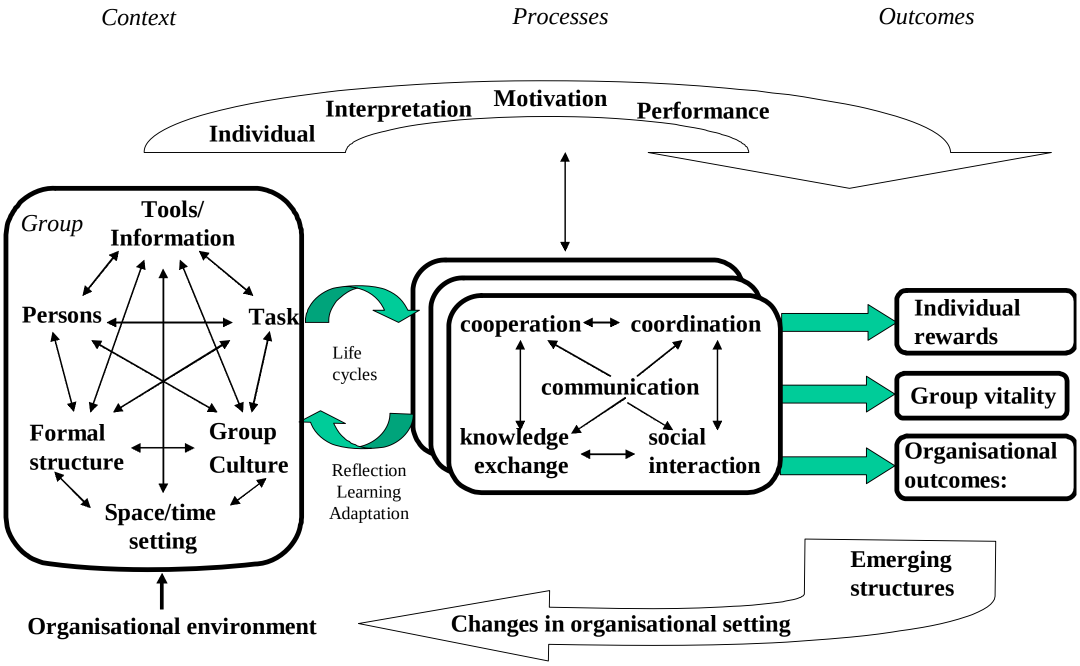
So far, the development of virtual teams has mostly been technology driven, almost neglecting other aspects of work, such as knowledge sharing, combining expertise, and dividing tasks. As a consequence, the performance of many virtual teams is far below their potential, thus producing poor business results (e.g., Jarvenpaa & Leidner, 1998).

In order to reach this optimal level of functioning, these new types of collaboration require new ways of organizing and managing. Major challenges for both managers and employees are the consequences of dealing with virtual teams. Systematic insight in the design and performance of effective (global) virtual teams is therefore an important prerequisite. It is clear that virtual teams may face substantial barriers for effective cooperation and that the probability of failure is ever present. The next section presents a model for analyzing the reasons for failure and can support the design of virtual groups.

ANALYZING VIRTUAL TEAMS: A MODEL

The model is based on a general model of group functioning, called the Dynamic Group Interaction model (DGIn-model), which is applied in several case studies (Andriessen, 2002; Andriessen & Verburg, 2004). The purpose of this model is not to limit the analysis of collaborative activities to specific aspects, but to structure the analysis by providing ideas and insights that have proven their value in other contexts.

Figure 1. Adapted from the Dynamic Group Interaction model (DGIn-model) (Andriessen, 2002)



In this model, elements of several theories are brought together. Three levels of behavior are taken into account: individual goal-directed behavior and cognitive processes (based on Action Theory, Activity Theory, Media Richness Theory); interpersonal and group processes (Activity Theory, Adaptive Structuration Theory, Social Information Theory, Coordination Theory); and a macro-social perspective (Structuration Theory). The various notions are brought together in a heuristic model concerning group processes, related to traditional 'input-process-output' schemas (see, e.g., McGrath, 1984; Hackman, 1987; Kraemer & Pinsonneault, 1990; McGrath & Hollingshead, 1994). However, they are enriched with interpretative and structurational notions and feedback cycles (see Figure 1).

The DGIn-model has the following four basic principles that can be applied to virtual teams:

1) Effectiveness—Some virtual groups cooperate only once, so in those cases vitality and continuity of the group as outcomes may not be that interesting for the members. In case of real (project) teams, however, it is not enough to come up with clear results and with rewards for their members. They also need to cater for group vitality and continuity in order to be effective. Virtual teams do not differ from conventional teams in this respect. However, developing vitality is more difficult than in co-located groups. The specific problems are related to the other principles of the model.

2) The quality of group processes—Six basic group processes were distinguished: communication, and the five other processes that can only exist on the basis of communication (cooperation, coordination, learning, reflection, and team building). These processes need to be aligned.

The type of *communication*—mediated to a smaller or larger extent—constitutes the core dimension for the concept of 'virtuality'. In case of virtual groups, the model implies that collaboration, coordination, knowledge exchange, social interaction, and reflection need to be adjusted to the degree of mediation of communication. This is reflected, among other things, in the fact that both remote *cooperation* and *social interaction* in mediated meetings need to be much more explicitly structured than face-to-face meetings in order to be effective. The already mentioned lack of non-verbal cues in communication, resulting in problems with 'awareness' of availability and state of others, makes it difficult to interact. Overall, face-to-face meetings allow for more flexibility during meetings and do not need to be as structured as mediated meetings. It is important to provide minutes of virtual meetings, as these help to assure that all members understand the same conclusions. In case of virtual student teams, Cramton (1997) showed that team members have difficulty in extracting information about the context in which their distant partners operate, while members themselves often fail to provide important information about their own context.

Globally distributed teams should give sufficient time and attention to group members who are less assertive than most members from a number of Western countries. *Leadership and coordination* of virtual teams therefore play a critical role in facilitating the work and organization of virtual teams (Bell & Kozlowski, 2002). In general the activities of virtual teams appear to need much more preparation and explicit coordination than co-located teams. The role of coordinators is, therefore, vital for the performance of virtual teams.

3) The quality and match of the 'context' characteristics—The quality of group processes depends on characteristics of the 'context'. Six groups of characteristics are distinguished: the task of the team, tools, member characteristics (knowledge, skills, attitudes), team structure (such as role division and meeting type), culture (norms, trust, cohesion, cognitive distance), and time-space setting (e.g., geographical distribution). The context characteristics need to match each other in order to optimally support the group processes.

ICT support. The technical tools and their usage should be adjusted to the virtuality of the group. The following suggestions can be made:

- Virtual groups require information storage and exchange tools.
- Virtual groups may benefit from a database with information on background and expertise of the group members (*'yellow pages'*).
- Virtual groups with intensive and non-routine interaction may benefit from tools for synchronous communication: chat features, where possible video links.
- Virtual groups with complex and time-sensitive tasks require workflow management tools for providing information regarding the progress of the project and activities of group members.
- The tools have to be easy to use and equally accessible to all members.
- Group members should be sufficiently trained in remote interaction and in using the technology.
- Global virtual teams should be careful in choosing and using the right tools. Research suggests that people from some cultures prefer direct expression of ideas, whereas others may be more sensitive to non-verbal cues and group relations (see Trompenaars, 1993, for examples). The first group of people would probably prefer a collaboration tool that enables synchronous communication, such as telephone, video, and chat. People from the other group would be happy with an asynchronous communication tool enabling them to express themselves more carefully. The choice for a suitable collaboration tool to facilitate both groups is, therefore, complicated.

Storage of information. Special attention should be given to information (document) exchange and storage. Effective virtual teams rely heavily on information exchange. Systems and procedures that allow for swift information exchange are therefore a prerequisite. Such systems need to be usable and accepted by all members of the team. In multicultural teams, such systems are not always easy to obtain. Differences in preferred practices of communication and storing information will limit the choice of an equally useable tool.

Cultural diversity may be large in virtual teams. In order to avoid conflicts and facilitate a smooth work process, group members should be trained to understand the potentially disturbing effect of diversity in national, organizational, and professional cultures (Dubé & Paré, 2004). The next step is to learn about each other's background so that differences in solving problems and ways of working will not form a source of major misunderstanding. As soon as members respect and trust distant team members, virtual teams will be able to benefit from the diversity of their members.

4) Development and adaptation: Team building—Groups develop and tools are adopted and adapted, through interpretation, interaction processes, and feedback. One of the processes through which this development and adaptation can be explicitly structured is team building. Team building proves to be a critical aspect of team performance and acts as the foundation for the development of necessary levels of trust, cohesion, and cognitive closeness among team members. In many cases, team building in virtual teams can benefit strongly from a face-to-face kick-off meeting (see Maznevski & Chudoba, 2001, for an overview). Coordinators should be alert to organize such meetings whenever needed or possible.

FUTURE TRENDS

As more and more organizations will explore the opportunities of working across boundaries, the number of virtual teams will increase in the coming years. These teams will experience the complexity of coordination of cross-border work activities. Future research in the area of virtual team analysis will highlight the relationship between virtuality and team effectiveness more closely. Especially, research with regard to the coordination and management of virtual teams will get more attention. So far, research into coordination of virtual teams has primarily focused on the role of leaders of virtual teams (e.g., Cascio & Shurygailo, 2003). Other possible ways of coordination in virtual contexts, such as the successful use of groupware tools and the role of substitutes for leadership, did not receive much attention yet, but will be trends for research in coming years.

CONCLUSION

Virtual teams offer great opportunities for collaboration across boundaries, which have encouraged many companies to form such teams. However, virtual teams also face challenges, particularly in the areas of communication and coordination. We have presented the DGIn-model for team analysis. On the basis of our analysis, we recommend that virtual teams should more explicitly pay attention to issues of team building, awareness, preparation, and information storage in order to work and collaborate effectively. Virtual teams should also benefit from the use of specialized groupware tools if applied properly.

KEY TERMS

Action Theory: Perspective on action facilitation that makes a distinction between acts, actions, and operations in performing a task. A basic principle of the theory is that the tools used should provide sufficient feedback to allow for adaptation of task execution.

Group Dynamics: Field of inquiry dedicated to advancing knowledge about the nature of groups.

Groupware: ICT applications that support communication, coordination, cooperation, learning, and/or social encounters through facilities such as information exchange, shared repositories, discussion forums, and messaging.

Dynamic Group Interaction (DGIn) Model: In this model elements of several theories with regard to group performance are brought together. Three levels of behavior are taken into account: individual goal-directed behavior, group processes, and a macro-social perspective. The various notions are brought together in a heuristic model concerning group processes. They are related to traditional input-process-output schemas.

Media Richness Theory: Theory on mediated communication that highlights the extent to which a medium is capable of sending rich information (i.e., text, smell, pictures, noise, etc.), as well as the proposition that media use is most adequate if the medium is matched with the complexity of the task at hand.

Structuration Theory: A theory of societal processes on a high abstraction level. Adaptive Structuration Theory (AST) focuses on the analysis of the way existing technologies are taken up by groups and evolve in their role during the appropriation process (i.e., the process of adaptation to new technical tools, which changes the original situation).

Team: A collection of individuals who see themselves and who are seen by others as a social entity, who are interdependent because of the tasks they perform as members of a group, who are embedded in one or more larger social systems (e.g., community, organization), and who perform tasks that affect others.

'Virtuality': The extent to which a group is geographically distributed, is organizationally and culturally diverse, has different timeframes for work, communicates electronically, and whose members are freelance or have fixed contracts with an organization.

A

Animated Characters within the MPEG-4 Standard

Françoise Prêteux

Marius Preda
Institut National des Télécommunications/Groupe des Ecoles de Télécommunications, France

INTRODUCTION

The first 3D virtual human model was designed and animated by means of the computer in the late ’70s. Since then, virtual character models have become more and more popular, making a growing population able to impact the everyday real world. Starting from simple and easy-to-control models used in commercial games, to more complex virtual assistants for commercial[1] or informational[2] Web sites, to the new stars of virtual cinema,[3] television,[4] and advertising,[5] the 3D character model industry is currently booming.

Moreover, the steady improvements within the distributed network area and advanced communication protocols have promoted the emergence of 3D communities[6] and immersion experiences (Thalmann, 2000) in distributed 3D virtual environments.

BACKGROUND

Animated Characters and 3D Standards

Creating, animating, and most of all, sharing virtual characters over Internet or mobile networks require unified data formats. If some animation industry leaders try—and sometimes succeed[7,8]—to impose their own formats in the computer world mainly by making available powerful authoring platforms, the alternative of an open standard is the only valid solution ensuring interoperability requirements, specifically when hardware products are to be built.

A dream of any content producer can be simply formulated as “creating once and reuse for ever and everywhere, in any circumstances.” Nowadays, content should be carried by heterogeneous networks (broadcast, IP,[9] mobile), available anywhere and for a large scale of devices (PCs, set-top boxes, PDAs,[10] mobile phones), and profiled with respect to user preferences. All these requirements make that the chain where content is processed more and more complex, and a lot of different actors must interfere: designers, service providers, network providers, device manufacturers, IPR[11] holders, end-users, and so on. For each one, consistent interfaces should be created on a stable and standardized basis.

Current work to provide 3D applications within a unified and interoperable framework is materialized by 3D graphics interchange standards such as VRML[12] ISO/IEC 14772-1:1997 and multimedia 2D/3D standards such as MPEG-4–ISO/IEC 14496. Each one addresses, more or less in a coordinated way, the virtual character animation issue. Moreover, some research groups proposed dedicated languages for modeling virtual faces and bodies, such as Face Markup Language (FML) and Virtual Human Markup Language (VHML). In the VRML community, the H-Anim[13] group released three versions of their specifications (1.0, 1.1 and 2001), as did the SNHC[14] sub-group of MPEG: MPEG-4 Version 1 supports face animation, MPEG-4 Version 2 supports body animation, and MPEG-4 Part 16 addresses the animation of generic and articulated virtual objects (including human-like). In MPEG-4, the specifications dealing with the definition and animation of human avatars are grouped under the name FBA—Face and Body Animation—while those referring to generic models are called BBA—Bone-Based Animation. The next section analyses the main similarities and differences of these two standardization frameworks: VRML and MPEG-4.

The VRML standard provides a textual description of 3D objects and scenes. It focuses on the spatial representation of such objects, while the time behavior is less supported. The major mechanism for supporting animation consists of defining it as an interpolation between key-frames.

The MPEG-4 standard, unlike the previous MPEG standards, does not only cope with highly efficient audio and video compression schemes, but also introduces the fundamental concept of media objects such as audio, visual, 2D/3D natural, and synthetic objects to make up a multimedia scene. As established in July 1994, the MPEG-4 objectives are focused on supporting new ways (notably content-based) of communicating, accessing, and manipulating digital audiovisual data (Pereira, 2002). Thus, temporal and/or spatial behavior can be associated with an object. The main functionalities proposed by the standard address the compression of each type of media objects, hybrid encoding of the natural and synthetic objects, universal content accessibility over various networks, and interactivity for the end-user. In order to specify the spatial and temporal localization of an object in the scene, MPEG-4 defines a dedicated language called BIFS—Binary Format for Scenes. BIFS inherits from VRML the representation of the scene, described as a hierarchical graph, and some dedicated tools such as animation procedures based on interpolators, events routed to the nodes, or sensor-based interactivity. In addition, BIFS introduces some new and advanced mechanisms such as compression schemes to encode the scene, streamed animations, integration of 2D objects, new 3D objects, and advanced time control.

In terms of functionalities related to virtual characters, both VRML and MPEG-4 standards define a set of nodes in the scene graph to allow for a representation of an avatar. However, only the MPEG-4 SNHC specifications deal with streamed avatar animations. A major difference is that an MPEG-4-compliant avatar can coexist in a hybrid environment, and its animation can be frame-based synchronized with other types of media objects, while the H-Anim avatar is defined in a VRML world and must be animated by VRML generic, usually non-compressed, animation tools.

The question that arises now is how to find a good compromise between the need for freedom in content creation and the need for interoperability? What exactly should be standardized, fixed, invariant, and in the mean time, ideally impose no constraints on the designer creativity? The long-term experience that the MPEG community has makes it possible to formulate a straight and solid resolution: in the complex chain of content, producing-transmitting-consuming the interoperability is ensured by only standardizing the data representation format at the decoder side. Pushing this concept to its extreme, an MPEG ideal tool is that one for which two requirements are satisfied: the designer can use any production tool he/she possesses to create the content, and it can be possible to build a full conversion/mapping tool between this content and an MPEG-compliant one. The same principle was followed when MPEG released the specifications concerning the definition and the animation of the virtual characters: there are no “limits” on the complexity of the virtual character with respect to its geometry, appearance, or skeleton and no constraints on the motion capabilities.

MAIN THRUST OF THE ARTICLE

The animation method of a synthetic object is strongly related to its representation model. A simple approach often used in cartoons is to consider the virtual character as a hierarchical collection of rigid geometric objects called segments, and to obtain the animation by transforming these objects with respect to their direct parents.

The second method consists of considering the geometry of the virtual character as a unique mesh and to animate it by continuously deforming its shape. While the former offers low animation complexity with the price of the seams at the joints between the segments, the latter ensures a higher realism of the representation, but requires more computation when synthesizing the animation. Both methods are supported by the MPEG-4 standard and will be detailed in the next sections.

Segmented Character: MPEG-4 FBA Framework

First efforts to standardize the animation of a human-like character (an avatar) within MPEG-4 were finalized at the beginning of 1999 and published as FBA. The approach used here consists of considering the avatar as a hierarchical structure of 3D rigid objects, each one corresponding to an anatomical segment (arm, forearm, etc.). There are no constraints on the geometry of a segment, but the hierarchical structure is predefined. The animation is performed by updating the geometric transformation between the segments. A separate, so-called FBA stream contains the compressed version of those transformations, expressed as extrinsic properties of an anatomical segment, that is, its 3D pose with respect to a reference frame attached to the parent segment.

The orientation of any anatomical segment is expressed as the composition of elementary rotations, namely twisting, abduction, and flexion. For some segments only one or two elementary rotations are supported. Hence, 296 angular joint values are enough to describe any 3D posture of a virtual human-like character. The angular values are specified with respect to the local 3D coordinate system of the anatomical segment. The origin of the local coordinate system is defined as the gravity center of the joint contour common to the considered anatomical segment and its parent. The rotation planes are specified, and/or anatomical segment rotation axes are standardized.

Due to the rigid nature of the anatomical segments, when performing the animation, seams can occur at joints between segments. This effect can be corrected by using local deformation tables that give hints on how to locally update the position of certain vertices on the anatomical segment with respect to the animation parameters (Capin, 1999; Preda, 1999, 2002).

To animate the face of the avatar, FBA uses a surface-based model driven by control points: a standardized number of key points (84) corresponding to the human features (e.g., middle point of upper lip) is defined on the face surface. Each control point can be locally translated on one, two, or three directions with respect to the face-specific animation parameters also defined in the FBA stream. It is possible to define a deformation behavior expressing how the translation of a key point is extended in its neighborhood. The complete animation is then performed by deforming the mesh in the vicinity of the key points (Doenges, 1997; Escher, 1998; Lavagetto, 1999).

Seamless Character: MPEG-4 BBA Framework

The purpose of this section is to introduce the animation framework for generic virtual objects as specified in Part 16 of the MPEG-4 standard. This framework is founded on a generic deformation model (Preda, 2002b), which relies on a deformation controller defined by means of a geometric support, an influence volume around this support, and a measure of affectedness within the influence volume. A best compromise between the efficient control of the geometrical support and appropriate volume specification is ensured by the 1D controller. For such a reason, MPEG-4 standardized two instances of the 1D deformation model, (1) bone controller and (2) muscle controller. The Skeleton, Muscle, and Skin (SMS) framework is built around these concepts—bone and muscle. An articulated character is now defined as a seamless mesh representing the skin, and a hierarchical structure of bones and muscles is attached to the skin. The geometric transformations of the bones and muscles lead to translations to the skin's vertex level. For one bone, the geometrical transformation is obtained by composing elementary transformations as rotations and, optionally, translations and scale factors. For one muscle, the main mechanism for deforming it consists of updating the curve-control points. Updating the degree of influence of the control points is also allowed. The efficient representation of the animation parameters is addressed by: (1) enriching the animation capabilities with temporal interpolation and inverse kinematics support; and (2) supporting the two data compression techniques, one using prediction, the second a DCT transform. The compressed representation of the animation parameters are grouped together in a so-called BBA stream, this stream being considered as an elementary MPEG-4 stream. It can be multiplexed with video, audio, and scene streams, allowing to build enriched multimedia applications.

In addition to the two controllers, bone and muscle, within the first amendment of AFX specifications, a morph space can be used to further control the animation quality. The tool standardized here consists of creating a base and some target shapes, and animating the shape as a result of weighting between target shapes. The origin of this technique is the 2D image-based face animation.

The main differences between the two animation frameworks developed by MPEG-4, FBA and BBA, consist of the geometry representation approach and skeleton structure: FBA builds the virtual character as a collection of 3D objects, and BBA considers the entire skin as a unique object; for FBA the skeleton structure is fixed (established by the standard), while for BBA the designer is free to build any kind of structure able to represent and animate a large category of objects (plants, animals, humans). Both approaches allow very low bit-rate animation (2-50kbps) by adopting compression techniques for the animation parameters.

FUTURE TRENDS

In recent years, major improvements have been reported in the field of virtual character animation, ranging from the creation of realistic models used in cinema movies, the development of animation production tools (e.g., motion capture systems), to the production of online animation in television shows and content streaming in distributed environments. However, research in this field is still in an initial stage and presents challenging issues. Despite large ongoing efforts, computer vision technologies for tracking human motion have not yet reached a level of maturity satisfactory for commercial use. In order to decrease the production cost of 3D content, retargeting motion from a motion capture data set to different avatars is still a hot topic of research. Another important research activity is oriented towards behavioral models for avatar or/and crowds, building autonomous agents able to own intelligence, making virtual characters "live" with the appropriate emotional content, and so forth. As a content representation standard, MPEG-4 did not explicitly analyze these issues closely, but provides a low-level framework able to represent/compress/transmit and playback the content. This approach, together with the extensibility offered by an open standard, allows content creators and researchers to imagine up-to-date and high-level tools and algorithms to provide content, map the results into a low-level representation, and then use the MPEG-4 chain for transmission and playback of this content.

CONCLUSION

This article is devoted to the standardization of virtual character animation. In particular, the MPEG-4 Face and Body, as well as the Skeleton, Muscle, and Skin animation frameworks have been presented. A generic deformation model and its implementation in the MPEG-4 standard through the bone and muscle controllers have been introduced.

KEY TERMS

Avatars: Synthetic representation of a human body able to be animated. Avatars are often used in games for representing players or in virtual environments when the presence of the user must be visible.

BBA (Bone-Based Animation): A part of MPEG-4 specifications dealing with the definition and the animation at very low bit rate of a generic articulated model based on a seamless representation of the skin and a hierarchical structure of bones and muscles.

FBA (Face and Body Animation): A part of the MPEG-4 specifications dealing with the definition and the animation at very low bit rate of an avatar represented as a segmented object.

H-Anim (Humanoid Animation): Part of VRML specifications consisting of node prototypes allowing the definition of an avatar.

MPEG (Motion Picture Expert Group): Marketing name of the "ISOIEC SC29 WG11" standardization committee, affiliated with the ISO (International Standardization Office) and creator of the multimedia standards: MPEG-1, MPEG-2, MPEG-4, MPEG-7, and MPEG-21.

SMS (Skeleton, Muscle, and Skin): An animation framework based on BBA.

SNHC (Synthetic and Natural Hybrid Coding): An MPEG working group dealing with specifications of 3D graphics tools, and integration of synthetic and natural media in hybrid scenes.

Virtual Character: Synthetic representation of an entity (humans, animals, plants) able to be animated.

VRML (Virtual Reality Markup Language): Officially called ISOIEC 14772, this standard is the first attempt to provide a unified representation for 3D objects and 3D scenes.

Antecedents of Trust in Online Communities

A

Catherine M. Ridings
Lehigh University, USA

David Gefen
Drexel University, USA

INTRODUCTION

Online virtual communities have existed on the Internet since the early 1980s as Usenet newsgroups. With the advent of the World Wide Web and emphasis on Web site interactivity, these communities and accompanying research have grown rapidly (Horrigan, Rainie, & Fox, 2001; Lee, Vogel, & Limayem, 2003; Petersen, 1999). Virtual communities arise as a natural consequence of people coming together to discuss a common hobby, medical affliction, or other similar interest, such as coin collecting, a devotion to a rock group, or living with a disease such as lupus. Virtual communities can be defined as groups of people with common interests and practices that communicate regularly and for some duration in an organized way over the Internet through a common location or site (Ridings, Gefen, & Arinze, 2002). The location is the "place" where the community meets, and it can be supported technologically by e-mail listservs, newsgroups, bulletin boards, or chat rooms, for example. The technology helps to organize the community's conversation, which is the essence of the community. For example, messages in a community supported by a listserv are organized in e-mails, sometimes even grouping together several messages into an e-mail digest. In bulletin board communities, the conversation is organized into message threads consisting of questions or comments posted by members and associated replies to the messages.

Virtual community members form personal relationships with strong norms and expectations (Sproull & Faraj, 1997; Sproull & Kiesler, 1991), sometimes developing deep attachments to the communities (Hiltz, 1984; Hiltz & Wellman, 1997). These developments are interesting, because the members of virtual communities are typically strangers to one another and may never meet face to face. Additionally, the nature of computer-mediated communication is such that nonverbal cues that aid in the interpretation of communication, such as inflections in the voice, gestures, dress, tone, physical personal attributes, and posture, are missing (Sproull & Kiesler, 1991), making the communication open to multiple interpretations (Korenman & Wyatt, 1996). Yet, despite these limitations, many virtual communities flourish by exchanging messages and building their conversation base. A key ingredient in sustaining the conversation in the community is the existence of trust between the members. Trust has a downstream effect on the members' intentions to give and get information through the virtual community (Ridings et al., 2002).

This chapter examines emergent virtual communities, that is, those arising without direction or mandate from an organization, government, or other entity for an expressed economic or academic purpose. For example, a discussion board for a strategic partnership work group between two companies or a chat room for a class taking a college course would not be considered emergent virtual communities. However, an online forum established by the Breast Cancer Young Survivors Coalition so that women could discuss their battles with the disease would be considered an emergent virtual community.

BACKGROUND

Trust is an essential ingredient in social relationships (Blau, 1964; Luhmann, 1979), and understanding and defining trust are dependent upon the situation in which they are considered. In communities, in general, trust is an integral part of interpersonal relations among members and defines an individual's expectations and behavior (Luhmann, 1979; Rotter, 1971). Trust has many definitions. It has been defined as a willingness to take a risk associated with the behavior of others (Mayer, Davis, & Schoorman, 1995) and, more generally, as a method of reducing social uncertainty (Gefen, Karahanna, & Straub, 2003; Luhmann, 1979). In this sense, trust is used in the virtual community to reduce social complexity associated with the behavior of other members, and as a way of reducing the fear that the trusted party will take advantage by engaging in opportunistic behavior (Gefen et al., 2003), much as it does in communities in general (Fukuyama, 1995).

Participating in a virtual community entails exposure to risk. Opportunistic behaviors could include selling personal information that was confidentially provided, adopting a fictitious persona, deliberately and stealthily marketing products and services when this is prohibited, flaming or spamming, making unfair practical jokes at members, providing false information, and, in general, behaving in a dysfunctional manner that ruins the community. Such behavior also applies to other types of communities, except that in the case of an online community, the anonymity provided by the Internet makes such behavior much easier to accomplish by the perpetrator and much harder to notice by the victim.

Scholarly research on trust has shown that trust is a multidimensional concept consisting of beliefs in ability, benevolence, and integrity (Blau, 1964; Butler, 1991; Giffin, 1967; Mayer et al., 1995; McKnight, Choudhury, & Kacmar, 2002). Ability deals with beliefs about the skills or expertise that another (i.e., trusted parties) has in a certain area. Ability relates to the belief that the other person knows what he or she is talking about. Because virtual communities are almost always focused on a specific topic, concerns about the abilities of others with respect to this topic are important. Benevolence is the expectation that others will have a positive orientation or a desire to do good to the trustee, typically by reciprocating with appropriate advice, help, discussion, and so on, such as contributing to the ongoing discussion with the intent to help, support, and care for others. Benevolence is important in virtual communities, because without positive reciprocation, the community would not exist. Integrity is the expectation that another will act in accordance with socially accepted standards of honesty or a set of principles, such as not telling a lie and providing reasonably verified information. Integrity applies in the virtual community context, because it is the existence of norms of reciprocity, closely linked with benevolence, that allow the community to properly function.

Research based upon surveying members of virtual communities has found that integrity and benevolence are united in this context, because the expected mode of behavior in many of the virtual communities is one of benevolence (Ridings et al., 2002). Hence, adhering to this expected mode of conduct, integrity, should overlap with actually behaving so, namely, with benevolence. Conformance to socially acceptable behavior or standards (integrity) and a desire to do “good” to others (benevolent intentions) are synonymous in the virtual community environment.

THE ANTECENDENTS OF TRUST

Trust in a virtual community is built through several mechanisms that are germane to the online context. As in personal contacts where successful interpersonal interaction builds trust (Blau, 1964; Gefen, 2000a; Luhmann, 1979), the responsiveness of other community members is necessary for trust to develop (Ridings et al., 2002). This can be shown through adherence to the social norms of the community (benevolence and integrity) and competency in the topic (ability). Members who post messages most often expect responses, and when these responses are absent, late, or lacking in number, there is no successful interpersonal interaction, and that hinders the development of trust. Responsiveness is also evident by members indicating gratitude for timely help. Trust is also built by reading what others post. If others post personal information about themselves, they appear less as strangers and more as acquaintances or friends. Divulging gender, age, name, e-mail address, or a personal problem may also add to the credibility of the member (ability) as well as make it easier for other members to shape beliefs regarding adherence to the community’s standards and principles (integrity and benevolence). Personal information can also be provided in site profiles. Thus, the confiding of personal information also builds trust in other members of a virtual community (Ridings et al., 2002). Finally, humans have some degree of a general willingness to depend on others, known as disposition to trust (McKnight, Cummings, & Chervany, 1998), and this has been found to be stable across situations (Mayer et al., 1995). In the virtual community where people are unfamiliar with one another, disposition to trust, at least initially before extensive interactions take place, is also an important factor leading to the development of trust in others. Disposition to trust has been empirically found to be directly related to trust in virtual settings (Gefen, 2000a; Jarvenpaa, Knoll, & Leidner, 1998) and in virtual communities, in particular (Ridings et al., 2002).

Because virtual communities lack an enforceable legal system to ensure appropriate behavior online, the actual membership in the community and the feeling of being part of a community, even if a virtual one, may provide a possible way to enforce honest behavior. Virtual communities enhance honest behavior through creating what Ba (Ba, 2001; Ba, Whinston, & Zhang, 2003) called a trusted third party (TTP) certification mechanism. Considering the problems with the three current trust-building mechanisms in online markets (feedback, insurance or guarantee, and escrow), as pointed out theoretically by Ba and with some empirical support by Pavlou and Gefen (2004), extralegal mechanisms might be especially useful in virtual communities. Extralegal mechanisms, such as gossip, reproach, and community appreciation, and the praise and sanctions they bring, may serve to create trust just as they do in regular community settings.

Another way virtual communities may be applied to build trust, according to Ba, is through the sense of community, that, as we know from economics, is crucial when there is a separation in time between the quid and the pro (Ba, 2001). Moreover, if the members of the community are held responsible for the actions of an offender, there will be more social pressure to adhere to the rules. This might only work with online groups with a strong sense of community, but many virtual communities are precisely that.

Trust also has implications with regard to user privacy. Many virtual communities center on personal topics, such as medical conditions, legal issues, or occupations. Participants may care to be anonymous when communicating in such communities. However, the economic viability of virtual communities may depend on the sale of advertising space or products to users. To accommodate this action, reliance is placed on the provision of user demographics, e-mail addresses, and traffic statistics, information somewhat at odds with the protection of user privacy. It may be possible for virtual communities to incorporate concepts of procedural fairness, where the provision and collection of personal information is perceived as conducted fairly. Procedural fairness has been found to address privacy concerns of customers. Culnan and Armstrong found that procedural fairness builds trust that customers have for an organization using personal information for marketing purposes (Culnan & Armstrong, 1999). Such procedural fairness policies could also be applied in the virtual community context.

FUTURE TRENDS

There are many directions to be investigated from the basic understanding of trust in virtual communities. It may be that trust develops differently in different kinds of communities. For example, trust in medical-based communities may be based more heavily on certain attributes than trust in communities organized for fans of a particular sports team. The level of trust for an individual may be related to the use of the community. Demographic variables such as gender, race, and culture may also influence trust and its development (Gefen, 2000b). Longitudinal studies of virtual communities may yield more information about the development of trust over time.

CONCLUSION

Virtual communities are a key resource on the Internet for individuals looking to exchange information with others as well as Web site sponsors desiring to provide interactivity to their sites. For virtual communities to survive, they must have conversation, and for the conversation to grow and flourish, there must exist trust between the virtual community members. Trust in the other members' abilities and benevolence and integrity is necessary, and this trust has been found to be built by the responsiveness of others, the confiding of personal information, and the member's general disposition to trust.

KEY TERMS

Disposition to Trust: A tendency to believe in the goodness of others based on lifelong socialization.

Reciprocity: Returning favors, which is a major way of building trust.

Trust: A willingness to take for granted that another person will behave as expected in a socially constructive manner. Trust generally reduces the perceived risk that another person will behave in an opportunistic manner.

Trust in Ability: The belief that a person has subject matter expertise in a certain area.

Trust in Benevolence: The belief that a person has a positive orientation or a desire to do good to others.

Trust in Integrity: The belief that a person will act in accordance with socially accepted standards of honesty or a set of principles.

Virtual Community: A group of people with common interests and practices that communicates regularly and for some duration in an organized way over the Internet through a common location or site.

"Anytime, Anywhere" in the Context of Mobile Work

Mikael Wiberg
Umea University, Sweden

INTRODUCTION

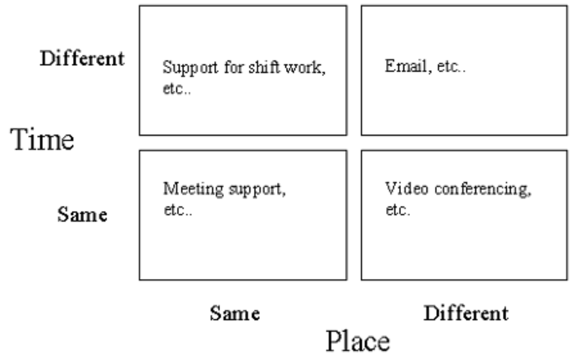
Kleinrock (1996, 1998) claims that advanced wireless technologies, the Internet, Global Positioning Systems, portable and distributed computing, and so forth will realize the vision of "anytime, anywhere" computing. We can today see the first signs of this vision. For example, telework is now possible, remote organizations can be engaged in close cooperation, and people can form communities on the Internet. The world has become a "global village," some claim (Castells, 1996; Preece, 1994), where you can interact with anybody independent of time and space.

The vision of anytime and anywhere describes a situation where people can do tasks wherever they want and without any consideration for time. Related to the vision is the 2x2 matrix often used in the field of CSCW (computer-supported cooperative work) to denote different kinds of computer-supported collaboration (e.g., Baecker et al., 1993; Johansen, 1988). This model has the dimensions of time and place, where each can be same or different. The model is shown in Figure 1 below.

The vision of anytime and anywhere is tasks that can be done independent of time and place, that is, in any of the four scenarios. This does not say anything about where or when the tasks should be done, only that these dimensions should not restrict them.

It is interesting to notice that the model does not take into consideration *mobility*. It assumes that people are either in the same place or in a different place, and whether or not they are mobile does not seem to make a difference.

Figure 1. Model showing different scenarios for groupware (Ellis et al., 1991)



BACKGROUND

In the past, people traveled because they had no choice. If you wanted to do business or talk to remote friends, you had to meet them face to face. However, transportation costs prohibited certain meetings and activities. A long series of technological developments (including the pony express, railroads, automobiles, and the telephone) have aimed at lowering the costs associated with transaction and conversation. Computer-mediated communications are the most recent development in that progression. Even so, people still travel and still meet in person.

To summarize, the adoption of Internet technologies, mobile phones, and so forth have increased and, in a sense, made the world smaller. Compared to 10 years ago, it is today much easier to communicate with remote sites, and the frequency of communication in many organizations has increased accordingly. Some people have even talked about the global village (Preece, 1994). A parallel trend is that people travel more than they used to do. According to predictions, this trend will sustain and even increase. For example, the national road agency of Sweden reports the number of flights will increase by a factor of four in the next 10 years. How can it be that the global village is so mobile? If people can interact and work independent of time and space, why then do they spend more and more time traveling? Is that not a paradox?

Reviewing the literature on the topic, we find no research that has explored this apparent paradox. Authors are either concerned with remote interaction (e.g., Brave, Ishii, & Dahley, 1998; Ellis et al., 1991; Kuzuoka, 1992; McDaniel, 1996; Tang & Minneman, 1991), mobility (e.g., Bejerano & Cidon, 1998; Luff & Heath, 1998; Porta, Sabnani, & Gitlin, 1996), or mobility as anytime, anywhere work (e.g., Dix, Rodden, Davies, Trevor, Friday, & Palfreyman, 2000; Perry, O'hara, Sellen, Brown, & Harper, 2001). Furthermore, research on mobility has mainly dealt with technology issues, for example, limited battery life, unreliable network connections, varying channel coding and characteristics, volatile access points, risk of data loss, portability, and location discovery (e.g., Bhagwat, Satish, & Tripathi, 1994; Dearle, 1998; Francis, 1997; Varshney, 1999). Accordingly, no research so far has explored the relation between, on one hand, the global village, with its idea that distance plays no role, and on the other hand, the trend of increased mobility. How do the two trends hang together?

EXPLORING THE "ANYTIME, ANYWHERE" MOBILITY PARADOX

In order to investigate this seeming paradox, we conducted an empirical study of mobile telecommunication engineers in a Swedish company (Wiberg & Ljungberg, 2000). Using qualitative research methods, we studied to what extent the work tasks they do are dependent on time and place. We analyzed the data using a 2x2 matrix, with the two axes, "time" and "space," which both have the categories "dependent" and "independent." One of the four situations is "anytime, anywhere," while the other three are dependent on time, place, or both (see Figure 2).

We found instances of work in all four categories. Some traveling seems very difficult to escape, simply because there are places that staff need to visit physically to do their job. For example, to repair a telephone pole, you need to go to it. We also found there are time frames that staff cannot escape. For example, rebooting parts of the telephone network has to be done at night. Lastly, there are work tasks that seem pretty much independent of time and space, for example, scheduling and rescheduling of activities.

As observed during this empirical study, there were just tiny parts of service work possible to perform anytime and anywhere. Most of the work is dependent on spatial factors such as the location of a breakdown in the telephone network system, the location of the client, and so forth, or has time-related dependencies such as fixing problems within 24 hours or coordinating schedules to cooperate around larger problems. For a more thorough description of the empirical material, see Wiberg and Ljungberg (2000). Overall, we found there are the following:

- traveling that seems difficult to remove because of places that people have to visit physically, for example, telephone poles, customers' houses since not all customers are mobile, network routers, locations where new cables need to be drawn, and so forth,
- time frames that seem very difficult for staff to not do certain tasks within, for example, customer service within 24 hours, rebooting parts of the telephone network has to be done at night, and so forth, and
- tasks that do not seem to be restricted by time and place, for example, scheduling and rescheduling of the activities over the day, coordination of activities between the technicians, experience and knowledge sharing among the technicians, and so forth. These tasks, however, are important for them since they are alone in their cars most of the day.

Accordingly, the vision of anytime and anywhere is not easy to realize in the case of the mobile workers we studied.

FUTURE TRENDS

Both work and leisure activities are becoming increasingly mobile. To describe the mobile worker, new concepts have been coined. Some examples are "road warriors" and "nomads" (Dahlbom, 1998) that distinguish mobile workers as moving from terms like distributed work, telework, and colocated work. One reason for this

Figure 2. Theoretical framework of the study

		Place Independent	**Place** Dependent
Time	**Independent**	**1. Anytime, anywhere**: tasks that can be done independent of time and place; they can be done anytime, anywhere	**2. Anytime, particular place**: tasks that need to be done in a particular place but can be done anytime
	Dependent	**3. Particular time, any place**: Tasks that can be done independent of place but at a certain time or in a certain order	**4. Particular time, particular place**: Tasks that must be done in a particular place within a particular time

increased mobility is the emergence of service work as the dominating profession in the postindustrial society. Service work very often takes place at the client site, and therefore it is often mobile. Another reason is the increased importance of cooperation in and between organizations. Some cooperation can take place remotely, but people also need to meet physically. A third important reason for increased mobility is the extensive adoption of mobile phones. Mobile phones enable people to be mobile and yet accessible. As people have become accessible independent of place, new ways of working have emerged in many organizations. So, for future development within this prominent area of mobile IT and mobility, it is important to keep in mind this “anytime, anywhere” paradox of the mobility vision.

CONCLUSION

This paper has shown some limitations to the vision of “anytime, anywhere” in the context of mobile work. Time and place are indeed very old ways for understanding context, and it seams like they are useful even for bringing light on the phenomena of the two parallel trends of the global village and mobility.

The paper has shown that work has moments, for example, time frames, which are not negotiable, so the work is dependent upon those. The paper has also shown that work has places of nonnegotiable importance; for example, you cannot reframe the earth by putting away distance nor go backwards in time, although computers are often described as being able to bridge those gaps in time and space. As seen above, there is not much service work possible to perform anytime and anywhere since service work is not only about moving around (i.e., mobility), but also about taking actions at various sites at specific times.

Kleinrock (1998) has argued the vision of mobility as being able to work anytime, anywhere. However, from the analysis of the empirical study presented above, we argue that there are several limits to that vision. In fact, this paper has argued that the concept of anytime and anywhere belongs to another trend, that is, the trend toward a global village, which is something altogether different from the trend of mobility. However, as the analysis has shown above, those two trends come together in practice.

So, finally, we conclude this paper arguing that the practical limitations of “anytime, anywhere” make it impossible for mobile service engineers to conduct work anytime, anywhere.

KEY TERMS

"Anytime, Anywhere" Work: Describes a situation where people can do tasks wherever they want and without any consideration for time; that is, their work can be done anytime, anywhere.

Colocated Work: Collaborative work carried out by several persons at the same geographical location.

Distributed Work: Collaborative work carried out by several persons at different geographical locations.

Global Village: As computers all over the world become interconnected via the Internet, and the frequency of communication in and between organizations, countries, cultures, societies, and so forth has increased accordingly via these networks, we can now on a daily basis and quite easily maintain contact with anybody independent of time and space; that is, we are able to interact anytime, anywhere.

Mobile Work: The ability to carry out work while geographically moving around.

"Particular Time, Particular Place" Work: Tasks that must be done in a particular place within a particular time.

Remote Interaction: Information-technology-mediated human-to-human communication over a distance.

Telework: Ability to carry out work from a distance, for example, sitting at home and doing office work. Telework does not imply that the worker is mobile (i.e., in motion) in any sense even though the concept of telework is sometimes used as a synonym for mobile work.

Application of Fuzzy Logic to Fraud Detection

INTRODUCTION

In light of recent reporting of the failures of some of the major publicly-held companies in the U.S. (e.g., Enron & WorldCom), it has become increasingly important that management, auditors, analysts, and regulators be able to assess and identify fraudulent financial reporting. The Enron and WorldCom failures illustrate that financial reporting fraud could have disastrous consequences both for stockholders and employees. These recent failures have not only adversely affected the U.S. accounting profession but have also raised serious questions about the credibility of financial statements. KPMG (2003) reports seven broad categories of fraud experienced by U.S. businesses and governments: employee fraud (60%), consumer fraud (32%), third-party fraud (25%), computer crime (18%), misconduct (15%), medical/insurance fraud (12%), and financial reporting fraud (7%). Even though it occurred with least frequency, the average cost of financial reporting fraud was the highest, at $257 million, followed by the cost of medical/insurance fraud (average cost of $33.7 million).

Statistical methods, expert reasoning, and data mining may be used to achieve the objective of identifying financial reporting fraud. One way that a company can justify its financial health is by developing a database of financial and non-financial variables to evaluate the risk of fraud. These variables may help determine if the company has reached a stress level susceptible to fraud, or the variables may identify fraud indicators. There are a number of methods of analysis that may be used in fraud determination. Fuzzy logic is one method of analyzing financial and non-financial statement data. When applied to fraud detection, a fuzzy logic program clusters the information into various fraud risk categories. The clusters identify variables that are used as input in a statistical model. Expert reasoning is then applied to interpret the responses to questions about financial and non-financial conditions that may indicate fraud. The responses provide information for variables that can be developed continuously over the life of the company. This article summarizes the specifics of fraud detection modeling and presents the features and critical issues of fuzzy logic when applied for that purpose.

BACKGROUND

Fraud Detection

The problem of fraudulent financial reporting is not limited to the U.S. In 2002, the Dutch retailer, Ahold, disclosed losses of $500 million related to accounting at its U.S. subsidiary (Arnold, 2003). Recently, Parmalat, an Italian firm, declared insolvency as a result of fraudulent financial reporting. The CEO of Parmalat has been accused of mishandling $10 billion and of hiding losses in offshore funds and bank accounts. The scandal at Parmalat could also have serious consequences for the company's auditor (Gallani & Trofimov, 2004).

The auditor's responsibility for fraud detection in the U.S. has been defined in Statement on Auditing Standards No. 99, *Fraud Detection in a GAAS Audit* (AICPA, 2002). This statement has four key provisions (Lanza, 2002): (1) increased emphasis on professional skepticism, (2) frequent discussion among audit team personnel regarding the risk of misstatement due to fraud, (3) random audit testing of locations, accounts, and balances, and (4) procedures to test for management override of controls. Auditors are discouraged from placing too much reliance on client representation and are required to maintain a skeptical attitude throughout the audit. The standard encourages auditors to engage in frequent discussion among engagement personnel regarding the risk of material misstatement due to fraud. SAS 99 also requires auditors to inquire of management and others not directly involved with fraud, perform analytical procedures, and conduct necessary tests to assess management override of controls. Finally, auditors are advised to evaluate the risk of fraud and steps taken by the client to mitigate the risk of fraud.

The U.S. Congress in 2002 passed the Sarbanes-Oxley Act, which spells out a number of steps firms must take to minimize fraudulent financial reporting. This legislation requires the principal executive officer and the principal financial officer of publicly traded companies to certify the appropriateness of the financial statements and disclosures in each quarterly and annual report that their company issues. These officers are also responsible for establishing and maintaining internal controls within the company. Further, they must disclose to auditors and the audit committee of the board of directors any fraud, whether or not material, involving management or employees who have a significant role in defining or implementing internal controls. As this law goes into effect, evaluation and reporting of a company's internal controls and financial statements in order to detect fraud becomes even more critical, and must be on-going.

Prior research shows that various kinds of decision aids may be used to assist the auditor in detecting financial reporting fraud. Bell, Szykowny, and Willingham (1993) used bivariate and cascaded logit to assess the likelihood of management fraud. Their model achieved within-sample correct classification of 97% on the fraud observations and 75% on the non-fraud observations. Hansen, McDonald, Messier, and Bell (1996) used a generalized qualitative response model to predict management fraud. They reported 89.3% predictive accuracy over 20 trials. Bell and Carcello (2000) developed a logistic regression model as a decision aid to assist in the auditor's fraud decision. Auditors may also use an expert system as a decision aid to assist in fraud determination. Eining, Jones, and Loebbecke (1997) examined the effect that the use of an expert system has on auditor decision-making ability in detecting fraud. Their research showed that in allowing the interaction between the auditor and the system, the expert systems that have been used to assist auditors in complex decision processes often give results that are more accurate and consistent. Similarly, Whitecotton and Butler (1998) found that allowing decision makers to select information for the decision aid increases decision aid reliance. Fuzzy clustering may also be used as a decision aid for an auditor to detect fraudulent financial reporting (Lenard & Alam, 2004).

Fuzzy Clustering

When available data does not suggest a clear answer, decision makers often look for patterns or groups in the underlying data to make a decision (Alam, Booth, Lee, & Thordarson, 2000). While discriminant analysis and logistic regression assign observations to groups that were defined in advance, cluster analysis is the art of finding groups in data (Kaufman & Rousseeuw, 1990). Fuzzy set theory, introduced by Zadeh (1965), attempts to classify subjective reasoning (e.g., a human description of "good", "very good", or "not so good") and assigns degrees of possibility in reaching conclusions (Lenard, Alam, & Booth, 2000). As opposed to hard clustering, where there is a clear-cut decision for each object, fuzzy clustering allows for ambiguity in the data by showing where a solution is not clearly represented in any one category or cluster. Fuzzy clustering shows the degree to which (in terms of a percentage) an item "belongs" to a cluster of data. In other words, a data item may belong "partially" in each of several categories. The strength of fuzzy analysis is this ability to model partial categorizations.

Lau, Wong, and Pun (1999) used neural networks and fuzzy modeling to control a plastic injection-molding machine. They suggested that the neural network and fuzzy technology complement each other and offset the pitfalls of computationally intelligent technologies. Alam et al. (2000) used a combination of fuzzy clustering and self-organizing neural networks, and were successful in identifying potentially failing banks. Ahn, Cho, and Kim (2000) reported results using these technologies to predict business failure, and stressed the importance of these predictions as useful in aiding decision makers. Lenard et al. (2000) used fuzzy clustering to identify two different categories of bankruptcy. Companies placed in the second bankrupt category exhibited more extreme values in terms of the financial ratios used in the study. Companies either showed much better results (such as a high current ratio) than would be expected for a company facing bankruptcy, or the companies showed very poor results, such as a much higher debt ratio than any of the other bankrupt companies in the data sample. Lenard and Alam (2004) operationalized a fuzzy logic model for fraud detection in an Excel spreadsheet. By using the fuzzy logic model to develop clusters for different statements representing red flags in the detection of fraud, non-financial data was included with financial statement variables for the analysis. The overall prediction accuracy for the model was 86.7%.

Nolan (1998) used expert fuzzy classification and found that fuzzy technology enables one to perform approximate reasoning, as when a student assignment is graded as "very good", or "not so good", and improves performance in three ways. First, performance is improved through efficient numerical representation of vague terms, because the fuzzy technology can numerically show representation of a data item in a particular category. The second way performance is enhanced is through increased range of operation in ill-defined environments, which is the way that fuzzy methodology can show partial membership of data elements in one or more categories that may not be clearly defined in traditional analysis. Finally, performance is increased because the fuzzy technology has decreased sensitivity to "noisy" data, or outliers. Ammar, Wright, and Selden (2000) used a multilevel fuzzy rule-based system to rank state financial management. The authors used fuzzy set theory to represent imprecision in evaluated information and judgments. Pathak, Viyarthi, and Summers (2003) developed a fuzzy logic based system for auditors to identify fraud in settled claimed insurance. They believe that their system was able to cut costs by detecting fraudulent filings.

CRITICAL ISSUES OF FUZZY LOGIC

The fuzzy clustering procedure used by Lenard et al. (2000) and Lenard and Alam (2004) is called FANNY (Kaufman & Rousseeuw, 1990). The program FANNY uses "fuzziness" to partition objects by avoiding "hard" decisions, or clustering into fixed, definite categories. For each item in the dataset, the algorithm provides k+1 pieces of information, where k is the number of clusters that are used in the clustering algorithm. The k+1 pieces of information are: U_{iv}, the membership coefficient of item i in cluster v, v = 1 ... k, and S_i , the silhouette coefficient of item i. A higher value of U_{iv} indicates a stronger association of item i and cluster v. The silhouette coefficients satisfy the constraints $-1 \leq S_i \leq 1$ and indicate how a well-clustered object uses average distances from its own cluster to the closest neighboring clusters. The closer S_i is to 1 the better the clustering of an individual item. A value of S_i close to -1 indicates that an item may be assigned to more than one cluster (Alam et al., 2000). The Euclidean distance measure is used to compute distances between objects and to quantify the degree of similarity for each object. The degree of similarity for each objects *i* and *j* is computed as follows (Kaufman & Rousseeuw, 1990):

$$d(i,j) = \sqrt{(x_{i1} - x_{j1})^2 + (x_{i2} - x_{j2})^2 + \ldots + (x_{ip} - x_{jp})^2} \tag{1}$$

where the p^{th} measurement of the i^{th} object is given by x_{ip} and *d(i,j)* is the actual distance between objects *i* and *j*.

Several authors have expanded upon the fuzzy clustering algorithms. Van den Bergh and van den Berg (2000) developed a competitive learning algorithm using fuzzy frequency distributions. They emphasized that sometimes the discovery of exceptions is more important than the main rules. For example, profit opportunities often seem to appear randomly and infrequently, so the agent should concentrate on detecting the unusual, abnormal states, or exceptions, rather than the average normal states (van den Bergh & van den Berg, 2000). Their algorithm seeks to find a mapping from an *M*-dimensional input space X into an *N*-dimensional output space *Y*, given a representative data set *S*. The set *S* contains *P* data pairs $(x_p; y_p)$. The final formula for the mapping is depicted as:

$$y_b = \sum_{c=1}^{C_y} \overline{y_c} \quad \mathrm{X} \quad u_c^{-Y} \mid u_b^{-X} \tag{2}$$

Thus, the sum of output cluster centroids y_c is weighted by the "local" membership values $u_c^{-Y} \mid u_b^{-X}$.

Fuzzy clustering algorithms have also been extended by the work of Kaymak and Setnes (2000), who proposed fuzzy clustering algorithms with volume prototypes and similarity based cluster merging. These extensions reduce sensitivity of the clustering algorithms to bias in data distribution, and help determine the number of clusters automatically.

Finally, Mashor (2001) proposed a clustering algorithm called adaptive fuzzy *c*-means clustering. In this method, each data sample is assigned a membership grade to indicate the degree of belonging to each center rather than assigning the data sample to one center as in "hard" clustering algorithms like the *k*-means clustering. In addition, the clustering program is not as sensitive to initial centers and gives better performance. The algorithm only requires the data to be presented once, instead of requiring multiple presentations, and as such reduces the computational load.

Identifying the number of clusters in fuzzy clustering is a challenging task. The optimal clustering should consider both fuzzy compactness and separation. The current state of the art does not provide a theoretical basis for an optimal choice of clusters. The objective function based fuzzy clustering algorithms are often used to divide the data into a predetermined number of clusters. The fuzzy *c*-means algorithm is one of the most popular objective functions used for fuzzy clustering. It uses the similarity between objects to measure the distances between clusters. The validity of the clusters is often assessed after the clusters have been formed. Validity Measures typically address the issues of the compactness of the clusters and the distances between them (e.g., Pal & Bezdek, 1995; Xie & Beni, 1991). Gath and Geva (1989) proposed a validity measure, which is a ratio between fuzzy compactness and separation. Bensaid et al. (1996) argued that combining the validity guided clustering algorithm with the fuzzy *c*-means considerably improves the partitions generated by fuzzy *c*-means alone. Various other studies have addressed the issue of the number of clusters, but there is no generally accepted approach of a priori selecting the appropriate number of clusters. Cluster validity tests are the only means available to decide whether the number of clusters used captures the underlying characteristics of the data. Investigating and resolving these issues is crucial in the analysis of financial statement data. The assignment to a particular cluster would determine whether or not the data being analyzed is a high "red flag" indicator of fraud.

FUTURE TRENDS

In addition to fraud determination, there are also other decisions that accounting and financial personnel make that affect financial reporting. Specifically, in the field of auditing, there is the auditor's decision reflected in the audit report about whether the company can continue as a going concern. The auditor uses financial statement and non-financial statement data, and a framework of questions to make the going concern judgment. The auditor also applies judgment in the consideration of materiality. Materiality judgment is closely linked to the analysis of fraud because the auditor must decide the extent to which a discrepancy affects the credibility of financial statements. These decisions may be enhanced by the use of statistical models, expert reasoning, data mining tools, and now fuzzy logic, to provide support for the auditor's judgment.

CONCLUSION

Financial statement information is used by management, employees, outside analysts, investors and creditors to assess the health of publicly traded companies. Just as this information is now readily available through the Internet and online financial services, so should tools that help in the analysis of that information be readily available or easily obtained. As the different methods of fuzzy analysis become more prevalent, there will be additional opportunities for using fuzzy logic in various other applications.

KEY TERMS

Cluster Analysis: Defining groups based on the "degree" to which an item belongs in a category. The degree may be determined by indicating a percentage amount.

Data Mining: Using powerful data collection methods to analyze a company's database or data stores and select information that supports a specific objective.

Expert Reasoning: Implementing rules or procedures, often programmed to occur automatically, in order to make a decision. Background and heuristics that identify how to reach a conclusion are based on the knowledge of human experts in that field.

Fraudulent Financial Reporting: Intentional or reckless conduct, whether by act or omission, that results in materially misleading financial statements.

Fuzzy Logic: A mathematical technique that classifies subjective reasoning and assigns data to a particular group, or cluster, based on the degree of possibility the data has of being in that group.

Internal Controls: Procedures applied by a business organization that ensure information is safeguarded, that it is accurate and reliable, and that it is processed efficiently and in accordance with management's prescribed policies.

Management Fraud: A situation in which management misrepresents the financial condition of their firm. They may do so for personal financial gain or to disguise the financial results of their company.

Application Service Provision for Intelligent Enterprises

Matthew W. Guah
Warwick University, UK

Wendy L. Currie
Warwick University, UK

ROAD TO ASP

Several historical shifts in information systems (IS) involved strategies from a mainframe to a client server, and now to application service provision (ASP) for intelligent enterprises. Just as the steam, electric, and gasoline engines became the driving forces behind the industrial revolution of the early 1900s, so the Internet and high-speed telecommunications infrastructure are making ASP a reality today. The current problem with the ASP model involves redefining success in the business environment of the 21st century. Central to this discussion is the idea of adding value at each stage of the IS life cycle. The challenge for business professionals is to find ways to improve business processes by using Web services.

It took mainframe computers a decade or two to become central to most firms. When IBM marketed its first mainframe computer, it estimated that 20 of these machines would fulfil the world's need for computation! Minicomputers moved into companies and schools a little faster than mainframes, but at considerably less costs. When the first computers were applied to business problems in the 1950s, there were so few users that they had almost total influence over their systems. That situation changed during the 1960s and 1970s as the number of users grew. During the 1980s the situation became even tighter when a new player entered the picture—the enterprise (McLeord, 1993). In the 21st century, information systems are developed in an enterprise environment (see Diagram 1).

Beniger (1986) puts forth a seemingly influential argument that the origin of the information society may be found in the advancing industrialisation of the late nineteenth century. The Internet is simply a global network of networks that has become a necessity in the way people in enterprises access information, communicate with others, and do business in the 21st century. The initial stage of e-commerce ensured that all large enterprises have computer-to-computer connections with their suppliers via electronic data interchange (EDI), thereby facilitating orders completed by the click of a mouse. Unfortunately, most small companies still cannot afford such direct connections. ASPs ensure access to this service costing little, and usually having a standard PC is sufficient to enter this marketplace.

The emergence of the ASP model suggested an answer to prevailing question: Why should small businesses and non-IT organisations spend substantial resources on continuously upgrading their IT? Many scholars believed that outsourcing might be the solution to information needs for 21st century enterprises (Hagel, 2002; Kern, Lacity & Willcocks, 2002; Kakabadse & Kakabadse, 2002). In particular, the emergence of the ASP model provided a viable strategy to surmount the economic obstacles and facilitate various EPR systems adoption (Guah & Currie, 2004). Application service provision—or application service provider—represents a business model of supplying and consuming software-based services over computer networks. An ASP assumes responsibility of buying, hosting, and maintaining a software application on its own facilities; publishes its user interfaces over the networks; and provides its clients with shared access to the published interfaces. The customer only has to subscribe and receive the application services through an Internet or dedicated intranet connection as an alternative to hosting the same application in-house (Guah & Currie, 2004). ASP is an IT-enabled change, a different and recent form of organisational change, evidenced by the specific information systems area (Orlikowski & Tyre, 1994). ASP has its foundations in the organisational behaviour and analysis area (Kern et al., 2002).

The initial attempt—by the ASP industry to take over the business world—was fuelled by the belief that utility computing offered a new business model to customers, similar to electricity, gas, and water. The commercialization of the Internet meant that, as network traffic increased in a firm's data centre, IT architecture would trigger other resources into action, including idle servers, applications, or pools of network storage. The firm would pay only for the amount of time it used the services. Thus, the concept of 'software-as-a-service' was created

(Kakabadse & Kakabadse, 2002). Accessing IT resources in this way would result in reduced up-front investment and expenditure, enabling firms to buy services on a variable-price basis (Dewire, 2000). This fuelled opportunities in the late 1990s for service providers to offer software applications and IT infrastructure on a rental, pay-as-you-go pricing model (Bennet & Timbrell, 2000). An ASP could be a commercial entity, providing a paid service to customers (Dussauge, Hart & Ramanantsoa, 1994) or, conversely, a not-for-profit organisation supporting end users (Currie, Desai & Khan, 2003).

ASP AREAS OF CONCERN

As evidence relating to the reality and basic features of the ASP market continues to grow, there begins to be less concern about confirming that any structural economic shift has continued historically, and more concern about understanding how the ASP industry is performing, and its impacts on productivity, investment, corporate capital formation, labour force composition, and competition.

The ASP business model is premised on the formation of strategic alliances and partnerships with technology and service providers (Ferergul, 2002). Telecommunications firms entering the ASP market with large IT infrastructures needed to partner with ISVs and hardware manufacturers. One of the significant strategic alliances was between Cable & Wireless (IT infrastructure), Compaq (hardware manufacturer), and Microsoft (ISV). Pure-play ASPs without a large investment in IT infrastructure needed to form strategic alliances with data centre and colocator firms (telcos) and ISVs. Some of the major reasons for businesses to implement an ASP business model are list in Table 1.

The ASP model was highly volatile, dynamic, and immature. A recent review of the ASP industry concluded that technological factors like scalability, the managerial aspects of speed and focus, and the behavioural aspects of price and flexibility were the key drivers of the model. The inhibitors of the model were poor connectivity, lack of trust in the model, reluctance to be locked into long-term contracts with suppliers, lack of customisation, poor choice and suitability of software applications from ASPs, and few opportunities to integrate disparate applications across technology platforms and business environments. These factors and others led Hagel (2002, p. 43) to conclude:

"ASPs in many respects represented a false start in the efforts to break out of the enterprise straitjacket. In particular, few of them adopted Web services architectures as their technology platform. Instead, they attempted to build businesses on the Internet using traditional technology architectures…this proved to be a significant flaw in the early ASP model and explains many difficulties these businesses experienced."

The business environment for intelligent enterprises (see Diagram 1) includes the enterprise itself and everything else that affects its success, such as competitors; suppliers; customers; regulatory agencies; and demographic, social, and economic conditions (Guah & Currie, 2004). As a strategic resource, ASP helps the flow of various resources from the elements to the enterprise, and through the enterprise and back to the elements.

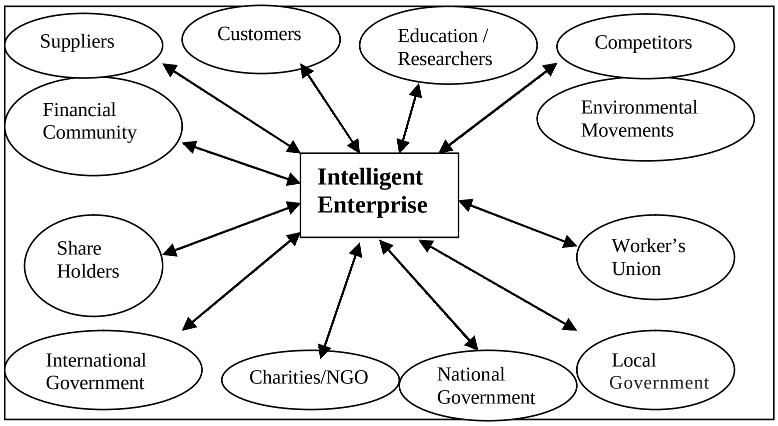
THE FUTURE OF THE ASP MODEL

According to Forester Research, the proportion of ASP business in the outsourcing market peaked at about $800 million in 2000 and was projecting for $25 billion by 2005. However, it actually declined by the year 2002 (due partly to the effect of stock market collapse) and currently is being projected at $15 billion by 2006. The overall business interests in the ASP model will continue to rise, with proportionally higher rates of investment by vendors

Table 1. A list of motivational factors to implement an ASP strategy

- To take maximise the capabilities of the Internet's latest technology
- To increase sales of products and services
- To reach a highly desirable demographic market
- To stay on top of competition
- To make changing information available quickly
- To test new products and services on the market
- To boast morale among staff and customers
- To experiment with an Internet model to business IT outsourcing

Diagram 1. A tool for controlling influences in a complex environment



versus traditional outsourcing. We attribute this optimistic forecast to four trends:

- continuing improvements in capabilities and cost-performance characteristics of Remote Support Services by vendors,
- improvements in capabilities and cost-performance characteristics of the technology at the system or application level,
- continual development of the telecommunications infrastructure to support ASP performance, and
- gradual reduction of institutional and social barriers to the introduction of the ASP model as a viable business strategy.

There are numerous papers warning that such accelerated Web service evolution increases the difficulty that other competitors have in adapting to ASP (Gottchalk, Graham, Kreger & Snell, 2002; Hondo, Nagaratnam & Nadalin, 2002; Stencil Group, 2002). By modifying the nature and the relative importance of the key factors for success in the ASP industry, Web service technological changes that are introduced by one or more of the vendors can lead to favourable changes in the competitive environment. In an industry built upon high volume, new technologies that are introduced by some of the competitors that nullify or minimise the impact of scale can significantly alter the nature of the competitive environment by making size a drawback rather than an advantage.

Diagram 2 shows that the holistic approach to technology always seems to work better than the piece-meal approach to information systems solution. Early stages of Web services are represented by a two-legged table. The current version of Web services being practiced by vendors after the dot.com crash is represented by the three-legged table in Diagram 2. But an even more successful model of Web services would be a properly architecture four-legged table, represented above. The analogy here is that a two-legged table is less stable than a three-legged table, while a four-legged table is even firmer.

CONCLUSION

We can safely conclude that policy makers in all fields, not just in IS, are forced into ill-considered conclusions and recommendations because they still view their management strategies in pre-Internet terms. Moreover, they are still constrained by statistical calculations based on outmoded and obsolete classification approaches, as well as on invalid assumptions about the fundamental sources of profit and capital formation—without full consideration for business environment.

Rethinking your business in terms of Internet economy, formulating new strategies for gaining competitive advantage, and raising the level of awareness of people throughout your enterprise to the notion that information itself can and should be looked upon as a strategic corporate asset¾these are great steps, but only the first steps for success in the 21st century. In addition, both structural and procedural changes must take place for an intelligent enterprise to put its convictions into operation. Could ASP provide you with such a necessary tool thereby directing your focus into the reality of a 21st century intelligent organisation?

Table 3.Summary of areas affecting the growth of the ASP market

Widespread model ignorance and perceptions among small and medium businesses. Lack of adequate understanding of the ASP business model and its understanding.

IS infrastructure raises a broad range of economic, social, and technical issues. Who should pay for infrastructure? Who should have access to/control over them and at what cost? Which technology should it include? Where ASP is involved, the economic question often puts telephone companies against cable companies, both of whom can provide similar capabilities for major parts of the telecommunications system.

Telecommunications facilitates ASP emancipation. Telecommunications has become virtually inseparable from computer with a paired value that is vital for integrating enterprises. As an e-commerce phenomenon, a few of the essentials of an ASP infrastructure are Common Carriers, Value-Added Networks, Private Line, and Private Networks.

Issues of security. As a program executed upon accessing a Web page, ASP carries a security risk because users end up running programs they don't know and/or trust. The latest solution is encryption, but does any mathematical encryption guarantee absolute security? No. Just as a physical lock cannot provide absolute safety, encryption cannot guarantee privacy—if a third party uses enough computers and enough time, they will be able to break the code and read the message. The encryption system only guarantees that the time required to break the code is so long that the security provided is sufficient. When someone asserts that an encryption scheme guarantees security, what they actually mean is that although the code can be broken, the effort and time required is great. Thus, an encryption scheme that requires a longer time to break than another scheme is said to be 'more secure'.

Overcoming organisational obstacles to a commercial future. The issue of organisation is based on the way ASP has evolved. The ASP industry lacks the type of clear organisation that would make it easy to use as a reliable and profitable business model.

ASP as competitive investment. Not so much return on investment for ASP, rather what is the cost of not investing? Will an enterprise lose customers and market share because it does not have a particular technology in place? Can you enter a new line of business without investing in the technology that competitors have adopted? What kinds of services do customers expect? These are competitive investment issues raised by ASP.

Change is also an opportunity. One stimulus for ASP solution implementation is its intention to transform the enterprise. In this sense, the investment in ASP is part of a larger change programme that is meant to enable intelligent enterprises' virtual and multiple-team structures. The resulting contributions can be described as part of the outcome of a general change effort.

Social-technical issues. The social objectives refer to the expectations of major stakeholders (i.e., employees). An ASP business model that provides information and tools for employees increases involvement because they reinforce the employee's authority and responsibility for work. Those that provide information to managers or quality inspectors but do not support employees can reduce involvement by reinforcing the suspicion that the employee is not really responsible.

Tangible and intangible benefits. The tangible benefits of an ASP solution can be measured directly to evaluate system performance. Examples include reduction in the time for completion of transaction, improvement in response time, reduction in the cost of assets, and reduction in the error rate. Intangible benefits affect performance but are difficult to measure because they refer to comparatively vague concepts. A few intangible benefits of a solution are: better coordination; better supervision; better morale; better information for decision making; ability to evaluate more alternatives; ability to respond quickly to unexpected situations; and organisational learning. Although hard to quantify, intangible benefits are important and shouldn't be ignored, as many IS benefits to organisations are intangible.

The role of government. Modernisation of the machinery and process of government will accommodate many Internet strategies like ASP. This will involve reform of intellectual property law to accommodate access to and exploitation of works via the Internet. It will include administration of Internet domain names on an international basis. Finally, the facilitation of e-commerce development will include national and international initiatives and measures to protect both suppliers and consumers operating within this global electronic marketplace.

Blurring in-house IT and ASP services. As the industry evolves and becomes more complex, the need for new services and specialisation in the division of labour continues to increase. In-house migrates into strategic management and monitoring of IT standard, while ASP migrates into value-added services so that 'business IT becomes a service in a package form'. As the boundaries between in-house and ASP become more blurred through the use of improved communications technologies, the opportunities for entrepreneurs continue to increase.

KEY TERMS

ASP: A third-party service firm that deploys, manages, and remotely hosts software applications through centrally located services in a rental or lease agreement

(ASP Consortium, 2000). Such application deliveries are done to multiple entities from data centres across a wide area network (WAN) as a service rather than a product, priced according to a license fee and maintenance contract set by the vendor. An ASP is considered by many to be the new form of IT outsourcing, usually referred to as application outsourcing.

ASP Aggregator: The ASP aggregator model is based on the premise that the rapid proliferation of firms offering ASP services has created an overly complex market for medium-sized enterprises to deal with when investigating application outsourcing options.

Agent-Based Approach to ASP: This approach to ASP is well equipped to address the challenges of multi-market package to e-procurement. Service agents within the ASP model are the system's gateway to external sources of goods and services. These agents are usually aware of the source's market model and of the protocols it uses (Zhang et al., 2000). Service agents are not only able to determine which requests it can service, but also proactively read these requests and try to find an acceptable solution.

Common Carriers: Companies that are licensed, usually by a national government, to provide telecommunications services to the public, facilitating the transmission of voice and data messages.

Infrastructure: An emerging class of companies have opted to approach the ASP market by providing infrastructure management and outsourcing services to ASPs, freeing up their resources to focus more directly on application management issues (telco, data centre, networking).

Internet Service Providers (ISP): Provides access to the Internet via different communications channels such as traditional telephone lines or a high-speed fibre optics channel.

Pure-Play ASP: Those with non-specific industry-required product or service, except Internet/Web-enabled software applications (e-mail/security/disaster recovery). Firms offering this service suffer from the sales of unprofitable commodity applications and therefore have greater reliance on venture capitalist funding as they operate in a rather unstable, volatile, and dynamic market.

Vertical Service Provider (VSP): Vertically focused ASPs offering industry-specific applications are also emerging. Their basic premise is that each industry (health, finance, transportation) has its own unique set of characteristics that can best be served by companies that focus exclusively on the given industry.

Virus: A malicious code added to an e-mail program or other downloadable file that is loaded onto a computer without the user's knowledge and which runs often without the user's consent. Computer viruses can often copy themselves and spread themselves to a user's e-mail address book or other computers on a network.

Web Services: Web Services technology is one of the most important foundations for ASP new-game strategies. Thus, by accelerating the pace of Web services in the industry, a competitor with good capability in the technology reinforces its own competitive position.

Applying a Metadata Framework to Improve Data Quality

Victoria Youngohc Yoon
University of Maryland, Baltimore, USA

Peter Aiken
Defense Information Systems Agency, USA

Tor Guimaraes
Tennessee Technological University, USA

INTRODUCTION

The importance of a company-wide framework for managing data resources has been recognized (Gunter, 2001; Lee, 2003, 2004; Madnick, Wang & Xian, 2003, 2004; Sawhney, 2001; Shankaranarayan, Ziad & Wang, 2003). It is considered a major component of information resources management (Guimaraes, 1988). Many organizations are discovering that imperfect data in information systems negatively affect their business operations and can be extremely costly (Brown, 2001; Keizer, 2004). The expanded data life cycle model proposed here enables us to identify links between cycle phases and data quality engineering dimensions. Expanding the data life cycle model and the dimensions of data quality will enable organizations to more effectively implement the inter- as well as intra-system use of their data resources, as well as better coordinate the development and application of their data quality engineering methods.

BACKGROUND

The proposed model has a number of inputs/outputs distributed throughout eight phases: metadata creation, metadata structuring, metadata refinement, data creation, data utilization, data assessment, data refinement, and data manipulation. Each of these phases is described next in more detail.

Two possible cycle "starting points" are shown bolded in Figure 1. The first starting point is applicable to new systems where there exists no data to be migrated, and/or converted from existing system(s). In these instances, the model cycle begins with metadata creation and proceeds counter- clockwise around the cycle. However, according to a survey of CIOs by Deloitte & Touche (1996), an average of more than 90% of organizational legacy systems were scheduled to be replaced by 2001. Legacy systems continue to impede business effectiveness for many. Only 6% of insurers plan to replace their systems in the next two years, while 29% plan to replace their legacy systems within four years (Chordas, 2004). In a survey of 115 business-technology professionals conducted by Optimize Research, 42% called their legacy IT a barrier to innovation and flexibility, while 8% said that it bogs down business and is expensive to maintain (Whiting, 2003). Thus, it is more likely that an organization's legacy data will become the major data asset to be managed. In these cases where data already exist, structural data quality re-engineering becomes necessary, and the cycle begins with data assessment. Next, each cycle phase is described in more detail.

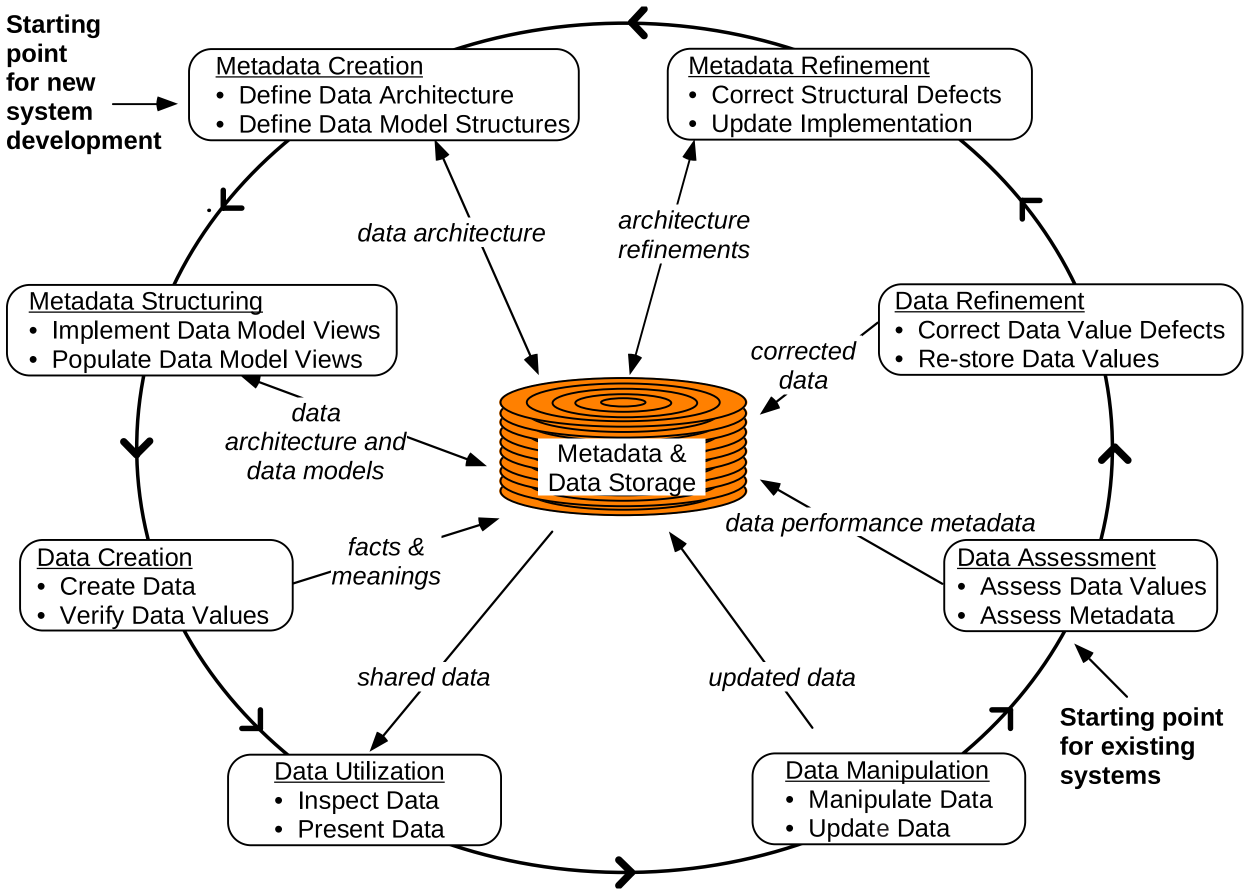
Metadata Creation

When the requirements dictate that users interact with multiple systems across functional area boundaries, a formal organizational data architecture is required to coordinate data quality engineering efforts. While all organizations have data architectures, only formally specified architectures can be formally managed. This phase typically corresponds to increasing awareness of data as an organizational asset. The architectural metadata created and evolved consist of the organizational data architecture structure definitions and specific associations among individual system data models.

Metadata Structuring

This phase focuses on developing a framework guiding the organizational data architecture implementation as it populates data models in the next phase. Metadata creation is followed by the development of a data model structure. Data models must also be evolved. The term

Figure 1. Newly proposed eight phases of extended data life cycle model with metadata sources and uses



"structuring" indicates the iterative development process that occurs as the organizational data architecture structure developed during the previous phase is populated with metadata. Defining data model structures permits organizations to understand the categories of data that comprise its data models. The process consists of populating the data architecture with data models describing the various specific systems. Each data model corresponds to one physical occurrence. In addition, when physically implemented, logical model components can be physically implemented by multiple systems, accessing common DESs. The process of defining data models as components extends the organizational data architecture comprehensiveness. Metadata structuring is complete when all entities can be associated with specific model components. Perfect model metadata occurs when a correct data model exists for each physical system, and each physical system component is associated with one and only one common organizational data architecture component.

Metadata Refinement

At various points, portions of some metadata can be determined imperfect. Architecture refinement implements an iterative approach to refining the existing metadata-based concepts, correcting factual errors, and evolving the structure to a more perfect state. This usually occurs in response to data assessment activities.

Data Creation

Data creation occurs when data values are captured from some external source and stored in systems. Data sources can range from a point of sale terminal, to EDI, to floppy disk exchange. Data creation is the most popular focus of data quality engineering efforts. These are commonly implemented as edit masking, range checking, or other forms of validation. Data value quality efforts are aimed at perfecting data values as they are captured and before they are stored or re-stored in the database.

Data Utilization

Data utilization occurs as the data are provided as information in response to a request from a user or a process. The focus of data quality engineering efforts for this phase is on appropriate data representation; that is, taking data from a storage location and properly presenting it to a user or a process as requested.

Data Assessment

Often occurs in response to complaints of imperfect data. It is assessed formally or informally to determine data suitability for current or future use. If data are judged inadequate, the assessment also determines if the problem causes are practice caused or structurally caused. Practice-caused problems are corrected through the data refinement phase, while structural problems are amended through the metadata refinement, creation, structuring phases. Structural changes must be applied at an organizational architecture level.

Data Refinement

If the cause of imperfect data is determined to be practice-oriented, the data values are corrected using a data refinement procedure. Data refinement refers to the process of altering data within the existing data structures. This continues to be a popular focus of data value quality engineering efforts.

Data Manipulation

Often times data are accessed in order to be altered, deleted, or otherwise manipulated. Data manipulation is the process of altering data forms or data values. Any change can introduce error, and the data quality engineering focus is similar to that described previously.

Developers have typically been task oriented when developing specific systems based on data modeling. Most data quality methods are also usually system focused, limiting their usefulness beyond the specific system boundaries. From an organizational perspective, absence of data definitions shared across functional areas makes data interchange among systems considerably more difficult. Thus, quality considerations based on these three dimensions can be insufficient to insure overall data quality. The increasingly widespread requirement that users interact with multiple systems, and the need for developers to build more highly integrated systems, demand an additional data quality dimension. Therefore, we propose a fourth dimension to data quality, which addresses organizational data architecture, to coordinate data management activities in cross-functional system development and operations. The chief characteristic of this dimension is an architecture providing an effective linkage between the organization-wide user data requirements and the specific systems implemented to satisfy such requirements.

Quality Engineering Dimension Attributes

Based on our literature survey, quality attributes for data values, data representations, and data models are recapped in Figure 2. Accompanying each attribute is its source(s) of reference(s) in the literature and a brief description.

Absent from the presently available literature are the attributes corresponding to data architecture quality. A list of nine organizational data architecture attributes is proposed as a collection of desirable characteristics for such architectures. This list has been developed based on the experience within the Department of Defense's (DOD) Center for Information Management's Information Engineering Directorate, where the second author worked as Program Manager and participated in the development of a DOD-wide data architecture development. We propose these attributes to increase reader awareness and further discussion in this critical area. The proposed attributes are:

Architectural Completeness

The architecture is comprehensive enough to be used by any functional area of the organization wishing to utilize it.

Architectural Correctness

The information describing the architecture is correctly represented with the appropriate methodology. That is, the organization can use the methodology to maintain uniform data definitions throughout the organization.

Management Utility

The data architecture is widely used by the organization in strategic planning and systems development as an indication of its utility. In practice, architectures too often wind up as shelf-ware.

Data Management Quality

The organization as a whole is data driven. Data models are developed and managed from an organization-wide perspective, guided by the organizational data architecture. Data are managed with distributed control from a centralized unit.

Data Sharing Ability

The data architecture serves as the basis for negotiating and implementing intra-organizational data exchange agreements by anticipating, defining and managing data sharing requirements within the organization and among its business partners using organization-wide standard metadata definitions.

Functional Data Quality

Data are engineered in support of business functional area requirements where data elements for individual systems are derived from organizational metadata requirements and implemented using organizational systems designed to support information representation.

Data Operation Quality

Data quality engineering is established as a functional area actively and consistently applying data quality engineering methods to data elements.

Evolvability

The organizational data architecture is maintained in a flexible, evolving fashion to enable the fulfillment of future user requirements.

Organizational Self-Awareness

Organization ability to investigate architecture use, and determine the types of value that it provides to end users. Feedback helps data architects refine the architecture to make it more useful organizationally.

FUTURE TRENDS

It is widely recognized that a company's data resources are vitally important for effective organizational operations. However, many organizations have experienced substantial financial losses and other negative impacts caused by imperfect data. A major reason for the negative impact is the lack of effective guidelines for data quality management. The problem is exacerbated by increased company dependence on computer technology for business operations and by strategic requirements necessary to improve company global competitiveness. To properly manage any data resource, companies must understand the roles it plays, its properties, the opportunities offered and the steps to take to explore those opportunities. While data present great possibilities there are also special challenges that must be addressed (Levitin & Redman, 1998).

Further adding to the problem is the trend toward systems integration within and among companies that has forced IS departments to change focus from developing and operating relatively isolated applications to new ones capable of supporting cross-functional and interorganizational business processes. Faced with such demands, data resources managers have received little guidance from researchers addressing the complete range of data quality dimensions they have to cope with. In order to obtain the required level of data quality, systems development efforts must consider all dimensions of data quality, including: data value; representation; data model; and data architecture quality. Based on previous research, a more comprehensive data quality model has been proposed, as well as the attributes applicable to each quality dimension. The scope of data quality engineering should be changed from multiple-triples within systems to organization-wide triple management. Data quality engineering will be more effective when also focused on rooting out structure-oriented causes of imperfect data by ensuring the quality of shared data across system boundaries, with common data definitions.

SUMMARY AND CONCLUSION

There are challenges and opportunities inherent in managing data. Development and use of the more comprehensive data quality metadata model will enable organizations to more effectively manage those dimensions, enhancing data quality. Data resources managers are encouraged to consider the expanded data life cycle model proposed here, and the attributes necessary to implement an organization-wide data architecture, for benchmarking purposes against their companies' presently used methodologies and data management activities.

Figure 2. Recap of research contributions to the attributes of data quality

	Described By:	Larry P. English	K. Laudon	A. Levitin and T. Redman 93	C. Fox, A. Levitin, & T. Redman 94	T. Redman 92	E. Tufte	Definition
Dimension	**Attribute**							
Data	Timeliness	X					X	Data should be promptly presented to the user at the time when it is needed.
Representation	Conciseness						X	Data presented to the users match user breadth/depth requirements without data loss.
Quality	Clarity						X	Data are presented in a form that is easiest for the user to understand given the request circumstances
	Consistency					X		Data presented to the users lacks nothing with respect to the user's information requirements.
	Detail					X		Data are presented in the level of detail most appropriate for the user's need.
	Accessibility						X	Data presented to the users is free from retrieval fault, data displayed unaltered from what was stored.
	Order							Data are presented in a sequence fitting the users need and their cognitive style.
	Flexibility					X		Data are able to be easily transformed between systems, formats, media to best match user needs.
	Portability					X		Data are able to be migrated from application to application without data loss.
	Presentation appropriateness	X					X	Data are presented in a format facilitating user comprehension.
	Media					X		Data are presented using media most effective for user comprehension.
	Unambiguousness/interpretability					X	X	Data presented to the users requires no interpretation to comprehend the correct value.
Data	Completeness	X	X		X	X		Attributes of entities requiring values have them.
Value	Correctness/accuracy	X	X		X	X		Data values maintained are free from fault, recording defects, or damage.
Quality	Currency				X	X		Data values maintained are the most up-to-date and match user expectations.
	Time Period					X		Data values maintained cover the time period required by the users.
	Clarity		X					Data values maintained match the breadth and depth of the user request parameters.
	Precision				X			Data values are maintained with the amount of precision or detail required by the user.
	Reliability				X			Data values stored can be depended upon by the user under stated conditions.
	Consistency					X		Data values continue to be maintained in a steady, dependable manner.
	Timeliness				X			Data values are updated as often as the user requires.
	Relevance					X		Data values stored are directly responsive to the specific user needs.
Data Model Quality	Completeness	X						The model is comprehensive enough to be used for a reference - containing complete enough subject areas to be of use.
	Definition clarity/unambiguity	X		X		X		The model is developed and maintained according to generally accepted modeling principles indicating the modelers consistently and correctly applied the techniques.
	Relevance			X		X		The model contents represent the facts of interest to the user.
	Value obtainability			X		X		The data model is structured so that users can obtain the facts they require.
	Comprehensiveness			X		X		This quality attribute addresses the issue "Did the modelers include all of the information they desired to in the model? Is this model populated with sufficient data to be useful?"
	Essentialness			X		X		The model contains only those elements fundamentally required to describe the subject.
	Attribute granularity			X		X		The model is structured so that it manipulates the level of detail desired by the users.
	Domain precision	X		X		X		The model maintains the factual precision desired by users.
	Naturalness			X		X		The model 'fits' with the way users assimilate facts into their work processes.
	Occurrence identifiability			X		X		The model maintains sufficient access means to uniquely identify facts required by users.
	Robustness			X		X		Both the model component definitions and the relationships between the entities are free from interpretation-based faults.
	Flexibility			X		X		The model maintained in a fashion where it is able to be useful in multiple applications
	Minimally redundant					X		The model is implemented using minimal factual duplication to meet user needs.

KEY TERMS

Data: Combination of facts and meanings that are processed into information.

Data Architecture: The underlying set of rules and descriptions of relationships that govern how the major kinds of data support the business processes defined in the business architecture.

Data Quality: A dimension or measurement of data in reference to its accuracy, completeness, consistency, timeliness, uniqueness and validity. Data are considered to be of high quality if they have all of the above attributes.

Data Resource Management: The analysis, classification and maintenance of an organization's data and data relationships.

Legacy Systems: Older computing technology used by an organization over time. Legacy systems perform business-critical functions and can be integrated with newer systems.

Metadata: Information that refers to one or more other pieces of information that can exist as separate physical forms. In short, data about data. In the information technology world the term is often used to indicate data that refers to digital resources available across a network.

Metadata Framework: A series of guidelines describing potential components required to define, describe, publish and maintain metadata.

Resource: Asset or means that fulfills a requirement.

Archival Issues Related to Digital Creations

Mark Kieler
Carnegie Mellon University, USA

Michael J. West
Carnegie Mellon University, USA

INTRODUCTION

The authors define "intellectual creations" as human expressions embodied in text, music, or other forms of art. Increasingly, we encode these creations in digital formats that have extremely short life cycles. Eventually, backward compatibility is lost. Thus, after very little time, a digital encoding format becomes obsolete, and intellectual works encoded in the format may become irretrievable. In contrast, the cultural worth of an intellectual creation may not be realized for generations. Additionally, future generations must access artifacts, including intellectual creations, to understand a culture in historical context. We contend that technology – intensive storage and manipulation of data may result in an inability to gain this access. Technology creators have some responsibility to facilitate future retrieval through careful documentation, and by selective maintenance of hardware that may be required to access archival media.

BACKGROUND

Cultural artifacts nearly always outlive the technologies that made them possible, which is particularly obvious with digital technology. Imagine the discovery hundreds of years from now of a floppy diskette containing a document written in WordStar®. Once a code has been lost, have all texts written in that code been lost as well?

At some point, supporting a technology is no longer economically viable if it is abandoned by enough people. It ceases to exist except in archival form. Currently, home videocassettes are being replaced by the DVD (Digital Video Disc), which subsequently will also be superceded.

Linguists stress the organic nature of language, which it is in constant evolution. Grammars are codifications constructed of "snapshot images" of spoken and written language usage. Despite the fact that both are considered examples of English, speakers of the vernacular of Shakespeare and the vernacular of rap music would find each other incomprehensible. With technology, as with language and culture, timing is everything, and context plays an important role in shaping how we interact with each other and with technology.

HOW DO WE KNOW ABOUT PAST CULTURES?

In engineering, Shannon (1948) described elements of a communications system: An information source generate data. A transmitter encodes information to travel over a channel through distance and time. At the other end, a receiver decodes the signal for the destination, which is the person or thing for which the message is intended. Since we are worried about humans, we consider them to be the source and destination. While parts of the transmission system have changed greatly over time, one could certainly argue that technology has caused the other portions of the system to change more rapidly than the human elements. Linguists, beginning with Ferdinand de Saussure, established semiotics as a science of signs, which likewise focuses on the sender and the receiver of a message. Semiotics also posited the arbitrary nature of the sign and looked at the ways human languages encode and transmit messages. (Saussure, 1974).

Physical artifacts that survive from the distant past reveal much about a culture, depending on their purpose and the quality of materials from which they are made. Our record from ancient civilizations is far from perfect, but archaeologists can construct some details about them from these clues.

Significant events have often been recorded in the living embodiment of a storyteller, and oral traditions still form an important part of many cultures. The historical record has often been related by language, as well as by performance (e.g., a ritual dance). Some of these oral histories survived long enough to be recorded in other more permanent media. However, not only have many oral traditions died with the last generation of storyteller, others have assumed inaccuracies and exaggerations as a result of being passed serially through generations.

As languages evolved and became standardized, it became possible to encode events in written form. Because writing has traditionally been the province of the learned few, written documents were recorded on long-lived media, and special care was accorded to their storage. Fortunately, many ancient documents have survived, albeit, with significant degradation. Given the constant change in a living language, when a culture dies, the language often dies with it. Language experts attempt to reconstruct meaning by looking for patterns that may establish types of words and contexts and similarities to more modern languages.

In addition to printed text, human expression is also accomplished through artistic means such as music, painting, and dance. While we only have been able to preserve musical and dance performances for a relatively recent portion of human history, for centuries we have had a written procedure for recreating music, using notes, measures, and time definitions. The methods for recording dance instructions are much less standardized and rely on interpretations and tradition.

Art works degrade over time, depending on the types of inks, paints, or dyes used, the media on which they are deposited, and overall interaction with the environment. Even sculpture is subject to environmental degradation, such as damage from acid rain.

THE INTRODUCTION OF TECHNOLOGY

The invention of the printing press made wide distribution of printed information possible, and wood pulp-based paper made it affordable for the general public. However, unlike expensive fiber-based paper, pulp-based paper has usually been manufactured through an acid-based process, and residual acid in the paper eventually destroys it. Thus, paradoxically, fiber-based books from the 19th century are often more legible than their 20th century wood pulp counterparts.

Text

Text was the first means of expression to be converted into electrical form. In fact, text went "direct to digital." Morse code is a duration-encoded digital signal, unrecognizable to anyone who does not understand it. Initially, storage was primitive, used mainly to "buffer" the information until a human could reconvert it to text. Thus, long-term storage and archiving of Morse code traffic was not an issue.

The first modern bit encoding of text occurred in 1874. Emile Baudot, a French telegraph engineer, devised a 5-bit code for each letter of the alphabet. Unlike Morse code, each symbol had a fixed length representation, dependent only on the presence or absence of electrical current. The Baudot code was durable, used by news service teletypewriters throughout the 1970s (Freed, 1995). Crude paper tape punches were often utilized for storage. The digital code could be read, albeit slowly, merely by holding the tape up to a light.

ASCII (American Standard Code for Information Interchange) uses 7 bits. The added bits allowed upper and lower case letters, as well as numbers, punctuation, and other special characters. It endures as the "plain text" standard.

The rise of WYSIWYG (what you see is what you get) computer interfaces, and the availability of sophisticated word processing programs, made it possible to digitally encode additional expressions to text. Different art styles of text (fonts) could be used, and these could embody visual variations such as italics, bold, superscripts and subscripts, and underlines. Word processing evolved to encode these variations. This was accomplished by adding bits to the original text data, or by software commands that controlled a section of ASCII text. These techniques represent a deviation from international standards into conventions of the word processing software. As the level of sophistication increases, we become increasingly unable to understand an encoded section of text without the software used to create it. In fact, the actual text becomes only a tiny portion of the code. If the page is graphically encoded, as occurs in programs such as Adobe Acrobat®, then plain text representations are lost all together (Kieler et al., 2004).

Audio and Visual Technology

Storage of audio and visual data began in the 19th century and progressed in sophistication throughout most of the 20th century. While not strictly correct in each instance, the general paths of progress could be viewed as follows:

- Visual Still and Audio-Only, to Visual Motion, to Visual Motion with Audio
- Mechanical or Chemical-Based Recording, and Storage to Electronic Recording and Storage
- Mechanical Reproduction to Electronic Reproduction
- Analog Encoding to Digital Encoding

The most significant impediments to easy retrieval of an intellectual creation involve electronic encoding and storage, and digital conversion.

Electronic encoding of visual information marks the historical point where the original signal cannot be recovered merely by converting stored data directly into light or motion. The visual image is stored as a series of lines, and voltage references signal new lines or new collections of lines (*frames*). Thus, one must be able to properly decode the various electronic levels and pulses unique to the method, and understand how the lines are ordered and encoded in order to correctly reconstruct the scanned image. Incompatible formats include PAL (Phase Alternating Line), NTSC (National Television Standards Committee) and SECAM (Systéme Electronique Couleur Avec Mémorie) (Abbott, 1994).

With the advent of magnetic storage, one could no longer directly "see" the information on the storage medium without a great deal of technological aid. As an example, by the late 1920s, light modulation of audio onto motion picture film was possible (Hochheiser, 1992), and both audio and video information are clearly visible on the film. In contrast, the advent of practical magnetic video recording in 1956 (Shima, 1984) resulted in a signal which can only be observed using microscope techniques (Chinn, 1957).

Finally, digital data types in streams of 1s and 0s are indistinguishable without the reverse algorithm to retrieve the original information. The significance is that in addition to the physical details of how the data was encoded, we also need mathematical processing information on how the data was changed after its conversion. Data protection techniques, including public and private key cryptography, hashing algorithms, and other methods (Wayner, 1997), added on top of the conversion technique, have deliberate obscuration of data as their intent. Thus, the data is not readable, even when the encoding techniques are known, unless the proper decrypting information is available.

Lossy Encoding

An additional dilemma is that digital conversions result in massive amounts of data. Compact disc audio, for instance, necessitates a bit rate of 4.32 million bits per second (Carrasso et al., 1982). Efficient storage and transmission virtually require data reduction. We must actually throw away some of the original information (hence the term *lossy*) to make any real progress in storage efficiency. We discard information based on redundancies in the retained data, or upon deeming it insignificant through models of human perceptual limitations. For instance, Moving Picture Experts Group Layer 3 audio (MPEG 3 or MP3) achieves a better than 10 to 1 savings (Jack, 1996). However, the encoded audio bit stream now represents a set of mathematical manipulations on top of the interleaving, control, data, and error correction algorithms of the storage format. It has become impossible to reconstruct the data without complete knowledge of each of these transformations.

IMPACT ON LONG-TERM DATA AVAILABILITY

If intellectual creations are stored in formats that require an exact knowledge of the encoding transforms, the issue for society is whether any of these techniques will be available, or even remembered, in the distant future.

In the short term, there is no problem, as new formats usually incorporate backward compatibility and conversion. Eventually, however, the overhead needed to retain compatibility hampers the effectiveness of a system. As demand collapses, the resources that support an obsolete format must be utilized for other purposes.

The digital revolution has compressed the time scale. Tremendous gains in hardware and software capability have resulted in unprecedented rates of obsolescence. For example, in both popular personal computing formats, operating systems have migrated to 32-bit code, abandoning the previous 16-bit systems. In doing so, they have shed much backward compatibility with the previous systems (White, 2002.) This transition has occurred in a mere 20 years. Thus, the ability to retrieve data created with a 16-bit program may well be lost once the last 16-bit compatible system is "upgraded."

New generations of artists and creative personalities use electronic and especially digital formats as freely as their predecessors used physical media. While most popular culture intellectual creations have little lasting value, a few will be significant enough to be studied and preserved far into the future. The problem is that human society does not always immediately recognize an intellectual work's significance, and it may fall into obscurity for decades or even centuries. A cursory encyclopedia search (Compton's, 1994) reveals examples from many fields. For example, painter Sandro Botticelli's works remained obscure from the late 1400s until the 19th century.

While not individually significant, ordinary popular culture creations collectively can reveal a great deal about a period in society. However objective evaluation often requires the passage of at least several decades. Even then, critiques and judgments may go through many modifications and revisions before any consensus is reached.

MINDSETS: CREATORS OF TECHNOLOGY VERSUS CREATORS OF IDEAS

Technology creators derive value from innovation. Profits and employment fall once a particular technology generation "matures" and a "shakeout" era ensues, where only the most efficient producers prevail. Software and digital data can be infinitely replicated with no degradation. Thus, barring legal impediments, there is virtually no value in creating additional copies. Even with legal protections against duplication, others may create software that operates differently but accomplishes the same goal. These characteristics shape the mindset of technology creators into a "cult of the new." Obsolescence is the fuel for continued employment and profitability.

With intellectual creations, there is also a progress-oriented motivation. Artists do not merely rest on past achievements. However, since these creations embody a combination of knowledge, ideas, and interpretation, their value is not necessarily superceded by later works. While only a few will have lasting value to society, there is no way to know when this value will finally be appreciated. The finest intellectual works must prove their value repeatedly through decades and centuries of cultural change.

The issue is that these works are increasingly created through a technological process that need only prove itself until the next "better" innovation comes along. The potentially tremendous but unpredictable future value of key intellectual works may never be realized if they are embodied in a technical process that has zero value five years later. While future societal worth is of little present economic value to the creation of intellectual work, the encoding technology creator derives nothing beyond the initial sale of the software.

Certainly, the same could be said of those who produce physical creative media such as paint or canvas. However, the medium usually survives regardless of the intentions of its original manufacturer. Deterioration is directly observable, and can often be repaired to foster preservation. With modern technology, however, the "medium" is a combination of the physical storage object and the encoding software/hardware systems. Even if the storage object can last centuries, the ability to retrieve it is governed by entities that have, if anything, a *dis*incentive to ensure continued long-term accessibility. This leaves society with no way to rediscover and realize the benefits of important intellectual creations in the distant future.

FUTURE TRENDS

While it is unfair to lay all responsibility for long-term accessibility on technology creators, it is clear that the nature of digital innovation fosters the problem. Among engineering ethicists, there is general agreement that those who create technology have a unique insight into potential side effects. Harris, Pritchard, and Rabins (1992) discuss the need for "preventive ethics" in engineering. Shinzinger and Martin (2000) describe engineering as social experimentation. This implies a responsibility for technology creators to envision possible social consequences and, at the very least, take steps to inform others of their existence and nature. This is especially true where the complexity of the technology is transparent to the end-user.

Thus, while digital technology creators may not solely be responsible for ensuring future accessibility of works expressed through their technology, one could argue that they have a responsibility to enter into dialogues about preserving accessibility, and to design their encoding technology to foster preservation.

Currently, preservation awareness is coming, not from the technology developers, but rather from the software archivists. Pennavaria (2003) details a number of concerns and efforts of groups such as the American Library Association and the American Film Institute. Although technologists are involved in these efforts, they tend to deal only with existing analog and digital formats. Also, they tend to concentrate largely on the deterioration mechanisms of the physical media, as opposed to preserving the availability of playback hardware and decoding software.

Some hardware, such as silicon chips, could last for centuries. Conversely, other pieces of machinery clearly have a limited shelf life due to physical deterioration and wear. It is the "soft" items, such as encoding and decoding software and the underlying algorithms and manipulations, that have the greatest chance to be lost, owing to their short lifetimes. Only the creators of these artifacts can take steps to ensure their survival. This implies a responsibility that the technologists cannot ignore. The broader culture must also realize the problem and work with the technologists to foster preservation. Otherwise, much of our current culture will disappear in less than a century.

CONCLUSION

The attractiveness and availability of digital processing has resulted in its use by creators of intellectual content. The rapid turnover of digital applications may make access to these creations impossible within a very short period, compared to the time it takes for society to determine their ultimate worth. Technology creators must work with society leaders to ensure that intellectual creations are not lost forever.

KEY TERMS

Analog: Encoding a physical phenomenon by a direct, perceptually continuous variation of a physical property such as electromagnetic intensity (recording tape), mechanical displacement (Vinyl disk), or opaqueness (photographic film).

ASCII: American Standard Code for Information Interchange. A standard method of encoding upper and lower case text and other symbols with a 7-bit code.

Baudot: A 5-bit standard encoding method for uppercase letters, Invented by Emilie Baudot in 1874.

Intellectual Creation: Any work of creation, such as authorship, visual arts, performing arts, or music.

Lossy Encoding: Removal of data that represents redundant information, or differences presumed imperceptible to humans, in order to reduce stored or transmitted quantities of digital data.

Masking: In psychoacoustic models, the ability of a loud tone to block the perception of sounds or noise occurring in nearby frequencies.

Psychoacoustic Models: Models of human aural perception, especially with regard to the ability or inability to perceive signals that are masked by other signals.

Semiotics: A theory of signs and the use of signs in languages. Semiotics posits the arbitrary nature of the sign and looks at how human languages encode and transmit messages.

Wood Pulp: An inexpensive paper stock. Acid, used as part of the production process, frequently remains in the paper and causes its destruction. This destruction is rapid compared to paper made from fiber.

WYSIWYG: "What you See is What you Get." A user display that shows text and graphical information exactly as it will appear in print or other subsequent distribution. This includes expressional and artistic variations of text fonts, such as italics, bold, and underlined text.

Artificial Intelligence Techniques in Medicine and Health Care

Rezaul Begg
Victoria University, Melbourne, Australia

INTRODUCTION

Now-a-days, researchers are increasingly looking into new and innovative techniques with the help of information technology to overcome the rapid surge in health care costs facing the community. Research undertaken in the past has shown that artificial intelligence (AI) tools and techniques can aid in the diagnosis of disease states and assessment of treatment outcomes. This has been demonstrated in a number of areas, including: help with medical decision support system, classification of heart disease from electrocardiogram (ECG) waveforms, identification of epileptic seizure from electroencephalogram (EEG) signals, ophthalmology to detect glaucoma disease, abnormality in movement pattern (gait) recognition for rehabilitation and potential falls risk minimization, assisting functional electrical stimulation (FES) control in rehabilitation setting of spinal cord injured patients, and clustering of medical images (Begg et al., 2003; Garrett et al., 2003; Masulli et al., 1998; Papadourokis et al., 1998; Silva & Silva, 1998).

Recent developments in information technology and AI tools, particularly in neural networks, fuzzy logic and support vector machines, have provided the necessary support to develop highly efficient automated diagnostic systems. Despite plenty of future challenges, these new advances in AI tools hold much promise for future developments in AI-based approaches in solving medical and health-related problems. This article is organized as follows: Following an overview of major AI techniques, a brief review of some of the applications of AI in health care is provided. Future challenges and directions in automated diagnostics are discussed in the summary and conclusion sections.

ARTIFICIAL INTELLIGENCE TECHNIQUES

There have been a number of artificial intelligence (AI) tools developed over the past decade or so (cf., Haykin, 1999; Keckman, 2002). Many of these have found their applications in medical and health-related areas. Commonly applied AI techniques can be listed as:

- Neural Networks
- Fuzzy Logic
- Support Vector Machines
- Genetic Algorithms
- Hybrid Systems

In the following, we give a brief overview of neural networks, fuzzy logic and the relatively new support vector machines.

Neural Networks

Artificial neural networks work much like the human brain and have the ability to learn from training data and store knowledge in the network. In the learning phase, it maps relation between inputs and the corresponding expected outputs. During the learning phase, knowledge is acquired and stored in the network in the form of synaptic weights and biases. This knowledge is used to make future predictions in response to new data or inputs during the testing phase. Usually, the network has one input and one output layer, and one or more hidden layers depending on the complexity of the problem. Learning can be supervised; that is, the network is provided with both the inputs and their desired outputs during the leaning process, or it can be unsupervised or self-organizing learning. There are a number of learning algorithms available (Haykin, 1999), and among them back-propagation learning algorithm is the most widely used. In this method, an error signal based on the difference between network-generated output (g_i) and desired output (d_i) is propagated in the backward direction to adjust the synaptic weights according to the error signal. During the learning process, the aim is to minimize an objective function such as the mean-squared error (E),

$$E = \frac{1}{n}\sum_{i=1}^{n}(d_i - g_i)^2$$

Neural networks are frequently used as diagnostics, and therefore it is important to have good generalization ability, that is, good performance in predicting results in response to unseen data. One limitation of neural networks is the possibility of being stuck in local minima during training rather than converging to the global minimum. To overcome this the network is usually trained several times with random initial weights to avoid converging to the local minima. Neural networks have found the majority of their applications in pattern recognition, time-series prediction, signal processing and financial forecasting.

Fuzzy Logic

Fuzzy sets were introduced by Zadeh (1965), and they deal with imprecise and uncertain information or data. Naturally, this has been found suitable for many medical and health-related problems, as it relates to the way humans think. Since the early work of Zadeh, there has been an exponential rise in the number of scientific papers applying fuzzy sets in biology, medicine and psychology areas (Teodorescu et al., 1998).

Support Vector Machines

Support vector machines are a relatively new machine learning tool and have emerged as a powerful technique for learning from data and solving classification and regression problems. This has been particularly effective for binary classification applications. SVMs originate from Vapnik's statistical learning theory (Vapnik, 1995). SVMs perform by nonlinearly mapping the input data into a high dimensional feature space (by means of a kernel function) and then constructing a linear optimal separating hyperplane by maximizing the margin between the two classes in the feature space.

For m training data with input-output pairs $(y_1,\boldsymbol{x}_1),\ldots,(y_m,\boldsymbol{x}_m)$ where each input data $\boldsymbol{x}_i \in \Re^N$ belongs to a class $y_i \in \{-1,+1\}_{i=1,\ldots,m}$, the decision function for a new data $(\boldsymbol{x}_i)$ can be given by the sign of the following function (Gunn, 1998):

$$\mathrm{f}(x) = sign\left(\sum_{i \in SVs} \alpha_i y_i \mathrm{K}(\chi_i, \chi) + \mathrm{b}\right)$$

where, a_i is a nonnegative Lagrange multiplier corresponding to $\boldsymbol{x}_i$, $K(.)$ is a kernel function and b is the bias. The Lagrange multipliers are obtained as the solution of a convex quadratic programming problem. The data points $\mathbf{x}_i$s corresponding to $a_i>0$ are called support vectors. Such $\boldsymbol{x}_i$s are the only data points in the training set relevant to classification since the decision surface is expressed in terms of these points alone (support vectors, SV). For linearly separable problems, the number of SVs and the hyperplane are determined by a subset of the training set only. For nonlinearly separable problems, a_i in SVs are constrained by an upper bound C, which is regarded as a regularization parameter. This parameter makes a trade-off between margin maximization and minimization of classification errors in the training data set (Gunn, 1998).

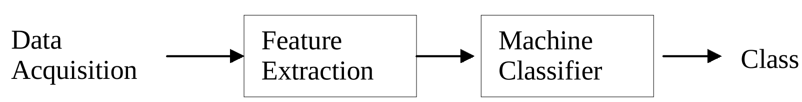
Hybrid Systems

Recently, researchers have started looking into ways of combining various AI tools in order to maximize performance of the AI system. The main idea behind this is to offset limitation of one system by cascading with another AI tool. As a result, hybrid systems like Neuro-Fuzzy (neural networks and fuzzy logic), Neuro–SVM (neural networks and support vector machines) and Fuzzy-SVM (fuzzy logic and support vector machines) systems have evolved. Hybrid systems have been applied in many applications, including some biomedical areas (Teodorescu et al., 1998).

APPLICATIONS IN HEALTH CARE AND MEDICINE

In addition to applications in medical diagnostic systems, AI techniques have been applied in many biomedical signal-processing tasks, including analysis of ECG, EEG and human movement data (Nazeran & Behbehani, 2001). Neural network models have played a dominant role in a majority of these AI-related applications in health and medicine. Many of these applications are for pattern recognition or classification. A typical classification application usually has a number of steps or procedures as shown by the flow diagram (see Figure 1). This involves feature extraction from the input data before feeding these features to the classifier for designing and developing

Figure 1. Stages of a typical pattern recognition task



automated classification models, and finally testing the models for generalization.

Medical Decision Support Systems

Medical decision support systems (MDSS) are designed to construct a knowledge database by way of receiving a list of symptoms as input features and their corresponding disease type(s) as the output. Such a developed symptom-to-disease mapping system then facilitates the diagnostic process by generating new responses due to a new set of symptoms. Neural networks have been used to aid MDSS. Silva and Silva (1998) developed such a neural network-based MDSS system for a relatively small set of 20 randomly selected diseases and reported encouraging results. Disease symptoms in this study were represented as sinusoidal damped waveforms. Hybridization has been shown to improve diagnostic accuracy. For example, Dumitrache et al. (1998) reported an improvement in accuracy (by 28%) for medical diagnosis in cardiac disease using a hybrid decision-making system compared to a classical expert system.

Cardiology

Several studies have applied neural networks in the diagnosis of cardiovascular disease, primarily in the detection and classification of at-risk people from their ECG waveforms (Nazeran & Behbehani, 2001). Celler and Chazal (1998) have applied neural networks to classify normal and abnormal (pathological) ECG waveforms: 500 ECG recordings (155 normal and 345 abnormal) were used to extract features from the QRS complex for training and testing the classifier. The abnormal ECG recordings had six different disease conditions. The classifier was able to recognize these waveforms with 70.9% accuracy.

Electroencephalography

AI tools, including neural networks, fuzzy clustering and SVMs, have been shown to be useful for analyzing electrical activity of the brain, the electroencephalogram (EEG) signals. Features extracted from EEG recordings of the brain have been used with AI tools for improving communication between humans and computers and also for effective diagnosis of brain states and epileptic seizures (Garrett et al., 2003; Geva & Kerem, 1998; Nazeran & Behbehani, 2001).

Opthalmology

Neural networks have been shown to be an effective diagnostic tool to identify glaucoma disease. Glaucoma is more prevalent in older age and can cause loss of vision. Papadourokis et al. (1998) applied backpropagation neural network to classify normal patients and patients with glaucomatic optic nerve damage from perimeter examination. Several neural network models were tested using 715 cases, including 518 glaucoma cases, and they reported 90% recognition accuracy with two hidden layer networks and training with 80% of the input data. In an effort to compare effectiveness of different AI techniques in recognizing glaucoma diagnosis, Chan et al. (2002) used standard automated perimetry data to compare classification performance of several classifiers including multiplayer perceptron and support vector machines (SVM). In-depth analysis of performance of these classifiers was carried out using areas under the receiver operating characteristic (ROC) curves and also sensitivity (true positive rates) and specificity (1 - false positive rates) measures. Machine classifiers were found to perform superiorly in the classification tasks, whereas SVM showed significantly improved performance compared to a multiplayer perceptron. A self-organizing fuzzy structure has also been developed and applied to predict the onset of hypoglycemia for diabetic patients (Hastings et al., 1998).

Gait Analysis and Rehabilitation

Gait is the systematic analysis of human walking. Various instrumentations are available to analyze different aspects of gait (cf. Begg et al., 1989). Among its many applications, gait analysis is being increasingly used to diagnose abnormality in lower limb functions, and also to assess the progress of improvement as a result of treatments and interventions. Recently, neural networks and fuzzy logic techniques have been applied for gait pattern recognition and clustering gait types. Barton and Lees (1997) classified gait patterns based on hip-knee angle diagrams and Holzreiter and Kohle (1993) used neural network models to identify normal and pathological gait patterns from measurements of foot-to-ground reaction forces using force platforms. Wu et al. (1998) applied a back propagation neural network to classify gait patterns of patients with ankle arthrodesis and normal subjects, and reported a superior classification by the neural networks compared to statistical technique (linear discriminant analysis) (98.7% vs. 91.5%). Gait analysis is being increasingly used in rehabilitation settings, and also combining with AI techniques to improve gait control and functionality. Tong and Grant (1998) applied neural networks to optimize sensor sets for control of FES system in people with spinal cord injury and showed improvements in accuracy as a result of neural network aided control. Fuzzy logic has also been recently applied with great success in: clustering children gait with and without neurological disorder (O'Malley, 1997) and also detection of gait events such as the foot contact and take-off during walking in the analysis of paraplegic gait (Skelly & Chizeck, 2001).

Support vector machine (SVM) has recently been applied to classify young and elderly gait patterns (Begg et al., 2003). Gait changes with aging, with potential risks of loss of balance and falls. Recognizing gait patterns with potential falls risks would help to detect at-risk people so that rehabilitation programs could be undertaken to minimize the risk of falls. AI techniques such as neural networks and SVMs have demonstrated their potentials for detecting gait degeneration due to aging and appear to have potential applications in falls prevention in the elderly.

SUMMARY AND FUTURE TRENDS

There are plenty of future challenges for AI to be routinely used in medicine and health. The use of automated medical decision support system in routine use in the clinic would make a significant impact on our health care system.

One possibility is that health care in the future will be built on knowledge networks (Erlandson & Holmer, 2003). Applications of telemedicine and informatics in health care can help to provide support to patients in remote areas, and to share expert knowledge or limited resources. Furthermore, effective networking between informatics and biomedical engineering can also help to complement each other's knowledge and to fight in partnership the various challenges faced by the medical and health care systems.

One major aim of a classification task is to improve its recognition accuracy or generalization performance. Selecting features that offer the most discriminatory information between the classes or medical groups could help to improve classification accuracy. At the same time, removing redundant features might also improve the medical recognition task. It has been demonstrated in a number of studies that selecting a small number of good features in fact improves the recognition accuracy (Begg et al., 2003; Chan et al., 2002; Yom-Tov & Inbar, 2002), in addition to the added advantages of classifier simplicity and fast processing time. Therefore, a pattern recognition task may be improved by decomposing it into the following stages (see Figure 2):

Recently hybrid systems are emerging, combining various AI tools with improved performance in medical diagnosis and rehabilitation. Application of hybrid systems in medical diagnosis has already provided increased efficiency in diagnosis of cardiac disease by as much as 28% compared to classical expert system. This and other applications provide much hope and encouragement for more future applications based on hybridization of AI systems in helping to solve problems in medicine and health care.

CONCLUSION

Artificial intelligence, particularly neural networks, fuzzy logic and the recently introduced support vector machines, played a key role over the years for many important developments in medicine and health care. Despite such developments there are many future challenges and currently only a few AI-based systems are routinely used in the clinical setting. Continued developments in AI fields are providing much impetus that is needed to tackle the many problems of the health care system.

KEY TERMS

ECG: The electrical activity of the heart recorded from the body surface using electrodes as electrical potential is known as electrocardiogram or ECG.

EEG: The electrical activity of the brain recorded from the scalp as electrical potential is known as electroencephalogram or EEG.

Fuzzy Logic: The concept of fuzzy logic is that many classes in the natural environment are fuzzy rather than crisp. It deals with imprecise and uncertain data.

Gait Analysis: Analysis of human walking patterns. It is used to analyze abnormality in lower limb problems and assess treatment or intervention outcomes.

Hybrid Systems: Integration of two or more artificial intelligence tools to improve efficiency or system performance.

Neural Networks: Neural networks resemble the human brain and able to store knowledge during training and use this for decision making during testing phase.

Support Vector Machines: Introduced by Vapnik and capable of learning from data for solving classification and regression problems.

A

Artificial Neural Networks in Financial Trading

Bruce Vanstone
Bond University, Australia

Clarence Tan
Bond University, Australia

INTRODUCTION

Soft computing represents that area of computing adapted from the physical sciences. Artificial intelligence (AI) techniques within this realm attempt to solve problems by applying physical laws and processes. This style of computing is particularly tolerant of imprecision and uncertainty, making the approach attractive to those researching within "noisy" realms, where the signal-to-noise ratio is low. Soft computing is normally accepted to include the three key areas of fuzzy logic, artificial neural networks, and probabilistic reasoning (which includes genetic algorithms, chaos theory, etc.).

The arena of investment trading is one such field where there is an abundance of noisy data. It is in this area that traditional computing typically gives way to soft computing, as the rigid conditions applied by traditional computing cannot be met. This is particularly evident where the same sets of input conditions may appear to invoke different outcomes, or there is an abundance of missing or poor-quality data.

Artificial neural networks (ANNs) are a particularly promising branch on the tree of soft computing, as they possess the ability to determine nonlinear relationships and are particularly adept at dealing with noisy data sets.

From an investment point of view, ANNs are particularly attractive, as they offer the possibility of achieving higher investment returns for two distinct reasons. First, with the advent of cheaper computing power, many mathematical techniques have come to be in common use, effectively minimizing any advantage they had introduced (Samuel & Malakkal, 1990). Second, in order to attempt to address the first issue, many techniques have become more complex. There is a real risk that the signal-to-noise ratio associated with such techniques may be becoming lower, particularly in the area of pattern recognition (Blakey, 2002).

Investment and financial trading is normally divided into two major disciplines: fundamental analysis and technical analysis. Papers concerned with applying ANNs to these two disciplines are reviewed.

BACKGROUND

There are a number of approaches within the literature that deal with applying ANN techniques to investment and trading. Although there appears to be no formal segmentation of these different approaches, this review classifies the literature into the topics proposed by Tan (2001), and augments these classifications with one more category, namely, hybrid. These categories of ANN, then, are as follows:

- Time series—Forecast future data points using historical data sets. Research reviewed in this area generally attempts to predict the future values of some time series. Possible time series include base time series data (e.g., closing prices) or time series derived from base data (e.g., indicators, which are frequently used in technical analysis).
- Pattern recognition and classification—These are attempts to classify observations into categories, generally by learning patterns in data. Research reviewed in this area involved the detection of patterns and segregation of base data into "winner" and "loser" categories as well as in financial distress and bankruptcy prediction.
- Optimization—This involves solving problems where patterns in the data are not known, often nonpolynomial (NP)-complete problems. Research reviewed in this area covered the optimal selection of parameters and determining the optimal point at which to enter transactions.
- Hybrid—This category was used to distinguish research that attempted to exploit the synergy effect by combining more than one of the above styles.

There appears to be a wide acceptance of the benefit of the synergy effect, whereby the whole is seen as being greater than the sum of the individual parts. This can be easily seen by inspecting the following reserach, which clearly shows that Hybrid techniques account for about one third of the research reviewed.

Further, the bias in this style of research toward technical analysis techniques is also evident from the research, with one third of the research pursuing the area of pattern recognition and classification. Technical analysis particularly lends itself to this style of research, as a large focus of technical analysis concerns the detection of patterns in data and the examination of the behavior of market participants when these patterns are manifest.

MAIN THRUST OF THE CHAPTER

This section briefly considers the characteristics of each of the four main categories described above. The selected papers were chosen as they are representative of current research directions, represent an important change in direction for this style of research, or represent a novel approach.

Research into Time Series Prediction

The area of time series predictions is normally focused on attempting to predict the future values of a time series in one of two primary ways:

- Predicting future values of a series from the past values of that same series
- Predicting future values of a series using data from different series

Typically, current research in this area focuses on predicting returns, or some variable thought to correlate with returns (e.g., earnings). Some researchers focus on attempting to predict future direction of a series (e.g., increasing from last known value, decreasing from last known value, no change). Research of this nature is essentially a classification problem and is discussed in the relevant section.

The following papers were selected and reviewed as they are representative of the current research in time series prediction. The authors of those papers are Chan and Foo (1995), Quah and Srinivasan (2000), Yao and Poh (1995), Hobbs and Bourbakis (1995), Austin et al. (1997), and Falas et al. (1994). The papers reviewed consider both fundamental and technical data. For example, Falas et al. (1994) used ANNs to attempt to predict future earnings based on reported accounting variables. They found no significant benefit using ANNs compared to the logit model and concluded that the accounting variables chosen were not appropriate earnings predictors. This conclusion represents one of the major problems encountered when working with ANNs, namely, their nonexistent explanatory capability. It is common to find conclusions of this type when reviewing ANN research, with noncorrelation often being reported as wrongly chosen input variables. Quah and Srinivasan (2000) used mainly accounting variables to predict excess returns (with limited success). Chan and Foo (1995) used ANNs to predict future time series values of stock prices and used these "future" values to compute a variety of technical indicators. The ANN produced showed particularly promising results. The authors concluded that the networks' ability to predict allows the trader to enter a trade a day or two before it is signalled by regular technical indicators, and this accounts for the substantially increased profit potential of the network.

In many ways, these two primary prediction methodologies relate to technical analysis strategies. For example, the use (and projection) of a moving average over a series of stock prices could be regarded as predicting future values of a series (the moving average) from past values of the same series. Indicators in technical analysis are often composed of a number of constituent data items, like price, volume, open-interest, etc. These indicators are commonly used to give indications of the future direction of price.

Research into Pattern Recognition and Classification

Pattern recognition techniques and classification techniques have been grouped together, as their goal is normally not to predict future values of a time series, but to predict future direction of a time series. For example, the primary goal of a chartist (a style of technical analyst) is to attempt to predict trend turning points by studying chart price action, looking for certain patterns. Chartists have noticed that these patterns tend to recur and are reasonably reliable indicators of the future direction of price trends. There are a number of these chart patterns, and different analysts attach different weightings to the predictive power of any given pattern. Also, these patterns normally need to be confirmed by values from another time series (such as volume) to be considered reliable. For more detail on this area, the reader is encouraged to refer to Pring (1999). Nonpattern matching techniques that also attempt to predict the future direction of a time series are also classification problems. Often, in addition to predicting the future direction of a time series, classification research attempts to classify stocks into two main groups, namely, "winners" and "losers," as in bankruptcy and financial distress predictions.

The following papers, listed by author, were selected and reviewed as they are representative of the current research in pattern recognition and classification: Tan (1996), Tan and Dihardjo (2001), Mizuno et al. (1998), Baba et al. (2001), Skabar and Cloete (2001), Suh and LaBarre (1995), Fu et al. (2001), Kamijo and Tanigawa (1990), Baba and Handa (1995), and Baek and Cho (2000). As described above, the research can generally be classified as winner and loser detection, or pattern matching. The works of Tan (1996), and later, Tan and Dihardjo (2001), use the concept of winner and loser classification, as do Longo, Suh and LaBarre (1995) and Skabar and Cloete (2001). Specifically, Skabar and Cloete do not predict winners and losers but predict two disparate categories, namely, "up" and "down" (direction of returns). The work of Kamijo and Tanigawa (1990) provides an excellent example of pattern matching, with the authors building ANNs to identify "triangle" patterns in stock market data (the triangle is a specific pattern used in technical analysis).

Classification involving pattern matching could also be validly discussed under the section above on time series prediction, due to the fact that pattern constructs must occur in specific time order, and the majority of patterns are not time invariant. This leads to the desire of researchers to identify time invariant patterns or attempt to determine a fixed period of time in which a pattern should occur. The work of Fu et al. (2001) provides examples of using genetic algorithms to "fix" the length of patterns, making them suitable for study using ANNs.

Research into Optimization

The focus of optimization is directed toward research that uses soft computing specifically to attempt to optimize an otherwise accepted achievable result. Typical of this style of research paper, an already accepted result is discussed and then considered for optimization. The optimization is characteristically proven by excess returns compared to the unoptimized case.

For an example of this style of optimization using ANNs, an index arbitrage timing has been proposed by Chen et al. (2001). Their model attempts to optimise the correct entry point timing for index arbitrage positions. Current arbitrage models propose establishing an arbitrage position immediately as an opportunity arises; the neural network approach is to attempt to locate the timing when there will be a maximum basis spread for the arbitrage, thereby increasing profit potential. Their research concludes that the neural model significantly outperforms the traditional approach.

Research into Ensemble Approaches

Research is classified as an ensemble approach if it combines work from more than one of the areas described below, effectively attempting to leverage the synergy effect by achieving an end result greater than that expected from each of the individual constituents. Among soft-computing research, there is a growing trend toward using the ensemble approach to analysis.

The following papers (listed by author and date of publication) were selected and reviewed, as they are representative of the current research in ensembles: Liu and Lee (1997), Leigh et al. (2002), Baba et al. (2002), Jang et al. (1991), Wong and Lee (1993), Chenoweth et al. (1995), and Abdullah and Ganapathy (2000). The majority of the ensembles draws their components from a variety of soft-computing methods. The use of ANNs and genetic algorithms (GAs) together is popular, and is used by Leigh et al. to combine pattern recognition techniques with price forecasting. Another approach combining ANNs and GAs is provided by Baba et al., using ANNs for their predictive ability and GAs to determine the best way to react to that information. Some ensembles combine multiple ANNs, for example, Jang et al. combine two ANNs: one that takes a short-term view of market movement, and one that takes a longer-term view. They then build a model that reacts to a weighted output sum of the outputs of both models. Liu and Lee (1997) and Abdullah and Ganapathy (2000) also used ensembles of ANNs and concluded that the predictive ability of the ensemble approaches exceeded that of the individual ANNs. Other research reviewed combined ANNs with fuzzy logic and expert systems.

FUTURE TRENDS

Essentially, the field of financial trading is in a state of transition between traditional pricing models, the efficient market hypothesis, and ideas about behavioral finance. The challenge that presents itself is how best to unify financial trading pricing models. There is much debate about the validity of the efficient market hypothesis, which effectively contends that prices cannot be predicted using methods such as technical analysis. There is a large body of evidence that appears to contradict the efficient market hypothesis, and there seems little chance of academically moving forward en masse unless an alternative valid pricing model exists. This offers substantial opportunity for soft-computing research techniques, particularly neural models. These models are capable of acting as universal approximators and determining complex nonlinear relationships. The goal with these methods is to attempt to mine deep relationships that can shed new light about the behaviour of markets and prices. These new relationships would inherently provide more scope for developing feasible and effective pricing models.

CONCLUSION

This chapter has surveyed recent and key literature in the domain of applying ANNs to investment and financial trading. Within the context of investment discipline, this survey shows that the majority of this type of research is being conducted in the field of technical analysis. As discussed earlier, soft computing is particularly data intensive, and it is suggested that this observation goes some way to explaining this obvious bias in research.

Within the area of soft-computing styles, the survey finds that the majority of research is within the area of both hybrid systems and pattern recognition and classification. It is suggested that the reason for this is that the technical analysis approach lends itself to the pattern recognition and classification areas. Also, many hybrid systems include pattern recognition and classification as one of their constituents.

KEY TERMS

Continuation Pattern: A pattern in technical analysis that suggests, on the balance of probabilities, that price trend will continue in its current direction.

Fundamental Analysis: The use of company-reported financial data to determine an intrinsic (or fair value) for a security. Used to identify cases where companies are undervalued, with a view to profiting from the future price movements. This style of analysis is generally long term.

Noisy Data: This term is generally used to describe data and data sets in which there is a low signal-to-noise ratio. Any algorithm attempting to filter out the signal has to be capable of identifying and dealing appropriately with noise. In this sense, noise is that element of the data that obscures the true signal.

Reversal Pattern: A pattern in technical analysis that suggests, on the balance of probabilities, that price trend will change direction.

Technical Analysis: The study of the behaviour of market participants, as reflected in the technical data. Used to identify early stages in trend developments, with a view to profiting from price movements. This style of analysis is generally short term.

Technical Data: "Technical data" is the term used to describe the components of price history for a security. These components are open price, low price, high price, close price, volume traded, and open interest.

Technical Indicators: Technical indicators are produced as results of various computations on technical data. They are primarily used to confirm price action.

Triangle Pattern: A triangle is a particular pattern observed using technical analysis. There are a variety of circumstances under which a triangle can occur, and dependent on the circumstances, the triangle can be either a reversal or continuation pattern.

Artificial Neural Networks Used in Automobile Insurance Underwriting

Fred L. Kitchens
Ball State University, USA

INTRODUCTION

As the heart of the insurance business, the underwriting function has remained mostly unchanged for nearly 400 years when Lloyd's of London was a place where ship owners would seek out men of wealth. The two would contractually agree to share the financial risk, in the unlucky event that the ship would be lost at sea (Gibb, 1972; Golding & King-Page, 1952).

Today, insurance underwriters perform a similar function on behalf of their respective insurance companies. Underwriters gathering pertinent information and analyze their potential clients to determine whether or not they should underwrite the risk; and if so, what premium they would require for the insurance policy. Insurance companies employ actuaries to help the underwriter in this process by studying past insurance losses and making predictive models for future risks. Using traditional statistical methods, insurance actuaries look for loss-contributing characteristics within the risk (Webb, Harrison et al., 1992). When the actuaries find positive relationships between the policy characteristics and subsequent losses, they create "underwriting guidelines" for the underwriters to follow, when analyzing potential clients (Malecki & Underwriters, 1986).

For hundreds of years, actuaries used pencil and paper to perform their statistical analysis; it was a long time before they had the help of a mechanical adding machine, still longer before they had computers. As recently as 1981, computers were not considered important to the underwriting process. Leading experts in insurance underwriting believed that the human-judgment factor involved in the insurance underwriting process was too complex for any computer to handle as effectively as a human underwriter (Holtom, 1981).

Recent research in the application of technology to the underwriting process has shown that Holtom's statement may no longer hold true (Kitchens, 2000; Lemaire, 1985; Rose, 1986). The time for computers to take-on an important role in the insurance underwriting judgment process may be here. The author intends to illustrate the applicability of artificial neural networks to the insurance underwriting process.

BACKGROUND

The American Institute for Chartered Property Casualty Underwriters reports that the most common considerations found in automobile underwriting guidelines are: age of operators, age and type of automobile, use of the automobile, driving record, territory, gender, marital status, occupation, personal characteristics of the operator, and physical condition of the vehicle. Traditionally, these comprise the basic variables used in determining the acceptability, classifying, and rating of private passenger automobile insurance policies (Malecki & Underwriters, 1986).

Private passenger automobile insurance is well suited for artificial intelligence applications applied to the underwriting function. There are three primary reasons for this: there is a fixed set of finite data used to make the underwriting decision; policies are highly standardized; and deviations from the standard insurance contract are rare.

In recent years, researchers have considered the application of computers to the process of automobile insurance underwriting. Two studies attempted to predict the acceptability of a given policy from a broad underwriting standpoint (Gaunt, 1972; Rose, 1986). Two other studies considered the possibility of predicting a loss on an individual-policy basis (Lemaire, 1985; Retzlaff-Roberts & Puelz, 1966). Another study focused the relationship between premium and customer retention from year-to-year. One study was designed to predict losses on individual policies using artificial neural networks (Kitchens, 2000).

The recent use of artificial neural networks represents what may result in the most accurate application of computers in the underwriting process. Originally developed in the 1940's, artificial neural networks were designed to replicate and study the thought process of the human brain (Cowan & Sharp, 1988). Early research showed that all processes that can be described with a finite number of symbolic expressions could be represented with a finite number of interconnected neurons (Whitley, Starkweather et al., 1990). Thus, artificial neural networks also provide a means of economic problem solving.

The author believes that for a number of reasons discussed in the following section, artificial neural networks can be successfully applied to the insurance underwriting process in order to reduce the ratio of insurance losses to insurance premiums.

NEURAL NETWORKS FOR INSURANCE UNDERWRITING

Artificial neural networks were first developed in the 1940's as a mathematical model used to study the human thought process (Cowan & Sharp, 1988). McCulloch and Pitts in 1943 proved that all processes which can be described with a finite number of symbolic expressions can be represented in a network of interconnected neurons (Whitley, Starkweather, & Bogart, 1990). This makes the artificial neural network a mathematical modeling tool in addition to a representation of the human brain.

Using a data set consisting of dependent and independent variables, an artificial neural network can be trained until it converges on an optimal solution for the dependent variable(s). If properly developed, the resulting model will be at least as accurate as traditional statistical models (White, 1989).

The insurance business, as practiced in the United States, has certain characteristics that produce less than optimal financial results. There are five basic reasons that the unique abilities of artificial neural networks can improve the underwriting process:

First, an artificial neural network model will be successful because the inequity of the current rate classification system will allow neural networks the opportunity to more accurately assess the risk level of each and every individual policy holder, rather than a class of policy holders (Wood, Lilly et al., 1984).

Second, an artificial neural network model will produce improved results because current actuarial methods of study will benefit from the broad range of available tools " such as more recent developments in the field of artificial intelligence (Cummins & Derrig, 1993; Kitchens, 2000).

Third, an artificial neural network model will improve the current state of actuarial research. Traditionally, the primary method of research in this field has been to predict the *pure premium* (the amount of premium required to pay all of the losses in a given class of insured accounts, a.k.a. "relative rates"). In comparison, *actual premiums* include the pure premium along with other important factors such as profit margin and operating expenses. The traditionally used pure premium models follow an actuarial approach, but not necessarily an underwriting approach. While it is intended to reduce corporate loss ratios, current actuarial research does not take an underwriting approach to the process. A fresh perspective on the problem could produce improved results.

Fourth, an artificial neural network will produce improved results because historically, statistical models used in predicting insurance losses have been able to produce only marginal incremental improvements. Given the current state of technology, the time has come for new insurance actuarial models to take advantage of the available speed and flexibility of artificial neural networks to solve what is clearly a complex problem, which will require extensive training and is likely to involve a complex architecture (Kitchens, 2000).

Fifth, even if the actuarial models are "perfect" (which the author contends they are not), the neural network should be capable of at least matching the current statistical results, if not improving upon them. This is because artificial neural networks comprise a class of nonlinear statistical models whose processing methods are designed to simulate the functioning of the human brain (Hawley, Johnson et al., 1990). The advantage of neural network models over other modeling methods grows with the complexity of the relationship between input and output variables; however, greater complexity of the underlying relationships between variables requires a more complex design (Lee, White et al., 1993). Provided the appropriate network architecture, a neural network output function can accurately approximate any mathematical function (White, 1989). Further, a model can achieve any degree of desired accuracy if the neural network is properly designed (Funahashi, 1989).

NEURAL NETWORK MODELS: DESIGN ISSUES

Automobile accidents occur with a certain degree of randomness, and it is expected that they will be very difficult to predict on an individual-policy basis. Previous research has shown that an underwriter's ability to predict the actual value of a paid claim is exceedingly difficult, if possible at all (Kitchens, Johnson et al., 2001). However, a successful system needs only to predict the incident (occurrence) of a loss, not the dollar value. In addition, a successful model would not have to predict each and every accident, as long as the predictions that the model makes are accurate. In fact, a new model needs only to outperform any current models, in order to prove its self worthwhile. As an industry rule-of-thumb, the average loss-to-gross-premium ratio is approximately 60%. The rest of the collected premium is used to pay operating expenses and a small profit of approximately 3%. Thus, if a new model could reduce losses by 1%, it would represent a 33% increase in operating profit. If a corresponding decrease in operating expenses such as loss-adjustment expenses is incurred, the operating profit could be increased by as much as 53%. This in itself is not a justification for using artificial neural networks, but it is enough incentive to try nontraditional techniques.

While it is theoretically possible for a computer program to handle the underwriting function, a reliable model has not yet been developed. Aside from the practical development, the human-side must also be considered. It will take time for society, insurance regulators, and the insurance industry to understand and accept a computer-based underwriting model. The development of a computer-based model that might aid the underwriter in the decision making process will be a good first step. An artificial neural network as an underwriter's tool could be used in several ways " to confirm an underwriter's decision; to provide a suggested course of action; or to handle routine policies, allowing the underwriter to spend more time on more complex policies. As an underwriter's tool, a model should be useful, reliable, and convenient while providing information of value. While there may be many methods of designing such a tool, the author believes that artificial neural networks hold the greatest likelihood of success.

In the development of an artificial neural network model as an underwriter's tool, several things must be determined: the output required, the input variables, the type of artificial neural network, the architecture of the artificial neural network, and the interpretability of the output.

The underwriter's decision-making process boils down to two basic decisions. First, he must decide whether to accept or reject the risk. Second, if accepted, a decision as to the premium that will be charged must be made.

Depending on the purpose of the model, the required output may place stringent requirements on the required input. One reason all previous models have had limitations on their applicability has been due to the lack of quantity or quality in the available data sets used to generate the model.

For purposes of insurance loss-prediction modeling, the Genetic Adaptive Neural Network (GANNT) algorithm is an appropriate choice. The GANNT algorithm is designed to overcome difficulties associated with the popular gradient and backpropagation techniques (Dorsey & Mayer, 1994).

The genetic algorithm was first proposed in 1975 (Holland, 1975; Nygard, Ficek et al., 1992). It was shown that the biological evolutionary process could be applied to an artificial mathematical modeling system (Konza, 1992). The concept is based on the theory that an optimization problem can be encoded as a list of concatenated parameters (nodal weights), which are used in the artificial neural network (Whitley, Starkweather et al., 1990). The genetic algorithm works through a process of modeling founded on the biological process by which DNA replicates, reproduces, crosses over, and mutates (Crane, 1950). These procedures are then modeled in a computer-based algorithm to solve complex problems (Nygard, Ficek et al., 1992). The actual operations of the genetic adaptive neural network training algorithm are explained in detail by Dorsey, Johnson, and Mayer (1991).

RESULTS

Recent research has shown that the automobile insurance underwriting process practiced in the United States is lacking in precision. Underwriters are not efficiently utilizing all of the information available to them. The current human-based underwriting process uses only a portion of the available information. In some cases, so much valuable information is overlooked that the remaining unutilized information can be used to make a more accurate accept/reject decision than the initial underwriter made (Kitchens, 2000). With the benefit of the flexibility and adaptability of an artificial neural network, the unutilized information may be used in the future to make more accurate and more precise underwriting decisions.

FUTURE TRENDS

Future research should be focused on two primary areas. First, to be properly trained, an artificial neural network requires data from both the "accepted" and the "unaccepted" policies. Thus, some effort needs to be focused on obtaining information about the policies that are currently being rejected by the underwriter. This is difficult information to obtain because insurance companies have no reason to track losses on policies they previously rejected. But, this data will be valuable in the development of a more complete underwriting model.

Second, future research should go beyond the accept-or-reject decision, and investigate the premium-setting decision. A model capable of second-guessing an underwriter's accept-or-reject decision might be capable of reducing an insurance company's losses. But, a model that can both accept-or-reject, and set the premium, might be capable of reducing the cost of underwriting, streamline the business process and produce policies that are more appropriately-priced.

CONCLUSION

Since insurance underwriting began 400 years ago, until recently, the biological neural network (human brain) has been the fastest, most efficient, and most readily available information processing tool available. It has naturally been the tool of choice for underwriters when making accept-or-reject and pricing decisions on insurance policies.

In 1981, it was a common belief that computers could not be used to replace insurance underwriters (Holtom, 1981). In the past 20 years or so, computers and technology have made tremendous advancements. During the same time period, sophisticated mathematical models and the algorithms used to generate them, including the Genetic Adaptive Neural Network Training Algorithm, have taken advantage of increased computing power and availability. Artificial neural networks and the technology used to run them have been shown to out perform the traditional human-based mental decision making practices, in both speed and accuracy; if only for limited domains and applications, such as insurance underwriting.

KEY TERMS

Actuary: A statistician who practices the collection and interpretation of numerical data; especially someone who uses statistics to calculate insurance premiums.

Artificial Neural Network: (commonly referred to as "neural network" or "neural net") A computer architecture, implemented in either hardware or software, modeled after biological neural networks. Nodes are connected in a manner suggestive of connections between the biological neurons they represent. The resulting network "learns" through directed trial and error. Most neural networks have some sort of "training" algorithm to adjust the weights of connections between nodes on the basis of patterns found in sample or historical data.

Backpropagation: A learning algorithm for modifying a feed-forward neural network which minimizes a continuous "error function" or "objective function". Back-propagation is a "gradient descent" method of training in that it uses gradient information to modify the network weights to decrease the value of the error function on subsequent tests of the inputs. Other gradient-based methods from numerical analysis can be used to train networks more efficiently.

Biological Neural Network: A network of neurons that function together to perform some function in the body such as thought, decision-making, reflex, sensation, reaction, interpretation, behavior, and so forth.

Genetic Algorithm (GA): A class of algorithms commonly used for training neural networks. The process is modeled after the methods by which biological DNA are combined or mutated to breed new individuals. The crossover technique, whereby DNA reproduces itself by joining portions of each parent's DNA, is used to simulate a form of genetic-like breeding of alternative solutions. Representing the biological chromosomes found in DNA, genetic algorithms use arrays of data, representing various model solutions. Genetic algorithms are useful for multidimensional optimization problems in which the chromosome can encode the values for connections found in the artificial neural network.

Insurance: Protection against future loss. In exchange for a dollar value (premium), insurance is a promise of reimbursement in the case of loss. Contractual arrangement of insurance may be voluntarily or by government mandate (such as minimum requirements for automobile insurance for licensed drivers).

Nodal Connections: Connections between nodes in an artificial neural network. They are communication channels that carry numeric data. They simulate the axons and dendrites used to carry electrical impulses between neurons in a biological neural network.

Node: A mathematical representation of a biological neuron. Multiple layers of nodes are used in artificial neural networks to form models of biological neural networks.

Risk: An individual or organization's exposure to a chance of loss or damage.

Underwriter (Insurance Underwriter): An employee of an insurance company whose job duties include analyzing an application for insurance and making a decision whether to accept or reject the application. If accepted, the underwriter further determines the premium to be charged. Underwriters also review existing insurance contracts for renewal.

A

Assessing the Value of Information Systems Investments

Charlene A. Dykman
University of St. Thomas, USA

INTRODUCTION

Accurate assessment of the potential or realized value and impact of an information systems investment is becoming increasingly important. While hardware and software are, to a large extent, becoming commoditized, the overall cost of information systems projects continues to increase. Labor and other organizational costs continue to escalate. The result is that IS professionals must begin to view their systems projects with a business perspective. Such a business perspective includes the application of various quantitative approaches to assessing the value of information systems.

BACKGROUND

Strategies for success in an increasingly information and technology intensive business climate often include major investments in information systems, including hardware, software, networks, and personnel. Investments in information systems continue to rise in both percentage of operating budget and total dollars. And yet, significant early research showed no correlation between expenditures for information technology and any known measure of productivity (Brynjolfsson, 1993; Brynjolfsson & Hitt, 1996; Landauer, 1995; Strassman, 1990, 1997a; Weill, 1992). Although a major expenditure, most companies do not calculate the return on investment (ROI) of the information system investment like they do with other major expenditures. Nor is there much consideration of the social/subsystem cost and benefits of major information systems investments (Ryan, Harrison & Schkade, 2002). Why not?

In the technology and business climate of today, executives, in many cases, seem to have bought into the idea that they have no choice. We see small organizations making major investments in monolithic ERP systems such as SAP and PeopleSoft. Executives seem to have been convinced, by their IS staff, by the vendors, and by the media hype about leading edge technologies, that they must implement the latest fad or methodology in order to remain competitive. We seem to have forgotten that these types of investments are "business" and "organizational" decisions rather than simply "technology" decisions. There is clearly a need to use standard business practices in evaluating the potential costs and benefits of our investments in information systems and the associated technology (Davis, 2002; Talon & Gurbaxani, 2000).

Just as expenditures rise, many information systems projects are judged as failures. We hear repeatedly that information systems fail to deliver on the promises made and the expectations generated. These failures result in a costly mistake for the organization and the project manager. When projects fail, the dollars invested have been wasted and there is a clear impact on the bottom line of the organization. Additionally, several researchers have found that the intangible costs can also be very significant. This is known as the social subsystem cost and many researchers opine that these costs need to be more seriously considered (Ryan, Harrison & Schkade, 2002).

But what if the project is a success? The chairman of the board has just asked you how much of the investment has delivered quantifiable benefits, since your company has just spent eight months and millions of dollars implementing a new business application. Trying to justify expenditures is very common practice in business. It is relatively easy to quantify and justify expenditures for a piece of manufacturing equipment, additional personnel, or payroll processing systems. Trying to quantify and justify an integrated information system (IS) is not quite as easy. Many of the benefits realized from an IS are intangible and managers are not quick to recognize such benefits, just as they often undervalue such benefits. Some recent researchers have begun to show a payoff for IT investments (Brynjolffson & Hitt, 1995; Dewan & Min, 1997; Hitt & Brynjolfsson, 1996; Stratopoulos & Dehning, 2000). However, it is not clear when and where these payoffs will be found. Many business executives balk at measuring the value and performance of something so intimidating, complex and, well, so technical. However, a bottom line focus is really required, especially in organizations that have a very public image to present.

The information systems arena is facing continued scrutiny, due to the escalating costs that seem to spiral out of control. Stakeholders cannot afford to ignore assessment of the value of information systems, given the huge amount of expenditures invested in these systems. As the technology sector on Wall Street has come under increasing scrutiny, organizations have become extremely cost conscious. Some researchers urge that stock market impact must be evaluated, especially as these investments relate to e-commerce and/or outsourcing (Hayes, 2000; Subramani & Walden, 2001). Not only have IS expenditures skyrocketed over the past few years, but also internal corporate departments have become much more aware of the charges incurred through chargeback algorithms over which they have little control. This directly impacts the bottom line of the firm. If we are serious about being good stewards of the organization's resources, changing the approach to information technology investment decisions can decrease expenses and increase revenue opportunities.

ASSESSING THE BENEFITS OF AN INFORMATION SYSTEM INVESTMENT

Determination of the benefits and quantification of their projected value to the organization is a multifaceted task that is still more art than science. In fact, Ryan et al. (2002) found that there is a tendency for executives to view the post-implementation benefits as being more important than the implementation costs. There is renewed interest in establishing formal processes for managing IT investments due to the history of large capital investments with poor track records for success and perceptions of low return in value to the organization (Kim & Sanders, 2002). The ultimate value of IT is how it impacts business processes in line with the strategy of the organization. A good business case for an investment will show the appropriate linkage to this strategy. There are a variety of methods used to assist in this valuation:

- No justification: This includes a summary of operating and capital costs for the project and ongoing use of the system. There is no benefits analysis. This is used, and rightly so, for "cost of doing business" projects. Unfortunately, the real problem surfaces when every information systems investment decision is lumped into the "cost of doing business" group. This is an easy way to avoid scrutiny of the real expected cost or payoff from this investment. Senior general management in the firm must limit projects that fall into this "loophole" in order to accurately assess the costs and benefits of their IT investments.
- Total cost of ownership: This method is often used by consulting firms and includes the summation of all costs (purchase, operation, maintenance, and disposal of technology) to compare costs within a product line. Notice again that there is only a focus on costs, not on the organizational benefits to be derived from this investment.
- Financial metrics: These methods focus on costs and benefits in financial terms, including interest rate information and the time value of money. Several researchers have stressed the importance of accounting techniques in valuing IT investments (Dehning & Richardson, 2002). Several key financial indicators, also known as accounting performance measures, should be used in financial analysis. These include the net present value (NPV), return on investment (ROI) and the internal rate of return (IROR) calculations. Real option evaluation includes the notion of uncertainty and risk (Li & Johnson, 2002). The question that is asked with real option evaluation is whether making the investment today has enough net present value to make up for losing the option to delay the investment (Carlsson & Fuller, 2000). Microsoft's Rapid Economic Justification Model, through a five-step process of discernment, attempts to align IT investments with the success of the business by defining critical success factors, assigning probabilities to risks, and so forth. This approach is quite comprehensive, but hardly rapid.
  While appealing, the big risk with financial metrics is "spurious exactitude". We tend to believe, because there is a number associated with something, that we are really able to measure the phenomenon quantitatively. While it is imperative that we take a hard dollar approach to these hard to define and difficult to quantify variables, we must not lose sight of the threat to the validity of these results. Just because we cannot do it perfectly, does not mean that we should not do it. The process of such evaluation has a value in and of itself, in requiring us to focus on the business, its goals and strategies and to break down the components of a project and discern the relationships between the project and the business goals.
- Information economics: This is a scoring method that addresses the value of the information that results from the use of the system. This is difficult to measure since information itself is an intangible. Additionally, information itself has no inherent value. Value can be derived only when information is applied to specific organizational processes. If we are, for example, trying to evaluate the benefit of governmental spending on major information systems to track terrorists, then we can easily see the value of the information that might be provided. This is often compounded by that fact that the

information already exists in the organization, just not in as convenient a format, or in a way that it can easily be manipulated. At that point we are really looking at the "value-added" component of this investment.

- Balanced score card: This is a sophisticated management framework that translates strategy and vision into operational tactics. Measures and metrics for aligning processes with vision and the initiatives needed to meet the objectives of the business are identified. This complex method requires total organizational support to be successful. However, there is food for thought in just understanding the dimensions that are addressed by this method. We see once again the importance of the overall strategy of the organization in directing the investments made in the information systems arena.

FUTURE TRENDS

Investments in information systems represent major crossroads for 21st century organizations. These decisions are all unique decisions, at a point in time in the history of an organization and its competitive environment. Additionally, this point in time perspective is true of the technology itself. How many projects have we all seen that took so long to get to completion that the technology was obsolete when it was finally implemented? We must move quickly and decisively in the business of information systems. This brings risks that must be minimized through:

- Alignment of the technological environment with the organization's strategic plan. Of course, this presupposes that the organization has a strategic plan that can be translated into clear operational goals and measurements with well-defined operational processes and systems solutions. The successful chief information officer will be working at a level, with corporate leadership, where he or she can influence this process.
- The framing of all information systems investments around business requirements rather than technology requirements. This is not about technology looking for organizational problems to solve. Planning does not begin with preconceived hardware and software recommendations.
- The establishment of performance improvement goals and holding managers accountable for meeting them. Even when the benefits of information systems investments are intangible, managers must be measured against the accuracy of their tangible financial projections and the impacts on the social subsystem. These projects must be incorporated into the operating budget and long-term financial plan for both the IS function and the overall organization. Every investment must be justified with concrete revenue (benefit) and expense commitments.

CONCLUSION

Though the costs associated with implementing a new information system may seem exorbitant, the costs associated with delaying or not installing a new system (lost opportunity costs) may be even more devastating to an organization. As the use of information systems technology increases in most industries, so do the capital expenditures. Even though the cost of computer technology is becoming more affordable, the business process needs that can be addressed through information systems continue to increase. This contributes to the escalating aggregate costs of information systems.

It really is time for the academics to take a look at the various approaches to valuation of information systems projects and find out whether any of these are really working. We need to begin to understand the contingencies that are involved in deciding which approach to use for a specific project. In some ways, valuation of IT investments begins to look like economic impact assessments trying to determine the financial impact of, for example, a city hosting the Super Bowl or Olympics. Does anyone ever really see if these projections are accurate? Until we are able to do so in the realm of IT valuation, there will always be doubts about the numbers given in support of a project.

Determination of the benefits to be gained from a particular IS investment can be problematic, because information itself is an intangible. The various issues and approaches discussed in this article give an understanding of the questions that need to be asked and the information that needs to be gathered in order to begin the process of evaluating the potential benefits of an information systems investment. Remember that information systems investments are *business* decisions, not *technology* decisions. We must learn to make a business case in support of our recommendations and finally to compare the impact of the system to the expected benefits that were used to justify the investment in the first place. Finally, we must evaluate the accuracy of these projections after the information systems project is finished.

KEY TERMS

Accounting Performance Measures: Evaluation of the impact of information systems investments including typical accounting rations such as return on assets and return on equity.

Balanced Score Card: A management framework for translating strategy into tactics through identification of metrics for aligning processes with visions. Initiatives needed to meet the objectives of the business are identified.

Direct Impact: Information technology investments that can be evaluated as causally related to reduced cost or increased profits. For example, more effective management of inventory leads to reduced inventory carrying costs.

Indirect Impact: Information technology that is not clearly related to measurable impact. For example, a new system helps executives make better decisions through providing access to better or more accurate information.

Information Economics: A scoring method that assesses the value of the information that results from the use of an information system.

Market Performance Measures: Measures of impact that focus on event studies, market valuation of common equity, and Tobin's q as used to assess impact of investment in information systems technology.

Productivity Paradox: Major information technology investments with negative or zero documented returns. "Absence of positive relationship between spending on information technology and productivity or profitability" (Dehning, 2002).

Rapid Economic Justification Model: A Microsoft model that attempts to align information technology investments with the success of the underlying business through defining corporate strategy, critical success factors, project risks and impacts. Based loosely of the total cost of ownership approach to information technology investment evaluation.

Real Option Method: An evaluation approach that focuses on the notion of uncertainty and probability of risk. The theory is that a firm should invest today only if the net present value of the project is high enough to compensate for giving up the value of the option to delay the project.

Social Subsystem: The internal climate and culture of an organization, usually seen as several continua focusing on dimensions such as structure, randomness, stress, empowerment of individuals, knowledge-sharing, and so forth.

Strategic Relevance: A measure of the degree to which information systems directly facilitate the attainment of the organization's strategic goals.

Total Cost of Ownership: An evaluation method with a broad perspective on the costs of system ownership, including training, lost productivity during learning cycles, maintenance, and so forth. TCO methodologies bring into focus a softer side of the cost equation.

Audience Response Systems and Face-to-Face Learning

David A. Banks
University of South Australia, Adelaide, Australia

INTRODUCTION

Audience Response Systems (ARS) are gradually being introduced into educational settings, having previously proved their value in business. Hand-held keypads allow students to enter data in response to questions or statements displayed on a public screen. The captured data is displayed on the public screen and enables both academic and students to immediately see how the whole group has responded. The anonymity afforded by an ARS encourages individuals to fully participate without fear of ridicule or loss of face.

The technology is simple to use by both students and academics, can be used with large or small groups and has applications in all topics of study and at all levels of study. ARS are highly portable, require very little set-up time and are easy to use by anyone who has had some experience with software such as PowerPoint.

BACKGROUND

ARS developed within the general area of Computer Supported Collaborative Work (CSCW) and have been used in the business community since the late 1980's. Early work in the use of computer-based systems was concerned with providing managers with decision support tools that would provide support for, and improve effectiveness of, decision-making especially when dealing with semi-structured or unstructured situations. The systems were developed to be under the control of decision makers and support the process rather than attempt to automate it. Keen & Scott Morton (1978) initially described as Decision Support Systems they have also been described as Group Decision Support Systems (GDSS). Mallach (1994, p.7) defines a GDSS as "an information system whose primary purpose is to provide knowledge workers with information on which to base informed decisions". Young (1989, p.8) describes the key feature of such systems as being that "… they are intended to interact with and enhance the special mental capabilities of the user, thereby facilitating learning, creativity…". A key word in the name of these systems is "support", that is, they enhance the process they are supporting by providing rapid data capture, effective processing tools and immediate feedback to the participants as part of a broader human process.

The initial systems were based on personal computers and often appeared in networked laboratory-type settings but smaller hand-held systems using keypads were developed. From the early 1990's onwards these systems have been adopted by a growing number of businesses and are now most commonly described as ARS. The relatively low cost and ease of use meant that they attracted the attention of champions in organizations who often had a specific use for the system, often in the areas

Table 1. Typical uses for ARS in business

Quality (Self assessed, Baldrige, EQA…)	Control risk self assessment (CRSA)
Evaluating new product ideas	Budget and capital resource allocation
Corporate governance	Succession planning
Appointment interviews	Corporate ethics
Team building	Idea sharing, testing, approval
Conflict management	Customer value, customer satisfaction
Employee and customer focus groups	Stress management
Counselling related	Time and Project Management
Readiness for change	Benchmarking
Tapping employee wisdom	Product development

of quality self-assessment or team building. The initial emphasis on decision-making has now been broadened by recognition that these systems can provide support for a wide range of business processes. The feature of anonymity provided by these systems offers an opportunity for use in environments where there may be holders of widely differing levels of organisational power and authority engaged in discussion. The ease of use, portability, and flexibility in application provides an opportunity for groups to engage in a variety of reflective practices, with groups ranging from eight through to several thousand participants.

Typical business uses for these systems are shown in Table 1. Many of them offer great potential for adoption in higher education learning environments where they can be used as support tools in a variety of subject areas and teaching and learning philosophies.

PRACTICAL SYSTEMS

In practice these systems comprise hand-held input devices that transmit data to a receiving device connected to a personal computer. Software processes the data and presents it in a variety of formats to the participants for discussion. Key components of the system are:

- Hand-held input devices. A variety of sizes and designs exist, the credit-card size keypad (Figure 1) being typical of the most recent development.
- Receiver. Utilizes infrared or other wireless communication media to collect data from the keypads.
- Software. Manages collection and processing of data and supports display of the data in a variety of presentational formats. The software may be embedded in other container software such as PowerPoint. The output from the system is usually displayed on a public screen via a data projector (Figure 2).

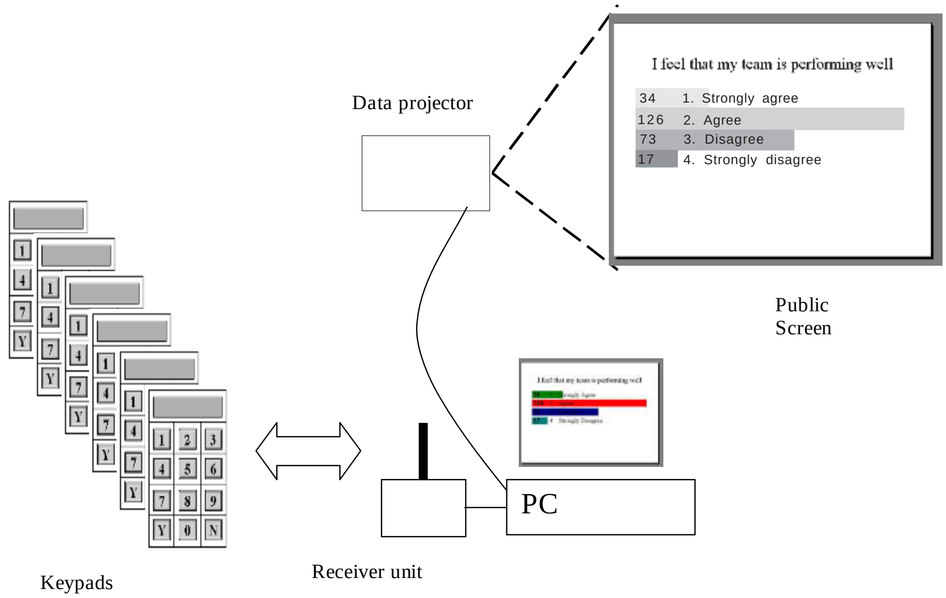
ARS IN HIGHER EDUCATION

The purpose of an ARS is to provide a system and set of tools that can support groups engaged in a face-to-face process that involves examining propositions, exploring alternatives and obtaining timely feedback from the participants engaged in the process. Draper and Brown (2004, p20) suggest that "The dream of personal teaching is really about adaptive teaching; where what is done depends on the learner's current state of understanding". ARS can provide timely feedback to support this adaptive

Figure 1. Credit-card size keypad (image courtesy of KEEpad Pty Ltd)

teaching goal, but Draper and Brown make the point that this can only be achieved through appropriate pedagogic design and action and not through the technology alone. In one-to-one or small group settings the learning facilitator may have a sense of the current state of the learner if the learner feels sufficiently comfortable in revealing it. With large groups in more formal settings the availability of cues to the learning facilitator can be more limited. The immediate feedback that an ARS offers can publicly identify differences or similarities of opinion within groups and provide a trigger for further discussion or analysis of data and re-adjustment of pacing or content. ARS can be used with both large (hundreds of participants) and small groups to support lectures, workshops, seminars, and to explore a wide range of subjects. They can be used at undergraduate and postgraduate levels, and within traditional and post-modern paradigms. Subject areas that value discussion, debate, multiple interpretations and direct challenges to accepted wisdom can benefit from this technology, but equally an ARS can be used in subject areas where demonstration of understanding of a fixed body of knowledge is vital. ARS can be used for formative and summative assessment, in the gauging of preliminary level and subsequent stages of understanding of a subject and in the exploration of the concepts that underpin critical issues.

Figure 2. Component parts of an ARS



Mitchell (2001) suggests that ARS can be used for mechanistic purposes such as monitoring class attendance via individual handsets, providing instant marking and feedback and for gathering data that can be used to support research activities related to classroom processes. McCabe, Heal and White (2001) used an ARS to support Computer Assisted Assessment (CAA) approaches with mathematics students and consider that it not only reinforced existing CAA activities but also served as a valuable tool for motivating higher levels of student learning. Hunt, Irving, Read and Knight (2003) used an ARS in a first-year information systems unit, in a decision-making subject in a third-year psychology course and also with second-year BSc Pharmacy students. In the pharmacy course questions were posed via the ARS and the resulting answers were displayed and discussed by the whole group. A key issue here is that what is being sought is not necessarily a "correct" answer but instead an examination and exploration of all possible answers and the reasons that individuals give for selecting a specific answer. The students expressed enthusiasm for the system, particularly in its ease of use, the ability to discuss answers immediately after making their choice and in the way it helped students identify where further reading was required. Importantly they also found it to be both easy and fun to use.

Post graduate HRM and MBA students using case-based approaches supported by an ARS indicated that the level of participation and number of ideas generated and explored was greater than usual and that the influence of individual personalities was greatly reduced (Jones, Gear, Connolly & Read, 2001). The students also observed that the technology was simple to use and to some extent became "invisible" to the users. Williams (2003) notes that students on an MBA course using an ARS were strongly in favour of the technology and had negative views about passive learning approaches that simply involved reading or listening. Uhari, Renko and Soini (2003) report that 80% of students studying a pediatric's course felt that an electronic voting system helped improve their learning and enhanced questioning during lectures. Witt (2003) found that 87% of students studying in a statistics for psychologists course saw more benefits than disadvantages in the use of keypads.

In a session run by the author in 1995 an ARS was used to explore students' evaluation of an engineering course (Banks, 2001). Students scored each item of the course feedback instrument using individual keypads instead of the normal paper and pencil approach. Once all items were completed they were worked through again, the students being shown the distribution of their scores and invited to comment. It quickly became evident that the criteria used to generate the scores differed widely from student to student and some discussion took place about what common and appropriate criteria might be. After some discussion the items were scored again and it was noted that greater consensus was evident in the second data set. This approach provided an opportunity for students to develop a common understanding of the criteria used in course evaluation and thus generated a more consistent interpretation of the evaluation instrument. The students found the opportunity to discuss their individual and collective views of the course to be a valuable experience.

The author has more recently used ARS to support peer review session in a Collaborative Information Systems Masters course (Banks, 2003). In this course students work in small groups collaboratively producing conference-style papers and peer review is an integral part of the learning process. Peer review was originally summative and was carried out by means of a paper-based instrument. In response to a student suggestion, a “diagnostic” electronic peer review session was introduced early in the course. This offers an opportunity for students to become aware of the perceptions of their peers of their performance against a number of agreed group performance indicators. The use of this diagnostic session allows problems to be surfaced and identified, solutions discussed and action plans developed before any major tensions affect the groups. The author has also used an ARS to support a “lost in the desert” scenario (Banks and Bateman, 2004) that allows groups to see how individuals and groups perform and to act as a trigger for discussion of issues of communication, trust, negotiation, and teamwork in general.

ISSUES IN THE USE OF ARS IN HIGHER EDUCATION

Benefits of Anonymity

In groups where a number of different cultures are represented there is a danger that in traditional face-to-face settings some students will not offer an answer for fear of “loss of face”. Some shy students may also feel inhibited in large groups and thus not feel able to contribute to the discussion. The anonymity afforded by an ARS provides an opportunity for these potentially disadvantaged students to fully participate in the learning process. The author has noticed that in small group peer review sessions, there is a tendency for overseas students to talk quite comfortably to the data on the screen rather than feel personally challenged. The system appears to offer a decontextualisation of the student data and permits a more open discussion than has been experienced with traditional face-to-face peer review sessions. On the other hand, anonymity can mean that students enter data mischievously, safe in the knowledge that they cannot be identified.

More Than Just the Numbers

For in-class summative tests the ability to use an ARS to collect numeric data from the individual keypads is an obvious asset. However, in more discursive learning environments the distribution patterns of the data can form a trigger for critical discussion. The issue is not what the average or mean score is, but in trying to determine why a particular pattern of data is captured. Differences in scoring patterns by students suggest differing worldviews or interpretations of the data and this provides an opportunity for reflection, sharing of views, critical thinking and deep learning.

Educational Paradigm

This technology can be used with any subject, at any level of education and within any educational paradigm. The paradigm that appears to be common to most current users of ARS is that of constructivism.

Constructivist approaches are based on the premise that learners should engage in active construction of their own knowledge rather than passively receive the views of others. This process requires that learners engage in critical and reflective behaviour and this takes place in response to interactions with other individuals as part of a social sense-making process. The emphasis in terms of teaching moves away from a “sage on the stage” model with lectures as information delivery mechanisms, towards a “guide on the side” model where the focus is upon challenge or justification of prevailing views. The approach exposes students to new experiences and modes of thinking and enables them to examine their own ideas and to determine the extent to which the new experiences make sense in the light of these ideas. They are also encouraged to consider the number of possible alternative explanations for what they have experienced and to evaluate the usefulness of a number of different perspectives (Dufresne, Gerace, Leonard, Mestre & Wenk, 1996). This critical process can take place within a structured learning environment through “justificatory arguments” which are “brought forward in support of assertions, in the structures they may be expected to have, the merits they claim and the ways in which we set about grading, assessing and criticising them” (Toulmin, 1958, p.12). ARS can provide a valuable support mechanism for such approaches.

Question, Then Question Again

By asking a question a number of times and critically evaluating the distribution of the ARS responses it becomes possible to explore the reasons for the differing or changing responses. Gauging the responses of students through the use of an ARS allows for quick and multiple loops around the material if learning appears to be problematic. d'Inverno, Davis and White (2003) report that the use of an ARS suggests that typically around 40% fail to identify the correct answer to simple questions, and that if the same question is asked again around 20% still provide the wrong answer. (They do, however, suggest that there may be some deliberate entry of incorrect answers as not all students feel that the technology offers them benefit.)

Over-Use of the Technology

Over-use or inappropriate use may trivialise the technology and lead to student dissatisfaction. The software for ARS typically interfaces with PowerPoint, and the risk of building a mechanized performance rather than genuinely engaging the learner must be borne in mind. As with any technology it should only be used when it offers a tangible benefit to the process.

Accessibility/Equity for All Students

One potential problem with the introduction of an ARS is that of the provision of the keypads for students. Even though the cost of keypads is already low, and falling, the provision of one keypad per student clearly represents a large investment and technology management issue for an educational institution. Ownership of keypads by the institution also raises the problem of issuing and collecting the keypads before and after learning sessions, maintenance and so on. On way to overcome this problem is to make the students responsible for the keypads. This can be achieved through the currently developing approach of providing students with shrink-wrapped packages of textbooks and keypad, the cost of the keypads being built in to the package purchase price.

FUTURE TRENDS

ARS have shown a dramatic growth in recent years. The increased availability of such technology combined with falling prices and innovative distribution models such as shrink-wrapping with textbooks should encourage more educators to adopt ARS. The simplicity of use and natural integration with all subject areas and teaching styles should ensure the painless adoption of the technology across institutions. Such widespread adoption will mean that students feel that the purchase of personal keypad systems represents a good investment.

In the near future, systems that utilise personal digital assistant (PDA) technology and mobile phone technology will add text input, further increasing the versatility and power of these systems. There are many research questions to be explored as this technology is introduced. These will include the potential for the use of the technology to promote deep learning, the long-term reactions of students to the technology versus the initial novelty factor, the effectiveness at different levels of study and in different subjects, and many other areas of concern will offer many opportunities for investigation. The use of frequent in-course evaluations rather than a single exit evaluation will allow student concerns to be addressed in a more timely way and will also allow discussion to take place between teacher and learner about both the evaluation instrument and the meaning of the captured data.

The ARS itself will provide a vehicle to support the gathering of research data in actual teaching and practice. The availability of data immediately after a session has been conducted should allow timely adjustments to be made in pacing and content.

CONCLUSION

Considerable time and effort is being invested in distance learning via the web, but it is equally important that the benefits of technology are applied to support and enhance more traditional face-to-face learning environments.

ARS provide educators with an opportunity support their existing teaching and learning strategies in a way that provides them with improved, immediate and dynamic insight to the progress of learners. Students have an opportunity to engage with learning in an active way that helps them see how they, and their peers, are performing on a moment-to-moment basis. The opportunities for learning to be a shared experience are improved and there is the potential for engagement with subject material at a deep level.

KEY TERMS

Anonymity: A feature of an ARS that can protect the identity of a participant.

Audience Response System (ARS): An electronic system designed to support and enhance face-to-face group interaction by means of individual hand-held communication devices.

Computer Supported Collaborative Work (CSCW): Use of computer-based technology, including ARS, to support group processes.

Constructivism: An educational approach that takes the view that knowledge must be constructed within the cognitive structure of each individual.

Group Decision Support System (GDSS): A collection of hardware and software used to support decision-makers.

Keypad: A hand-held device that allows a participant to communicate data to an Audience Response System.

Audience-Driven Web Site Design

Olga De Troyer
WISE Research Group, Vrije Universiteit Brussel, Belgium

INTRODUCTION

In the last few years, Web sites have evolved from a simple collection of hypertext pages towards applications supporting complex business processes. Although it is still easy to publish a couple of pages, more and more it is recognized that appropriate design methods are needed to develop more complex Web sites. In the past, Web sites were created opportunistically without prior planning or analysis, and without any regard for methodology, resulting in the classical maintenance problems and development backlog. At the same time, a new problem unknown in classical information systems emerged: competition for the visitor's attention. Especially for commercial Web sites, it is important to hold the interest of the visitors and to keep them coming back. As stated by usability expert Jakob Nielsen: "all the competitors in the world are but a mouse click away" (Nielsen, 2000). Much more than in "classical" software systems, the *usability* of Web sites is a primary factor for their success.

BACKGROUND

One way to deal with the usability of a Web site is by assessing the usability of the Web site and improving the Web site afterwards. There are different ways to assess the usability of a Web site. The techniques that can be used are mainly the same as those used in usability testing of classical user interfaces, for example heuristic evaluation, expert-based evaluation, experimental evaluation, interviews, questionnaires… (Nielsen & Mack, 1994). Another approach to enhance usability (and complementary to the first approach) is to use a Web site design method that ensures a higher usability. The first methods proposed for Web site design are HDM (Garzotto, Paolini & Schwabe, 1993) and its successors HDM2 (Garzotto, Paolini & Mainetti, 1993) and OOHDM (Schwabe & Rossi, 1995), and RMM (Isakowitz et al., 1995) were originally designed for hypertext applications or came from the database research community. These methods used database design methods like E-R (Chen, 1976) or OMT (Rumbaugh et al., 1991), and focused on the organization of the data to be presented on the Web site. These methods could solve to some extent maintenance problems, but they did not address usability. Essential for good usability in Web sites is meeting the needs of the (different) visitors. WSDM was one of the first Web site design methods to recognize this. This method was presented at the WWW7 conference (1998) as a "user-centered" design method for Web sites (De Troyer & Leune, 1998). The starting point in the approach is the set of potential visitors (audiences) of the Web site. The method recognizes that different types of visitors have different needs and that this should drive the design of the Web site rather than the organization of the available data. Later on (De Troyer, 2001), the authors renamed their approach from "user-centered" to "audience-driven" to avoid confusion with the term "user-centered" from the HCI (human computer interaction) field. In HCI, a user-centered approach refers to a design process in which users are actively involved (by interviews, scenario analysis, prototyping, evaluation…). This explicit involvement is not necessary in WSDM. Often, most of the Web site users will be unknown; they cannot be interviewed in advance and they cannot be involved in the development process. In the audience-driven approach as defined by WSDM, the users play a central role but it is not necessary to involve them actively in the design process.

APPROACHES TO STRUCTURE WEB SITES

When designing a Web site, there are two important questions to be answered:

1. What information and services should be provided?
2. How should all this information and services be structured?

There exist different approaches to answer these questions. One of them is the audience-driven approach. Two other possible approaches are the *data-driven* approach and the *organization-driven* approach.

In a data-driven approach, the data (and services) available in the organization (in databases, brochures, internal documents…) are the design's starting point. Following this approach, the structure of the Web site will reflect the way the data are structured and maintained in the organization and the content will parallel the internal data. The same applies for services or functionality. Forms available in the organization will be converted into e-forms, and the current way of working will be reflected on the Web site. The advantage is that structuring the Web site is easy and that management of the Web content can be done in parallel with the internal data. However, the disadvantages are: (1) the data are presented and organized the way they are used in the organization. This is not necessarily how people external to the organization need them; (2) some information may be missing because it was not available in the form of a specific document and the designers were not aware of the fact that users may need it; (3) all information and all services are offered to all users. As a consequence, visitors may be drowned in information.

In an organization-driven approach, the internal structure of the organization is the starting point: the structure of the Web site reflects the structure of the organization. This approach is often used for large organizations with a lot of divisions, for example a university Web site that reflects its internal structure into faculties, departments and research institutes. As for the data-driven approach, it is easy to structure the Web site and the development and maintenance of the different parts can be assigned to the different divisions of the organization. The disadvantage is that it may be very difficult for visitors not familiar with the internal structure of the organization to know where to look for information.

In the audience-driven approach, the information and services needed in the Web site are determined by the needs and requirements of the target audiences (users). Also the main structure of the Web site will be based on the different types of audiences. This last point differentiates the audience-driven approach from many so-called user-centered approaches. We illustrate this with a university Web site. Following the audience-driven approach, the university Web site would (at least) contain a part with general information interesting to all visitors; a part with information specific for students and lecturers; and a part containing information for researchers and third parties interested in research. This approach gives consideration to the fact that Web sites usually have different types of visitors that may have different needs. Clearly, such Web sites may have a higher usability than the one structured using a data-driven or organization-driven approach. However, the downside of the medal is that the effort needed to design the Web site is higher and that the task of maintaining may be spread over the organization (usually, there will be no one-to-one mapping from the structure of the Web site onto the structure of the organization).

AUDIENCE-DRIVEN APPROACH

To arrive at an audience-driven organization of the Web site, the different types of audiences and their needs are identified already in an early stage of the design process. This is done by looking at the activities of the organization and the roles people play in these activities. These people are the potential users of the Web site. Next they are classified into *audience classes* by collecting their requirements (information, as well as functional, and usability requirements). Users with the same information and functional requirements become members of the same audience class. Users with additional requirements form audience subclasses. In this way a hierarchy of audience classes can be constructed, which will be the basis for the main structure of the Web site. For each audience class, a separated *audience track* will be created. Such an audience track can be considered as a sub-site that will provide all the information and services needed by the members of this audience class. To fill in the detailed navigation and content of such a track, the requirements of the corresponding audience class are translated into task- and object models. A task model is defined for each information- and functional requirement of each audience class. Each task defined in the task model is decomposed into elementary tasks, and temporal relationships among the tasks are expressed. For each elementary task an object model (called "object chunk") is created, which models the information and/or functionality needed to fulfill the requirement of that elementary task. In the next step, the task models of an audience class are translated and combined into an audience track. All audience tracks together form the navigational model. The navigational model defines the conceptual structure of the Web site and describes how the members of the different audience classes will be able to navigate through the site and perform the tasks. Based on this conceptual structure, a page structure will be defined as well as the "look and feel" of the Web site. The aim is to create a consistent, pleasing and efficient look and feel for the conceptual design made by taking into consideration the usability requirements and characteristics of the audience classes. If needed, a logical data design (database schema, XML schema, etc.) is made by integrating the different object chunks. Finally, the Web site can be realized using the chosen implementation environment, for example, HTML or XML.

FUTURE TRENDS

In the last years, many different researchers have recognized the need to take the users into consideration during the development process and adopted either the user-centered approach from the HCI field (as in Cato, 2001; Lazar, 2001; McCracken & Wolfe, 2004) or an approach similar to WSDM's audience-driven approach with respect to the fact that it is necessary to give due attention to the users but not necessary to actively involve them in the design process (as in Bomsdorf & Szwillus, 2003; Brinck, Gergle & Wood 2002; Lengels, 2002). More and more, we see that methods and approaches for Web site design incorporate all the goodies known from user interface design and usability research. It is expected that both fields will continue to combine in the future (a good example of this is the book by McCracken & Wolfe, 2004) and will benefit from each other.

In addition, we think that it is useful to combine different approaches to structure Web sites to accommodate the different ways users are working. For example some people prefer to use a search engine to locate the information; others may be more comfortable with the data-driven approach, while in some situations an organization-driven approach may be more appropriate. We expect that it must be possible to combine all of them with the audience-driven approach in a single Web site.

CONCLUSION

There exist different approaches to elicit and structure the information and services in a Web site. In the audience-driven approach, this is done by taking the different audiences of the Web site as the starting point. This results in Web sites where the information and the services are organized according to the needs of the different audience classes. This may result in higher usability, which is a primary factor for the success of a Web site.

KEY TERMS

Audience Class: Group of target visitors of a Web site with the same requirements.

Audience-Driven Web Design: The different audiences and their requirements are taken as the starting point for the design of the Web site. The information and services in the Web site are organized around the different audience classes.

Audience Track: Part of the Web site that provides information and services specifically tailored to an audience class.

Data-Driven Web Design: The data available in the organization are taken as the starting point for the design of the Web site.

Organization-Driven Web Design: The structure of the organization is taken as the starting point for the design of the Web site. The structure of the organization is reflected in the Web site.

Usability: The extent to which a product or system can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use.

User-Centered Web Design: The requirements of the users of a Web site play a central role in the design process.

Audio Analysis Applications for Music

Simon Dixon
Austrian Research Institute for Artificial Intelligence, Austria

INTRODUCTION

The last decade has seen a revolution in the use of digital audio: The CD, which one decade earlier had taken over the home audio market, is starting to be replaced by electronic media which are distributed over the Internet and stored on computers or portable devices in compressed formats. The need has arisen for software to manage and manipulate the gigabytes of data in these music collections, and with the continual increase in computer speed, memory and disk storage capacity, the development of many previously infeasible applications has become possible.

This article provides a brief review of automatic analysis of digital audio recordings with musical content, a rapidly expanding research area which finds numerous applications. One application area is the field of music information retrieval, where content-based indexing, classification and retrieval of audio data are needed in order to manage multimedia databases and libraries, as well as being useful in music retailing and commercial information services. Another application area is music software for the home and studio, where automatic beat tracking and transcription of music are much desired goals. In systematic musicology, audio analysis algorithms are being used in the study of expressive interpretation of music. Other emerging applications which make use of audio analysis are music recommender systems, playlist generators, visualisation systems, and software for automatic synchronisation of audio with other media and/or devices.

We illustrate recent developments with three case studies of systems which analyse specific aspects of music (Dixon, 2004). The first system is BeatRoot (Dixon, 2001a, 2001c), a beat tracking system that finds the temporal location of musical beats in an audio recording, analogous to the way that people tap their feet in time to music. The second system is JTranscriber, an interactive automatic transcription system based on (Dixon, 2000a, 2000b), which recognizes musical notes and converts them into MIDI format, displaying the audio data as a spectrogram with the MIDI data overlaid in piano roll notation, and allowing interactive monitoring and correction of the extracted MIDI data. The third system is the Performance Worm (Dixon, Goebl, & Widmer, 2002), a real-time system for visualisation of musical expression, which presents in real time a two dimensional animation of variations in tempo and loudness (Langner & Goebl, 2002, 2003).

Space does not permit the description of the many other music content analysis applications, such as: audio fingerprinting, where recordings can be uniquely identified with a high degree of accuracy, even with poor sound quality and in noisy environments (Wang, 2003); music summarisation, where important parts of songs such as choruses are identified automatically; instrument identification, using machine learning techniques to classify sounds by their source instruments; and melody and bass line extraction, essential components of query-by-example systems, where music databases can be searched by singing or whistling a small part of the desired piece. At the end of the article, we discuss emerging and future trends and research opportunities in audio content analysis.

BACKGROUND

Early research in musical audio analysis is reviewed by Roads (1996). The problems that received the most attention were pitch detection, spectral analysis and rhythm recognition, areas which correspond respectively to the three most important aspects of music: melody, harmony and rhythm.

Pitch detection is the estimation of the fundamental frequency of a signal, usually assuming it to be monophonic. Methods include: time domain algorithms such as counting of zero-crossings and autocorrelation; frequency domain methods such as Fourier analysis and the phase vocoder; and auditory models which combine time and frequency domain information based on an understanding of human auditory processing. Recent work extends these methods to find the predominant pitch (e.g., the melody note) in a polyphonic mixture (Gómez, Klapuri, & Meudic, 2003; Goto & Hayamizu, 1999).

Spectral analysis is a well-understood research area with many algorithms available for analysing various classes of signals, such as the short time Fourier transform, wavelets and other more signal-specific time-frequency distributions. Building upon these methods, the specific application of automatic music transcription has a long research history (Chafe, Jaffe, Kashima, Mont-

Reynaud, & Smith, 1985; Dixon, 2000a, 2000b; Kashino, Nakadai, Kinoshita, & Tanaka, 1995; Klapuri, 1998, 2003; Klapuri, Virtanen, & Holm, 2000; Marolt, 1997, 1998, 2001; Martin, 1996; Mont-Reynaud, 1985; Moorer, 1975; Piszczalski & Galler, 1977; Sterian, 1999; Watson, 1985). Certain features are common to many of these systems: producing a time-frequency representation of the signal, finding peaks in the frequency dimension, tracking these peaks over the time dimension to produce a set of partials, and combining the partials to produce a set of notes. The differences between systems are usually related to the assumptions made about the input signal (e.g., the number of simultaneous notes, types of instruments, fastest notes, or musical style), and the means of decision making (e.g., using heuristics, neural nets or probabilistic reasoning).

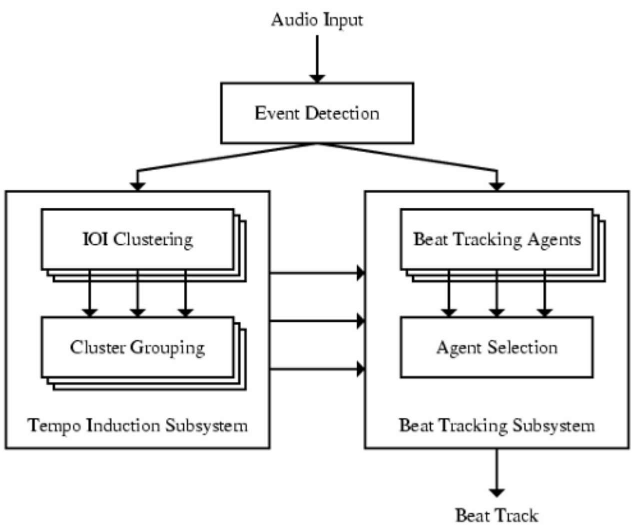
The problem of extracting rhythmic content from a musical performance, and in particular finding the rate and temporal location of musical beats, has also attracted considerable interest in recent times (Allen & Dannenberg, 1990; Cemgil, Kappen, Desain, & Honing, 2000; Desain, 1993; Desain & Honing, 1989; Dixon, 2001a; Eck, 2000; Goto & Muraoka, 1995, 1999; Large & Kolen, 1994; Longuet-Higgins, 1987; Rosenthal, 1992; Scheirer, 1998; Schloss, 1985). Previous work had concentrated on rhythmic parsing of musical scores, lacking the tempo and timing variations that are characteristic of performed music, but recent tempo and beat tracking systems work quite successfully on a wide range of performed music.

Music performance research is only starting to take advantage of the possibility of audio analysis software, following work such as Scheirer (1995) and Dixon (2000a). Previously, general purpose signal visualisation tools combined with human judgement had been used to extract performance parameters from audio data. The main problem in music signal analysis is the development of algorithms to extract sufficiently high level content, since it requires the type of musical knowledge possessed by a musically literate human listener. Such "musical intelligence" is difficult to encapsulate in rules or algorithms that can be incorporated into computer programs. In the following sections, three systems are presented which take the approach of encoding as much as possible of this intelligence in the software and then presenting the results in an intuitive format which can be edited via a graphical user interface, so that the systems can be used in practical settings even when not 100% correct. This approach has proved to be very successful in performance research (Dixon et al., 2002; Goebl & Dixon, 2001; Widmer, 2002; Widmer, Dixon, Goebl, Pampalk, & Tobudic, 2003).

BEATROOT

Compared with complex cognitive tasks such as playing chess, beat tracking (identifying the basic rhythmic pulse of a piece of music) does not appear to be particularly difficult, as it is performed by people with little or no musical training, who tap their feet, clap their hands or dance in time with music. However, while chess programs

Figure 1. System architecture of BeatRoot



compete with world champions, no computer program has been developed which approaches the beat tracking ability of an average musician, although recent systems are approaching this target. In this section, we describe BeatRoot, a system which estimates the rate and times of musical beats in expressively performed music (for a full description, see Dixon, 2001a, 2001c).

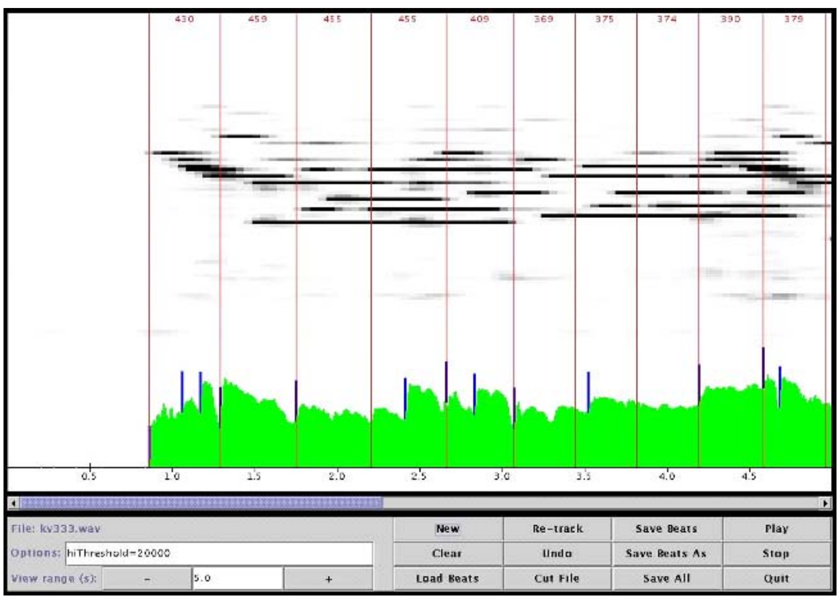
BeatRoot models the perception of beat by two interacting processes (see Figure 1): The first finds the rate of the beats (tempo induction), and the second synchronises a pulse sequence with the music (beat tracking). At any time, there may exist multiple hypotheses regarding each of these processes; these are modelled by a multiple agent architecture in which agents representing each hypothesis compete and cooperate in order to find the best solution. The user interface presents a graphical representation of the music and the extracted beats, and allows the user to edit and recalculate results based on the editing. Input to BeatRoot is either digital audio or symbolic music data such as MIDI. This data is processed off-line to detect salient rhythmic events, using an onset detection algorithm which finds peaks in the slope of the amplitude envelope of the signal (or a set of frequency bands of the signal). The timing of these events is then analysed to generate hypotheses of the tempo at various metrical levels.

First, inter-onset intervals (IOIs), the time differences between pairs of onsets, are calculated, and then a clustering algorithm is used to find groups of similar IOIs which represent the various musical units (e.g., half notes, quarter notes). Information about the clusters is combined by identifying near integer relationships between clusters, in order to produce a ranked list of tempo hypotheses, which is then passed to the beat tracking subsystem.

The beat tracking subsystem uses a multiple agent architecture to find sequences of events which match the various tempo hypotheses, and rates each sequence to determine the most likely sequence of beat times. Each agent represents a specific hypothesis about the rate and the timing of the beats, which is updated as the agent matches the detected onsets to predicted beat times. The agent also evaluates its beat tracking, based on how evenly the beat times are spaced, how many predicted beats correspond to actual events, and the salience of the matched events, which is calculated from the signal amplitude at the time of the onset. At the end of processing, the agent with the highest score outputs its sequence of beats as the solution to the beat tracking problem.

BeatRoot is written in Linux/C++, and comprises about 10,000 lines of code, with a graphical user interface consisting of 1,000 lines of Java. The user interface allows playback of the music with the beat times marked by clicks, and provides a graphical display of the signal and the beats with editing functions for correction of errors or selection of alternate metrical levels (Figure 2).

Figure 2. Screen shot of BeatRoot processing the first five seconds of a Mozart piano sonata, showing the inter-beat intervals in ms (top), calculated beat times (long vertical lines), spectrogram (centre), waveform (below) marked with detected onsets (short vertical lines) and the control panel (bottom)



BeatRoot is open source software (under the GNU Public License), and is available from:

http://www.oefai.at/~simon/beatroot

The lack of a standard corpus for testing beat tracking creates a difficulty for making an objective evaluation of the system. The automatic beat tracking algorithm has been tested on several sets of data: a set of 13 complete piano sonatas, a large collection of solo piano performances of two Beatles songs and a small set of pop songs. In each case, the system found an average of over 90% of the beats (Dixon, 2001a), and compared favourably to another state of the art tempo tracker (Dixon, 2001b). Tempo induction results were almost always correct, so the errors were usually related to the phase of the beat, such as choosing as beats onsets half way between the correct beat times. Interested readers are referred to the sound examples at:

http://www.oefai.at/~simon

Presently, BeatRoot is being used in a large scale study of interpretation in piano performance (Widmer, 2002; Widmer et al., 2003), to extract symbolic data from audio CDs for automatic analysis.

JTRANSCRIBER

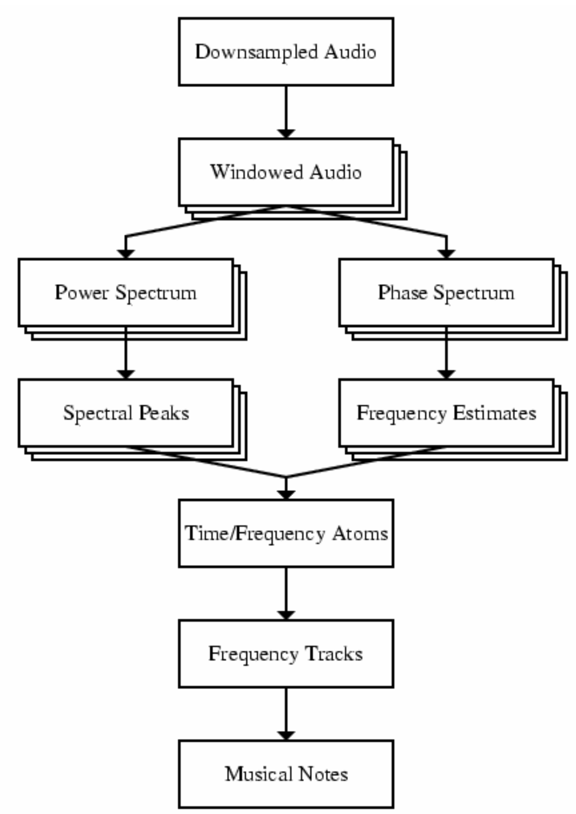
The goal of an automatic music transcription system is to create, from an audio recording, some form of symbolic notation (usually common music notation) representing the piece that was played. For classical music, this should be the same as the score from which the performer played the piece. There are several reasons why this goal can never be fully reached, for example, that there is no one-to-one correspondence between scores and performances, and that masking makes it impossible to measure everything that occurs in a musical performance. Recent attempts at transcription report note detection rates around 90% for solo piano music (Dixon, 2000a ; Klapuri, 1998; Marolt, 2001), which is sufficient to be somewhat useful to musicians.

A full transcription system is normally conceptualised in two stages: the signal processing stage, in which the pitch and timing of all notes is detected, producing a symbolic representation (often in MIDI format), and the notation stage, in which the symbolic data is interpreted in musical terms and presented as a score. This second stage involves tasks such as finding the key signature and time signature, following tempo changes, quantising the onset and offset times of the notes, choosing suitable enharmonic spellings for notes, assigning notes to voices in polyphonic passages, and finally laying out the musical symbols on the page. Here, we address only the first stage of the problem, detecting the pitch and timing of all notes, or in more concrete terms, converting audio data to MIDI.

The data is processed according to Figure 3: The audio data is averaged to a single channel and downsampled to increase processing speed. A short time Fourier transform (STFT) is used to create a time-frequency image of the signal, with the user selecting the type, size and spacing of the windows. Using a technique developed for the phase vocoder (Flanagan & Golden, 1966), a more accurate estimate of the sinusoidal energy in each frequency bin can be calculated from the rate of change of phase in each bin.

The next step is to calculate the peaks in the magnitude spectrum, and to combine the frequency estimates to give a set of time-frequency atoms, which represent packets of energy localised in time and frequency. These are then combined with the atoms from neighbouring frames (time slices), to create a set of frequency tracks, representing the partials of musical notes. Frequency tracks are assigned to musical notes by estimating the most likely set of fundamental frequencies that would give rise to the

Figure 3. Data processing steps in JTranscriber



observed tracks, and the pitch, onset time, duration and amplitude of each note are estimated from its constituent partials.

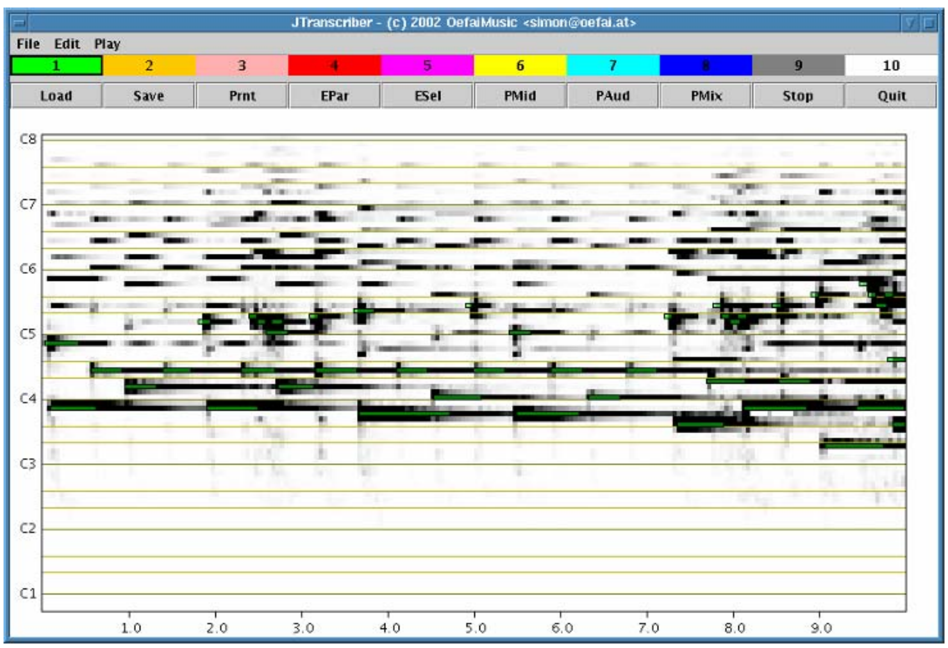
An example of the output is displayed in Figure 4, showing a spectrogram representation of the signal using a logarithmic frequency scale, labelled with the corresponding musical note names, and the transcribed notes superimposed over the spectrogram in piano roll notation. (The piano roll notation is colour and partially transparent, whereas the spectrogram is black and white, which makes the data easily distinguishable on the screen. In the grey-scale diagram, the coloured notes are difficult to see; here they are surrounded by a solid frame to help identify them.) An interactive editing system allows the user to correct any errors made by the automatic transcription system, and also to assign notes to different voices (different colours) and insert high level musical structure information. It is also possible to listen to the original and reconstructed signals (separately or simultaneously) for comparison.

An earlier version of the transcription system was written in C++, however the current version is implemented entirely in Java. The system was tested on a large database of solo piano music consisting of professional performances of 13 Mozart piano sonatas, or around 100,000 notes (Dixon, 2000a), with the results that approximately 10-15% of the notes were missed, and a similar number of the reported notes were false. The most typical errors made by the system are thresholding errors (discarding played notes because they are below the threshold set by the user, or including spurious notes which are above the given threshold) and octave errors (or more generally, where a harmonic of one tone is taken to be the fundamental of another, and vice versa).

THE PERFORMANCE WORM

Skilled musicians communicate high-level information such as musical structure and emotion when they shape the music by the continuous modulation of aspects such as tempo and loudness. That is, artists go beyond what is prescribed in the score, and express their interpretation of the music and their individuality by varying certain musical parameters within acceptable limits. This is referred to as expressive music performance, and is an important part of Western art music, particularly classical music. The Performance Worm (Dixon et al., 2002) is a real-time system for tracking and visualising the tempo and dynamics of a performance in an appealing graphical format which provides insight into the expressive patterns applied by skilled artists. This representation also forms the basis for automatic recognition of performers' style (Widmer, 2002; Widmer et al., 2003).

Figure 4. Transcription of the opening 10s of the second movement of Mozart's Piano Sonata K332. The transcribed notes are superimposed over the spectrogram of the audio signal (see text). It is not possible to distinguish fundamental frequencies from harmonics of notes merely by viewing the spectrogram.

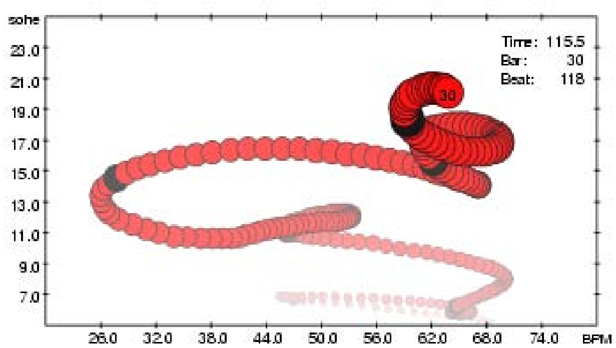


The system takes input from the sound card (or from a file), and measures the dynamics and tempo, displaying them as a trajectory in a 2-dimensional performance space (Langner & Goebl, 2002, 2003). The measurement of dynamics is straightforward: It can be calculated directly as the RMS energy expressed in decibels, or, by applying a standard psychoacoustic calculation (Zwicker & Fastl, 1999), the perceived loudness can be computed and expressed in sones. The difficulty lies in creating a tempo tracking system which is robust to timing perturbations yet responsive to changes in tempo. This is performed by an adaptation of the tempo induction subsystem of BeatRoot, modified to work in real time. The major difference is the online IOI clustering algorithm, which continuously outputs a tempo estimate based only on the musical data up to the time of processing. The clustering algorithm finds groups of IOIs of similar duration in the most recent eight seconds of music, and calculates a weighted average IOI representing the tempo for each cluster. The tempo estimates are adjusted to accommodate information from musically-related clusters, and then smoothed over time by matching each cluster with previous tempo hypotheses. Figure 5 shows the development over time of the highest ranked tempo hypothesis with the corresponding dynamics.

The Performance Worm is implemented in about 4,000 lines of Java, and runs in real time on standard desktop computers. The graphical user interface provides buttons for scaling and translating the axes, selecting the metrical level, setting parameters, loading and saving files, and playing, pausing and stopping the animation.

Apart from the real-time visualisation of performance data, the Worm can also load data from other programs, such as the more accurate beat tracking data produced by BeatRoot. This function enables the accurate comparison of different performers playing the same piece, in order to characterise the individual interpretive style of the performer. Current investigations include the use of AI pattern matching algorithms to learn to recognize performers by the typical trajectories that their playing produces.

Figure 5. Screen shot of the performance worm showing the trajectory to bar 30 of Rachmaninov's Prelude op.23 no.6 played by Vladimir Ashkenazy. The horizontal axis shows tempo in beats per minute, and the vertical axis shows loudness in sones. The most recent points are largest and darkest; the points shrink and fade into the background as the animation proceeds.



FUTURE TRENDS

Research in music content analysis is progressing rapidly, making it difficult to summarise the various branches of investigation. One major initiative addresses the possibility of interacting with music at the semantic level, which involves the automatic generation of metadata, using machine learning and data mining techniques to discover relationships between low-level features and high-level concepts. Another important trend is the automatic computation of musical similarity for organising and navigating large music collections. For other developments in this area, interested readers are referred to the web site at:

http://www.semanticaudio.org

CONCLUSION

The three systems discussed are research prototypes, whose performance could be improved in several ways, for example, by specialisation to suit music of a particular style or limited complexity, or by the incorporation of high-level knowledge of the piece being analysed.

This is particularly relevant to performance research, where the musical score is usually known. By supplying a beat tracking or performance analysis system with the score, most ambiguities are resolved, giving the possibility of a fully automatic and accurate analysis.

Both dynamic programming and Bayesian approaches have proved successful in score following (e.g., for automatic accompaniment, Raphael, 2001), and it is likely that one of these approaches would also be adequate for our purposes. A more complex alternative would be a learning system which automatically extracts the high-level knowledge required for the system to fine-tune itself to the input data (Dixon, 1996). In any case, the continuing rapid growth in computing power and processing techniques ensures that content-based analysis of music will play an increasingly important role in many areas of human interaction with music.

ACKNOWLEDGEMENTS

The Austrian Research Institute for Artificial Intelligence ackowledges the financial support of the Austrian Federal Ministry for Education, Science and Culture (BMBWK) and the Austrian Federal Ministry for Transport, Innovation and Technology (BMVIT). This work was supported by the START programme (project Y99-INF) of the BMBWK. Special thanks to the Bösendorfer Company, Vienna, for performance data used in this work.

KEY TERMS

Automatic Transcription: The process of extracting the musical content from an audio signal and representing it in standard music notation.

Beat Tracking: The process of finding the times of musical beats in an audio signal, including following tempo changes, similar to the way that people tap their feet in time to music.

Clustering Algorithm: An algorithm which sorts data into groups of similar items, where the category boundaries are not known in advance.

Frequency Domain: The representation of a signal as a function of frequency, for example as the sum of sinusoidal waves of different amplitudes and frequencies.

Music Content Analysis: The analysis of an audio signal in terms of higher-level (cognitive) properties such as melody, harmony and rhythm, or in terms of a description of the signal's component sounds and the sound sources which generated them.

Music Information Retrieval: The research field concerning the automation of access to music information through the use of digital computers.

Onset Detection: The process of finding the start times of notes in an audio signal.

Time Domain: The representation of a signal, such as the amplitude or pressure of a sound wave, as a function of time.

Automation of American Criminal Justice

J. William Holland
Georgia Bureau of Investigation, USA

INTRODUCTION

Criminal Justice has been one of the public sectors in the forefront of the move toward automation and digital government. The effect of computerization on American criminal justice has been profound and it has transformed the criminal justice process in many fundamental ways. Starting with President Lyndon Johnson's government commission, *The Challenge of Crime in a Free Society: A Report by the President's Commission on Law Enforcement and the Administration of Justice*, public and private experts in criminal justice and technology laid out the information needs of the criminal justice system and the computer systems to meet those demands. At a time when computerization was minimal throughout the criminal justice system, these task force members developed the blueprint for today's multilayered automated criminal justice environment (Dallek, 1998, pp. 405-407, 409-411; *Challenge of crime in a free society*, 1967, pp. 268-271).

Among the major recommendations of the commission were the creation of a national directory of offenders' criminal records, what came to be known as Computerized Criminal History (CCH) and the development of similar directories at the state level. The commission also called for federal coordination of standards for criminal justice information and sharing. Finally, the report urged that a study of fingerprint classification techniques be undertaken with a view to automating much of the fingerprint search and identification effort and that work be intensified to create a national linkage of files on wanted persons and stolen vehicles under the name of the National Crime Information Center (NCIC) (*Challenge of crime in a free society*, 1967, pp. 255, 268-271; *Task force report: Science and technology*, 1967, p. 69).

BACKGROUND

One of the earliest responses to this report was the creation of the Law Enforcement Assistance Administration (LEAA) within the United States Department of Justice (DOJ). In 1969, LEAA funded Project SEARCH to create a nationwide computerized criminal history system. From this initial effort, SEARCH quickly evolved into an independent consortium of states with the mission of demonstrating a computerized system for the electronic exchange of criminal history information. On the national level, the United States Attorney General assigned management responsibility for the interstate and national portion of this system to the Federal Bureau of Investigation. The states also formed the National Law Enforcement Telecommunications System (NLETS) electronically linking the states as well as the FBI and the Royal Canadian Mounted Police. By 1976, 26 states had used LEAA funding to create state level central repositories for computerized criminal history information (U.S. Department of Justice, 2001c, p. 26).

It became apparent during the last half of the 1970s, however, that greater decentralization of the nation's criminal history systems was urgently needed. To respond to these issues and concerns, the various states, FBI and SEARCH created the Interstate Identification Index or Triple I (III) concept in 1980 (U.S. Department of Justice, 2001c, pp. 26-27, 76-82, 88). Designed to replace a centralized national criminal history file, III was an index of criminal offenders that pointed to the state or states where detailed criminal history information could be found. There was widespread acceptance of III for criminal justice purposes: By 2001, 43 states participated. Legal restrictions and concerns, however, limited use of III for non-criminal justice use and weakened any effort to achieve a truly decentralized criminal history system. Consequently, the FBI continued to maintain criminal histories on individuals to meet interstate non-criminal justice needs (U.S. Department of Justice, 2001c, pp. 76-82).

Another factor that prevented the decentralization of criminal history information was the vast effort required in the time-consuming fingerprint identification process. A new system called the NCIC classification was implemented in the 1970s. It did little, however, to speed up the overall identification process (*Challenge of crime in a free society*, 1967, p. 255; *Task force report*, 1967, p. 16; Ms. Shirley Andrews, personal communication, September 9, 2002).

During the mid 1980s, new technological solutions for fingerprint identification emerged on the market. These systems, called automated fingerprint identification systems (AFIS), significantly reduced the manual tasks needed to search a fingerprint and made true searching of latent crime scene fingerprints possible. By the close of the 1980s, many states and a few local agencies had purchased these systems. Most were stand alone systems dedicated to the fingerprint input, search, and presentation of potential candidates for human comparison. A few states, however, attempted to expand the capabilities of these systems and link them to other criminal history processes. When combined with the proven effectiveness of the AFIS latent search capability, the new technology contained the potential to transform criminal justice systems (U.S. Department of Justice, 2001b, pp. 43-44; U.S. Department of Justice, 2001c, pp. 61-63).

In the early 1990s, efforts were made through the National Institute of Standards and Technology (NIST) to devise a national fingerprint transmission standard; an effort spearheaded by the FBI. By 1993, a national standard for the electronic interchange of fingerprint information was approved by NIST and became the basis for the electronic linkage of local jurisdictions to state criminal history bureaus and the FBI. It formed the basis for the emerging national network of real-time identification and criminal history systems (See *Data format for the interchange of fingerprint, facial, and SMT information*, originally issued in 1993, amended in 1997 and further amended in 2000; U.S. Department of Justice, 2001c, pp. 61-63.)

CURRENT AND FUTURE TRENDS IN CRIMINAL JUSTICE AUTOMATION

Building on these past activities in fingerprint and criminal history automation, emphasis within state and national criminal justice circles has shifted to the need to share information, what is known as integrated criminal justice. With the explosion of the Internet and simultaneous cost limitations on criminal justice system development, both federal and state funding entities require that new criminal justice system developments build in the concept of information sharing, realignment of processing functions, and greater involvement of all criminal justice parties in individual systems development. The goal of this new focus is to eliminate duplicate entry of the same information and increase the overall completeness and accuracy of criminal justice information. (U.S. Department of Justice, 2001c, pp. 63-65; Harris, 2000, pp. 7, 14, 18-20, 41; U.S. Department of Justice, 2001b, pp. 47-48, 50; *Planning the integration of justice information systems*, 2002, pp. 2-3.)

Integrated justice efforts, however, have also resurrected older worries about privacy of such information and merged them with new concerns about greater linkage of criminal justice and non-criminal justice information on individuals. Questions about release of integrated information are linked to serious questions about the accuracy of the information released. These fears are intensified as private companies demand access to criminal history information, gathered at public expense, to market to customers for profit. In many jurisdictions, the old line between public and private responsibilities and authority has faded as private companies have assumed many of the traditional criminal justice information systems functions. In addition, the heightened threat of terrorist attacks has led to efforts to gather large amounts of information on individuals into databases to search for terrorist patterns. These efforts have collided with fears about loss of privacy and misuse of such information by the government. Initiatives such as the Total Information Awareness effort and the MATRIX project to correlate private and public data on suspicious individuals have ground to a halt in the face of protest from citizens fearful of the loss of civil liberties. (Ideas that mattered in 2003:9. No future for terror market, 2003; MATRIX Updates, 2003; *Planning the integration of justice information systems*, 2002, p.5; Stanford, 2003; U.S. Department of Justice, 2001a, pp. 8, 12; U.S. Department of Justice, 2001b, pp. 2-3, 27-28, 50).

CONCLUSION

In 1967, a national commission developed *The Challenge of Crime in a Free Society*, the roadmap for today's highly automated but incomplete criminal justice system. This report served the nation well but it is time to move beyond its confining vistas, time to recognize that dramatic developments in computer technology and digital government demand new answers to old questions and the formulation of entirely new questions. The events of September 11, 2001 have raised anew questions about lack of information on potential threats to society and posed new questions on how we as a nation can weave together governmental and private computerized information to detect dangerous individuals intent on mass murder without compromising constitutional safeguards and individual liberties. It is time to convene a new national task force charged with the duty to assess the challenge of crime and terror in a free digital society. Only then can criminal justice automation and digital government move forward in a planned and comprehensive way.

KEY TERMS

Automated Fingerprint Identification System (AFIS): A system that provides computerized fingerprint identification of arrestees, applicants for licensing and employment, and crime scene fingerprints of potential suspects.

Computerized Criminal History (CCH): A system containing offenders and their individual arrests, final disposition of those arrests, and custodial information for those arrests.

Federal Bureau of Investigation (FBI): The federal government's investigative, forensic, and criminal justice information system entity. It is part of the U.S. Department of Justice.

Interstate Identification Index (III): a national index of offenders housed at the FBI that points an inquiring entity to those states that contain detailed criminal histories on the requested individual.

Multistate Anti-Terrorism Information Exchange (MATRIX): A consortium of states attempting to create a database of public and private information on individuals to allow for advanced searches to uncover suspicious criminal and/or terrorist activity.

National Crime Information Center (NCIC): A national center housed at the FBI that provides 24 hour a day, seven day a week, real time access to law enforcement for warrants, stolen vehicles and other articles.

National Institute of Standards and Technology (NIST): A federal government standards setting body housed in the U.S. Department of Commerce.

National Law Enforcement Telecommunications System (NLETS): A state managed national network that provides state to state communications as well as links to the FBI and other large scale criminal justice entities.

SEARCH Group, Inc: A state managed consortium that represents the states as a body on criminal justice information systems issues at the national level.

Total Information Awareness: A discontinued effort by the federal government to create a vast database containing public and private information on individuals to allow for advanced search techniques to uncover suspicious activity or indications of possible terrorist links.

Autopoietic Approach for Information System Development

El-Sayed Abou-Zeid
Concordia University, Canada

INTRODUCTION

In the last decade a new generation of information systems (IS), such as enterprise resource planning, Web-based information systems and knowledge management support systems, have emerged in response to ever-changing organizational needs. As these systems are socio-technical phenomena in which social and technical factors interweave the ways in which people work, the issue of "how to integrate the work activity and social context of users into the IS which is being designed" becomes one of the principal problems of IS development (Bai et al., 1999). Therefore, the need for new information system design theories is recognized. According to Walls et al. (1992), an "IS design theory" must have two aspects—one dealing with the description of the system and one dealing with the prescription, that is, the process of developing of the system. The prescription aspect includes a description of procedures and guidelines for system development. In addition, these two aspects have to be grounded on theories from natural or social sciences, that is, kernel theories. Therefore, the development of new IS design theories requires a closer look at the system theories that go beyond the traditional system theory that is based, among other things, on Cartesian dualism, that is, mind/body or cognition/action, and on a model of cognition as the processing of representational information (Mingers, 2001). One of the candidate theories is the theory of autopoiesis, which can be best viewed as a system-grounded way of thinking with biological foundations, together with its extension into social domain.

THEORY OF AUTOPOIESIS

In order to conceive of living systems in terms of the processes that realized them, rather in terms of their relationships with an environment, Maturana and Varela (1980) coined the word *autopoiesis* (autos = self, poienin = creation, production) to denote the central feature of their organization, which is "autonomy". The meaning of this word coveys the very nature of living systems as systems that maintain their *identity* through their own operations of continuous self-renewal. Moreover, these systems could only be characterized with *reference to themselves* and whatever takes place in them, takes place as necessarily and constitutively determined in relation to themselves, that is, *self-referentiality*.

One of the key concepts of autopoiesis is the distinction between organization and structure. On one hand, organization is the capability of a system to re-produce its identity by referring constantly to itself, through the alternate re-production of its components together with the component-producing processes, that is, the capability of a recursive self-reproduction. On the other hand, *structure* is the realization of a system's organization through the presence and interplay of its components in a specific realization space. While *organization* is necessary to establish system unity and identity, *structure* is necessary because different spaces of its actualization impose different constraints on systems' components (Maturana & Varela, 1980). By rough analogy, an algorithm for solving certain problem can be viewed as a description of the system's organization, whereas the corresponding computer program can be viewed as the realization of this organization (structure) in a certain space (programming language).

Autopoietic Systems

An autopoietic system is defined by Maturana and Varela as

"a network of processes of production, transformation and destruction of components. These components constitute the system as a distinct unity in the space of its actualization and they continuously regenerate and realize, through their interactions and transformations, the network of processes that produce them." (Maturana & Varela, 1980, p. 135)

Among the distinct characteristics of the autopoietic systems, the most relevant ones are:

- The simultaneous openness and closure. Autopoietic systems are *open* with respect to structural interaction with the environment, that is, *structural openness*, which is unavoidable consequence of the fact that system elements must satisfy the particular requirements of the physical domain in which they occur, while they are *closed* with respect to their own organization, that is, *organizational closure*. The recognition of *the simultaneous openness and closure* of autopoietic systems is in opposition to the tradition for which a system is one or the other but not both. This interpretation is possible only because of the clear distinction between organization and structure (Bednarz, 1988).

- Structural determination. The state transition a system undergoes in response to environmental perturbations is entirely determined by its structure at that time. Moreover, a system specifies which environmental perturbations may trigger which structural changes. In other words, the environmental perturbations could trigger the system's structural changes but can never determine or direct these changes. Moreover, a system specifies which environmental perturbations may trigger which structural changes. Over time, through ongoing interactions with the environment, an autopoietic system will experience what Maturana and Varela (1992) describe as a *structural drift*, or a gradual change to their structure. The nature of this change is determined by previous system's history of structural changes, that is, its *ontogeny*.

Higher-Order Autopoietic Systems

Two (or more) lower-order autopoietic systems can be "structurally coupled" to form higher-order autopoietic system. Structural coupling is the ongoing process of the congruent structural changes between two (or more) systems that results from recurrent interactions between (among) them. Therefore, structural coupling has connotations of coordination and co-evolution. Moreover, following structural determination principle, two structurally coupled systems means that each of them selects from its possible structural changes those which are compatible with those in the other system and, at the same time, are suitable for the maintenance of its identity.

Social systems, such as enterprises, are constituted through the process of third-order structural coupling, or social coupling, the one that occurs between (or among) two (or more) second-order autopoietic systems. However, the unique feature of any human social system, such as an enterprise, is that the social coupling among its constituents occurs through "language in the network of conservations which language generates and which, through their closure, constitute the unity of a particular human society" (Maturana & Varela, 1992, p. 196). From this perspective, language is viewed as an example of social structural coupling that generates the self and creates meaning through interactions with others. Moreover, language represents what Maturana and Varela would describe as a consensual domain, which is the domain of arbitrary and contextual interlocking behaviors (Mingers, 1995a, p. 78). Within a consensual domain, two autopoietic systems would be able to observe the attribution of meaning to common events and undertake coordinated actions.

Autopoiesis and Cognition

Cognition is the term conventionally used to denote the process by which a system discriminates among differences in its environment and potential states of that environment. The evidence for this cognition is effectiveness of system behavior in response to the environmental perturbations. Today's dominant perspective on cognition, and consequently IS, is the idea that effective action is explainable in terms of manipulating formal and static representations of the objective reality (Mingers, 2001).

According to theory of autopoiesis, perception is neither objectivist nor purely constructivist (Varela, 1992, p. 254). Rather, it is co-determined by the linking of the structure of the perceiver and the local situations in which it has to act to maintain its identity. This is the basis of *enactive (embodied) cognition*, which implies that the autopoietic system's activities condition *that can be perceived* in an environment, and these perceptions, in turn, condition future actions. In this view, "A cognitive system is a system whose organization defines a domain of interactions in which it can act with relevance to the maintenance of itself, and the process of cognition is the actual (inductive) acting or behaving in this domain" (Maturana & Varela, 1980, p. 13). In addition, cognitive domain of an autopoietic system is defined as the domain of all the interactions in which it can enter without loss of identity (Maturana & Varela, 1980, p. 119).

APPLICATIONS OF THE CONCEPTS OF AUTOPOIESIS IN IS DEVELOPMENT RESEARCH

The use theory of autopoiesis in IS research can be classified into two main categories: metaphoric and theory-oriented approaches (Beeson, 2001).

Metaphoric Approaches

Kay and Cecez-Kecmanovic (2002) used the concepts of *social coupling* and *consensual domain* to explain processes underlying the IS-organization relationship and how it impacts on the competitive advantage of an organization. They showed how processes of recurrent interactions between members of different groups, that is, analysts, the IS team, and external clients, within the organizations work environment gave rise to commonalities in understanding, which in turn enabled continual IS organization co-emergence. In the same vein, Maula (2000) used the concepts of structural openness and organizational closure to identify two major knowledge management (KM) functions in four consulting firms. The first KM function, sensory function, is the realization of the structural openness of the firm and its structural coupling with its environment. The second KM function, memory function, is the realization of the concepts organizational closure and self-referentiality that enable the firm's effective functioning and continuous renewal. Finally, Carlsen and Gjersvik (1997) used autopoiesis metaphor to analyze possible organizational uses of workflow technology. They argued against "generic" business processes except as starting points for organizational adaptation. In addition, they indicated that the concept of autopoiesis implies that process models should include references to richer descriptions of the organizational environment and the environment the work process is situated in.

Theory-Oriented Approaches

Bai and Lindberg (1999) used first and second order cybernetics, together with Luhmann's social autopoiesis theory (Luhmann, 1995) and Engeström's activity theory (Engeström, 1987) to develop a framework for studying the relationship between IS design activity, use activity,

Table 1. Autopoietic implications for IS development

Characteristics of Autopoietic Systems	**Implications for IS Development**
Organizational Closure and Self-Referentiality	**Insider frame of reference.** The organizational closure and self-referentiality of an enterprise suggest it is best understood from *inside*. Therefore, an interpretive or hermeneutic approach could more reliably and intelligibly account for the experiences, intentions and interpretations of its members. Moreover, the main role of system developer is the role of "*catalyst* and/or *emancipator*" (Hirschheim et al., 1989), who helps an enterprise's members to develop the necessary inquiring, collaborative and communicative patterns needed to continuously explicate their information requirements. **Historicity.** As an enterprise is continuously reproducing itself, it must do so with constant reference to itself, its past practices, values, decisions, contracts, and commitments (Truex et al., 1999). Therefore, explicating an enterprise's history is an essential element in developing new knowledge and in introducing a new IS (von Krogh et al., 1994)
Structural Determination and Structural Coupling	**Context-dependency of IS development methodology.** Viewing ISD methodology as the means for realizing structural coupling between an enterprise and its new IS implies that it cannot be separated from an enterprise's context. In other words, autopoietic metaphor of an enterprise and its IS suggests "strong" approaches to systems development instead of the commonly used "weak" approaches (see key terms).
Embodied Cognition	**Minimal set of initial requirements.** The autopoietic view of cognition implies that requirements are always in motion, unfrozen, and negotiable (Truex et al., 1999). Therefore, information system development can be viewed as open-ended bootstrapping process that starts with a minimal set of requirements. Moreover, formal representation must be subordinated to the fostering of mutual understanding and coordinated action in the development team and between the team's members and the stakeholders (Beeson, 2001; Kay & Cecez-Kecmanovic, 2002).

and the embedded social context. This framework sheds light on the complex social context within which IS development takes place, and provides an epistemological understanding of the relationship among the elements involved in IS development. Moreover, it can be used to develop methodologies for the practice of IS development, and guide various research activities, such as the socio-technical approach.

IMPLICATIONS FOR IS DEVELOPMENT AND RESEARCH

The autopoietic metaphor provides ways of thinking about the mechanisms underpinning the development and the introduction of IS in an enterprise. Here third-order autopoietic system is used as a metaphor to explore referential correspondence between the characteristics of autopoietic systems and an enterprise and its IS. For example, organizational closure of autopoietic system implies that it is homeostatic and its own organization is the fundamental variable to be maintained constant. This concept may be used to explain why the behavior of IS developers and users seems to be stuck sometimes in persistent patterns or repertoires (Beeson, 2001). Moreover, the difficulties of system integration may be better understood from a perspective of structural coupling than from one of rational design or negotiation (Beeson, 2001). Structural coupling concept can also be used to explore the way common understandings between an enterprise's members emerge as a function of interactions in the work environment (Kay & Cecez-Kecmanovic, 2002).

From autopoietic view introducing a new IS in an enterprise can be conceptualized as a kind of perturbation that provokes or triggers an enterprise's structural-determined responses. Therefore, IS development process can be viewed as the means for realizing structural coupling between an enterprise and its new IS and becomes an integrated aspect of the recurrent interactions between developers and users in the work environment. Table 1 summarizes the implications of theory of autopoiesis for IS development process.

KEY TERMS

Cognitive Domain: The domain of all the interactions in which it can enter without loss of identity (Maturana & Varela, 1980, p. 119).

Consensual Domain: "The domain of interlocked conducts that results from ontogenetic structural coupling between structurally plastic organisms" (Mingers, 1995b).

Ontogeny: The history of structural changes that a system experiences without losing its identity.

Organization: The configuration of relationships among a system's components that define a system as a unity with distinctive identity, and determine the dynamics of interaction and transformations that it may undergo as such a unity.

Strong vs. Weak Methods: "Strong methods are those designed to address a specific type of problem, while weak methods are general approaches that may be applied to many types of problems" (Vessey et al., 1998).

Structural Coupling: The ongoing mutual co-adaptation between a system and its environment.

Structural Determination: The principle that the actual course of change in an autopoietic system is controlled by its structure rather than direct influence of its environment.

Structure: The physical embodiment of a system's organization in a certain physical domain.

B

Balancing Risks and Rewards of ERP

Joseph Bradley
Central Washington University, USA

INTRODUCTION

Enterprise Resource Planning (ERP) systems claim to meet the information needs of organizations. These off-the-shelf software packages replace hard to maintain solutions created by IS departments or older off-the-shelf packages that often provided only piecemeal solutions to an organization's information needs. ERP systems evolved from material requirements planning systems (MRP) and manufacturing resources planning systems (MRP II). ERP serves the entire enterprise, not just manufacturing and inventory control as with its predecessors. ERP integrates information for the entire organization in a single database. But ERP implementations are often complex and experience serious problems. Failures, abandoned projects and general dissatisfaction have been well publicized in the business press. ERP systems are "expensive and difficult to implement, often imposing their own logic on a company's strategy and existing culture" (Pozzebon, 2000).

BACKGROUND

Three characteristics distinguish ERP implementations from other IT projects (Somers, Ragowsky, Nelson, & Stern, 2001).

- ERP systems are "profoundly complex pieces of software, and installing them requires large investments of money, time and expertise" (Davenport, 1998).
- The packages may require changes in business processes and procedure, may induce customization, and leave the implementing firm dependent on a vendor for support and updates (Lucas, Walton, & Ginsberg, 1988).
- The adopting firm is usually required to reengineer its business processes. As a result, the project must be managed as a broad program of organizational change rather than a software implementation (Markus & Tanis, 2000; Somers et al., 2001).

Despite these risks, global firms were spending $10 billion on ERP software and another $10 billion on consultants to implement the systems in the late 1990s (Davenport, 1998). An AMR study expected firms to spend $47 billion on ERP packages in 2001(Cotteleer, 2002).

WHY DO FIRMS ADOPT ERP?

Firms adopt ERP for technical and business reasons. The technical reasons include: reducing systems operating costs, solving specific problems, such as Y2K, accommodating increased system capacity, and solving maintenance problems with legacy systems. Business reasons may include: presenting a single face to the customer, quoting realistic delivery times, accommodating business growth, improvement of business processes, standardization of data, reduction of inventory carrying costs, and elimination of delays in filling orders (Markus & Tanis, 2000).

Watson and Schneider (1999) attribute the rapid growth of the commercial market for ERP to the following factors:

- Use of the popular client/server platform.
- Can be used as an enabler for reengineering projects
- Y2K compliant.
- Marketed to CEO's and CFO's as "strategic solutions" rather than as transaction processing software.
- A way to outsource a significant part of the IS function. (Watson & Schneider, 1999).

Advantages of ERP systems include:

- Reliable information access by using a single database.
- Avoiding multiple data entries, reducing cost and improving accuracy.
- Delivery and cycle time reduction minimizing delays in reporting.
- Cost reduction including time saving and improved controls.
- Easy adaptability with business process options based on best practices easy to adapt.
- Improved scalability.
- Improved maintenance with long-term vendor contracts.
- Global outreach with extensions to modules such as CRM and SCM.

- E-commerce and e-business capabilities (Rashid, Hossain, & Patrick, 2002).

An example of a decision to adopt an ERP system is provided by Geneva Pharmaceuticals, a manufacturer of generic drugs. Faced with eroding margins and continuing price pressure, the existing systems were proving inadequate. Data shared across business units had to be re-keyed resulting in frequent errors. Data was locked in "functional silos" and did not support new processes. Geneva adopted ERP in order to:

- Implement best practices in business processes.
- Integrate data across business units (hence reduce Re-keying and maintenance costs).
- Enforce data standardization (to reduce software maintenance costs),
- Integrate well with new technologies or systems of acquired companies
- Provide scalability with growing product and customer base, and be Y2K (year 2000) compliant" (Bhattacherjee, 2000).

With the identification of the prospective benefits of ERP why have some firms not adopted ERP?

WHY DO FIRMS NOT ADOPT ERP?

Markus and Tanis (2000) identified three very broad categories of reasons why firms that otherwise have all or some of the reasons to adopt ERP systems, do not adopt it or only adopt ERP in part. These firms may adopt only certain modules and rely on legacy systems or new custom systems for their needs. Other firms may begin an implementation only to discontinue it for a variety of reasons. The reason for this non-adoption or partial adoption can be categorized as follows:

1. Lack of feature-function fit.
2. Company growth, strategic flexibility and decentralized decision-making.
3. Availability of alternatives to increase systems integration.

Lack of feature-function fit may be due to the design of most ERP for discrete manufacturing. Many companies have specialized processes common to their industry, which may not be solved by the best practices embedded in ERP systems. The various modules may not fully support process manufacturing industries, such as food processing and paper manufacturing, project industries, such as aerospace, or industries that manufacture products with dimensionality, such as clothing or footwear (Markus & Tanis, 2000). Although as the ERP market becomes saturated, vendors are designing packages for industries that were previously viewed as too complex.

Companies concerned with maintaining rapid growth rates, those needing strategic flexibility and those without a top down decision making style may be non-adopters or partial adopters of ERP systems. Dell Computer Corp. planned full implementation of SAP R/3 but discontinued the implementation after installing the human resource module. Dell's CIO expressed concern with the software's ability to keep pace with Dell's extraordinary growth rate. Visio, a software company subsequently acquired by Microsoft, expressed concern with the ability of SAP to handle the frequent changes it required to its sales analysis and commission requirements (Markus & Tanis, 2000).

The experiences of Dell and Visio focus on the need for efficiency and flexibility in dealing with the external environment and internal processes. In a stable environment, mechanistic structures are appropriate consisting of "high degrees of standardization, formalization, specialization and hierarchy" (Newell, Huang, Galliers, & Pan, 2003). In a dynamic environment, organic structures are needed to enable organizations to be flexible to change products, processes and structures. In these organizations low levels of standardization, formalization, specialization and hierarchy are most appropriate. ERP may maximize organizational efficiency at the cost of flexibility (Newell et al., 2003). The result may be an inability to respond quickly to changes in the environment, reducing the firm's competitiveness.

Organizational culture may also be a factor in non-adoption or partial adoption of ERP systems. Kraft Foods Inc. was highly decentralized but slowly moving to a one-company philosophy. ERP was regarded as culturally inappropriate with this strategy (Markus & Tanis, 2000).

Lean enterprises succeed "as a growth strategy for increasing sales by trimming the company's product delivery system into a competitive weapon" (Bradford & Mayfield, 2001). Lean enterprises have difficulty using ERP systems due to the lack of flexibility. "ERP creates many nonvalue-added transactions by making companies track every activity and material price in the factory. This is counter to Lean philosophy, which aims at speeding up and smoothing production" (Bradford & Mayfield, 2001).

Alternatives to ERP systems include data warehousing technologies that integrate data from source systems for query and analysis. These systems, sometimes described as "poor man's ERP," are limited by the quality of the underlying source systems (Markus & Tanis, 2000). In 1993 Great Atlantic & Pacific Tea Company, Inc. completed a supply chain and business process infrastructure based on a "robust data warehousing capacity for category management and other grocery-specific functionality" (Retek, 2003).

Other problems identified with implementation of ERP include time, expense, vendor dependence, complexity,

RISKS ASSOCIATED WITH ERP IMPLEMENTATION

Implementing ERP can be a risky proposition for firms. Brown and Vessey (2003) observe "although failures to deliver projects on time and within budget were an old IT story, enterprise systems held even higher risks - they could be a 'bet-our-company' type of failure" (Brown & Vessey, 2003).

Markus (2000) proposes 10 categories of IT related risks, all of which would apply to ERP systems:

Financial risk	Non-use, underuse, misuse risk
Technical risk	Internal abuse
Project risk	External risk
Political risk	Competitive risk
Contingency risk	Reputational risks

"IT-related risk includes anything related to IT that could have significant negative effects on the business or its environment from the perspective of an executive investing in IT" (Markus, 2000).

Some firms may be averse to the risks an ERP implementation can create. Scott (2003) discusses some of the risks identified by Markus (2000). He describes project risks, information systems risks, organizational risks, and external risks in ERP implementations.

Project risks stem from the customization of purchased packages and the difficulty of interfacing with legacy systems. When firms believe their business process are unique, they may customize ERP software instead of adopting best practices imbedded in a standard implementation. Data conversion can also be a problem when firms do not clean up their data before embarking on a project. After implementing SAP, Halliburton reported that inventory accuracy stood at less than 80% (Anderson, 2003). Project leadership, limiting project scope, avoiding customization, and a phased implementation (rollout) can minimize this risk (Scott, 2003).

Information systems risks arise from system performance problems ERP systems may be poorly configured or the hardware may need upgrading. Another risk arises when the use of multiple vendors creates the need for multiple interfaces. Multiple vendors contributed to the problems in the Hershey Food Corporation implementation. Information systems risks can be minimized by avoiding customization, use of data warehousing for reports and queries and avoiding multivendor implementations (Scott, 2003).

Organizational risks of a bad ERP implementation can impact the firm's operating profits. Customer deliveries can be delayed putting customer relationships at risk. Impacts can be with customers, financial performance, or internal business objectives. Organizational risks can be minimized with training and strong leadership, which assures that sufficient resources are allocated to the project and inspires employees who may resist the implementation (Scott, 2003).

External risks center on litigation associated with the implementation. Firms with implementation problems may sue consultants and/or ERP vendors. Overbilling by consultants and use of incompetent trainees have been sources of litigation (Scott, 2003). Gore-Tex claims its consultant promised expert staff and delivered incompetent trainees. Managing consultants, by specifying goals and individual competence of consultants, can minimize this risk (MacDonald, 1999).

Political risk occurs "if a dominant coalition attempts to use the ERP package as a means by which to impose its views on other functional areas" (O'Gorman, 2004). A case study at an international oil supply company where the ERP implementation was dominated by the financial management of the business left the supply chain management function without the tools they believed they needed (Bradley, 2004).

Another reason for non-adoption may be that a standard software package available to all potential purchasers may reduce a firm's competitive advantage. A resource-based view of the firm assumes that the individual firm's unique collection of resources and capabilities are a potential source of competitive advantage. Capabilities leading to competitive advantage may be embedded in current business processes.

To create competitive advantage such capabilities must be valuable, rare, costly to imitate and non-substitutable. "Valuable and rare organizational resource can only be sources of *sustained* competitive advantage if firms that do not possess these resources cannot readily obtain them" (Barney, 1991). An off-the-shelf package may be costly, but would not be rare or costly to imitate. Adoption of ERP packages based on "best practices" may cause the loss of the unique and valuable advantage imbedded in current business processes. A case study showed that:

…the introduction of SAP-specific business routines can threaten established core, enabling and supplemental capabilities and related knowledge sets. The integration of SAP's embedded business routines and reporting functionality contributed to the creation of (a) highly rigid reporting structures; (b) inflexible

managerial decision-making routines; and (c) reduced autonomy on the factory floor….(Butler & Pyke, 2004)

WELL PUBLICIZED FAILURES AND PROBLEMS

Numerous descriptions of ERP failures have appeared in the business press. The experience of serious problems at many well run, well-financed firms may be enough to discourage some firms from beginning an ERP implementation.

Hershey Foods embarked on an ERP investment in mid-1996 to solve its Y2K problems and improve its ability to perform just-in-time store deliveries to its customers (Severance & Passino, 2002). After spending $112 million on an ERP project, Hershey Foods Corporation was unable to fill Halloween candy orders in October 1999, resulting in a 19% drop in third quarter profits (Stedman, 1999). As a result of Hershey's problems its stock price fell by a third and the firm lost market share to Mars and Nestle (Severance & Passino, 2002). Hershey estimates it suffered a 3% permanent decrease in market share from this experience (Sutton, 2003).

A study by the PA Consulting Group found that "92% of companies are dissatisfied with results achieved to date from their ERP implementation and only 8% achieved a positive improvement in their performance" ("ERP Implementation Disappoints Companies," 2000).

Davenport (1998) identifies several unsuccessful implementation efforts:

- Fox-Meyer Drug claims that an ERP system led to its bankruptcy.
- Mobil Europe spent hundreds of millions on ERP, but abandoned the project when a merger partner objected.
- Dell found that its ERP system did not support its new decentralized management style.
- Applied Materials gave up on its ERP implementation when it became overwhelmed with the organizational changes it required.

ERP success stories receive much less publicity.

FUTURE TRENDS

Recently, the Gartner Group coined the term "ERP II" to describe a shift in ERP from an enterprise information base to moving information across the supply chain ("Taking the Pulse of ERP," 2001). New risks and challenges will be faced by organizations opening up information systems to supply chain partners. Supply chain partners could be potential competitors or pass information to existing competitors. Resolving trust issues will be key to advancement in ERP II. Gartner does not expect to see ERP II systems fully deployed before 2005 ("Taking the Pulse of ERP," 2001).

Small and mid-sized enterprises (SME) will become leading adopters of ERP system as the large company market becomes saturated. Vendors have been developing less expensive versions of their software to appeal to the SME market.

CONCLUSION

ERP implementation projects continue to present risks to adopting organizations. Continuing ERP spending demonstrates that most organizations have concluded that the benefits resulting from such implementations outweigh the substantial risks and cost of ERP systems. Perhaps the risks of not adopting ERP are determined to be greater than the risks faced by adopters. The prospect of extending ERP beyond organizational boundaries to supply chain partners makes ERP even more attractive and possibly more risky. Organizations will continue to adopt ERP as a strategic necessity to remain competitive in their industry, but few, if any, will gain any sustainable competitive advantage by adopting ERP.

KEY TERMS

Enterprise Resource Planning Systems (ERP): An off-the-shelf accounting-oriented information system that meets the information needs of most organizations. A complex and expensive information tool to meet the needs of an organization to procure, process and deliver customer goods or services in a timely, predictable manner.

ERP II: Opening up ERP systems beyond the enterprise level to exchange information with supply chain partners. ERP II extends beyond the four-walls of the business to trading partners.

IT-Related Risk: This risk includes "anything related to IT that could have significant negative effects on the business or its environment from the perspective of an executive investing in IT" (Markus, 2000).

Legacy Systems: Transaction processing systems designed to perform specific tasks. Systems that have become outdated as business needs change and the hardware and software available in the market place have improved.

Material Requirements Planning Systems (MRP): Processes that use bills of materials, inventory data and a master productions schedule to time phase material requirement, releasing inventory purchases in a manner that reduces inventory investment yet meets customer requirements.

Manufacturing Resources Planning (MRPII): Extends MRP by addressing all resources in addition to inventory. MRPII links material requirements planning with capacity requirements planning avoiding over and under shop loading typical with MRP.

B

Basic Notions on Multidimensional Aggregate Data

Maurizio Rafanelli
Italian National Research Council, Italy

INTRODUCTION

The term *multidimensional aggregate data* (MAD; see Rafanelli, 2003) generally refers to data in which a given *fact* is quantified by a set of *measures* obtained applying one more or less complex *aggregative function* (count, sum, average, percent, etc.) to row data, measures that are characterized by a set of variables, called *dimensions*. MAD can be modeled by different representations, depending on the application field which uses them. For example, some years ago this term referred essentially to statistical data, that is, data whose use is essentially of socio-economic analysis. Recently, the metaphor of the data cube was taken up again and used for new applications, such as On-Line Analytical Processing (OLAP), which refer to aggregate and non aggregate data for business analysis.

BACKGROUND

Generally there are two broad classes of multidimensional (statistical) data: microdata and macrodata. The former refers to SDBs containing elementary or raw data, that is, records of individual entities or events. The latter refers to databases containing multidimensional aggregate data, often shown as statistical tables, that result from the application of aggregate functions on raw data. Microdata are generally stored as relations in a relational database, and when an aggregation function is applied to them, the result is a complex data, called *macrodata*, which consists of a descriptive part and a summary part. The latter is called *summary attribute* or measure, and is characterized by the descriptive part mentioned above called *metadata*. Its simplest definition is "data describing data."

In order to model aggregate data, we define these data from both a conceptual and a logical point of view. The main difference between them is that in the case of conceptual data, which we will call *multidimensional aggregate data* (MAD), we do not consider their physical storage, while in the case of logical data, which we will call the *multidimensional aggregate data structure* (MADS), we refer explicitly to their physical storage. It is useful to remember that the *multidimensionality* concept was introduced by Shoshani and Wong (1985) describing a MAD as a mapping from the domains of the category attributes (independent variable) to the (numerical) domains of the summary attributes (dependent variable). Each category attribute often represents a level of a hierarchy present in that dimension of that MAD and ranges over an n-dimensional space (the space of the n-tuples of category attribute instances), from which derives the concept of *multidimensionality*.

We give now some definitions useful in describing the aggregation process, that is, the process that allows one to obtain the multidimensional *aggregate* database from a relational *disaggregate* database.

BASIC NOTIONS

Let Θ be the database universe, that is, the set of all the relations that form the very large relational database in which raw data (microdata) are stored. Let $\mathcal{R}$ be the subset of Θ relative to all the relations used in the definition of the multidimensional aggregate (macro) database and which, therefore, refers to all the phenomena studied. Note that each phenomenon consists of one or more *facts* that are the physical objects stored in the database. Let $\mathcal{R}_x = \{\mathcal{R}_i\}_{i=1,\ldots,h}$ be the set of all the relations $\mathcal{R}_1, \mathcal{R}_2, \ldots, \mathcal{R}_h$ (each of them with attributes different in number and names), which refer to the x-th phenomenon. Let $A^1_1, A^1_2, \ldots, A^1_{k_1}$ be the set of attributes of the relation $\mathcal{R}_1$, where the superscript refers to the index which characterizes the considered relation, k_1, is the number of attributes of this relation (i.e., its cardinality), each of which has a definition domain $\Delta^i_1, \Delta^i_2, \ldots, \Delta^i_{k_1}$, and likewise for the other relations. To clarify how the subsets of $\mathcal{R}$ to be aggregated are characterized, let us analyze the concept of the *category attribute*. A category attribute is the result of an abstraction on one or more attributes of the microdata; analogously its *instances* are the result of an abstraction on the (numerical, Boolean, string, etc.) values actually associated with the single microdata.

Definition 1. Let $\mathcal{R}$ be the set of all the relations used in the definition of a multidimensional aggregate database, let Ω be the set of all the attributes which appear in $\mathcal{R}$, let

$A_x \in \Omega$ be a generic attribute of this database, and let a_{xy} be one of its instances (with y = 1,…, k, where k is the cardinality of the definition domain of A_x). The logical predicate ($A_x = a_{xy}$), defined on the microdata of $\mathcal{R}$, is called *base predicate*.

Definition 2. The *base set* of the base predicate ($A_x = a_{xy}$) is the subset of Θ consisting of all microdata which satisfy the base predicate. In the following such a subset will be denoted by $B_{A_x} = a_{xy}$.

Let A be the subset of all the attributes of Ω that will become descriptive (or category) attributes or measures of all the MADs that will form the multidimensional aggregate database at the end of the aggregation process. Then $\mathcal{A}$ is the set of all and only the attributes that describe all the facts that appear in the multidimensional aggregate database. Many of these attributes appear in different relations of $\mathcal{R}$. Different attributes can contribute to form one *hierarchy*. Different hierarchies can belong to the same *dimension*, on the condition that pairs of hierarchies have at least one attribute in common. Note that parallel hierarchies, called *specialization hierarchies*, can exist. Moreover, other attributes, which do not appear in $\mathcal{A}$, can complete the hierarchies mentioned above (on the condition that the relationship between them and the other attributes of the same hierarchy is defined). $\mathcal{A}^*$ is the set of these last attributes plus the attributes of $\mathcal{A}$. We call these hierarchies *primitive hierarchies* because all the hierarchies that refer to one of them are included in it. Analogously, we call *primitive dimension* the dimension which includes all its primitive hierarchies.

Let $\mathcal{H}$ be the set of all the hierarchies (including the specialized hierarchies) defined in $\mathcal{A}^*$. Let $\mathcal{D}$ be the set of all the dimensions defined in $\mathcal{A}^*$ (which can consist of different hierarchies). Note that the users often give the name of a dimension to descriptive variables of a MAD which are, in reality, levels of a hierarchy relative to this dimension. Let Δ be the set of all the definition domains (i.e., of all the instances) of the attributes of $\mathcal{A}$, and let Δ* be the set of all the definition domains of the attributes of $\mathcal{A}^*$ which also include all the possible instances that each attribute can assume (therefore, also including the instances not present in the relations of Θ). We call *primitive domains* these definition domains. This means that all the attributes (and all the relative instances) which appear in the multidimensional aggregate database are part of $\mathcal{A}^*$ and Δ* respectively.

Category attributes are not the only metadata of multidimensional aggregate data: several other properties may provide a semantic description of the summary data. Among them we consider, in particular, the following:

- The *aggregation type*, which is the function type applied to microdata (e.g., count, sum, average, etc.) to obtain the macrodata (i.e., a MAD, see Rafanelli & Ricci, 1993), and which defines the *summary type* of the measure. This property must always be specified.
- The *data type*, which is the type of summary attribute (e.g., real, integer, non-negative real, non-negative integer).
- The *fact* $\mathcal{F}_j$ described by the multidimensional aggregate table considered (e.g., production, population, income, life-expectancy).
- Other properties may be missing, for example "data source" (which may be unknown), "unit of measure," and "unit of count," as defined in the following.

Let Γ be the set of the *functional dependencies* which are possibly present in the multidimensional aggregate database and which, therefore, exist among groups of attributes. Given a phenomenon x and given the set of relations $\mathcal{R}_x \subset \mathcal{R}$, we consider the subset of $\mathcal{R}_x$ formed only by the relations involved in the building of the fact $\mathcal{F}_j$. We call this subset an *aggregation relation*, and denote it by $\mathcal{R}_j^x$, where $\mathcal{R}_j^x = \{\mathcal{R}_{j,1}, \ldots, \mathcal{R}_{j,s}\}^x$. Every fact $\mathcal{F}_j$ has its own descriptive space formed by s category attributes (where s is the cardinality of the j-th fact), which are a subset of all the attributes in the relations $\mathcal{R}_j^x$. We denote the set of the above-mentioned s category attributes by $A_j^x = \{A_{j,ks}\}^x = \{A_{j1}, \ldots, A_{js}\}^x$. We call the relation β_j^x, formed by these attributes, a *base relation* of the fact $\mathcal{F}_j$.

The measure values are the result of the aggregation process, i.e., of the application of the aggregation function to the base relation of the fact. The fact obtained by this aggregation process is called *base fact*, because its representation cannot even be disaggregated (i.e., only more aggregate views can be obtained). Each fact consists of a set of materialized views, obtained by applying different operators of aggregation (roll-up, group-by), or of reduction of the definition domains of its category attributes (dice). This set of materialized views defines the *lattice* of this fact. The source of this lattice is formed by the total of all the summary category instances of the base fact, and the sink formed by all the summary category instances at the lowest level of disaggregation.

Let $\mathcal{F} = \{\mathcal{F}_j\}$ be the set of all the *fact names* described by the multidimensional aggregate database. Let $\mathcal{S} = \{\mathcal{S}_j\}$ be the set of all the subjects described in the facts, in other words, the "what is" of the summary attributes (Cars, People, Fruit, Workers, Dollars, etc.). Let $\mathcal{R}_j^x = \{\mathcal{R}_{j,1}, \ldots, \mathcal{R}_{j,s}\}^x$ be the subset of the relations in the microdatabase which are involved in the x-th fact. Let $A_j^x = \{A_{j,ks}\}^x = \{A_{j1},$

..., $A_{js}\}^x$ be the set of attributes of $\mathcal{R}_j^x$ which are the only ones considered in the building of this MAD.

Definition 3 Let $\{\mathcal{R}_1, \ldots, \mathcal{R}_s\}^j_x$ be the set of all the relations involved in the building of the generic j-th fact $\mathcal{F}_j$ of the x-th phenomenon π_x. These relations are included in $\mathcal{R}_x$ and have *all* the category attributes $A_j^x = \{A_{j,ks}\}^x$ of the fact $\mathcal{F}_j$ simultaneously present in it (and possibly other attributes which are not used in this aggregation process). "j" characterizes the different category attributes of $\mathcal{F}_j$. We call the relation (in non-normal form) formed by all the tuples of the previous set $\{\mathcal{R}_1, \ldots, \mathcal{R}_s\}^j_x$ *aggregation relation* $\mathcal{R}_j^x$ of the j-th MAD which describes the fact $\mathcal{F}_j$.

Definition 4. We call *aggregation schema* $A_i = \{A_{ij}\}$ of the i-th MAD, with the aggregation relation $\mathcal{R}_i$ which describes the fact $\mathcal{F}_i$, the set of all the names of the category attributes A_{ij} of the fact $\mathcal{F}_i$. This set defines the dimensions of the MAD. The number of these category attributes defines the *cardinality* of the MAD.

Definition 5. The *base relation* $\mathcal{R}_{Bi}$ of the i-th MAD (with its predefined descriptive space), which describes fact $\mathcal{F}_i$, is the subset of the aggregation relation $\mathcal{R}_i^x$ of this fact which has all and only the descriptive attributes A_{Bij} of the fact $\mathcal{F}_i$.

Definition 6. The *base schema* A_{ij} of the i-th MAD is the tuple of the base relation attribute names of the MAD.

Now we can describe the aggregation process, starting from a relational database of raw data Θ.

THE AGGREGATION PROCESS

The *first step* consists of defining the set $\mathcal{R}$ of all possible microdata relations to which the aggregation process must be applied, and, within it, to choose the set $\mathcal{R}_x$ of relations that refer to a given phenomenon πx.

Defined the set Ω of all the attributes which appear in $\mathcal{R}$, the *second step* consists of choosing attributes that will become descriptive (or category) attributes in the multidimensional aggregate database, that is, set $\mathcal{A}$, and of defining the possible functional dependencies, as well as the attributes that possibly complete the eventual existing hierarchies.

The *third step* consists of recognizing all the attributes that belong to the same dimension, and the hierarchies (and their specializations) within this dimension, i.e., sets $\mathcal{H}$ and $\mathcal{D}$. All the attributes which do not appear explicitly but which complete a given hierarchy have to be inserted into it. For example, the hierarchy of the dimension "space," i.e., Region → Province → City, is connected to the specialization hierarchies Region (of residence) → Province (of residence) → City (of residence).

At this point, the part of the multidimensional aggregate database which refers to the described phenomenon can be built repeatedly by performing the following steps:

Fourth step: Selection of the subset $\mathcal{R}_i$ of relations that are involved in the i-th fact, and of the set A^i_{kn} of attributes of $\mathcal{R}_i$ which are the only ones considered in the building of the MAD. At the end of the aggregation process, all the sets A_j of attributes will form the descriptive space of the multidimensional aggregate database. In this step we also define the subsets in $\mathcal{D}$ and in $\mathcal{H}$ which characterize respectively the dimensions and the possible hierarchies in each dimension of the fact. Therefore, a hierarchy represents the same dimension at different granularity levels.

An innovative feature of multidimensional aggregate data has been the introduction of a third type of attribute, namely the *implicit category attribute*, which can considerably enlarge and enhance the manipulation capabilities of an aggregate database. In fact, if one or more attributes which define the dimensions of a MAD have a definition domain formed by only one instance, we transform each of them into part of the "fact name" and call it "implicit attribute" or *implicit dimension*. Note that also implicit attributes contribute to MAD cardinality.

Fifth step: Application of the aggregation function to the attributes of the relations in A_j. The result of this operation is the numeric data which represent the measure carried out on microdata, called simply *measure* (or summary attribute.) Depending on the type of function applied, the parameters that characterize each fact have to be defined, including:

- the *summary type* which is defined by the aggregate function type applied to microdata (a count, a sum, etc.);
- the *count unit*—suppose that the result instances are 100, 213, 47, and so forth, and suppose also that the subject is "fruit." The count unit defines if, for example, 100 really means 100 (100 *x 1*), or 100,000 (100 *x 1,000*), or 100,000,000 (100 *x 100,000*), and so on;
- the *measure unit*—in the previous example, the number could be "number of pieces of fruit," or "kilograms," or "tons," and so forth; and
- the *data source* (this information is not always available).

In general, the aggregation function applied is initially a *count* or a *sum*. Subsequent aggregations can be obtained by applying algebraic operations and statistical-mathematic operations to these aggregate data.

Sixth step: Definition of the fact name (name of the MAD). At the end of the aggregation process all the names of the *facts* defined will form the set $\mathcal{F}$.

Seventh step: Definition of the subject described in the fact, by choosing it from among the attributes of the relations in $\mathcal{A}$*. At the end of the aggregation process, all the subjects described in the facts will form set $\mathcal{S}$.

Eighth step: Definition of possible *Notes* which characterize possible anomalies of the MAD (this step can be lacking).

When we apply the aggregation process, all the MADs produced are conceptual structures, that is, for each of them we have not yet defined how to store them in the database, or any order among the attributes of a fact or among the domain instances of each attribute. To store them we have to define these orders.

The result of this further step, the *ninth step*, is the definition for each MAD of a corresponding logical structure, called *multidimensional aggregate data structure* (MADS). In it each instance of the measured data is characterized exactly by a tuple, whose elements are defined by one instance for each dimension (category attribute) of the MAD.

Definition 7. An *aggregation process* is formally described by the six-tuple

$$< \mathcal{P}, \mathcal{R}_i, A_i, \mathcal{S}_i, \mathcal{N}, f_{agg} >,$$

where:

$\mathcal{P}$ is a fact name which identifies a fact universe $\mathcal{R}$ through a mapping φ; this mapping is defined from the fact set $\mathcal{F}$ to the powerset of Θ.

$\mathcal{R}_i$ is a set of relations involved in the building of the i-th MAD.

A_i is a set of the descriptive (category) attributes $\{A_{i,1}, A_{i,2}, \dots, A_{i,k}\}$ of $\mathcal{R}_i$ (with its own instance domains $\Delta(A_{i,j})$, with $j = 1,\dots, k$) on which to apply an aggregation function.

$\mathcal{S}_i$ is the *subject* which characterizes the measure of the MAD.

$\mathcal{N}$ is a numerical domain.

$f_{agg}: \mathcal{R}_i \rightarrow \mathcal{S}_i$ is an aggregation function (initially, in general, a sum or a count).

A MAD is, therefore, a concise representation of the aggregation process result.

Definition 8. Let H and K be two sets whose elements are sets; we define the *cross-intersection* of H and K, and denote it by $H \otimes K$, as the set of all the possible intersections between each element in H and each element in K:

$$H \otimes K = \{ j : j = h \cap k, h \in H, k \in K \}$$

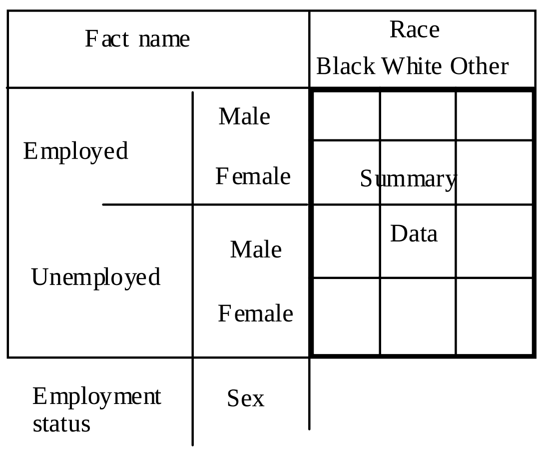
Now we describe the data structure of multidimensional aggregate data by a simple graphical representation.

THE DATA STRUCTURE

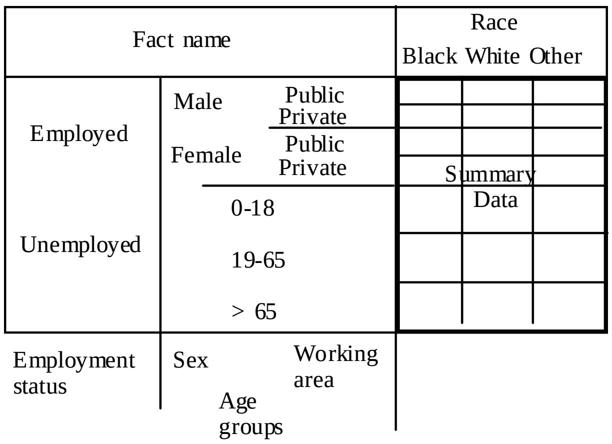
A measure of a MAD is described by a set of *dimensions*, that is, a set of category attributes; each of them can be a level of one of the possible hierarchies that form the primitive dimension. Each category attribute also has a *primitive category attribute*. The complexity of aggregate data is also due to the fact that the same operator may require different recomputation functions for the summary values, depending on the summary type of the multidimensional aggregate table, as illustrated in Rafanelli and Ricci (1993). Summary data are always fixed in time. It is always (implicitly or explicitly) present in every MAD, as well as the *space* dimension.

Most of the existing models for aggregate data represent a MAD as a mapping between category and summary attributes. The analysis of the aggregation process shows that a MAD represents a functional link between *aggregation sets* and *summary values*, rather than between tuples of category attribute instances and summary values. In Bezenchek, Rafanelli, and Tininini (1996), the formal definitions of a *simple, complex, and composite* MAD (and of the analogous MADS) are given. In the following figure we propose the tabular representation of a *simple, complex, and composite* MADS. A subtle distinction has to be made between the concepts of multidimensionality and of *polidimensionality*. The former refers to a data structure in which measured data is described by different parameters which define a multidi-

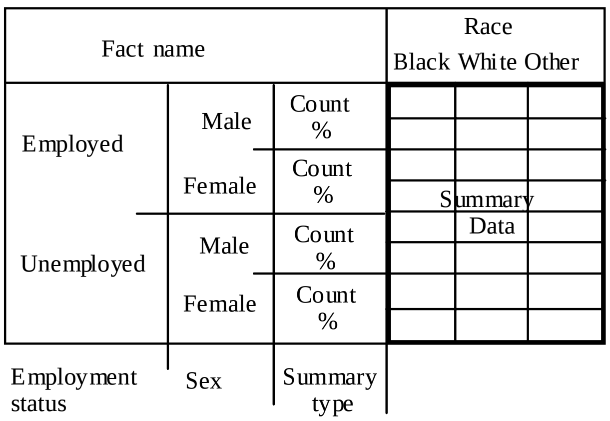
Simple MADS



Complex MADS



Composite MADS



mensional descriptive space. The latter refers to a descriptive space in which a category attribute has, for example, one part of its definition domain classified by one or more other category attributes, A, B, ... C, while the other part is classified by one or more different category attributes, E, F, ... H. Note that the number of the first and the second group of category attributes can be different. This situation exists in the complex MADS shown in the following. The difference between the simple/complex MADS and the composite MADS consists in their summary type, which is unique in the former and of at least two different types in the latter (in our case, Count and Percent).
Recently other proposals for modeling multidimensional databases have been presented, based on the cube metaphor, which represents the concept of multidimensionality by a three-dimensional representation (see Agrawal, Gupta & Sarawagi, 1997; Gyssens & Lakshmanan, 1997; Nguyen, Tjoa & Wagner, 2000; Pedersen & Jensen, 1999). Codd (1993) proposed the term On-Line Analytical Processing (OLAP) for rendering enterprise data in multidimensional perspectives, performing online analysis of data using mathematical formulas or more sophisticated statistical analyses, and consolidating and summarizing data according to multiple dimensions.

The new data models for OLAP typically categorize data as being "measurable business facts (measures) or dimensions." In OLAP research, most work has concentrated on performance issues. Techniques have been developed for deciding what subset of a data cube to precompute, for estimating the size of multidimensional aggregates and for indexing pre-computed summaries. Similarities and differences between OLAP and statistical databases are discussed in Shoshani (1997).

CONCLUSION

The MADS are data used all days by a large variety of users. The problems that arise in their manipulation are studied in different areas such as statistical data, geographical data, data warehouses, OLAP, and so forth. In this article, we gave some base concepts on their data structure and on the aggregation process that allows one to obtain them. Many other topics referring to multidimensional databases are treated in Rafanelli (2003).

KEY TERMS

Aggregation Process: The process that allows one to obtain multidimensional *aggregate* data from *disaggregate* data.

Category Attribute: The variable that describes the summary data of an aggregate data structure.

Data Multidimensionality: The set of dimensions of a table or a data cube.

Dimension: Corresponds to a perspective under which facts can be fruitfully analyzed. It is a structural attribute of a fact, that is, a list of members (variables), all of which are of a similar type in the user's perception of the data.

Fact: An entity of an application that is the subject of decision-oriented analysis. It is usually represented graphically by means of a table or, using a metaphor, by a data cube.

Hierarchy: An ordered structure, where the order is established between individuals or between classes of individuals; the ordering function may be any function defining a partial order.

Metadata: Data which describe other data.

Multidimensional Aggregate Data: Data in which a given *fact* is quantified by a set of *measures*, obtained applying one more or less complex *aggregative function* (count, sum, average, percent, etc.) to row data.

Summary Attribute: The numerical result of the application of *aggregative functions* to row data. It is described by the set of category attributes that form the multidimensional aggregate data structure (table or data cube).

Basics of the Triune Continuum Paradigm

B

Andrey Naumenko
Triune Continuum Enterprise, Switzerland

INTRODUCTION

This article reviews the Triune Continuum Paradigm - a logically rigorous theoretical base for organization of modern conceptual frameworks that are used for system modeling in different contexts (e.g., in software development, in enterprise architecture, in the architecture of financial services, in jurisprudence, etc.). This paradigm is an important contribution to the system modeling domain, because currently none of the prevailing system modeling frameworks has a satisfactory formal theoretical foundation.

The absence of a theoretical foundation for modeling frameworks leads to the practical application experiences where modelers are constrained to be guided by chance and not by a founded reason. This often leads to the inadequate choices of modeling frameworks; that is, to the situations where a chosen modeling framework is not designed to deal with the targeted modeling problems. Possible consequences of such choices include: incorrect (e.g., inadequate with regard to the requirements) information systems specifications, contradictory data architectures, incomplete service specifications, and so forth – all of these being the decisive contributions to failures of many projects. The paradigm that we review in this article fixes this problem, providing missing theoretical foundations for frameworks positioned in the domain of general system modeling.

Many of the existing system modeling frameworks appeared as an integration of the best modeling practices. The reviewed paradigm does not repudiate the practical experience that was gathered by these different frameworks, but fixes its inconsistencies and complements it, supporting with logically rigorous theoretical foundations. Therefore the paradigm brings a significant constructive potential to the evolution of modern system modeling frameworks. This potential could be realized if people responsible for the design of modeling frameworks and tools would heed the proposed paradigm.

BACKGROUND

The Cambridge Dictionary of Philosophy (Audi, 1999) provides the following definition of the term “paradigm”: “Paradigm, as used by Thomas Kuhn (The Structure of Scientific Revolutions, 1962), a set of scientific and metaphysical beliefs that make up a theoretical framework within which scientific theories can be tested, evaluated and if necessary revised.”

In practice, a paradigm is usually defined for a collection of sciences. In this context a paradigm introduces and justifies a set of basic assumptions and principles on which any of the sciences from the collection can rely as on their foundations. Then, starting from the principles provided by a paradigm, different sciences build their specific frameworks of knowledge. And if some sciences share the same paradigm then they can bind and synchronize their specific frameworks of knowledge. By doing so they can mutually enrich each other with the knowledge obtained from the different (but consistent with regard to the basic principles) points of view.

The Triune Continuum Paradigm (Naumenko, 2002) is a paradigm for general system modeling. Thus the Triune Continuum Paradigm serves the sciences that have diverse interests in system modeling. As any paradigm, it introduces and justifies a set of principles that provide the sciences with the necessary starting points for building their diverse conceptual frameworks of scientific knowledge; in our case - the principles that are necessary for building modeling frameworks.

THREE PRINCIPLES OF THE TRIUNE CONTINUUM PARADIGM

Triune Continuum Paradigm is composed of three principles.

The first principle is the result of application of the Tarski’s Theory of Truth (Tarski, 1956) for the case of general system modeling. This application allows the definition of coherent semantics for the concepts of a modeling framework. This is done by constructing formal descriptions for the relations between the subjects that are interesting to be modeled on one side, and the concepts that have to represent these subjects on the other side. This principle is necessary to assure the *coherency* and *unambiguity* within modeling interpretations performed using a single system modeling framework.

An application of the first principle provided by the Triune Continuum Paradigm results in a system modeling framework that features modeling terms with a coherently defined semantics in the form of Tarski's declarative semantics. The justifications of importance of this principle for the information systems modeling were presented and analyzed in details (Naumenko, Wegmann & Atkinson, 2003). In particular, it was demonstrated that Tarski's declarative semantics are:

- formally *sufficient* for the definition of the application scope of a modeling language;
- formally *sufficient* for unambiguity in coherency of interpretations within modeling representations;
- formally *necessary and sufficient* for unambiguity in adequateness of modeling representations.

The second principle of the Triune Continuum Paradigm is the result of application of the Russell's Theory of Types (Russell, 1908) for the case of general system modeling. This application defines the way to categorize concepts of a modeling framework so that in applications of this framework the concepts make up *internally consistent* structures of propositions. Thus this principle is necessary to assure the consistency of descriptions and specifications, which are constructed with the aid of the modeling frameworks.

The importance of this principle is justified by the fact that Russell's Theory of Types was formulated to resolve Russell's paradox, "the most famous of the logical or set-theoretical paradoxes" (Irvine, 2003). Thus with an application of the second principle of the Triune Continuum Paradigm, the resulting modeling framework in its own applications will produce internally consistent system specifications (i.e., system specifications that are devoid of self-contradictions).

The name of Triune Continuum Paradigm originates from the third principle of the paradigm, which is the notion of Triune Continuum, defined in Naumenko (2002). This notion introduces and justifies a minimal set of modeling concepts that are *necessary and sufficient* to cover the representation scope of the general system modeling domain on the most abstract level. This principle is necessary for different system modeling frameworks to justify the existence of their basic modeling concepts.

The idea of Triune Continuum was defined through the introduction of three continuums representing the scope of general system modeling. The first two continuums are:

- *spatiotemporal continuum* (where subjective space-time metrics are defined to be used in the subjective representations);
- *constitution continuum* (where subjective constitutional metrics are defined to be used in the subjective representations, e.g., objects defined in relation with their environments).

These two continuums are introduced in relation to each other as complements within the universal general system modeling scope. In other words: everything in the scope that is not space-time is constitution; and everything in the scope that is not constitution is space-time.

The third continuum is:

- *information continuum* (which emerges from the mutual relations of the first two continuums and contains the corresponding information about these relations, e.g., information about objects and their environments being related to the spatiotemporal intervals or to the points in space-time).

Thus the three continuums are *triune*: none of them exist without the others; either the three exist altogether, or they do not exist at all. Indeed, as soon as the first (spatiotemporal) continuum is introduced, everything in the universal scope that does not belong to the first continuum immediately shapes the second (constitution) continuum; and the third (information) continuum immediately emerges as the information about the mutual relations of the first two continuums (e.g., as spatiotemporal information about the constitution).

The third principle of Triune Continuum Paradigm is important for various system modeling frameworks that are used in diversified domains of human activity (e.g., the frameworks used to analyze, design and develop coherent structures providing useful functionalities in domains spread from jurisprudence and health care to software engineering and machine-building industries). Using the notion of Triune Continuum it is possible to introduce and justify minimal sets of modeling concepts that are necessary and sufficient for those diversified frameworks to cover their respective representation scopes.

APPLICATIONS OF THE TRIUNE CONTINUUM PARADIGM

The Triune Continuum Paradigm can be applied in practice either to improve an existing system modeling framework or to design a new system modeling framework for a given purpose. Let us mention here three of the existing applications of the paradigm:

- case of the Unified Modeling Language (UML);
- case of the Reference Model of Open Distributed Processing (RM-ODP);

- case of the Systemic Enterprise Architecture Methodology (SEAM).

The first two of the three cases illustrate the paradigm applications targeting improvements of the existing system modeling frameworks. The third case illustrates the paradigm application contributing to the design of a new system modeling framework.

Case 1: Triune Continuum Paradigm Application for UML

"The Unified Modeling Language (UML) is a language for specifying, visualizing, constructing, and documenting the artifacts of software systems, as well as for business modeling and other non-software systems" (OMG, 2003, section 1.1). UML is a proposition of the Object Management Group (OMG) that emerged from the integration of different industrial practical experiences and became an influential phenomenon in the system modeling. As a matter of fact, due to the multiple efforts of different interested parties, UML has gained a relative domination over the other modeling techniques in the current industrial practices. This is why it was interesting to apply the Triune Continuum Paradigm for the case of UML conceptual framework. Results of this application were presented to the UML research community (Naumenko & Wegmann, 2002). With the aid of the Triune Continuum Paradigm it was shown that in its current state the metamodel of UML features a number of undesirable properties, in particular:

- absence of an explicit structural organization defined for the UML metamodel;
- absence of Tarski's declarative semantics in the UML metamodel;
- absence of theoretical justifications for the UML metamodel to represent the modeling scope that is targeted by UML.

The paradigm-based solutions were presented for each of the three identified problems (Naumenko & Wegmann, 2002), providing designers of UML with the benefits of the paradigm's logical rigor, of its formal presentation and of its solid theoretical foundations.

Case 2: Triune Continuum Paradigm Application for RM-ODP

The Reference Model of Open Distributed Processing (RM-ODP) is an ISO and ITU standard for system modeling, designed to model ODP-systems (ISO/ITU 1998). The result of Triune Continuum Paradigm application for the RM-ODP case is especially interesting because it allowed accomplishing a single consistent formalization of the RM-ODP conceptual framework, providing the denotational semantics for the basic modeling and specification concepts of RM-ODP. Such formalization was officially declared as a goal of the ISO and ITU activities in the scope of RM-ODP standardization (ISO/ITU 1998). But this goal was not achieved by the standard; and so far the paradigm-based formalization remains the only solution achieving the defined objective.

The formalization was expressed in a computer interpretable form using Alloy formal description technique (Jackson, 2002). Alloy was chosen because of the public availability of the corresponding software tool, "Alloy Constraint Analyzer," which allows simulation of the instances of conceptual structures formalized with Alloy and representation of these instances in a graphical form. However, due to the nature of denotational semantics (Naumenko, Wegmann & Atkinson, 2003), any choice of the formal description technique does not change semantic interrelations within the formalization. So, another formal description technique could also be used to express the paradigm-based formalization of the RM-ODP conceptual framework in a computer interpretable form.

The paradigm-based formalization of RM-ODP presents a concrete example of formal ontology for general system modeling. Thanks to the Triune Continuum Paradigm, the metamodel that is realized by the formal ontology is internally consistent, introduces logical coherency of interpretation of a subject of modeling, defines formal semantics for the modeling concepts, and its models are verifiable with the aid of computer tools. These results were presented to the RM-ODP research community (Naumenko & Wegmann, 2001; Naumenko, Wegmann, Genilloud & Frank, 2001), and they attracted interest of the ISO/ITU committee that is responsible for the RM-ODP standardization. This provides the Triune Continuum Paradigm with a chance to influence future evolution of the ISO/ITU standard.

Case 3: Triune Continuum Paradigm Application for SEAM

The Systemic Enterprise Architecture Methodology (SEAM) is a methodology proposed by LAMS-EPFL (Wegmann, 2003) for system modeling in the domain of enterprise architecture, which is the domain that considers integration of IT systems and business systems in the context of an enterprise.

Applying the Triune Continuum Paradigm, a logically rigorous framework of concepts covering the representation scope of SEAM was designed and implemented as a specialization of the RM-ODP standard conceptual framework (ISO/ITU, 1998). Thus in this case the paradigm application provided a formal ontology for SEAM. The corresponding research results were reported to the enterprise architecture community (Wegmann & Naumenko, 2001) and provided the necessary basis for ongoing evolution of SEAM.

FUTURE TRENDS

The Triune Continuum Paradigm provides a set of theoretical foundations for different frameworks of knowledge belonging to the general system modeling domain. In most of the cases, currently existing industrial and academic frameworks for system modeling do not feature such theoretical foundations, because these frameworks are developed using so-called "best practices" approach (when results of different practical experiences of system modeling within a given domain are integrated to build a modeling framework for the domain). And if the "best practices" approach is not accompanied by theoretical foundations then it is impossible to justify a number of important properties for the resulting system modeling frameworks (e.g., to guarantee the necessity and sufficiency of a framework for its domain representation, to assure internal consistency within different pieces of practical experience integrated in a single framework, etc.).

So, the Triune Continuum Paradigm provides an indispensable contribution to the general system modeling. And the future trends should assure practical realization of the significant constructive potential that the paradigm features for those numerous system modeling frameworks that currently do not have satisfactory theoretical foundations. This potential will be realized through the paradigm applications to these concrete system modeling frameworks. Some of the examples of such applications were presented in this article.

CONCLUSION

The Triune Continuum Paradigm provides system modelers (in particular, IS modelers) with a set of principles that are essential to build adequate system modeling frameworks. These principles are based on the solid theoretical foundations discovered in the last century: Tarski's Theory of Truth was presented in 1935, while Russell's Theory of Types was formulated in 1908. The authors of these two theories, Alfred Tarski and Bertrand Russell, are recognized to be among the greatest logicians throughout the history of humankind. Thus the Triune Continuum Paradigm through its applications used in the computer-aided environment promotes the use of fundamental logical theories to the practices of regular modelers, information system designers and architects. The paradigm-based theoretically founded approaches to the information systems development make a constructive difference in the IS development projects where the usual "best practices methodologies" do not perform well enough due to a number of reasons (e.g., lack of flexibility, lack of representation possibilities, lack of internal consistency, etc.).

KEY TERMS

RM-ODP: Reference Model of Open Distributed Processing, an ISO and ITU standard for system modeling designed to model open distributed systems.

Russell's Theory of Types: A theory proposed by British logician Bertrand Russell to resolve Russell's paradox, which appears when the set of all sets that are not members of themselves is considered in naive set theory. The paradox is that such a set appears to be a member of itself if and only if it is not a member of itself.

SEAM: Systemic Enterprise Architecture Methodology, a methodology proposed by LAMS-EPFL for system modeling in the domain of enterprise architecture (the domain that considers integration of IT systems and business systems in the context of an enterprise).

Tarski's Theory of Truth: A theory proposed by Polish logician Alfred Tarski. The theory defines the criteria for a formal definition of a true sentence; the theory allows deriving the notion of Tarski's declarative semantics for a modeling language where the modeling language terms are put in the unambiguous correspondence with the subjects of modeling interest that they represent in applications of the language.

Triune Continuum: One of the principles of the Triune Continuum Paradigm. The principle introduces three continuums (spatiotemporal, constitution and information continuums) to justify a minimal set of modeling concepts that are necessary and sufficient to cover the representation scope of the general system modeling domain on the most abstract level.

Triune Continuum Paradigm: A paradigm for general system modeling. The paradigm introduces and justifies a set of principles that provide designers and architects of system modeling methodologies with the necessary theoretical support for building their modeling frameworks. The principles are derived from the Tarski's Theory of Truth, from the Russell's Theory of Types and use the notion of Triune Continuum.

UML: Unified Modeling Language proposed by the Object Management Group (OMG) for system modeling in the domains of software systems, of business systems and others.

Bayesian Analysis of Geographical Variation in Disease Risk

INTRODUCTION

Disease mapping is a big focus of interest in the area of public health (Bailey, 2001; Moore & Carpenter, 1999), and the geographical distribution of a disease has an important role in understanding its origin, its causes or its evolution.

In recent years, there have been many efforts to map mortality or incidence from diseases (see, for example, Lopez-Abente, Pollán, Escolar, Errezola & Abraira, 2001). The most widely used indicator in geographical representation is the standardized mortality ratio (SMR); this offers the advantage of eliminating the confounding effect of the variable by which it is adjusted, usually age, but presents certain drawbacks when the population size varies over the map (Breslow & Day, 1975). In such a case, estimators of different accuracy are obtained in each area; areas having small populations—and thus fewer cases—tend to register very extreme estimations of risk, which then dominate the map and hinder epidemiological interpretation. This is a particular problem for rare diseases where thousands of individuals are needed before a single case is expected to occur. This makes the necessity to utilize information from neighbouring areas in order to produce better estimates.

Alternative risk measures may be obtained by applying other modelling techniques that take the sources of spatio-temporal variation into account (Lawson, 2001). A simple technique consists of adjusting a Poisson regression model that displays a log-linear relationship between risk and space-time variables. While successful in reducing the variability in risk, this method continues to pose a number of drawbacks. First, in geographical areas having few cases, this model yields unstable estimations due to extra-Poisson variation. Furthermore, if the hypothesis of spatial independence between risks does not hold, the model is not appropriate, as it takes no account of a possible correlation between areas.

A possible solution to these problems is the Bayesian extension of the model introduced by Clayton and Kaldor (1987) and further developed by Besag, York, and Mollié (1991). Basically, this approach provides a way to integrate, in the estimation of the unknown relative risk, local information consisting of the observed and expected number of cases in each area and prior information on the overall variability of the relative risk, their potential similarity in neighbouring areas, and their connection with geographically defined covariates.

In this article, we compare the behaviour of the mentioned techniques with the purpose of estimating and mapping mortality relative risks in small geographical areas; this is illustrated by the analysis of the geographical variation in men lung cancer mortality in Galicia (Spain).

THEORETICAL MODELS

Classical Approach

Let O_i denote the number of observed cases, E_i the number of expected cases, calculated by using the population broken down by age for each area or geographical unit, plus the specific mortality rates, and let ξ_i be the relative risk (*RR*).

B

The classical approach to disease mapping is based on the assumption that, conditional on the E_i's being known, the ξ_i's are mutually independent. Moreover, each O_i follows a Poisson distribution with mean $E_i\xi_i$:

$$[O_i \mid E_i, \xi_i] \sim Poisson\,(E_i\xi_i)$$

Under these assumptions, the maximum likelihood estimate of ξ_i, denoted by $\hat{\xi}_i$, is the *SMR*:

$$\hat{\xi}_i = SMR_i = \frac{O_i}{E_i}$$

Hierarchical Bayesian Model

Bayesian methods estimate the risk of an area by incorporating information from adjacent areas, so as to reduce the effect of random fluctuations unrelated to the risk. Furthermore, on taking account of spatial correlation between adjoining areas, the resulting smoothed maps prove more informative (Banerjee, Carlin & Gelfand, 2004; Richardson, 2003; Wakefield, Best & Waller, 2000).

In the Bayesian approximation, Poisson variation is modelled at a first level, and a model for the relative risks is specified at a second level, with area-specific random effects further decomposed into two components: a spatially structured component that takes into account the effects that vary in a structured manner in space (clustering) and a component that models the effects that vary in an unstructured manner between one area and the next (heterogeneity).

The spatio-temporal hierarchical model is formulated as follows (Bernardinelli, Clayton, Pascutto, Montomoli, Ghislandi & Songini, 1995):

Let O_{ij} be the number of observed cases, E_{ij} the number of expected cases, and ξ_{ij} the *RR* in area *i* and period *j*. A likelihood model is specified for the vector of observed cases, given the risk vector

$$[O_{ij} \mid \xi_{ij}] \sim \text{Poisson}(E_{ij}\xi_{ij})$$

and the *RR* is modelled as

$$\log \xi_{ij} = \alpha + \phi_i + \theta_i + (\beta+\delta_i)t_j + \Sigma\,\gamma_k X_{ki}$$

where α is the mean of the logarithm for *RRs* over all areas, ϕ_i the clustering component, θ_i the heterogeneity component, t_j the time, β the mean of the time trend across all areas, δ_i the space-time interaction effect, and X_k indicate the covariates, with coefficients γ_k.

Estimation of the risk across time in each area is given by $\exp(\beta+\delta_i)$. Following the Bernardinelli, Clayton, Pascutto, Montomoli, Ghislandi, and Songini (1995) notation, δ_i is named the differential trend for area *i*: a value of $\delta_i<0$ indicates that the trend in area *i* is below the mean, while a value of $\delta_i>0$ implies that the trend in area *i* is above the mean.

Bayesian modelling requires specification of prior distributions for random effects. Several prior distributions can be considered, and next, we will describe the specifications used in the practical application.

The distribution model for the heterogeneity component is

$$[\theta_i \mid \theta_j, i\neq j, \sigma_\theta^2] \sim \text{normal}\,(\bar{\theta}_{-i}, \sigma_\theta^2)$$

where

$$\bar{\theta}_{-i} = \frac{1}{I-1}\sum_{j\neq i}\theta_j\,, \quad I = \text{number of areas.}$$

By virtue of this prior distribution, it is assumed that variation in risk between areas is independent and, as a consequence, posterior estimations of the area effect will tend towards an overall mean.

For the clustering component, the estimations of the risk in any area depend on neighbouring areas; this was achieved by allocation of weights. Specifically, weights were taken equal to one in cases where the areas were adjacent (i.e., share a common boundary) and zero in cases where they were not. The conditional autoregressive (CAR) model proposed by Besag, York, and Mollié (1991) was used:

$$[\phi_i \mid \phi_j, i\neq j, \sigma_\phi^2] \sim \text{normal}(\bar{\phi}_i, \sigma_i^2)$$

where

$$\bar{\phi}_i = \frac{1}{\sum_j w_{ij}}\sum_j \phi_j w_{ij}$$

$$\sigma_i^2 = \frac{\sigma_\phi^2}{\sum_j w_{ij}}$$

$w_{ij} = 1$ if i,j are adjacent (or 0 if they are not).

Parameters σ_θ^2 and σ_ϕ^2 control the variability of θ and ϕ. Following the recommendations of Bernardinelli, Clayton, and Montomoli (1995), gamma distributions were considered for these parameters.

In order to carry out a full Bayesian analysis, hyperprior distributions for α, β and γ_k must be specified; uniform priors (improper) were assumed for all these parameters.

Estimation of Hierarchical Bayesian Models

For the estimation of the hierarchical model simulation techniques are required; the most commonly used is the Gibbs Sampler, which belongs to the Markov chain Monte Carlo (MCMC) methods and is implemented in the software WinBUGS (Spiegelhalter, Thomas, Best, & Lunn, 2002).

A convergence analysis must be carried out in order to assess whether the Markov chain converges to the stationary distribution (for a review of convergence diagnostics, see Cowles & Carlin, 1996).

Selection of Models

To select the best model from a collection of different Bayesian models, what is used is the Deviance Information Criterion (DIC) proposed by Spiegelhalter, Best, Carlin, and Van der Linde (2002) that enables simultaneous assessment of fit and model complexity:

$$\mathrm{DIC} = D + p_D$$

where D is the deviance based on posterior means of the parameters, and p_D is the effective number of parameters, which is obtained by subtracting a plug-in estimation of the deviance, calculated using posterior means of the parameters, from the posterior deviance.

It must be stressed that DIC is not intended for identification of the correct model, but rather as a method of comparing a collection of alternative formulations.

PRACTICAL APPLICATIONS

The methods described in the previous section have been applied to the study of geographical variation in men lung cancer mortality from 1978 to 1998 in Galicia, (Spain).

Data

Galicia is a region situated in the northwest of Spain and divided into 315 municipal areas. The study period, 1978-1998, was divided into three sub-periods of seven years each: 1978-1984, 1985-1991, and 1992-1998.

Age was categorized as under 15 years, 15-24, 25-34, 35-44, 45-54, 55-64, 65-74, and over 74 years. Since very few deaths from lung cancer occur below age 44, we combine the first four categories.

Lung cancer mortality data in males, which consists of the number of lung cancer deaths in municipality i for time period j (i=1, …, 315 and j=1,2,3) were obtained from the Spanish National Statistics Institute for the period 1978-1986, and from the Galician Mortality Register for the period 1987-1998. Galician age-specific men population figures were obtained from the 1981 and 1991 Censuses and the 1986 and 1996 Population Registers.

Description of Covariates

The covariates we have considered are the total resident population per square kilometre (DEN) as a proxy for urban living, and a socio-economic score (SES), both at municipality level and referred to 1991. The SES, obtained using the methodology proposed in Silva-Ayçaguer (1997), is a summary of the following variables: infant mortality rate, population density, proportion of people that live in population centres with more than 1,000 inhabitants, proportion of men with high studies, proportion of active people in industrial activities, and proportion of people in households without running water or electricity.

Results

Before estimating and interpreting any results, the sensitivity of the conclusions to changes in Bayesian model specifications was investigated by using DIC. The best model in terms of DIC was the model that included the space-time interaction effects, without the heterogeneity term:

$$\log \xi_{ij} = \alpha + \phi_i + (\beta + \delta_i) t_j$$

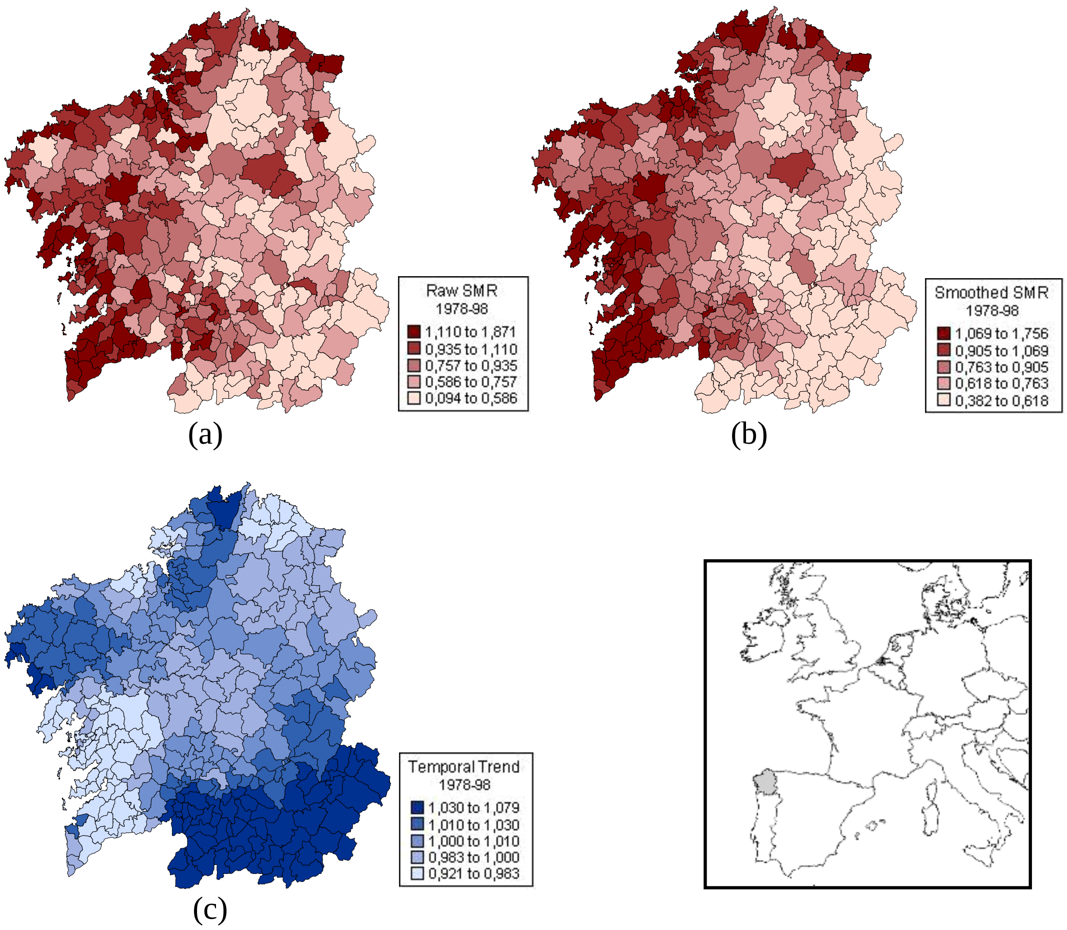
This model was, therefore, used for subsequent analyses, such as introduction of covariates.

Figure 1 shows the estimated *RR*s for lung cancer, obtained by classic approximation and Bayesian estimation.

The *RR*s are less variable in Figure 1(b) than in Figure 1(a), with the effect of smoothing being in evidence (*SMR*s ranges from 0,094 to 1,871; the Bayesian estimates of *RR* correct this dispersion, since the pulled estimates range from 0,382 to 1,756). The *SMR*s variability reflects random fluctuations due to different population size and corresponding small counts.

The maps highlight contrasts in the geographical distribution of risk; the northwest and the southwest

Figure 1. Lung cancer mortality in men in Galicia, 1978-1998: (a) Raw SMR; (b) Bayesian smoothed RR; (c) Temporal trend



parts of Galicia appear at higher risk. This pattern is stable in both maps, although, as expected, it emerges more clearly in the map obtained under the Bayesian model.

Figure 1(c) presents the temporal trend for lung cancer in the Galician municipalities and shows that, in areas with lower mortality, a rising trend has been in evidence over the course of the last few years.

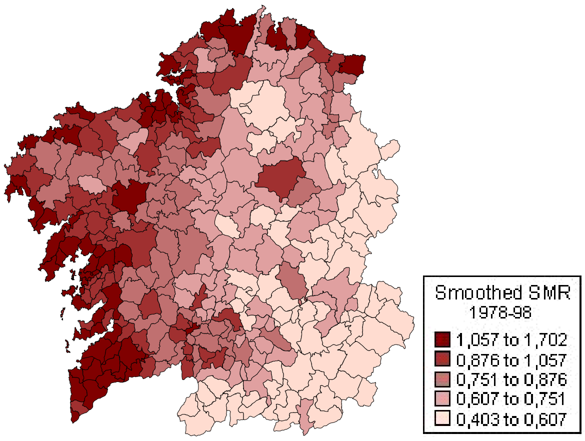
Figure 2 shows the estimations obtained by adjusting the model with both covariates. The *RRs* had shrunk further, that is, they have a smaller variation interval (*SMR*s ranges from 0.403 to 1.702). This result (the covariates providing information that helps to reduce the *RR*s variability), together with the fact that the DIC value for the model including the covariates is smaller than for the model without them, confirm the relationship between the covariates and the disease.

FUTURE TRENDS AND CONCLUSIONS

This study has addressed various issues in disease mapping: use of classical methods versus Bayesian models, choice of the prior distributions or incorporation of spatio-temporal structures. Its emphasis was more on comparing these methods with data than on making theoretical comparisons. Conclusions about comparison of methods have limited validity.

The use of Bayesian models for computing the *SMR* instead of the usual procedures is recommended. Maps of observed *SMR*s may be unstable and are prone to wrong interpretation, as attention is drawn to regions with high or low *SMR*s based on small populations. Smoothing overcomes the problem of overdispersion and enables us to highlight the differences between municipalities. The

Figure 2. Lung cancer mortality in men in Galicia, 1978-1998. Bayesian smoothed RR using the model with covariates.



estimation of the parameters of the hierarchical model can be carried out with algorithms belonging to the class of MCMC methods, which have improved in the last few years and allow us to compute summary statistics for the distribution of *RR*s.

The results obtained using Bayesian methods may be sensitive to the choice of priors. Nevertheless, Mollié (2000) discusses the insensitivity of these methods to the choice of priors, but in cases where data are sparse and there is a prevailing conviction of geographical variability, this independence ought to be explored with caution.

From this analysis, interesting results have arisen on the variability of the relative risks. There is indication that a main part of the variability is accounted for by a local clustering structure. Thus, there is some evidence that local risk factors, which might correspond to a complex combination of environmental and socio-demographic local characteristics, relatively stable over time, are influencing the spatial structure of lung cancer mortality.

By including covariate values measured on regions rather than individuals, this analysis is an example of "ecological modelling". As in any ecological study, and due to the "ecologic fallacy" (attributing effects measured in aggregate to individuals), one must interpret results with caution, even when pertinent covariates are included because there are many potential factors of bias which can create discrepancies between the results of a study that analyses data at an aggregate level and the results of those that do so at an individual level. Furthermore, cancer mortality rates rise with age, with the accompanying problem of worse diagnostic quality and ensuing death certification, which may lead to bias in estimation.

In this study, we assumed that the covariate measures are error-free. However, this is rather unrealistic. Indeed, Bernardinelli, Pascutto, Montomoli, and Komakec (1999) and Xia and Carlin (1998) incorporate covariate measures that are not error-free into the standard hierarchical Bayesian model, and demonstrate that when the underlying error is taken into account, estimations prove more accurate.

Subsequent investigations have led us to assess the extension of the model, with the introduction of the age factor and even its interaction with time because the mortality behaviour through the study years is different in the age-groups. This necessarily implies a greater number of observations, giving rise to problems in the production of sufficiently accurate posterior estimations.

Another improvement involves the choice of neighbours. A recent study (Best, Arnold, Thomas, Waller & Conlon, 1999) indicates that the option used in this paper yields better results, but it would nonetheless be interesting to experiment with other alternatives, such as taking all municipalities lying within a given radius of kilometres as neighbours, or taking *k* neighbours lying closest to a given municipality.

KEY TERMS

Clustering: Unusual grouping of events in space and/or time. It is also the tendency of observations to be situated closer to one another than they would be expected.

Deviance Information Criterion (DIC): Measure introduced by Spiegelhalter, Best, Carlin, and van der Linde (2002) as a tool for comparing and selecting complex hierarchical models. DIC combines a measure of fit, the deviance statistic, and a measure of complexity, the number of free parameters in the model. Since increasing complexity is accompanied by a better fit, the DIC trades off these two quantities.

Disease Mapping: It refers to the visual display of geographical patterns of disease in a map. The maps typically show standardized mortality or incidence ratios for geographic areas such as countries, counties, or districts.

Ecological Fallacy: The relationship between geographical variation in disease incidence or mortality and explanatory covariates (e.g., environmental agents or lifestyle characteristics) measured on groups is often interpreted as a proxy of the relationship between disease and exposure in individuals. However, the association observed at the group or ecological level will not necessarily represent the association between the corresponding variables at the individual level. This type of bias is known as ecological fallacy.

Heterogeneity: Effects that unobserved variables can introduce in disease rates and that vary in an unstructured manner in either space or time.

Hierarchical Bayesian Model: The enterprise of specifying a model over several levels is called hierarchical modelling, with each new distribution forming a new level in hierarchy. Suppose that we have a collection of observations $\boldsymbol{y}=(y_1, y_2, \ldots, y_k)$ that are assumed to come from a distribution $p(\boldsymbol{y}|\boldsymbol{\theta})$ where $\boldsymbol{\theta}=(\theta_1,\theta_2,\ldots,\theta_k)$. It can also be assumed that $\boldsymbol{\theta}$ is a random quantity draw from the distribution $p(\boldsymbol{\theta}|\boldsymbol{\lambda})$ where $\boldsymbol{\lambda}$ is a vector of parameters. In principle, the parameter $\boldsymbol{\lambda}$ can depend itself on a collection of other parameters. This sequence of parameters and distributions constitutes a hierarchical model. The hierarchy must stop at some point, with the remaining parameters known.

Prior Information: Existing knowledge about a phenomenon under investigation. This knowledge can be incorporated into a statistical analysis using probability distributions. For instance, in a hierarchical Bayesian model, prior information is the set of probability distributions of the parameters in the model.

Relative Risk: Measure that compares the incidence of a disease in a group of interest with the incidence in a control group.

Smoothing: Adjustment of mortality rates using a combination of the knowledge about the rate in each area and the knowledge about the rates in surrounding areas. The smoothing removes the noise in disease maps and allows to assess specific hypotheses concerning incidence or mortality.

Standardized Mortality Ratio (SMR): Ratio of the observed mortality in a group of interest to the expected mortality in that group, based on some standard population. It gives information about regions with unusual high or low numbers compared to the expected numbers.

Bayesian Machine Learning

Eitel J.M. Lauría
Marist College, USA

INTRODUCTION

Bayesian methods provide a probabilistic approach to machine learning. The Bayesian framework allows us to make inferences from data using probability models for values we observe and about which we want to draw some hypotheses. Bayes theorem provides the means of calculating the probability of a hypothesis (posterior probability) based on its prior probability, the probability of the observations and the likelihood that the observational data fit the hypothesis.

$$\mathrm{P}(H \mid D)=\frac{\mathrm{P}(D \mid H)\cdot \mathrm{P}(H)}{\mathrm{P}(D)} \tag{1}$$

$\mathrm{P}(H \mid D)$ is defined as the probability of a certain hypothesis based on a set of observational data given a certain context (posterior probability of hypothesis H); $\mathrm{P}(D \mid H)$ is the likelihood of the observations given a certain hypothesis; $\mathrm{P}(H)$ is the intrinsic probability of hypothesis H, before considering the evidence D (prior probability); and $\mathrm{P}(D)$ is the probability of the observations, independent of the hypothesis, that can be interpreted as a normalizing constant. Bayes rule can therefore be reformulated as shown in expression . This means that the probability of the hypothesis is being updated by the likelihood of the observed data.

$$\mathrm{P}(H \mid D) \propto \mathrm{P}(D \mid H)\cdot \mathrm{P}(H) \tag{2}$$

BACKGROUND

The practical application of Bayes rule to machine learning is rather straightforward. Given a set of hypotheses H and a set D of observational data we can estimate the most probable hypothesis H given D, by comparing different instances of the previous expression for each hypothesis H and choosing the one that holds the largest posterior probability (also called maximum a posteriori probability or MAP).

$$\text{Most probable } H \equiv H_{\mathrm{MAP}} = \arg\max \left[\mathrm{P}(D \mid H)\cdot \mathrm{P}(H)\right] \tag{3}$$

Suppose we have a classification problem where the class variable is denoted by C and can take values $c_1, c_2, \ldots, c_k$. Consider a data sample D represented by n attributes $A_1, A_2, \ldots, A_n$ of which the observations $(a_1, a_2, \ldots, a_m)$ have been taken for each instance of D. Suppose that each instance of the data sample D is classified as $c_1, c_2, \ldots, c_k$. The Bayesian approach to classifying a new instance would then be to assign the most probable target value (a class value of type c_i) by calculating the posterior probability for each class given the training data set, and from them choosing the one that holds the maximum a posteriori probability.

$$c_{\mathrm{MAP}} = \arg\max_{c_i \in C} \left[\mathrm{P}(D \mid c_i)\cdot \mathrm{P}(c_i)\right] \tag{4}$$

NAIVE BAYES CLASSIFICATION

Although the idea of applying full-blown Bayesian criteria to analyze a hypothesis space in search of the most feasible hypothesis is conceptually attractive, it usually fails to deliver in practical settings. Although we can successfully estimate $\mathrm{P}(c_i)$ from the training data, calculating the joint probability $\mathrm{P}(D \mid c_i)$ is usually not feasible: unless we have a very large training data set, we would end up with estimates that are representative of a small fraction of the instance space and are therefore unreliable. The naive Bayesian classifier attempts to solve this problem by making the following assumptions:

- Conditional independence among attributes of the data sample. This means that the posterior probability of D, given c_i is equal to the product of the posterior probability of each attribute.

$$\mathrm{P}(D \mid c_i) = \prod_{j=1}^{n} \mathrm{P}(A_j = a_j \mid c_i) \quad , c_i \in C \tag{5}$$

- The conditional probabilities of each individual attribute can be estimated from the frequency distributions of the sample data set D as N_{ij}/N_i, where N_{ij} is the number of training examples for which attribute $A_j = a_j$ and class value is c_i; and N_i is the number of training examples for which the class value is c_i. If the prior probabilities $P(c_i)$ are not known, they can also be estimated by drawing its probabilities from the sample data set of frequency distributions.
- To solve the cases in which there are very few or no instances in the data set for which $A_j = a_j$ given a certain class value c_i, which would in turn render poor estimates of $\mathrm{P}(A_j = a_j \mid c_i)$ or make it equal to zero, a common approach is to estimate $\mathrm{P}(A_j = a_j \mid c_i)$ as:

$$\mathrm{P}(A_j = a_j \mid c_i) = \frac{N_{ij} + \alpha_{ij}}{N_i + \alpha_i} \qquad (6)$$

where α_{ij} and α_i can be seen as fictitious counts coming out of our prior estimate of the probability we wish to determine. In rigor, this implies considering a conjugate prior probability given by a Dirichlet distribution (for more details see Ramoni & Sebastiani, 1999). A typical method for choosing α_{ij} and α_i in the absence of other information is to assume uniform distribution of the counts, which means that if an attribute has r possible values, $\alpha_{ij} = 1$ and $\alpha_i = r$. This results in:

$$\mathrm{P}(A_j = a_j \mid c_i) = \frac{N_{ij} + 1}{N_i + r} \qquad (7)$$

These assumptions have the effect of substantially reducing the number of distinct conditional probability terms that must be estimated from the training data. To illustrate the use of the naïve Bayes classifier, consider the example in Table 1 adapted from Mitchell (1997). We are dealing with records reporting on weather conditions for playing tennis. The task is to build a classifier that, by learning from previously collected data, is able to predict the chances of playing tennis based on new weather reports. We can estimate the class probabilities P(play=yes) and P(play=no) by calculating their frequency distributions as follows:

P(play=yes) = (# of instances were play=yes) / (total # of instances) = 9/14

P(play=no) = (# of instances were play=no) / (total # of instances) = 5/14

The conditional probabilities can be estimated by applying equation , as shown in Table 1(d). For a new weather report W={outlook=rain, temp=hot, Humidity=high, windy =false} the classifier would compute

Table 1. Weather data set

outlook	temperature	humidity	windy	play
sunny	hot	high	false	no
sunny	hot	high	true	no
overcast	hot	high	false	yes
rainy	mild	high	false	yes
rainy	cool	normal	false	yes
rainy	cool	normal	true	no
overcast	cool	normal	true	yes
sunny	mild	high	false	no
sunny	cool	normal	false	yes
rainy	mild	normal	false	yes
sunny	mild	normal	true	yes
overcast	mild	high	true	yes
overcast	hot	normal	false	yes
rainy	mild	high	true	No

(a) List of Instances

Attribute Name	Values
outlook	sunny, overcast, rainy
temperature	hot, mild cool
humidity	high, normal
windy	true, false
play (class attribute)	yes, no

(b) List of Attributes

(play = yes)	9/14
(play = no)	5/14

(c) Prior Class Probabilities

	play				play	
Outlook	yes	no		Humidity	yes	no
sunny	3/12	4/8		high	4/11	5/7
overcast	5/12	1/8		normal	7/11	2/7
rain	4/12	3/8				
Temperature				Windy		
hot	3/12	3/8		false	4/11	4/7
mild	5/12	3/8		true	7/11	3/7
cold	4/12	2/8				

(d) Conditional Probabilities

$$P(\text{play=yes} \mid W) = P(W \mid \text{play=yes}) \cdot P(\text{play=yes})$$
$$= \frac{4}{12} \cdot \frac{3}{12} \cdot \frac{4}{11} \cdot \frac{4}{11} \cdot \frac{9}{14} = 0.007084$$

$$P(\text{play=no} \mid W) = P(W \mid \text{play=no}) \cdot P(\text{play=no})$$
$$= \frac{3}{8} \cdot \frac{3}{8} \cdot \frac{5}{7} \cdot \frac{4}{7} \cdot \frac{5}{14} = 0.020499$$

and therefore predict that no tennis matches will be played.

Although naive Bayes classification makes a major simplification (conditional independence is a very strong assumption), in practice it often competes well with more sophisticated algorithms. See Rish (2001) for an empirical analysis of the naive Bayes classifier.

BAYESIAN BELIEF NETWORKS

Bayesian belief networks (BBNs) follow a middle-of–the-road approach when compared to the computationally intensive optimal Bayesian classifier and the oversimplified naive Bayesian approach. A BBN describes the probability distribution of a set of attributes by specifying a set of conditional independence assumptions together with a set of causal relationships among attributes and their related joint probabilities. When used in this way, BBNs result in a powerful knowledge representation formalism, based in probability theory, that has the potential of providing much more information about a certain domain than visualizations based on correlations or distance measures.

Building a Graphical Model

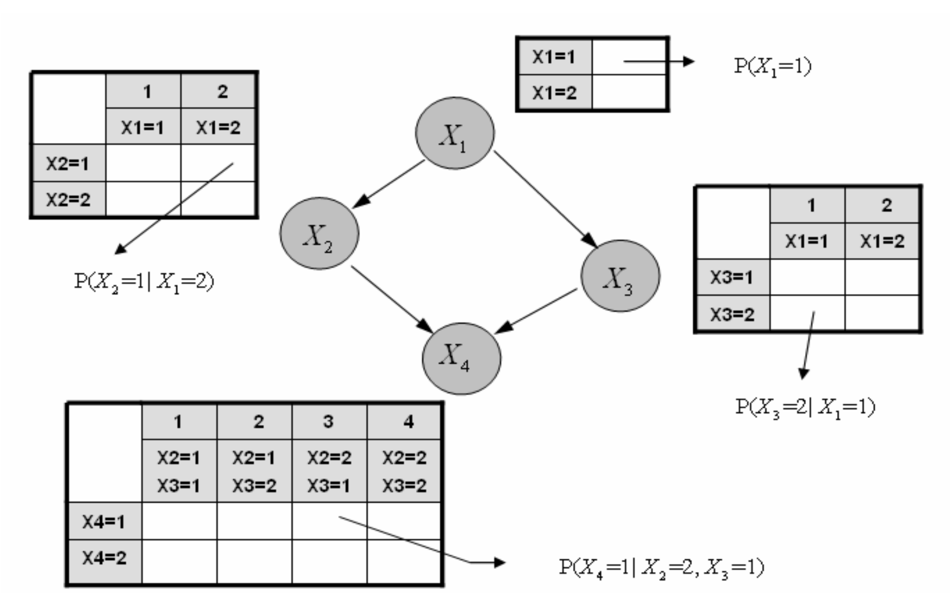
The set of relationships in a Bayesian network can be modeled by means of a directed acyclic graph (DAG), where each node represents a variable to which a group of conditional probabilities are attached. Given a set of variables $X_1, X_2, ..., X_n$, a directed acyclic graph (DAG) is constructed in which each node of the graph represents each of the variables and the arcs represent the relationship between the arcs (see Figure 1). Recalling the product probability rule, the joint probability distribution can be written as:

$$p(X_1 = x_1, X_2 = x_2, ..., X_n = x_n) = p(x_1, x_2, ..., x_n) = \prod_{i=1}^{n} p(x_i \mid x_{\text{pa}(i)}) \tag{8}$$

We use the notation $p(x_1, x_2, ..., x_n)$ as an abbreviation for the probability of a conjunction of particular assignments $x_1, x_2, ..., x_n$ to the set of variables $X_1, X_2, ..., X_n$, and $x_{\text{pa}(i)}$ is a vectorized notation to identify a given configuration of the list of direct parents of X_i, linked to X_i through the causal arcs in the graph model.

In addition to the graph structure, it is necessary to specify the parameters of the model. This means that we

Figure 1. Structure and parameters of a Bayesian network



must specify the conditional probability distribution at each node. If the variables are discrete, this can be represented as a table that lists the probability the child node takes on each of its different values for each combination of values of its parents (see Figure 1).

Inference in Bayesian Belief Networks

Once the belief network is formulated it can be used for probabilistic inference, that is, to make probabilistic statements concerning the network attributes (nodes). Since a BBN uniquely defines a joint probability distribution, any probability can be computed from the network by specifying the joint probability distribution and applying basic rules of probability, such as conditioning and marginalization.

As indicated before, because a BBN determines a joint probability distribution for the set of attributes in the network, the Bayesian network can, in principle, be used to compute any probability of interest. For problems with many variables, though, this approach is not practical. Pearl's message passing algorithm (1988) provides an improved approach for singly connected DAGs (graphs where no pair of nodes has more than one path). The new evidence is propagated over the network by sending messages to neighbor nodes. Through the arcs, acting as communication channels, the nodes send messages providing information about the joint probability distribution that is defined by the network and the evidence obtained so far. The algorithm has been extended to multiple connected DAGs where messages are passed in a junction tree that maps the original BBN (Jensen et al., 1990; Lauritzen & Spieglelhalter, 1988; Pakzad & Anantharam, 2002). Also, several approximate algorithms have been devised, based on Markov Chain Monte Carlo (MCMC) sampling (Heckerman et al., 1994; Neal, 1993) or variational methods (Jordan et al., 1997).

Training Bayesian Belief Networks

There are a number of possible scenarios to consider when addressing the problem of training a BBN:

- When the structure of the BBN is known and all the attributes for all the instances are observable in the training examples, learning the conditional probabilities is quite straightforward. We simply estimate the conditional probabilities by maximizing the likelihood of the training data, as in the case of the naive Bayes classifier (estimating relative frequencies with zero frequency corrections, for example).
- When the structure of the BBN is known but not all of the variables are observable (partially or totally) in the training data, we come across a more complicated problem. In such a case we can resort to algorithms intended to deal with missing values, such as the Estimation Maximization (EM) algorithm (Dempster et al., 1977). Another approach is assimilating the problem to the case of estimating the weights of the hidden nodes in a neural network. In that case a gradient ascent approach can be used, where the algorithm searches through the space of hypotheses corresponding to the set of all possible entries in the conditional probability table.
- When the structure of the network is not known, we face a problem of model selection, typically a much more complicated problem than the two previously described cases. The goal is to find the network, or group of networks that best describe the probability distribution over the training data. This optimization process is implemented in practice by using heuristic search techniques to find the best model over the space of possible BBNs. A scoring system is commonly used for choosing among alternative networks. Several scores have been considered, including the posterior probability of the model given the data, and approximations based on the Bayesian Information Criteria (Heckermann, 1999; Schwartz, 1978). Lam and Bachus (1994) and Lauría (2003) use scores based on the Minimum Description Length Principle (Rissanen, 1986, 1996), an information theoretic perspective of Occam's Razor principle according to which simple, sparse models should be preferred to complex overfitted models. Several authors discuss the idea of doing structure discovery by approximating the full Bayesian model averaging. Madigan et al. (1996) and Giudici et al. (2000) discuss the use of a MCMC search over the set of structures. Friedman and Koller (2001) introduce the idea of heuristic searching over orderings.

FUTURE TRENDS

Bayesian machine learning is being applied in a wide variety of domains, and the breadth of applications will undoubtedly increase in the future. Variations of the naive Bayes classifier are used in data mining and text summarization tasks (Arnborg, 2003; Eyheramendy et al., 2003; Peng & Schuurmans, 2003; Wiering, 2002). Lauría and Tayi (2003) describe the application of naive Bayes classification in network intrusion detection. Stewart (2002) uses a naive Bayes classifier to predict software project metrics. Friedman et al. (2000) use Bayesian networks to analyze gene expression data. Bilmes (2000) and Nefian et al. (2002) apply dynamic Bayesian networks to speech recognition. Onisko (2001) describes Hepar II, a system for diagnosing liver disorders. Kennett et al. (2001) have developed a weather forecasting system that predicts sea breezes. Hudson et al. (2001) have applied Bayesian networks as probabilistic expert systems for terrorist risk assessment. Breese and Heckerman (1996), and Jensen et al. (2001) target the problem of troubleshooting, fault diagnosis and reliability analysis. Microsoft has developed a number of Bayesian network applications, including Microsoft Office's Answer Wizard that uses naive Bayes to select help topics based on queries (Haddaway, 1999).

A plethora of theoretical and applied research is being performed in Bayesian networks and its related domains, including such topics as causality and Bayesian networks (Pearl, 2000), dynamic networks, learning with incomplete data, and cyclic networks. Heckerman (2000) points out that Microsoft uses dependency networks (a formalism similar to Bayesian networks that admits cyclical graphs) in two of its recent products—SQL Server 2000 and Commerce Server 2000—for both collaborative filtering and data visualization.

CONCLUSION

In this article we have provided an overview on Bayesian methods as applied to the field of machine learning. In doing so we have deliberately focused on reviewing the most relevant concepts, techniques and practical issues. Over the last few years, Bayesian machine learning has emerged as a prominent modelling and data analysis approach from which both academicians and practitioners can benefit. We envisage that Bayesian machine learning will continue to expand in the future both from a theoretical as well as a practical application perspective

KEY TERMS

Bayes' Rule: Shows how probabilities can be updated in the light of evidence. Bayes' rule derives from a simple reordering of terms in the product rule and by subsequently applying the law of total probability.

Bayesian Network: A graphical model that encodes the probability distribution of a set of random variables by specifying a set of conditional independence assumptions together with a set of relationships among these variables and their related joint probabilities.

Classification: Mapping a data item into one of several pre-defined categories. Stored data are used to locate data in predetermined groups. For example, a retail store chain could use customer purchase data to determine when customers visit and what they typically buy.

Directed Acyclic Graph: A graph in which each edge can be followed from one vertex to the next, and where no path starts and ends at the same vertex.

Naive Bayes: An extremely simple classification algorithm based on the use of the posterior probability as the defining criterion to choose among a set of hypotheses (classes). The naive Bayes classifier simplifies calculations by assuming conditional independence among the dataset attributes, given the class.

Probability: A number between 0 and 1 attached to a logical proposition that represents the degree of truth in that proposition.

Statistical Machine Learning: The process of deriving the parameters that characterize a statistical model from a set of observations.

Bayesian Modelling for Machine Learning

INTRODUCTION

Learning algorithms are central to pattern recognition, artificial intelligence, machine learning, data mining, and statistical learning. The term often implies analysis of large and complex data sets with minimal human intervention. Bayesian learning has been variously described as a method of updating opinion based on new experience, updating parameters of a process model based on data, modelling and analysis of complex phenomena using multiple sources of information, posterior probabilistic expectation, and so on. In all of these guises, it has exploded in popularity over recent years.

General texts on Bayesian statistics include Bernardo and Smith (1994), Gelman, Carlin, Stern, and Rubin (1995), and Lee (1997). Texts that derive more from the information science discipline, such as Mitchell (1997) and Sarker, Abbass, and Newton (2002), also include sections on Bayesian learning.

Given recent advances and the intuitive appeal of the methodology, Bayesian learning is poised to become one of the dominant platforms for modelling and analysis in the 21st century. This article provides an overview of Bayesian learning in this context.

BACKGROUND

Bayesian Modelling

Bayesian learning aims to provide information about unknown characteristics of a population (such as a mean and/or a variance) or about relationships between characteristics (for example, via a regression equation or a neural network). We often have a set of alternative models or hypotheses, H_1, H_2,…, H_m, that could describe these unknowns, such as possible values for the unknown mean or alternative neural network representations. The Bayesian approach allows prior beliefs about these models to be updated in the light of new data. The fundamental enabling mechanism is Bayes' rule:

$$p(H_i \mid D) = \frac{p(D \mid H_i)\, p(H_i)}{p(D)}, \qquad (1)$$

which states that the *posterior* probability $p(H_i|D)$ of a particular model, H_i, conditional on data, D, is proportional to the probability $p(D|H_i)$ of the data, given the model multiplied by the *prior* probability $p(H_i)$ of the model. The denominator $p(D)$, a normalizing constant designed to make the posterior probability sum or integrate to one, can be termed the probability of the data and is expressed as

$$p(D) = \sum_{i=1}^{m} p(H_i)\, p(D \mid H_i).$$

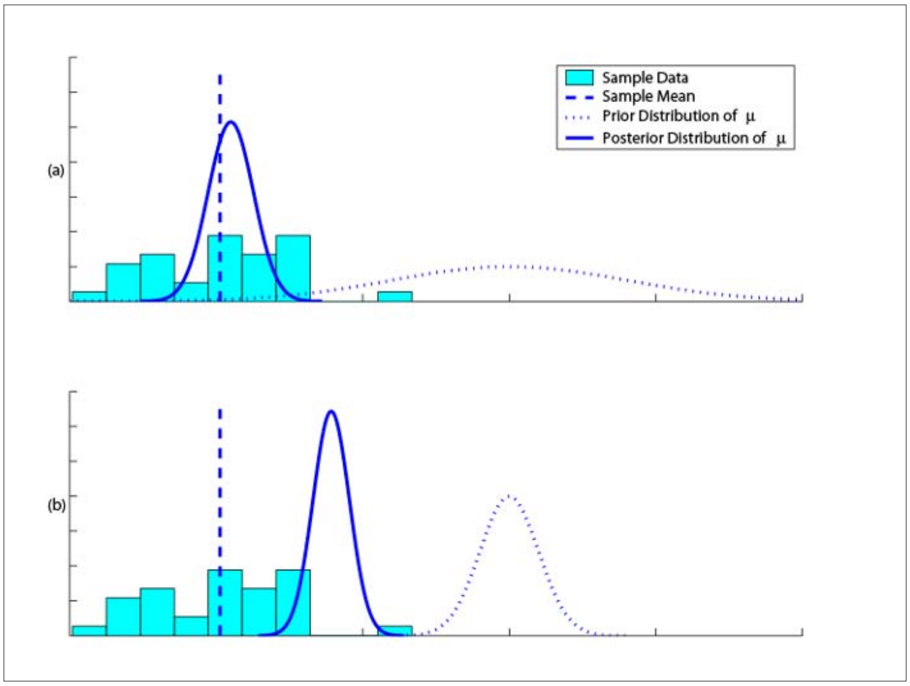
The number of plausible models might be infinite, for example, when the different models are represented by unknown values of a continuously distributed population mean. In this case, probability distributions become densities and the summation in $p(D)$ is replaced by an integral. In either case, it is this denominator, $p(D)$, that is often intractable. This motivates the development of numerical methods such as Markov chain Monte Carlo, described in the next section.

As a simple example, consider sampling n data points y_1, y_2,…, y_n from a population of normally distributed measurements in order to estimate an unknown mean, μ, and assume that the population variance, σ^2, is known. Thus, H is the set of all possible values that μ may take. The sample mean, $\bar{y}$, represents the information contained in the data so that $p(D|H)=p(\bar{y}|\mu)=N(\mu,\sigma^2/n)$.

In practice, we often have some prior knowledge about μ, such as, "μ is known from experience to be around a value μ_0." We might express this prior knowledge as $\mu \sim N(\mu_0, \tau_0^2)$, where τ_0^2 represents the uncertainty around the best guess, μ_0. Now, according to Bayes' rule:

$$p(H \mid D) = p(\mu \mid \bar{y}) \propto p(\bar{y} \mid \mu)\, p(\mu) = N(\mu_n, \tau_n^2) \qquad (2)$$

Figure 1.



with

$$\mu_n = \left(\frac{\mu_0}{\tau_0^2} + \frac{n\bar{y}}{\sigma^2}\right)\tau_n^2 \text{ and } \qquad \frac{1}{\tau_n^2} = \frac{1}{\tau_0^2} + \frac{n}{\sigma^2}.$$

The posterior distribution can be considered as a merging of the prior opinion about μ and the data. Figure 1 illustrates this updating of opinion about μ for different priors.

In 1a, the prior knowledge about μ is fairly vague. Thus, the posterior distribution for μ is dominated by the data. In 1b, the prior knowledge about μ is more precise and has more influence on the posterior distribution.

Bayesian Computation

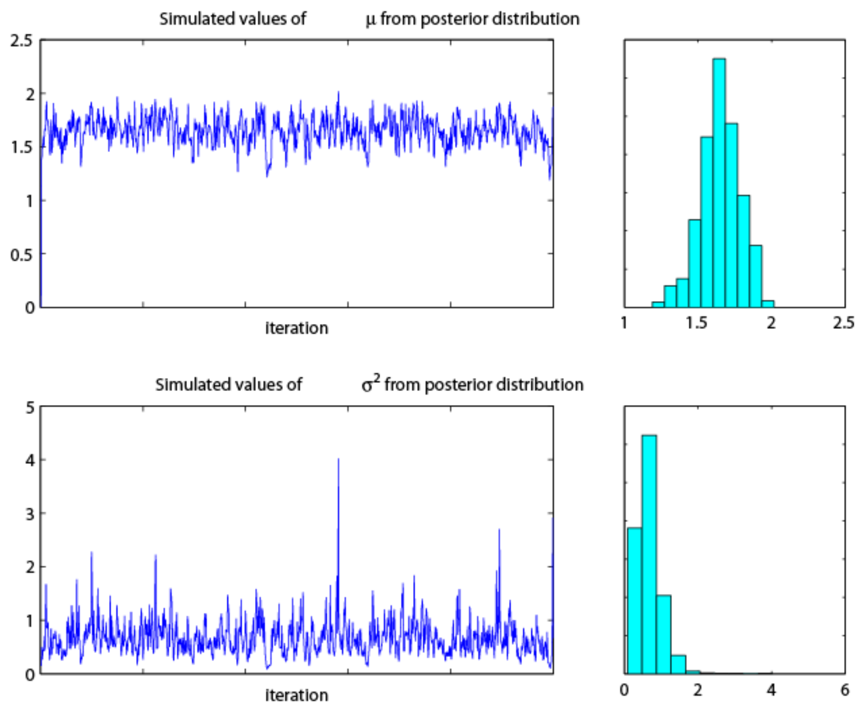
Continuing this example, suppose more realistically that σ^2 is also unknown. A distribution that reflects theoretical properties of a variance is the inverse Gamma distribution, so we might take $\sigma^2 \sim IG(a_0, b_0)$, where a_0 and b_0 are chosen to reflect our prior knowledge. Application of Bayes' rule results in a joint posterior distribution of μ and σ^2 that is nonstandard and multidimensional, making analytical solutions difficult.

A popular numerical solution is Markov chain Monte Carlo (MCMC). MCMC algorithms allow simulation from a Markov chain whose stationary distribution is $p(H|D)$. If it is not easy to simulate directly from $p(H|D)$, values can be proposed from some easily simulated distribution (such as uniform or normal) and accepted or rejected according to a rule that ensures that the final set of accepted values are from the target posterior distribution. If $p(H|D)$ is high dimensional, it can often be decomposed into a series of lower dimensional, conditional distributions, and (possibly different) MCMC algorithms can iterate around these, eventually forming a sample from the joint distribution (Besag, 1974).

For this example problem, a basic MCMC algorithm would be as follows.

- Choose initial values μ_1, σ_1^2
- Repeat for i=2:k for k large
  - Randomly draw σ_i from $\mu \mid \sigma_{i-1}^2, \bar{y}$ given in Equation (2).
  - Randomly draw σ_i^2 from the conditional posterior distribution $\sigma^2 \mid \mu_i, \bar{y} \sim IG(a_n, b_n)$, where $a_n = a_0 + \frac{1}{2}$ and $b_n = b_0 + \frac{n}{2}(\bar{y} - \mu_i)^2$
- Discard the first part of the above chain as "burn-in," in which the Markov chain is still approaching the target posterior distribution from the (perhaps unlikely) initial values.
- The remaining iterates, μ_i and σ_i^2, represent a large sample from the target posterior distribution. Graphs

Figure 2.



of μ_i and σ_i^2 or summaries such as $E(\mu)\approx\Sigma\mu_i/n$ can be used to present information about the posterior distribution. Figure 2 shows the results of using such an algorithm to simulate a sample from the posterior distribution.

Chen, Shao, and Ibrahim (2000) and Robert and Casella (1999) describe a wide range of methods for modelling and simulation of multiparameter data. While Metropolis-Hastings and Gibbs remain popular traditional MCMC algorithms, many variations have now been developed. The well-known variations include adaptive rejection sampling and adaptive rejection Metropolis sampling (Gilks, Roberts, & Sahu, 1998), slice sampling (Mira & Tierney, 2002; Neal, 1997), perfect simulation (Kendall, 1998; Propp and Wilson, 1996), delayed rejection sampling (Tierney & Mira, 1999), adaptive algorithms, black box algorithms (Chen & Schmeiser, 1998), and hybrid methods that employ combinations of MCMC algorithms in a single analysis (Tierney, 1994). For further description of Monte Carlo algorithms for Bayesian analysis, see Carlin and Louis (2000), Chen et al. (2000), Denison, Holmes, Mallick, and Smith (2002), Gustafson (2003), Ibrahim, Chen, and Sinha (2001), Robert (1998), Robert and Casella (1999), and West and Harrison (1997). Various software for MCMC is now available, including the freeware package BUGS (Spiegelhalter, Thomas, Best, & Gilks, 1995).

With all Monte Carlo methods, it is imperative to assess convergence, which includes ensuring that the length of burn-in is adequate (so that the effect of the initial values have worn off), the simulated values are indeed being drawn from the correct target distribution, the algorithm adequately explores the whole target space, and sufficient values are collected to allow adequate approximations of expectations of interest. Convergence assessment for MCMC includes theoretical evaluation exploiting the Markov chain features of these chains (Mengersen & Tweedie, 1996; Tierney, 1998; among many others) and empirical diagnostics (see, for example, Best, Cowles, & Vines, 1995, and stand-alone routines at http://lib.stat.cmu.edu).

Applications

Flexible, and if necessary quite complex, models can be constructed to reflect the linkages and uncertainties in any particular problem. The simple example described above could be extended further by placing priors on the hyperparameters μ_0, τ_0^2, a_0, and b_0 to create a hierarchical model. This extends to general hierarchical models (Congdon, 2001), neural networks (Neal, 1996), regression and classification trees and belief networks (Chipman, George, & McCulloch, 1998; Mello & Brown, 1999), and so on. For example, Bayesian belief networks, BBNs, describe associations between sets of variables. Prior knowledge informs the initial construction of the network and Bayes' rule is used to improve the network by learning both the parameters and the structure from the data. Similarly, a Bayesian neural network (BNN) applies a probabilistic interpretation to the traditional artificial neural network technique, using the training set of inputs and targets to calculate the predictive distribution of target values in a new test case, given the inputs for that case.

Bayesian learning has been used for pattern recognition (Serrano, Andreas, Savakis, & Luo, in press), mixture model identification (Ma, Wang, & Xu, 2004), artificial intelligence in medicine and neurocomputing (Cervera & del Pobil, 1997; Kononenko, 2001), operations research (Anderson & Vastag, 2004), and Internet evaluation and security (Cho & Cha, in press; Mladeni & Grobelnik, 2003). Bayesian networks have been applied to complex problems in areas as diverse as genetics (Hsu, 2004), agriculture (Moshou et al., 2001), marketing (Ahn & Ezawa, 1997), information retrieval (Campos et al., 2003), text classification (Klopotek, 2004), biomedicine (Lucas, van der Gaag, & Abu-Hanna, 2004), and forensics (Taroni, Biedermann, Garbolino, & Aitken, 2004). Bayesian genetic and evolutionary models, including neural networks, have also been described in an information science context (Pelikan, Goldberg, & Tsutsui, 2003) and applied to software failure time prediction (Tian & Noore, in press), drug discovery (Winkler & Burden, 2004), and environmental modelling (Danaher, Datta, Waddle, & Hackney, 2004).

FUTURE TRENDS

The theory of Bayesian modelling and analysis are comprehensively described by Bernardo and Smith (1994) and Robert (1994). These discussions include issues of point estimation, tests and confidence regions, admissibility and invariance, and priors. All of these areas are still actively researched. For example, priors may be objective so that they have no influence over the data (Bernardo & Smith) or subjective, reflecting expert opinion (Garthwaite & O'Hagan, 2000; Kadane and Wolfson, 1998). Gelman et al. (1995) discuss informative and noninformative prior distributions for single-parameter models. Berger and Berry (1988) maintain that no known method of statistical inference is completely objective, but that a Bayesian approach explicitly acknowledges and controls the subjective element through formulation of the prior distribution. Similarly, research continues into the ethics and practicalities of Bayesian hypothesis testing (Bernardo & Rueda, 2002) and empirical Bayes methods (Carlin & Louis, 2000).

The problem of learning about the model structure from the data, or model identification, remains an area of active research interest. For example, the alternative models, H_i, might represent a set of regression equations with different explanatory variables or mixture models with different numbers of components. While the traditional Bayesian approach to such model selection problems is through Bayes' factors (Bernardo & Smith, 1994), recent alternatives include methods based on building "reversible jumps" between models and then choosing the model as another step in the simulation (Green, 1995), and methods based on birth-and-death processes (Stephens, 2000). Instead of choosing a single model, the Bayesian paradigm also allows *model averaging*, in which parameter estimates, expectations, and predictions can be combined over some or all potential models. Effectively, a weighted sum of estimates over the set of models is taken, with the weights reflecting the posterior probability of each model given the data (Hoeting, Madigan, Raftery, & Volinsky, 1999).

Other models, such as generalized linear models, multivariate models, time-series, and spatial models, have also been cast in a Bayesian framework. See, for example, Carlin and Louis (2000), Congdon (2001), Gilks, Richardson, & Spiegelhalter (1996), and Gelman et al. (1995). These authors also describe methods for different study designs, nonstandard data, model checking, and sensitivity analysis.

Although the computational efficiency of Bayesian learning continues to improve, the computational cost can be high compared to other methods. However, Mitchell (1997) explains that even in those cases where a Bayesian algorithm is not practical as a final implementation, the Bayesian approach can often offer useful insight and/or provide a benchmark for quality decision making against which other methods can be assessed. Sometimes an alternative method can be viewed as a practical approximation to a more rigorous Bayesian method.

CONCLUSION

Bayesian learning differs from other algorithms in the way all relevant knowledge about model parameters and model structure and any associated uncertainty is expressed as probability distributions. In some applications, the Bayesian approach quite simply leads to efficient algorithms. In other applications, it is the Bayesian framework that is appealing. For example, the ability to explicitly combine prior knowledge with observed data is useful in any situation where expert opinion needs to be incorporated into the learning algorithm, in which information from different sources needs to be combined or where a model is regularly updated as more data arrives. The need to provide explicit prior distributions for all parameters is sometimes viewed as a disadvantage of Bayesian learning rather than a strength. Some critics object to the entire Bayesian approach, viewing the choice of the prior as arbitrary. Alternatively, the problem can be how to formulate the prior knowledge in a practical way including those situations where there essentially is no prior knowledge. Use of appropriate representational systems such as Bayesian networks can help.

Bayesian learning quantifies and highlights the inherent uncertainty in the model through the posterior distribution of the model parameters. This also makes it very easy to combine predictions from multiple models through a model-averaging approach rather than being restricted to a single most likely model.

Now established as an analytic tool, Bayesian learning still offers great opportunities for advancements in theory, methodology, computation, and applications. Importantly, the Bayesian revolution is interdisciplinary, bringing together probabilists, statisticians, computer scientists, information scientists, researchers, and practitioners.

KEY TERMS

Bayes' Rule: Mathematical equation relating prior and posterior probabilities.

Bayesian Learning: Learning algorithm based on Bayes' rule.

BBN: Bayesian belief network. A graphical model of joint probability distributions in which nodes represent random variables and arcs represent (causal) relationships. May also be called a causal net or influence diagram (see Jensen, 2001).

BNN: Bayesian neural network. A neural network where a Bayesian approach is used to calculate the posterior distribution for the weights. Rather than selecting the single most likely set of weights, model averaging is used to predict outputs.

Conditional Distribution: Probability distribution of a parameter, given the values of other parameters and/or the data.

MCMC: Markov chain Monte Carlo computational algorithms for estimating multidimensional integrals.

Posterior Probability: Probability distribution of an unknown characteristic after combining prior information and data.

Prior Probability: Probability distribution of a characteristic prior to observing data. Way of formalizing current knowledge about that characteristic.

Behavioral Factors in Strategic Alliances

STRATEGIC ALLIANCE

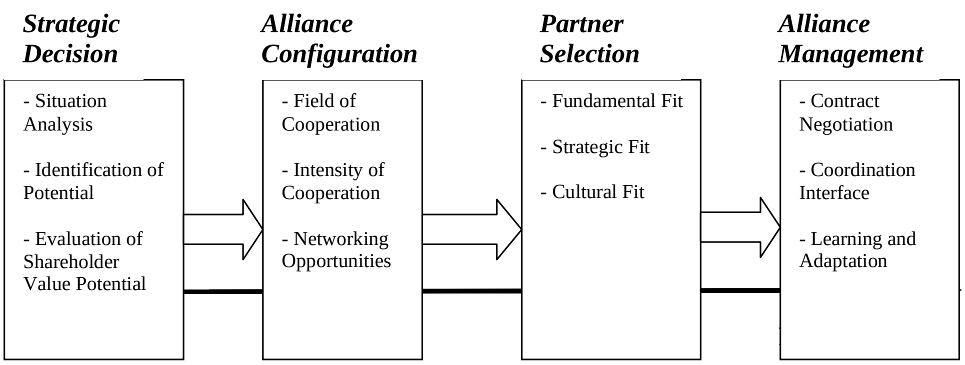
Recently, there has been a growing trend among information technology (IT) organizations to form strategic alliances to increase competitive advantages in the marketplace. For an organization to exploit the benefits of alliances, human factors and IT factors must be among the basic components of any strategic plan (Kemeny & Yanowitz, 2000). Despite the obvious need to consider human and IT factors when developing a long-term plan, many strategic plans developed in the past that led to alliances have failed to consider human aspects. Examples of failure in the implementation of IT systems due to the lack of consideration of human factors have come to light in recent years, but a comprehensive study of the consideration of human factors in the development of strategic alliances resulting in a major IT system alignment for a firm, is still rare in IT literature.

A successful alliance should not imply an imposition of one organization's culture over another. It is not a requirement that both organizations change the social structure, but the unique personalities of the two cultures should be considered when combining the resources of two organizations. The new organization should create a new working culture that brings together the best elements of each (Rule & Keown, 1998). Unfortunately, the creation of a new culture is rarely practiced, as alliances are often viewed solely from a financial perspective, leaving the human issues as something to be dealt with later, and many times with a minimal amount of effort. The creation of a new culture involves operations, sales, human resources management, technology, and structure, as well as many other internal and external entities and forces. It is undoubtedly an expensive and time-consuming endeavor to create a new working culture, but in the end, more value is created, and employees are more content and productive.

Strategic alliances are "co-operative relationships between two or more independent organizations, designed to achieve mutually beneficial business goals for as long as is economically viable" (Paris & Sasson, 2002). The main purpose of an alliance is to create one or more advantages such as product integration, product distribution, or product extension (Pearlson, 2001). In strategic alliances, information resources of different organizations require coordination over extended periods of time.

Bronder and Pritzl (1992) suggest that a strategic alliance exists when the value chains between at least two organizations (with compatible goals) are combined for the purpose of sustaining and/or achieving significantly competitive advantage. They derived four critical phases of a strategic alliance; namely, strategic decision for an

Figure 1. Strategic alliance phases (Bronder& Pritzel, 1992)



alliance, alliance configuration, partner selection, and alliance management, as shown in Figure 1. These four phases provide the basis for a continuous development and review of the strategic alliance, which increases the likelihood of the venture's success.

Typically, the first phase of a strategic alliance is the decision to go forward with the development of a strategic alliance (i.e., it asks this question: Is this strategic alliance justified?). Phase II (Configuration of a Strategic Alliance) focuses on setting-up the alliance's structure. Phase III (Partner Selection) is one of the most important success factors of the strategic alliance. This phase addresses whether the firms that are considering the partnership have characteristics that are conducive to a successful strategic alliance. Some of the concerns in this phase are fundamental fit (e.g., Do the company's activities and expertise complement each other in a way that increases value potential?), strategic fit (e.g., Do strategic goal structures match?), and cultural fit (e.g., Is there a readiness to accept the geographically and internally grown culture of the partners?). The final phase, Phase IV, is concerned with managing a strategic alliance (e.g., How do partners continually manage, evaluate, and negotiate within the alliance to increase the odds of continued success?). People-related issues are the major focus of this phase.

Before an organization commits to a strategic alliance, it should have a management plan developed to deal with the human behavior aspects of the newly created organization. Parise and Sasson (2002) discuss the knowledge management practices that organizations should follow when dealing with a strategic alliance. They break down the creation of a strategic alliance into three major phases.

- *Find:* making alliance strategy decisions and screening and selecting potential partners.
- *Design:* structuring and negotiating an agreement with the partners.
- *Manage:* developing an effective working environment with the partner to facilitate the completion of the actual work. This phase includes collecting data relating to performance and feedback from both partners on how they think the alliance is progressing. Managing relationships and maintaining trust are particularly critical during the Manage Phase.

The application of proper knowledge management techniques is especially important for a successful alliance (Parise & Sasson, 2002). There must be a systematic approach for capturing, codifying, and sharing information and knowledge; a focus on building social capital to enable collaboration among people and communities; an emphasis on learning and training; and a priority on leveraging knowledge and expertise in work practices. Parise and Sasson (2002) suggest a list of the building blocks of alliance management. Four of these building blocks relate specifically to human behavior factors.

- *Social Capital:* Building trust and communication channels that allow unambiguous discussions with the partner is a necessary ingredient for an effective relationship.
- *Communities:* Communities of practice allow for the sharing of personal experiences and tacit knowledge based on individuals with a common interest or practice. Communities can be realized by using electronic meeting rooms, forums, or more formal alliance group structures.
- *Training:* Companies that rely heavily on strategic alliances should provide formal training for managers and team members in their strategic plans. Providing staff with the skills necessary to exist in a new system (in this case, a strategic alliance) is often overlooked in the development of the new system.
- *Formal Processes and Programs:* Alliance know-how should be institutionalized. An example of this is Eli Lilly, a leading pharmaceutical firm, which created a dedicated organization called the Office of Alliance Management, which was responsible for alliance management.

The literature on strategic alliances shows that organizations that use alliance management techniques to provide for stress and knowledge management are more successful than those who do not. Leveraging knowledge management across a company's strategic alliance is a critical success factor for partnering companies. The greatest contributors to knowledge management in an organization are the information-literate knowledge workers—mainly the IT professionals.

CULTURAL ASPECTS IN ALLIANCES

Alliances among firms would naturally result in many organizational changes. Leavitt (1965) concluded that there are four types of interacting variables to consider when dealing with organizational change, especially in large organizations. These variables are task variables, structural variables, technological variables, and human variables. He proposed structural, technological, and people approaches to organizational changes, which derive from interactions among these four variables.

The four variables are highly interdependent so that a change in any one variable usually results in compensatory changes in other variables. The introduction of new technological tools (e.g., computers) may cause changes in structure (communication system), changes in people (their skills and attitudes), and changes in performance and tasks. Therefore, it is imperative to consider all areas that might be affected when a company plans to introduce change to an organization.

Pre-existing people-related problems at a target company often cause many alliances to fail to reach their full financial and strategic potential. Numerous case studies report failure of alliances due to a lack of consideration for the potential impact of behavioral and structural aspects (Numerof & Abrams, 2000). To build an effective alliance, institutions must pay particularly close attention to cultural, personality, and structural incompatibilities. Leaders from alliance institutions need to recognize the personality differences in their managers, as well as the demands required by the stage of the organizational life cycle stage that their organization is in (Segil, 2000). It has also been demonstrated that successful alliance partners share many strong similarities in performance and relationships (e.g., people skills) (Whipple & Frankel, 2000). Understanding potential incompatibilities gives institutions that are contemplating alliances a solid foundation on which to explore the feasibility of joint projects. It also increases the likelihood that the alliance will operate successfully (Whipple & Frankel, 2000).

Successful alliances are impeded when the culture of one or both associations highly differs in value. "High control value" is inconsistent with tolerance for ambiguity and the "willingness to compromise" often required for strategic alliances. Maron and VanBremen (1999) suggest the use of William Bridges' Organizational Character Index, which can be a useful tool for analyzing the cultural differences between two associations to determine how well they might work together. It promotes better understanding between two associations; it fosters an appreciation for what both partners could bring to an alliance; and it identifies underdeveloped qualities in both associations that could inhibit the success of an alliance.

IT ISSUES IN ALLIANCES

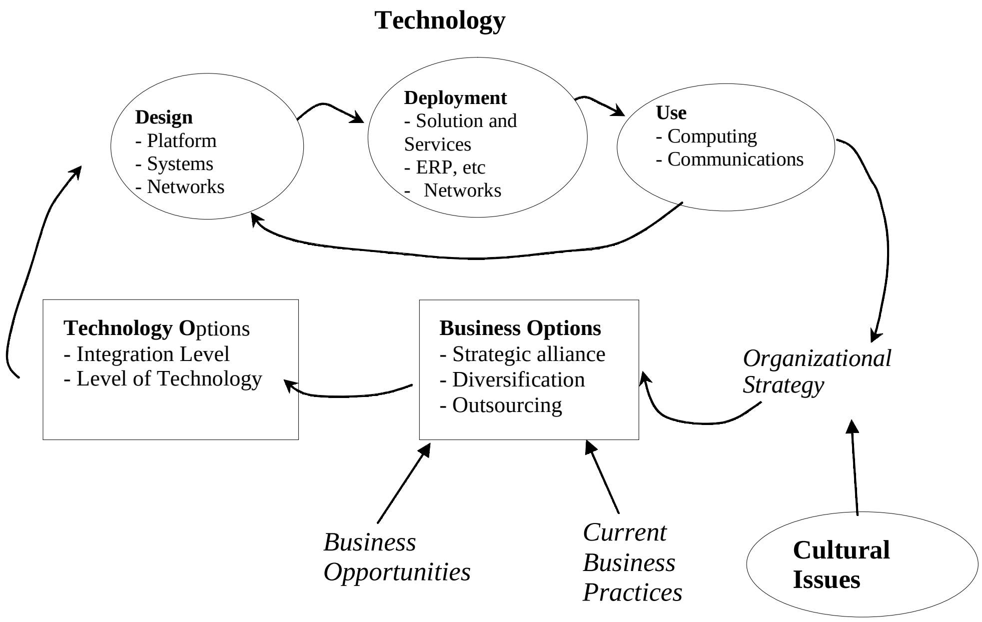
Long-term IT considerations, such as IT architecture, is another major consideration when developing a strategic alliance. A strategic consideration, such as new alliances, requires the visioning of a different IT architecture. Applegate, McFarlan, and McKenney (1999) view IT architecture as an overall picture of the range of technical options available to a firm, as well as standard business options. "Just as the blueprint of a building's architecture indicates not only the structure's design but how everything – from plumbing and heating systems, to the flow of traffic within the building – fits and works together, the blueprint of a firm's IT architecture defines the technical computing, information management and communications platform" (p. 209).

Figure 2 brings out the dynamic nature of the IT architecture development process. The technology component, shown by the dotted oval, is concerned with design, deployment, and how it is used. This part is the core of IT architecture, and a large proportion of IT professionals' time is devoted to these activities. Consideration of business options that feed to various technology options is a higher-level activity in the IT architecture development process. Business options such as strategic alliances, mergers and acquisitions, outsourcing, diversification, and so forth are influenced by major internal, as well as external, factors such as current business practices, business opportunities, and organizational strategy. There is a direct link between technology and organizational strategy. The technology (with its operational and technical settings) exerts a strong influence on the organization's future strategic direction. Thus, one can observe a close link between technical and other business factors, and, like ever changing business, the IT architecture is a dynamically evolving phenomenon (see Figure 2 through connecting lines).

An alliance can exist between any types of organizations. For example, a telecommunications organization could form an alliance for international joint ventures, or an alliance could be established between a banking organization and an IT supplier. The notion of developing a strategic alliance suggests that an organization's performance can be significantly improved through joint, mutually dependent action. For a strategic alliance to be successful, business partners must follow a structured approach to developing their alliances to ensure that all major items have been addressed, and should include, as part of this process, strategic planning, communication, efficient and effective decision-making, performance evaluation, relationship structure, and education and training.

Strategists have often suggested that organizations should consider entering into similar or somewhat related market sectors to broaden their product/service portfolios (Henderson & Clark, 1990; Markides & Williamson, 1997). Both of the dimensions of market (customer and product, Ansoff, 1986) in a related market can be identified easily and strategies formulated for deployment. The main advantage of adopting such a strategy is that an organization can easily use its competencies and strategic assets in generating a strategic competitive advantage (Markides & Williamson, 1997). Determining the design and the requirements of a new information system (IS) is a relatively simple task. In

Figure 2. Forces affecting overall IT architecture



contrast, diversification into a significantly different market for an IT/IS organization is a very challenging task that requires considerable evaluation of the IT infrastructure and human relations.

CONCLUSION

Strategic alliance is a complex business decision that involves careful consideration of business processes, IT architecture, human issues, and many other factors. Over emphasizing one factor or downplaying another may lead to a compromising situation that can have seriously negative consequences for both of the organizations involved. Behavioral issues in their broader sense impact all phases of a strategic alliance. For IT professionals, the understanding of behavioral or human issues is of critical importance in the analysis and design of the system that will support a strategic alliance. The new system must take into account not only traditional system design considerations, but knowledge management and its growing importance in system design, which increases organizational effectiveness and ensures the firm's long-term existence.

KEY TERMS

Alliance Management: Allows two different organizations to effectively work together and combine resources, which is expected to bring benefits to both organizations.

Culture: A societal manifestation influenced by traditions, religion, history, acceptable behavior, and many other factors.

IT Strategic Alliance: A broad agreement between business partners to operate cooperatively, usually facilitated by IT systems.

IT Architecture: A conceptual framework of IT in an organization that supports business processes. IT includes hardware, software, telecommunications, database management, and other information processing technologies used in computer-based information systems.

Information-Literate Knowledge Worker: A worker who knows what information is needed, knows how and where to obtain that information, understands the meaning of information, and can act based on the information to help the organization achieve its greatest advantage.

Strategic Planning: Corporate long-term planning that ensures the existence of an organization.

Behavioral Perspective of Groupware Adoption

Yining Chen
Ohio University, USA

Hao Lou
Ohio University, USA

INTRODUCTION

Over the past decade, groupware technologies, such as e-mail, electronic bulletin boards, and group support systems, have become an important part of the business-computing infrastructure in many organizations. This evolving software category has captured the attention and imagination of information technology professionals, line of business managers and end users, not to mention software suppliers. Organizations adopt groupware applications to enhance communication, collaboration, and coordination among group members and thus improve group performance ("Lotus Development," 1995). While some groupware applications, for example, e-mail, have been commonly accepted, many other applications, especially those that require significant collaboration and cooperation among users, are not widely used in organizations and their potential benefits are far from being fully realized (Orlikowski, 1993). Although many laboratory and field studies have consistently shown the relevance and positive impact of group support systems on group work, more research is needed in understanding how to increase the rate of diffusion and adoption of the technology (Nunamaker, 1997).

Behavioral-related elements (e.g., an individual's normative beliefs, attitude, and motivation), recognized by many, are the primary causes of users' resistance toward a newly implemented system or technology. Information technology (IT) research, however, tends to under-utilize existing knowledge in the behavioral science (Burton et al., 1993; DeSanctis, 1983; Melone, 1990; Turner, 1982). Expectancy theory has been recognized as one of the most promising conceptualizations of individual motivation (Melone, 1990; Snead & Harrell, 1995). Many researchers have proposed that expectancy theory can provide an appropriate theoretical framework for research that examines a user's acceptance of and intent to use a system (DeSanctis, 1983; Melone, 1990). This study uses expectancy theory as part of a student-based experiment to examine users' behavioral intention (motivation) to utilize a groupware application.

BACKGROUND

Groupware refers to a class of computer technologies designed to support communication, collaboration, and cooperation among a group of knowledge workers. It covers a variety of technologies, ranging from simple e-mail systems to complex workflow applications. Although the use of some groupware technologies, such as e-mail, has become ubiquitous, organizations have encountered many difficulties in adopting and utilizing more sophisticated groupware applications, such as group support systems and Lotus Notes (Nunamaker, 1997; Orlikowski, 1993).

Groupware applications are designed to support communication, cooperation, and collaboration among a group of users rather than to improve productivity of individuals. Therefore, usage and resulting benefits are only achieved if a majority of the users whose work is affected by a groupware application accept and use the system (Grudin, 1994). Otherwise, the application will not only fail to improve group performance but will also create additional communication and coordination barriers. While many factors (e.g., users' background and commitment, organizations' reward systems, work norms, and policies and procedures) can contribute to the success of a groupware application, achieving a "critical mass" of users has been recognized as one of the keys for successful groupware acceptance (Ehrlich, 1987; Grudin, 1994; Markus, 1990; Markus & Connolly, 1990). The intrinsic value of a groupware technology increases and becomes more apparent as more and more users accept the technology. Consequently, more and more functions are available to adopters, which in turn reinforce their opinion about the technology and reaffirm their acceptance decisions.

Expectancy theory is considered one of the most promising conceptualizations of individual motivation (DeSanctis, 1983; Melone, 1990). Expectancy models are cognitive explanations of human behavior that cast a person as an active, thinking, predicting creature in his or her environment. He or she continuously evaluates the outcomes of his or her behavior and subjectively assesses the likelihood that each of his or her possible actions will lead to various outcomes. The choice of the amount of effort he or she exerts is based on a systematic analysis of (1) the values of the rewards from these outcomes, (2) the likelihood that rewards will result from these outcomes, and (3) the likelihood of reaching these outcomes through his or her actions and efforts.

According to Vroom (1964), expectancy theory is comprised of two related models: the valence model and the force model. In our application of the theory, each user of a groupware application first uses the valence model to evaluate the application's outcomes (e.g., enhanced communication, increased ability to coordinate, better collaboration, and improved competence) and subjectively assesses the likelihood that these outcomes will occur. Next, by placing his or her intrinsic values (or weights) on the various outcomes, each user evaluates the overall attractiveness of the groupware application. Finally, the user uses the force model to determine the amount of effort he or she is willing to exert to use the application. This effort level is determined by the product of the attractiveness generated by the valence model and the likelihood that his or her effort will result in a successful use of the application. Based on this systematic analysis, the user will determine how much effort he or she would like to exert in using the groupware application.

The general research question examined by this study is "Can the valence and force models of expectancy theory explain the motivation of a user to use a groupware application?" Specifically, under the valence model, we investigate the impact of the potential outcomes of a groupware application upon users' motivation to use such an application. The four outcomes of groupware applications examined by this study are (1) enhancing communications among coworkers; (2) increasing ability to coordinate activities; (3) facilitating collaboration among coworkers; and (4) improving competence of job performance. Under the force model, we investigate the extent that the difficulty of using a groupware application will affect users' motivation to actually use the application.

RESEARCH METHOD AND RESULTS

The within-person or individual focus of expectancy theory suggests that appropriate tests of this theory should involve comparing measurements of the same individual's motivation under different circumstances (Harrell, Caldwell & Doty, 1985; Murray & Frazier, 1986). In response to this suggestion, this study adapts a well-established within-person methodology originally developed by Stahl and Harrell (1981) and later proven to be valid by other studies in various circumstances (e.g., Burton, Chen, Grover & Stewart, 1993; Geiger & Cooper, 1996; Snead & Harrell, 1995).This methodology uses a judgment modeling decision exercise that provides a set

Table 1.

If you use the groupware application (e.g., Domino Discussion or Lotus Notes) to the MAXIMUM extent in your job, the likelihood that:	
You will enhance your communications with your coworkers is	HIGH (90%)
You will improve your ability to coordinate job-related activities is	HIGH (90%)
You will achieve a better collaboration among your coworkers is	HIGH (90%)
You will increase your general level of competence in performing your job is ………	LOW (10%)

Table 2.

DECISION A: With the above outcomes and associated likelihood levels in mind, indicate the ***attractiveness*** to you of using the groupware application in your job.

-5	-4	-3	-2	-1	0	+1	+2	+3	+4	+5
Very Unattractive										Very Attractive

FURTHER INFORMATION: If you exert a great deal of effort to use Lotus Notes in your job, the likelihood that you will be successful in doing so is .... LOW (10%)

DECISION B: Keeping in mind your attractiveness decision (DECISION A) and the FURTHER INFORMATION, indicate the level of ***effort*** you would exert to use the groupware application.

Zero Effort										Great Deal of Effort

of cues, which an individual uses in arriving at a particular judgment or decision. Multiple sets of these cues are presented, with each representing a unique combination of strengths or values associated with the cues. A separate judgment is required from the individual for each unique combination of cues presented.

The participants are 86 business undergraduate students who enrolled in courses that utilize groupware applications. In each of the 16 proposed cases (groupware applications), the participants are asked to make two decisions. The first decision, Decision A, represents the overall attractiveness of using the groupware application, given the likelihood (10% or 90%) that the four second-level outcomes would result from the use. The second decision, Decision B, reflects the strength of a participant's motivation to use the groupware application, using (1) the attractiveness of the application obtained from Decision A and (2) the expectancy (10% or 90%) that, if the user exerts a great deal of effort, he or she would be successful in using the application. As an example, one of the 16 cases is presented next.

If you use the groupware application (e.g., Domino Discussion or Lotus Notes) to the MAXIMUM extent in your job, the likelihood that:

We first examine whether the valence model of expectancy theory can explain a user's perception of the attractiveness of using a groupware application. Through the use of multiple regression analysis, we seek to explain each participant's perception of the attractiveness of using a groupware application. Decision A serves as the dependent variable, and the four second-level outcome instruments serve as the independent variables. The resulting standardized regression coefficients represent the relative importance (attractiveness) of each of the second-level outcomes to each user in arriving at Decision A. The mean adjusted-R^2 of the regressions and the mean standardized betas of each outcome are presented in Table 1.

As indicated in Table 1, the mean R^2 of the individual regression models is .6876. The mean R^2 represents the percentage of total variation in users' response that is explained by the multiple regression. Thus, the relatively high mean R^2 indicates that the valence model of expectancy theory explains much of the variation in users' perception of the attractiveness of using a groupware application. Among the 86 individual regression models, 79 are significant at the level of .05.

The standardized betas of V1, V2, V3, and V4 are significant, at the level of .05, for more than half of the individuals. This implies that all four of the secondary outcomes are important factors, to a majority of the individuals, in determining the attractiveness of a groupware application. Although all four factors are important, some factors are more important than others. It is the *mean* of these standardized betas that explains how users, on average, assess the attractiveness of potential outcomes resulting from a groupware application. The users, on average, place the highest valence on the outcome V4. The other valences, in descending order of their strength, are V1, V2, and V3. These results imply that

*Table 3. Valence and force model regression results**

	N	Mean	Standard Deviatio n	Range	Frequency of Significance at .05

B1	86	.5997	.2530	-.1960 to 1.000	72/86
B2	86	.4976	.3110	-.2302 to .9763	64/86

* Results (i.e., mean, standard deviation, range, and frequency of significant at .05) of individual within-person regression models are reported in this table.
V1: valence of communication enhanced V2: valence of coordination ability increased
V3: valence of collaboration improvement V4: valence of competence improvement
B1: weight placed on attractiveness of the groupware application
B2: weight placed on the expectancy of successfully using the system

the users believe improving job competence (V4) is the most attractive outcome of a groupware application and improving collaboration among coworkers (V3) is the least attractive outcome. In the middle is the enhanced communication (V1) and increased coordination (V2).

We then examine whether the force model can explain a user's motivation to use a newly implemented groupware application. We again use multiple regression analysis to examine the force model (Decision B) in the experiment. The dependent variable is the individual's level of effort to use the groupware application. The two independent variables are (1) each user's perception about the attractiveness of the application from Decision A, and (2) the expectancy information (10% or 90%).

The mean R^2 (.7205) indicates that the force model sufficiently explains the users' motivation of using a groupware application. The mean standardized regression coefficient B1 (.5997) indicates the impact of the overall attractiveness of the groupware application, while B2 (.4976) indicates the impact of the expectation that a certain level of effort leads to successfully using the application. These results imply that both factors, the attractiveness of the groupware application (B1) and the likelihood that the user's efforts will lead to a successful use (B2), are of similar importance to the user's motivation.

FUTURE TRENDS

This study successfully applies a behavioral theory, expectancy theory, to a system implementation area. This application (1) helps close the gap between the capabilities of a groupware application and the extent to which it is used, and (2) responds to the claim of previous research that the gap can be better explained by behavioral elements rather than by technical attributes.

Future research should revalidate the application of expectancy theory in different contexts. Various factors such as social norms, one's job requirements, and organization's reward system can be examined for their impact on the valence and force models. Along with the direction of several recent studies (Lucas & Spitler, 1999; Szajna & Scamell, 1993), the relationship among attitude (i.e., perceived system quality, perceived usefulness, and perceived ease of use), intention, and actual use needs to be further validated. The ultimate goal of this line of research is to gain more rigorous and consistent insight into understanding the effectiveness of groupware applications and our ability to explain or predict user acceptance to a groupware application. To increase practical value and external validity, field studies that offer different conditions than lab environments using student subjects are necessary.

CONCLUSION

Groupware technologies have become an important part of the business computing and communicating infrastructure in many organizations. However, literature suggests that many groupware applications, especially those that require significant collaboration and cooperation among users, are still not adequately used (Nunamaker, 1997; Orlikowski, 1993). Their potential benefits are far from being fully realized due to the lack of user acceptance (Venkatesh et al., 2003). While there are studies that show the relevance and positive impact of group support systems on group work, very few have looked into users' perception of the groupware technologies and their motivation to participate (Nunamaker, 1997).

Expectancy theory is considered one of the most promising models of individual motivation. This study examines the use of expectancy theory in explaining the behavioral intention (motivation) to use a groupware application. Our results suggest that expectancy theory is appropriate for assessing and understanding users' motivation to use a groupware application and, subsequently, its acceptance and success. Since user acceptance is an essential antecedent of a successful groupware application, the results of this study should be considered thoughtfully when a groupware application is designed, implemented, and operated.

KEY TERMS

Critical Mass: A point at which a sufficient number of individuals have adopted an interactive communication technology to cause a rapid acceleration in its diffusion.

Expectancy Theory: Expectancy models are cognitive explanations of human behavior that cast a person as an active, thinking, predicting creature in his or her environment. He or she continuously evaluates the outcomes of his or her behavior and subjectively assesses the likelihood that each of his or her possible actions will lead to various outcomes.

Force Model: The force model shows that a user's motivation to exert effort into using an application is the summation of the products of the attractiveness of the application and the probability that a certain level of effort will result in successfully using the application.

Group Support Systems: Group support systems provide computer based support for group communication, decision making, and work activities of co-located (same time, same place) or dispersed (same time, different place; or different time, different place) members of a group.

Groupware Application: A class of computer technologies designed to support communication, collaboration, and cooperation among a group of knowledge workers.

User Acceptance: With respect to information technology in general, user acceptance has been conceptualized in several ways. First, it is equated with routinization, the point at which an innovation ceases to be perceived as something unusual and is considered to be a routine part of the process into which it was introduced. Second, user acceptance is equated with time since adoption, implying that an innovation that endures in an organization has been accepted. Finally, user acceptance is equated with usage. Usage is considered an objective measure of acceptance when certain conditions are met: (a) users are motivated to use the system; (b) users have convenient access to the system; and (c) users understand the system and what it can do.

Valence Model: The valence model shows that the overall attractiveness of an application to a user is the summation of the products of the attractiveness of those outcomes associated with the application and the probability that the application will produce those outcomes.

Benefits and Challenges of Blended Learning Environments

Charles R. Graham
Brigham Young University, USA

Stephanie Allen
Brigham Young University, USA

Donna Ure
Brigham Young University, USA

INTRODUCTION

The term "blended learning" has become a corporate buzzword in recent years (Lamb, 2001). Recently, the American Society for Training and Development identified blended learning as one of the top ten trends to emerge in the knowledge delivery industry in 2003 (Rooney, 2003). In higher education, the term blended learning is being used with increased frequency in academic conferences and publications. Issues related to the design and implementation of blended learning environments (BLE) are surfacing as technological advances continue to blur the lines between distributed learning and the traditional campus-based learning. Many universities are beginning to recognize the advantages of blending online and residential instruction. *The Chronicle of Higher Education* recently quoted the president of Pennsylvania State University as saying that the convergence between online and residential instruction was "the single-greatest unrecognized trend in higher education today" (Young, 2002). Along the same lines, the editor of *The Journal of Asynchronous Learning Networks* is predicting a dramatic increase in the number of hybrid (i.e., blended) courses to include as many as 80-90% of the range of courses (Young, 2002). The article provides an overview of blended learning environments (BLEs) and outlines the most common benefits and challenges identified in the research literature.

BACKGROUND

The use of the term "blended learning" is a relatively new phenomenon in higher education. Historically, academicians have referred to blended learning environments (BLEs) as hybrid environments. But with the explosion in the use of the term "blended learning" in corporate training environments, the academic literature has increasingly followed suit, and it is common to see the terms used interchangeably (Voos, 2003). In this section of the article, we address the following two questions:

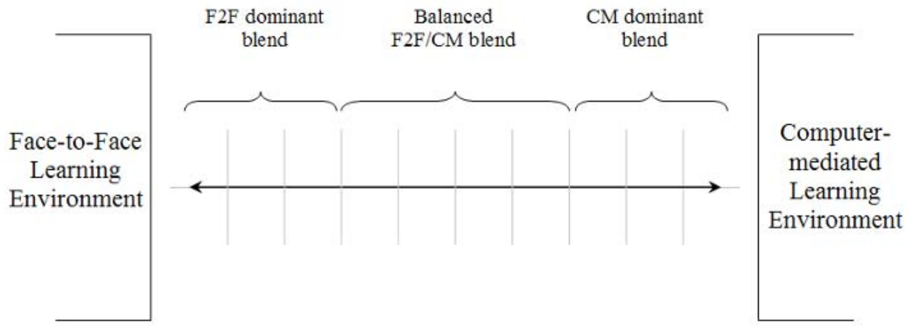
- What is being blended in a BLE?
- How much to blend in a BLE?

What Is Being Blended?

By nature, both the terms "hybrid" and "blended" imply a mixing or combining of *something*. It is that *something* that people do not always agree upon. Some understand blended learning to be a combination of different instructional methods (soft technologies) (Singh & Reed, 2001; Thomson, 2002), while others define blended learning as a combination of different modalities or delivery media (hard technologies) (Driscoll, 2002; Rossett, 2002). Blended learning is most commonly considered to be the combination of two archetypal "learning environments" using *both* the hard and soft technologies most common in each instructional environment. In short, *blended learning environments combine face-to-face (F2F) instruction with computer-mediated (CM) instruction*.

Blending occurs at the instructional (or course) level as opposed to the institutional level. A whole body of literature talks about dual-mode institutions that deliver both F2F and distributed instruction, but don't explicitly blend these environments at a course level (Rumble, 1992). Historically, the on-campus and distributed education branches of dual-mode universities served different populations of learners. However, increasingly the lines between traditional on-campus learners and distance learners are being blurred. This same phenomenon is happening between on-campus course offerings and distributed course offerings. This blurring of boundaries is often referred to as the "hybridization" of the university (Cookson, 2002).

Figure 1. Blended learning environments combine F2F and computer-mediated instruction



How Much to Blend?

As might be expected, no magic blend is optimal for all learning contexts. As Figure 1 suggests, a range of combinations can occur in a blended environment. Figure 1 divides this range into three general levels: blends that have a dominant F2F component, blends that have a dominant CM component, and blends that are fairly balanced in mixing the two environments. In higher education and corporate training, blends of all varieties exist. At the F2F end of the spectrum, many on-campus instructors and corporate trainers are enhancing their courses or training programs by using computer-based technologies. In these instances, the instructors and trainers may change what they do in the F2F environment because of the added CM portion, but they typically do not reduce the F2F contact time. At the computer-mediated end of the spectrum, an increasing number of higher education distributed education courses have a F2F component. These courses range from requiring F2F orientation activities and in-person testing (Martyn, 2003; Schrum & Benson, 2000) to allowing for optional participation in discussion or lecture sessions. In the corporate world, companies often add F2F sessions to e-learning training modules (Bielawski & Metcalf, 2002; Thorne, 2003) to give employees the chance to practice and apply skills and knowledge they've gained via the online instruction. In the middle of the spectrum, both university courses and corporate training modules reduce F2F class time by increasing the time the learners spend in online instructional activities.

Why Blend?

There are many reasons why an instructor or corporate trainer might choose to design a BLE over a non-blended environment. The most predominant benefits and challenges in the literature are presented in the following two sections.

Benefits to Blending

The phrase most commonly used by advocates of BLEs is that they allow one to have the "best of both worlds" (Morgan, 2002; Young, 2002). BLEs can also mix the least effective elements of both worlds if they are not designed well. Beyond this general statement, we identified three major themes that are often referred to as reasons for blending: (1) more effective pedagogy, (2) increased convenience and access, and (3) increased cost effectiveness.

More Effective Pedagogy

The opportunity to improve upon prevalent pedagogical practices is one of the most commonly cited possibilities that blending provides. For example, in the on-campus environment much of teaching and learning is still focused on the "transmission" model with the lecture used by 83% of higher education instructors as the predominant teaching strategy (U.S. Department of Education, 2001). Constraints such as class duration, size, and location can provide a formidable barrier to making changes to that strategy. Introducing online instructional components opens the range of instructional strategies that can be used. Proponents of BLEs have mentioned such benefits as:

- an increase in active learning strategies used (Collis, 2003; Morgan, 2002);
- a change from a more teacher-centered to learner-centered focus (Hartman, Dziuban, & Moskal, 1999; Morgan, 2002);
- a greater emphasis on peer-to-peer learning (Collis, 2003);
- a change in the way faculty allocate time, allowing for increased mentoring of individual students

(Bourne, 1998; Waddoups, Hatch, & Butterworth, 2003); and
- the possibility for interaction with remote experts or remote peer review of projects (Levine & Wake, 2000).

In distance education, there is often a similar problem of focusing on "transmissive" rather than "interactive" learning strategies (Waddoups & Howell, 2002). This typically results from making large quantities of information available on the Web for students to learn independently of anyone else. Many learners are not ready for this type of independent online learning and feel isolated in distance learning courses as a result. BLEs are seen as one way to balance independent learning with human interaction (Hartman et al., 1999; Morgan, 2002). Adding a F2F component to a distance course or online training program can improve social interaction and facilitate future online interaction (Willett, 2002). Occasional F2F interaction can also motivate students to discipline themselves in a predominantly online course (Leh, 2002).

Convenience and Access

Many learners want the convenience of a distributed learning environment, yet don't want to sacrifice the human touch they are used to in the F2F class environment. BLEs are viewed as a way to balance these two factors by increasing convenience, but still maintaining some F2F contact (Collis, 2003; Morgan, 2002). Reducing the amount of F2F seat time reduces time and place constraints for learners (Hartman et al., 1999; Leh, 2002), as well as commuting stress (Willett, 2002) for individuals who travel distances and then have to fight for parking on campuses with large commuter populations.

In corporate settings, increased convenience and access to instructional materials are also compelling reasons for adopting blended learning solutions. Access to training materials was significantly increased when many companies adopted e-learning materials in the form of self-paced computer-based training and Web-based training. However, interaction with fellow learners and instructors was severely limited, if not completely

Table 1. Four general categories describing technology use in Pew grant projects

Technology Use	Description
Technology Enhanced	• F2F contact time (seat time) is not reduced. • Technology may be used to engage learners in activities that were not possible or practical in a F2F classroom (e.g., simulations, online tutorials, individualized assessment and feedback, etc.). • Technology may change the nature of the F2F contact (e.g., information transmission via technology enabling discussion rather than lecture in class; change from lecture to tutoring in computer lab, etc.)
Reduced Seat Time	• F2F contact time is reduced to accommodate time spent in computer-mediated learning activities.
Entirely Distributed	• Courses that have no F2F contact with instructors or learners and are conducted entirely via the internet or other technological tool. • Courses may include both synchronous or synchronous distributed interaction. • Courses may be self paced independent study or more collaborative.
Distributed with optional F2F sessions	• Required components of courses are entirely distributed (see above) but optional F2F sessions can be attended (lectures, discussion sessions, one-on-one lab help, etc.)

annihilated with the computer-mediated delivery method on its own. As a result, completion rates of e-learning courses often sagged dramatically (Singh & Reed, 2001). Much of the slump has been attributed to the lack of a social, interactive, mentored learning environment. Blended learning approaches are popular because they provide the convenience and accessibility of e-learning environments, while simultaneously promoting personal interaction.

Cost Effectiveness

Cost effectiveness is a third major benefit that can result from using BLEs. On the academic side, The Center for Academic Transformation, with the support from the Pew Charitable Trusts, recently completed a three-year grant program designed to support universities in redesigning their instructional approaches using technology to achieve cost savings and quality enhancements. Grant awards were used in the redesign of large enrollment introductory courses offered at 30 institutions across the U.S. In order to achieve cost savings, many of the redesign efforts transformed traditional F2F lecture-based course offerings to courses with a blend of F2F and CM instruction. Table 1 details four general patterns of technology use identified in the PEW-sponsored courses.

Just as higher educational institutions look for cost savings from BLEs, most corporations that adopt blended learning solutions do so because they are a cost-effective means of training and distributing critical information to employees. Numerous studies indicate that travel costs and time associated with corporate training objectives could be reduced by as much as 85% using blended learning methods (Singh & Reed, 2001). For example, a report on an executive MBA program for mid-career doctors shows that blended learning programs can be completed in half the time and at less than half the cost of classroom based instruction (Jones International University, 2002). Another report on corporate blended learning indicates that blended learning solutions can be cost-effective for companies because they provide a means of reaching a large, globally-dispersed audience in a short period of time with both a consistent and a semi-personal content delivery (Bersin & Associates, 2003).

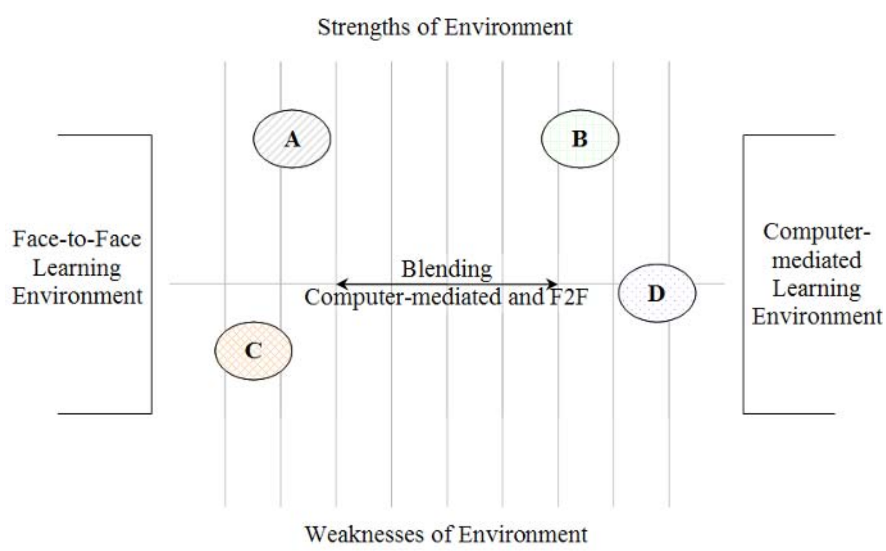
Challenges to Blending

The current literature tends to focus much more on the positives of BLEs than the challenges that institutions, instructors, and learners face from adopting BLEs. Three major categories of challenges addressed in the literature are: (1) finding the "right" blend, (2) the increased demand on time, and (3) overcoming barriers of institutional culture. These three main challenges will be addressed individually in the following sections.

Finding the Right Blend

The most significant challenge faced by people developing and delivering BLEs is identifying the instructional

Figure 2. Blending the strengths of F2F and CM learning environments (Adapted from Osguthorpe and Graham, 2003, p. 229)



strategies that match well with the conditions that are present in these two quite different environments. This challenge is complex because it relates to achieving the right blend, both from a learning and cost-effective standpoint.

Both F2F and CM learning environments have affordances that endow them with particular strengths and weaknesses. The affordances enable the effective use of particular instructional methods within the specific learning environment. By blending F2F with CM instruction, the range of possible instructional strategies that can be used is greatly increased. From a pedagogical standpoint, the goal of blending learning environments for a particular context and audience is to find an appropriate combination of the two environments that takes advantages of the strengths of each environment and avoids their weaknesses (Martyn, 2003; Osguthorpe & Graham, 2003). Figure 2 adds a dimension to Figure 1 and shows how blended solutions can either capitalize on the strengths of both learning environments or not. In Figure 2, for example, blends A and B both capitalize on the strengths of both environments while blends C and D use methods in an environment for which they are not well suited.

Increased Demand on Time

Both faculty instructors and corporate trainers are generally comfortable with creating and presenting instructional materials either in a F2F or in a CM learning environment, but not necessarily in both learning environments. When institutions decide to utilize both learning environments for a single course offering, the time demands of the instructor or trainer increase because now instructional materials must be develop for both CM and F2F environments. Additionally, instructors and trainers typically incur an increase in the time they spend interacting with learners in BLEs. When BLEs are instituted, instructors and trainers who have typically only interacted with students in either F2F or CM learning environments now are responsible for interacting with the students in both environments. As Hartman studied BLEs in higher educational institutions, he found that adding an online component to a F2F course put increased time demands and stress on the faculty developing and delivering the blended course (Hartman et al., 1999).

Overcoming Barriers of Institutional Culture

There are cultural barriers for both learners and instructors that must be overcome in order to use BLEs. The CM components of BLEs require a large amount of self discipline on the part of the learners because learning in that setting is largely independent (Collis, 2003). In current higher educational online learning environments, students tend to procrastinate when they have little required contact (Leh, 2002). In corporate settings, many employees don't finish online courses because they lack the discipline or the motivation to complete the courses. Currently, the culture in both higher educational institutions and corporations allows for student dropouts and don't necessarily require the learners to have the discipline to finish an online course. If BLEs are to be highly successful, the culture of these organizations, as it relates to persistence, must change.

Another cultural element that can work against the use of BLEs is organizational and management support. In higher educational institutions, faculty may hesitate to try blended approaches because they are not sure that they have departmental support or that it fits into the culture of the department or greater institution (Hartman et al., 1999). Similarly, management support for BLEs is essential if they are to succeed in corporations because executives have a large influence on company culture (Bersin & Associates, 2003).

FUTURE TRENDS

Blended learning environments promise to be an important part of the future of both higher education and corporate training. Over the past decade, with the increased availability of technology and network access, the use of BLEs has steadily grown. However, the amount of research done related to the design and use of BLEs is relatively small and additional research is needed. In particular, research is needed that will help instructors to understand the strengths and weaknesses of methods used in F2F and CM instructional environments and know how to appropriately combine both types of instruction. Cases across various levels and types of blends need to be documented and analyzed in order to better understand the tradeoffs that must be made when designing instruction in a blended learning environment.

CONCLUSION

During the past decade, online learning has made huge strides in popularity in both higher education and corporate sectors of society. The use of technology has increased access to educational resources and facilitated communication in a way that was not previously possible. Despite the strengths that online learning environments provide, there are different strengths inherent in traditional face-to-face learning environments. The current trend toward blending both online and F2F instruction is a positive direction that merits our further attention and study.

KEY TERMS

Affordances: Features of an environment or artifact that "afford" or permit certain behaviors.

Blended Learning Environment: A learning environment that combines face-to-face and computer-mediated instruction.

Distributed Learning Environment: A learning environment where participants are not co-located and use computer-based technologies to access instruction and communicate with others.

Dual-Mode Institution: Institutions that simultaneously offer on-campus courses and distance education courses.

Hard Technologies: Computer equipment, software, networks, and so forth.

Hybrid Course: Another name for a blended course. Typically, a course that replaces some F2F instructional time with computer-mediated activities.

Hybridization: The phenomenon occurring at universities where there is an increasing overlap of the boundaries of traditional on-campus courses and distance education courses.

Soft Technologies: Instructional innovations, methods, strategies, and so forth.

Best Practices for Effective Virtual Teams

D. Sandy Staples
Queen's University, Canada

Ian K. Wong
Queen's University, Canada

Ann Frances Cameron
Queen's University, Canada

INTRODUCTION

The use of teams as fundamental building blocks in organizations is growing (Furst, Blackburn & Rosen, 1999), as is the frequency of teams to be distributed geographically (which we call virtual teams). Virtual teams are now being used by many organizations to enhance the productivity of their employees and to reach a diversity of skills and resources (Majchrzak, Malhotra, Stamps & Lipnack, 2004). Virtual teams are groups of individuals who work on interdependent tasks, who share responsibility for outcomes, and who work together from different locations. While the use of virtual teams is more common in today's organization, the practices that make virtual teams most effective are not fully understood and challenges remain (Markus, 2004).

Virtual team best practices are identified below from three perspectives: organizational best practices, team leadership best practices, and team member best practices. Ideas for best practices were identified from three sources: six case studies of actual virtual teams (Staples, Wong & Cameron, 2004); the existing literature on virtual teams; and the existing literature on traditional (i.e., collocated) teams and telecommuting (i.e., research on virtual work at the individual level).

ORGANIZATIONAL BEST PRACTICES

There are six best practices that the organizations that have virtual teams should follow. Table 1 contains a list of these practices, each of which is explained next.

Carefully Select Team Members for Diversity

The importance of creating teams with the appropriate diverse mix of skills and individual traits was identified in the case studies and has been identified in the traditional team literature (e.g., Bettenhausen, 1991; Cohen, 1994). The distributed nature of virtual teams allows a diversity of backgrounds, experiences, ideas, thoughts, abilities, and perspectives to be assembled within a single team. Organizations forming virtual teams should take advantage of this, selecting team members with diverse backgrounds and skills. Working on a diverse team can also be more rewarding, interesting, and fun, as team members get the opportunity to learn about new cultures and interact with people beyond their own work location.

Supply Sufficient Resources and Support

Organizations have to supply virtual teams with sufficient resources, including such things as financial resources, time, facilities, hardware, software, communication channels, technical equipment, and proper training. The traditional team literature suggests that team building activities and training members how to work in teams is important because they ensure that employees develop the knowledge required to contribute to organizational performance (Cohen, 1994). In virtual teams where it is especially difficult for team members to get to know one another, organizations may need to provide extra resources for extensive team building exercises. Since virtual teams often need to communicate electronically, appropriate information technology (IT) equipment, training on how to use IT and communication systems, and constant technical support are also important to virtual teams (Duarte & Snyder, 2001; Fisher & Fisher, 2001; O'Hara-Devereaux & Johansen, 1994; Pinsonneault & Boisvert, 2001; Staples et al., 2004).

Develop Human Resource Policies that Stimulate High Virtual Team Performance

Policies must be designed in such a way that virtual team members are recognized, supported, and rewarded for their work (Duarte & Snyder, 2001). Providing team-based

Table 1. Organizational best practices for effective virtual teams

- Carefully select team members for diversity
- Supply sufficient resources and support to the team
- Develop human resource policies that reward team efforts and stimulate virtual team performance
- Provide appropriate autonomy to the team
- Use standard process and procedures
- Develop an organizational culture that stimulates the sharing of information

rewards to team members can increase team cohesiveness, motivation, and effectiveness (e.g., Cohen, Ledford & Spreitzer, 1996; Lawler, 1986, 1992). Since virtual team members are not seen every day in a central office, it is also possible that they may be overlooked for promotional opportunities (Duarte & Snyder, 2001). Therefore, special career development opportunities should be created for virtual team members so that this "out of sight, out of mind" phenomenon does not occur (Pinsonneault & Boisvert, 2001).

Provide Appropriate Autonomy to the Team

Consistent with traditional team research (Cohen & Bailey, 1997), virtual team members interviewed in the case studies reported that little involvement from senior management was usually preferred over hands-on management, as long as the organization still provided the funds and resources necessary. Worker autonomy is shown to have clear benefits such as enhanced worker attitudes and performance. Organizations should give team members the power to take action and make decisions while still providing the team with the information it needs to make sound business decisions (Cohen, 1994). Organizations should provide information on processes, quality, customer feedback, business results, competitor performance, and organizational changes.

Use Standard Processes and Procedures

The use of standard processes and procedures can reduce the time needed for team start-up and may eliminate the need for unnecessary reinvention of operating practices every time a new team is needed (Duarte & Snyder, 2001). For virtual teams that rarely meet face to face, standard communication procedures and policies are extremely important (Duarte & Snyder, 2001; Fisher & Fisher, 2001; Grenier & Metes, 1995). A good face-to-face start-up can allow team members to develop communication norms and agreements on how members are going to work together.

Develop an Organizational Culture that Stimulates the Sharing of Information

The organizational culture plays a large role in determining how well a virtual team functions within the organization since it influences how individuals in an organization behave. Therefore, organizations should work to build norms and values that promote communication and the sharing of information. The traditional team research also identified the importance of having a supportive culture. Therefore, organizations should create a cooperative work environment where norms are established that reinforce and support team behaviors such as sharing information, responding appropriately to team members, and cooperating (Bettenhausen, 1991). This has been found to be critical for effective team performance (Tjosvold, 1988).

TEAM LEADERSHIP BEST PRACTICES

There are six best practices relating to the leadership and management of the virtual team. Table 2 contains a list of all six team leadership practices, each of which is explained next.

Set Goals and Establish Direction

The virtual team literature strongly suggests that effective leaders understand the importance of defining a vision for the virtual team (Fisher & Fisher, 2001; Grenier & Metes, 1995; Lipnack & Stamps, 1997; O'Hara-Devereaux & Johansen, 1994). According to Lipnack and Stamps (1997), a predictor of virtual team success is the clarity of its purpose and vision. To succeed, teams must turn their purpose and vision into action by assigning roles and responsibilities (Fisher & Fisher, 2001; Grenier & Metes, 1995; O'Hara-Devereaux & Johansen, 1994; Pinsonneault & Boisvert, 2001) and setting goals (Lipnack & Stamps, 1997).

In the virtual team case studies, 64% of team members recognized this need to carefully set realistic, clear goals

Table 2. Management and team leader best practices for effective virtual teams

- Set goals and establish direction
- Provide feedback via coaching and modeling
- Build trust through open communication, honest behavior, and delivering on commitments
- Empower the team
- Motivate the team
- Use appropriate leadership styles at appropriate times

and timelines. To accomplish this, management and team leaders can first develop a 'roadmap' with realistic timelines that are compatible with the expectations of senior management. Next, the critical path through the project should be identified. Based on this path, major milestones should be set. Whether or not it affects them directly, all team members should be constantly reminded of the next milestone. Focusing on milestones and deliverable dates will help members keep the 'big picture' in mind when working on their individual tasks. Successful virtual teams are those that, with the help of a focused manager, are consistently able to meet these milestones within the allotted time.

Provide Feedback via Effective Coaching and Modeling

Team leaders need to provide members with timely feedback about their performance so team members know what they can do to continuously improve their performance (Duarte & Snyder, 2001). A manager's ability to provide remote employees with advice and help can increase the effectiveness of the remote employees (Staples, 2001). In virtual teams, this might require getting informal input from various people who interact with team members both within and outside of the organization. Virtual leaders also need to model appropriate virtual work habits (Staples, Hulland & Higgins, 1999). To accomplish this, the telecommuting literature suggests managers should keep remote employees well-informed of organizational activities, provide regular feedback on performance and progress, establish well-structured and constant communications, and be available at hours that fit with work routines of remote employees (Pinsonneault & Boisvert, 2001).

Build Trust Through Open Communication, Honest Behavior, and Delivering on Commitments

Without trust, productivity suffers as team members spend time playing politics instead of working on real business issues (Fisher & Fisher, 2001). To build trust, it is important for team leaders to communicate openly and frequently with team members. Perhaps the single most important variable that affects trust is honesty. Leaders who demonstrate openness about their actions will find that members respond with sincerity. How a leader listens and communicates with his or her team members is very much related to team effectiveness and trust (Cohen & Bailey, 1997). Listening to team members and visibly keeping commitments increases trust, whereas broken promises diminish it (Fisher & Fisher, 2001).

Empower the Team

This best practice is related to the organizational practice of more generally providing autonomy to teams. At a lower level, team leaders also have to provide the appropriate level of autonomy, setting overall team goals and establishing direction while allowing individual team members to decide how they carry out their own specific tasks (Cohen & Bailey, 1997; Fisher & Fisher, 2001). Leaders who trust team decisions can give the members a sense of ownership. This approach is particularly important in a virtual team environment where geographic separation makes micromanagement impractical.

Motivate the Team

In a virtual team environment where tasks may appear unconnected, the 'big picture' is not always easy to visualize and it may be difficult for employees to remain committed to the project. Thus, team leaders can play a key role in keeping virtual team members motivated. Motivation can be stimulated by making the importance of the team's task clear (such that passion for the team's cause is created) and by demonstrating how the project will result in significant outcomes for the individual team members (Fisher & Fisher, 2001; Staples et al., 2004). By linking team success to individual success and opportunities, team members will be highly motivated to succeed on the project.

Use Appropriate Leadership Style

Over a quarter of case study team members (Staples et al., 2004) reported that appropriate leadership at the *appro-*

priate time was one of the key elements of a successful virtual team. During the initial phases of the project, the appropriate leader is one who can "whip up enthusiasm" and motivate the team. During the later stages, the effective leader is someone who is "getting the right people together and keeping everybody on task and keeping everything going." Therefore, the style and activities of team leaders have to be appropriate for the stage the team is at and the needs at that particular time.

TEAM MEMBER BEST PRACTICES

Suggestions for what makes individual members of virtual teams effective include specific behaviors, as well as attitudes and beliefs. The five general characteristics of effective virtual team members are listed in Table 3 and described.

Communicate Effectively

Research in tradition teams and telecommuting recognizes that the ability to communicate effectively is a critical skill for telecommuters, remote workers, and managers of remote workers (Cohen, 1994; Pinsonneault & Boisvert, 2001; Staples, 2001). Eighty-four percent of team members interviewed in the case studies also recognized the importance of effective communication in building a successful team. Communication involves transferring ideas, sharing information, listening and internalizing the ideas of others, and notifying team members of any problems or issues. This can be challenging in a virtual team where face-to-face communication and impromptu meetings are infrequent, if not impossible. To solve this problem, virtual team members suggest working hard to keep lines of communication open, and developing or finding the right communications tools that make up for the loss of face-to-face time and provide for informal interactions. For example, team members can use e-mail or instant messaging as a "virtual coffee pot or water cooler" around which personal conversations can occur (O'Hara-Devereaux & Johansen, 1994). In addition, team members themselves have to be responsive, quickly returning telephone calls and responding to e-mails, even if it is just to say, "I don't have time right now, but I'll get back to you in two days with the answer." Recipients can also confirm that the message had been received and ensure that the major points in the message were understood. Setting communication norms such as these helps to avoid misunderstanding that can occur when communicating electronically.

Have the Necessary Skill Sets

The effectiveness of a team depends on the collective knowledge and skills of its members. In order to make good decisions, team members need the appropriate knowledge and skills (Cohen, 1994). Specific skills mentioned by the virtual team members in the case studies included: the ability to organize effectively, a strong competency in an individual's functional area of responsibility, adequate technical skills to use the information and technology tools available, and good time management skills. Specific social skills mentioned in the virtual team literature include learning how to negotiate creatively, mediating online disputes, and making new members of the team feel included (Grenier & Metes, 1995).

Be Highly Motivated

In some cases, a particular practice may exist on both the management and individual level. As described above, motivating is an activity that must be performed by team leaders. The self-managing nature of many virtual teams means that *self*-motivation and *self*-discipline are also essential. Virtual team members must be able to work independently and be motivated to make appropriate decisions. This is made possible by having clear goals and responsibilities, and having high personal commitment and motivation to the team, along with having the resources and information needed to do the job (Lipnack & Stamps, 1997). The ability to self-motivate is important since virtual team members are often working far apart from their other team members. Virtual workers should also have a low preference or need for social interaction or have the ability to fulfill this need outside of the work team (Pinsonneault & Boisvert, 2001).

Be Supportive of Other Team Members

The way in which team members interact with each other has an effect on team effectiveness (Cohen, 1994). Supporting team members involves working together with a sense of energy and team spirit, and sharing ideas and expertise to help others (Cohen, 1994). Several dimensions of a supportive team emerged during the case study interviews. First, team members felt that it was important to recognize when someone else did a good job, and to congratulate or thank them accordingly. Second, interviewees sought a respectful team environment where members were not afraid to openly discuss ideas. Third, interviewees reported that the ability to get along with other team members was an essential quality of an effective virtual team member.

Table 3. Team member best practices for effective virtual teams

• Communicate effectively
• Have the necessary skill sets
• Be highly motivated
• Be supportive of other team members
• Be action-oriented

Be Action-Oriented

Interviewees felt that individuals should have an action-oriented approach when participating in a virtual team. Phrases that case study members of one team used to describe a top performing virtual team member included: being a "doer"; being "proactive"; "uses an entrepreneurial approach"; and "looks for solutions." One virtual team member who was interviewed stated that successful virtual team members are those who "organize their thoughts into actions or proposals that get a good buy" or influence the rest of the group.

FUTURE TRENDS AND OPPORTUNITIES

As competition increases globally and trading barriers decline, the creation of teams comprised of members from many different locations is expected to become the norm. With this virtual team growth, knowing the best practices for team members, leaders, and organizations with virtual teams becomes even more important. While some useful best practices are explained above, some questions are left unanswered. These questions create many opportunities for future research in this area such as:

- Which of the best practices are most critical for team effectiveness?
- Does the impact of certain practices on effectiveness vary depending on the task and/or the organizational context? How?
- Does one set of practices (i.e., individual, managerial, or organizational) take precedence such that those practices have to be in place before the other practices have a positive effect?
- How does an organization ensure that best practices are followed?
- Can training programs be developed for managers and leaders, and for members of virtual teams? What should be in these training programs and how should they be delivered?
- Can policies be developed and norms established in organizations such that supportive practices, which research suggests leads to effective virtual work, are followed? How can this be done most effectively?

CONCLUSION

The ideas presented in this article should help organizations create and maintain more effective virtual teams. Individual virtual team members, virtual team leaders, and organizations can all follow best practices that contribute to virtual team effectiveness. Given the growing use of virtual teams in organizations today, there is a great need to more deeply understand what makes a virtual team effective. We hope we have made a contribution in that direction, and we look forward to other researchers and practitioners answering some of the questions posed previously.

KEY TERMS

Communication Norms: In the context of virtual teams, communication norms are typical routines and expectations for communicating within a virtual team using the communication media that the team has available to them (e.g., electronic communication such as e-mail or instant messaging, telephone, etc.). For example, responding within a day to all e-mails, even if just "I'm busy but will get to this tomorrow," is an example of a virtual team communication norm.

Organizational Culture: "The collective programming of the mind which distinguishes the members of one organization from another" (Hofstede, 1997).

Remote Worker: An individual who works at a different location than his/her co-workers and/or manager. That person is remote, in terms of physical presence from his/her colleagues.

Team Diversity: The combined variety of skills, backgrounds, experiences, ideas, thoughts, abilities, and perspectives that individuals bring to their team.

Team Effectiveness: The ability of a team to perform its tasks on time, on budget, and with acceptable quality, as well as the satisfaction, motivation, and commitment of the team members.

Telecommuting: The practice of working from the employee's home instead of physically commuting to a company office location. The connection to the office is done via telecommunications, rather than physically commuting (i.e., traveling) to the office.

Traditional Teams/Collocated Teams: A group of individuals who work on interdependent tasks, who share responsibility for outcomes, and who work together at the same location (i.e., their office/work area is in the same general location).

Virtual Coffee Pot/Virtual Water Cooler: Using electronic communication (such as e-mail or instant messaging) to conduct informal interactions (personal or non-work conversations) that would normally be discussed around the office water cooler in a face-to-face work environment.

Virtual Team: A group of individuals who work on interdependent tasks, who share responsibility for outcomes, and who work together from different locations (i.e., they are geographically dispersed, in terms of their normal work location).

Better Executive Information with the Dashboard Approach

Frédéric Adam

Jean-Charles Pomerol
Université Pierre et Marie Curie, France

INTRODUCTION

After more than 30 years of research on how the work of managers can be supported by computers, the observation that developing computer systems that are truly useful for top management is a highly complex and uncertain task is still as valid as ever. Information systems for executives raise specific problems, which have primarily to do with the nature of managerial work itself (Mintzberg, 1973), as they are intended to tackle the needs of users whose most important role is "to create a vision of the future of the company and to lead the company towards it" (King, 1985, p. xi).

BACKGROUND

The major difficulty in supporting managers with computer systems comes from the very nature of management work (Mintzberg, 1973, 1975, 1976), which is concerned with communication, coordination, and people's management for more than 80%. At the time of his research, Mintzberg (1973) had noted how little time is left for reflection and for "playing" with computer systems. This has been a significant difficulty from the origins of MIS systems because their primarily "operational" focus was not central to executives' concerns (Ackoff, 1967; Keen & Scott Morton, 1978). Twenty years later, this difficulty has also been largely responsible for the shift from decision support systems (DSSs) to executive information systems (EISs). EISs were intended to be very easy to use and to help users manipulate required data without the need for much training, which would be very attractive to top executives who want to have, at a glance, a very comprehensive view of their business. Specific descriptions of the differences between DSSs, EISs, and cooperative decision systems can be found in Pomerol and Brézillon (1998). Naturally, computer literacy among executives has increased to a great extent, notably thanks to the development of electronic mail and the World Wide Web. However, whatever designs were put forward over the years, it has remained true that managers are not inclined to spend countless hours browsing computer data, such is the time pressure under which they operate.

Beyond the time pressures under which executives must operate, there are issues of trust and of credibility of the information that can be found in a computer system, which mitigate against intensive executive reliance on information systems, especially in a long-term perspective. First of all, the lack of confidence of executives in their models has been noted by many researchers (e.g., Wallenius, 1975; Cats-Baril & Huber, 1987; Abualsamh, Carlin & McDaniel, 1990). The idea that decision makers need sophisticated models may actually be wrong. People in charge of the preparation of decisions would probably be able to understand and use smart models, but the high-level executives who most commonly make the final decisions are far too busy to train with and use involved systems. On the contrary, they appear to prefer simple systems that they trust and understand, and that display very timely simple information. More often, the data required to make the best decisions will already reside in some form or another in the database of the organization or can be captured with an online feed into a computer system, and what is really needed is a device to filter and display and to warn executives about the most important variances (Simon, 1977). As noted by Kleinmutz (1985): "the ability to select relevant variables seems to be more important than procedural sophistication in the processing of that information" (p. 696).

In EIS, the underlying models built into the system are normally very simple and easily understandable, which is a great help in increasing the acceptability of a computer system.

To conclude, the specificities of managerial decision making can be synthesized as follows:

- Most decisions are made very quickly under considerable time pressure (except some strategic decisions).
- Strategic decision making is often the result of collaborative processes.

- Most decisions are linked to individuals who have specific intentions and commitments to personal principles and ideas.

It is therefore very difficult to support managers, and despite many years of research, little is known about the way information systems could support such unstructured tasks.

A VEHICLE FOR INFORMATION REQUIREMENTS ANALYSIS: CRITICAL SUCCESS FACTORS

In pre-EIS days, Rockart (1979) put forward a methodology called critical success factors or CSF to guide information systems planning. The method had its advantages, though it failed to make a general impact on the planning process of organizations. Its potential in other areas, notably the development of information systems, has been explored by a number of researchers. It is argued in this article that it can be very useful as a guide for the development of executive systems, as both from an information content perspective as for the design of the interface of these systems.

CSF assumes that the performance of organizations can be improved by focusing on "the few key areas where things must go right for the business to flourish" (Rockart, 1979). In simple terms, the method seeks to isolate, using the expertise and gut feeling of managers, the factors which may make the difference between success and failure for the firm.

A number of key points about CSF make it a very attractive technique. First of all, while CSF is essentially a generic framework, it recognizes that all firms are different and operate in different markets. Thus, CSFs are different for different organizations. Secondly, the CSF theory takes into account that the needs of managers within the same organizations are also different based on their hierarchical level, but more importantly, based on their style and their specific areas of responsibility. In general, there are only a limited number of factors that each manager should monitor closely, and this guarantees that managers can concentrate their limited attention to factors that really matter and that are within their control. The attractive thing about this breakdown of responsibility is that the CSF sets controlled by the different managers add up to a complete organizational set that covers all the key areas of the business.

Van Bullen and Rockart (1986) identified a number of primary categories of CSF that are useful in guiding the analysis of the organizational CSF set. These generic sources of CSFs are: (1) the industry where the organization operates (these CSFs are shared by mainstream organizations in this industry), (2) the competitive position and strategy pursued by the organization (which are unique to its set of circumstances and objectives set by its top managers), (3) the environmental factors surrounding the organization (which it has no control over, but which it must monitor closely to compete), (4) temporal factors (which relate to specific events or change programs currently facing the organization, and require the temporary monitoring of additional factors), and finally, (5) CSFs that are specific to each manager and their role in the company. Other authors have added other potential sources such as CSFs related to the analysis of main competitors (especially industry leaders) and the evolution of their business (Leidecker & Bruno, 1984). These sources add up to a wealth of potential factors and measurements that are sufficient for effective monitoring of the business of most organizations.

Dashboards and Control Rooms

In the next stage of the development of executive systems, designers must create an interface for displaying the CSFs. The design of this interface is nearly as important as the selection of the indicators in shaping the perception of managers of the usefulness of their information systems and keeping their interest in the long run. One technique that has worked well in selecting and presenting indicators is the application of the dashboard concept to the management of organizations.

Fundamentally, the concept of dashboard reflects the application of the concept of control room to the management of the firm and echoes the call for a warning or exception reporting functionality in EIS-type systems. In engineering, the control room is a specially designed physical area of a plant where the proper operation of key equipment can be monitored. Control rooms have developed because of the need to monitor increasingly complex processes, such as petrol refining or the operation of nuclear power plants. The control room allows operators to control a process without looking at it with their own eyes, and with a degree of accuracy and completeness that could not be achieved with human perception alone.

This suggests that dashboards may be developed that considerably help managers in their day-to-day search for problems and matching solutions. Naturally, the nature of management itself is highly dynamic and diverse and involves consideration of infinite number of parameters in a way that is fundamentally different from the monitoring of a manufacturing process. Thus, management has a significant "human interaction" component that cannot easily be supported by computer systems. Simon (1977), Gorry and Scott Morton (1971), and others have commented comprehensively on the degree to which managerial decisions are programmable or not, however it remains that the implementation of many of the objectives of the firm, however elusive, can be monitored using a dashboard-type interface. Further, the CSF method can be a powerful vehicle in selecting the indicators to be shown on each manager's dashboard.

The difficulty with CSF-based dashboards resides in the operationalization of managers' key concerns and the identification of specific targets for CSF monitoring, the design of measurement logic for each indicator, and in the development of the interfaces that can be used by managers to easily and effectively review the performance of the firm in relation to each of the indicators.

TOWARDS A METHODOLOGY FOR DASHBOARD DEVELOPMENT

At the height of the EIS movement, King (1985) remarked:

"It is so easy to lose sight of reality—to believe that the computer model's numerical forecasts are real and that they describe future outcomes that will, in fact, come to pass…The computer model's forecasts are based solely on those predictions about the future that we are able to quantify. Those things that are not readily quantifiable are usually omitted, and in being omitted there is a danger that they may be ignored." (p. xi)

This illustrates the dangers inherent in approaching management based solely on numbers, however obtained. This also explains why observational plant tours are still regarded as one of the most reliable methods for collecting data in manufacturing environments (Jones, Saunders & McLeod, 1988). The basis of any dashboard approach to management must therefore take into account the following four key issues:

(1) *Limited Attention:* Given the limited attention of managers and the costs inherent in sourcing certain data, the indicators displayed on the dashboard must be carefully selected using the CSF.

(2) *Performance Measurement:* The measurements used to monitor indicators or CSFs are crucial. The usefulness and effectiveness of the dashboard is totally dependent on the accuracy of the data used and the realism of the calculations presented to managers.

(3) *Operator Training:* It is critical that managers understand the assumptions built into the dashboard and the algorithms used to reach the results presented to them. They must also be fully aware of how data are collected and what limitations applied to the accuracy of the measurements. For instance, drill down facilities can make the difference between "using information to manage more intelligently and more effectively and making the same old mistakes but with more speed" (Meall, 1990).

(4) *Dashboard Layout:* The layout of the dashboard has a direct impact on the understanding derived by managers. The interface of the dashboard must be consistent so that managers can visualize immediately where they should focus their attention as a matter of priority. Exception reporting and color coding (Watson, Rainer & Koh, 1991) can be used to achieve maximum visual impact.

It is also useful if the development of the dashboard can be operationalized as an evolutionary activity where managers can feed back their perception of the dashboards to developers so that the design can be improved over time and the indicators refined or replaced (as in the case of temporal CSFs). In this article, we propose a framework based on 11 questions to support this evolutionary process, and help managers and developers to establish a fruitful dialogue:

- **Question 1: Who will use the indicators?**
  The answer may not be simple when not one, but a number of individuals are interested in monitoring certain indicators. However, managers should concentrate on monitoring the parameters most closely associated with their own performance or that of the areas directly under their control.
- **Question 2: Can be mapped out to a specific objective at a higher level?**
  In the perspective of a top-down CSF exercise, indicators are mapped out to specific objectives pursued by top management. In a bottom-up scenario, it will help if indicators can be merged into higher level composite indicators presented to higher level managers. Developers can use the hierarchy of indicators as a blueprint for the drill-down facility to be built into the dashboard so that top managers can understand the underlying causes of poor or good performance.
- **Question 3: How frequently will managers need to monitor each indicator?**
  Managers' perception of how frequent significant or revelatory variations are likely to occur should be used as a guide for deciding how frequently indicators should be updated. The scope of the benefits that may arise as a result of the monitoring should also be considered if high costs are likely to be incurred.

- **Question 4: What calculation methods are available? What unit of measurement will be used?**
  The choice of calculation method can greatly influence the variation of an indicator and shift the burden of responsibility from one area to another. It can also influence the way the performance of operators or workshops is measured.
  The choice of the unit of measurement is normally straightforward for quantitative analysis, but can become far more complex for less tangible CSFs that involve the estimations of qualitative factors. Customer satisfaction, for instance, will require vision and creativity if it is to be measured properly. Some quantitative measures may be applicable such as the number of complaints received per time interval, but other measures may have to be found that can act as surrogates of customer satisfaction.
- **Question 5: What data source exists? What should be created?**
  Certain data may be missing from existing organizational information systems. Other data may reside in a proprietary system (e.g., a custom-built process control system) that does not integrate well with other systems. Significant investment in equipment and special devices (such as scanners and sensors) or in software such as OLAP and ROLAP (Relational OLAP) may have to be made.
- **Question 6: How detailed should the analysis presented in the dashboard be? How can the indicators be broken down to be more meaningful?**
  Many indicators are too broad to be suitably presented as one figure, and some disaggregating may be required. Typical organizations sell multiple products in multiple markets. Thus, sales figures need to be disaggregated to present £ figures, volumes, and variances for each product on each market while also presenting the aggregated data. Multi-dimensional modeling can be used to support the organization and retrieval of such data.
- **Question 7: What threshold values should be used to differentiate between adequate and inadequate performance? What comparisons can be made to assess the company's performance?**
  Absolute measurement figures presented by a dashboard may not be meaningful to managers unless they can be examined in light of other data. Most companies already have a tight budget system in place, and this can be used as a source of normative values.
- **Question 8: How can each indicator be represented for maximum visual impact?**
  Developers must seek to reduce information overload and use the latest graphical user interface (GUI) technology. Some software tool boxes are now available to help designers create displays and objects that mirror the type of controls normally found on dashboards. Gauges with specific color-coded threshold values can easily be created, and special charts can be made clickable to build intuitive drill down into the data. These speed up and facilitate the data reading of managers.
- **Question 9: What action must be taken when good or bad performance is measured? Is there scope for corrective action to be taken based on the indicator?**
  Whenever good or bad results are presented, managers should know what avenues can be pursued. Reporting mechanisms (e.g., electronic mail) can be built into the dashboard to facilitate and accelerate the dissemination of interesting results and their discussion. In the longer term, increased familiarity with indicators and what their evolution means should have practical decision-making implications for all managers and staff. Thus, users' reaction times to certain signals should be reduced and their responses should improve, especially in recurrent situations.
- **Question 10: How will indicators be monitored/archived in the long term?**
  A key element of our approach is the learning that can be achieved when CSFs are monitored over long periods of time. Staff and managers learn from regularly sampling their performance and that of their areas, and seeing it compared to other data, such as budgets and previous performance of industry standards. Greater learning will be derived if managers and staff set time aside to review and discuss indicators on a regular basis.
- **Question 11: Is there any potential bias inherent in the methods and data used for calculations? What incentives are being given to staff?**
  The development of new performance measurement systems, such as a dashboard of indicators, should always be guided by consideration of the incentives given to actors and the behavior likely to result from the implementation of the underlying indicators. There may also be a change management side to the project, as managers negotiate with staff the implementation of the system. Staff may object to a certain type of measurement (which they may perceive to be threatening or invasive) or the implementation of devices dedicated to monitoring their work.

CONCLUSION

The case for managing the firm solely based on numbers has already been argued and lost. At this point, it is well established that managing firms cannot and should not be compared to the administration of a power plant. This does not mean, however, that the concept of control room does not have potential when applied to the management of organizations. Faced with increasingly complex situations and responsibility for the administration of increasingly complex business processes, managers have less and less time to spend monitoring the key factors of the business. The development of a dashboard can speed up this process and help managers catch far more information than they normally would without assistance.

Following the steps highlighted in this article will also give organizations a much better idea of what parameters they should worry about and how to measure performance. Peter Swasey, one of the directors of the Bank of Boston, commented that "what you don't measure, you don't manage" (McGill, 1990). The preparatory analysis work on the CSFs of the firm will give much confidence to organizational actors that they understand their business and have a comprehensive hold upon its vital functions, and the dashboard ultimately developed will provide flexible and speedy access to vital information, thereby freeing time for other key activities such as business or staff development. As a by-product, managers may also be able to use the analysis carried out for their dashboard as a blueprint for the incentive systems of their company.

KEY TERMS

Control Room: A special location in a plant where operators can monitor a process in great detail without having to physically be looking at it. This is particularly useful in dangerous environments.

Critical Success Factors: A methodology for managing projects and firms that concentrates on the areas where things must go right if the endeavor is to flourish.

Dashboard: Specific display of information that presents key information about a process or device. A dashboard may or may not be computerized.

Evolutionary Design: System development methodology where an ongoing approach is taken to analyzing the requirements of the application.

Interface: Portion of a computer application that is used by the user to communicate with the application. It is particularly important for a dashboard, because it may impinge on the ability of users to properly interpret the variations in the indicators shown to them.

Managing by Numbers: A school of thought that sought to demonstrate that firms could be managed solely based on watching key (mostly financial) indicators. This is now largely discredited.

Model: A simplified representation of reality that concentrates on predicting how a factor or a series of related factors would evolve based on the variation of a set of parameters. Also, a simplified representation of reality.

Biblomining for Library Decision-Making

Scott Nicholson
Syracuse University, USA

Jeffrey Stanton
Syracuse University, USA

INTRODUCTION

Most people think of a library as the little brick building in the heart of their community or the big brick building in the center of a campus. These notions greatly oversimplify the world of libraries, however. Most large commercial organizations have dedicated in-house library operations, as do schools, non-governmental organizations, as well as local, state, and federal governments. With the increasing use of the Internet and the World Wide Web, digital libraries have burgeoned, and these serve a huge variety of different user audiences. With this expanded view of libraries, two key insights arise. First, libraries are typically embedded within larger institutions. Corporate libraries serve their corporations, academic libraries serve their universities, and public libraries serve taxpaying communities who elect overseeing representatives. Second, libraries play a pivotal role within their institutions as repositories and providers of information resources. In the provider role, libraries represent in microcosm the intellectual and learning activities of the people who comprise the institution. This fact provides the basis for the strategic importance of library data mining: By ascertaining what users are seeking, bibliomining can reveal insights that have meaning in the context of the library's host institution.

Use of data mining to examine library data might be aptly termed *bibliomining*. With widespread adoption of computerized catalogs and search facilities over the past quarter century, library and information scientists have often used bibliometric methods (e.g., the discovery of patterns in authorship and citation within a field) to explore patterns in bibliographic information. During the same period, various researchers have developed and tested data mining techniques—advanced statistical and visualization methods to locate non-trivial patterns in large data sets. Bibliomining refers to the use of these bibliometric and data mining techniques to explore the enormous quantities of data generated by the typical automated library.

BACKGROUND

Forward-thinking authors in the field of library science began to explore sophisticated uses of library data some years before the concept of data mining became popularized. Nutter (1987) explored library data sources to support decision-making, but lamented that "the ability to collect, organize, and manipulate data far outstrips the ability to interpret and to apply them"(p. 143). Johnston and Weckert (1990) developed a data-driven expert system to help select library materials and Vizine-Goetz, Weibel, and Oskins (1990) developed a system for automated cataloging based on book titles (also see Aluri & Riggs, 1990; Morris, 1991). A special section of *Library Administration and Management* ("Mining your automated system") included articles on extracting data to support system management decisions (Mancini, 1996), extracting frequencies to assist in collection decision-making (Atkins, 1996), and examining transaction logs to support collection management (Peters, 1996).

More recently, Banerjeree (1998) focused on describing how data mining works and ways of using it to provide better access to the collection. Guenther (2000) discussed data sources and bibliomining applications, but focused on the problems with heterogeneous data formats. Doszkocs (2000) discussed the potential for applying neural networks to library data to uncover possible associations between documents, indexing terms, classification codes, and queries. Liddy (2000) combined natural language processing with text mining to discover information in "digital library" collections. Lawrence, Giles, and Bollacker (1999) created a system to retrieve and index citations from works in digital libraries. Gutwin, Paynter, Witten, Nevill-Manning, and Frank (1999) used text mining to support resource discovery.

These projects all shared a common focus on improving and automating two of the core functions of a library—acquisitions and collection management. A few authors have recently begun to address the need to support management by focusing on understanding library users: Schulman (1998) discussed using data mining to examine changing trends in library user behavior; Sallis, Hill, Jance, Lovetter, and Masi (1999) created a neural network that clusters digital library users; and Chau (2000) discussed the application of Web mining to personalize services in electronic reference.

The December 2003 issue of *Information Technology and Libraries* was a special issue dedicated to the bibliomining process. Nicholson (2003) presented an overview of the process, including the importance of creating a data warehouse that protects the privacy of users. Zucca (2003) discussed an implementation of a data warehouse in an academic library. Wormell (2003), Suárez-Balseiro, Iribarren-Maestro, and Casado (2003), and Geyer-Schultz, Neumann, and Thede (2003) used bibliomining in different ways to understand use of academic library sources and to create appropriate library services.

We extend these efforts by taking a more global view of the data generated in libraries and the variety of decisions that those data can inform. Thus, the focus of this work is on describing ways in which library and information managers can use data mining to understand patterns of behavior among library users and staff and patterns of information resource use throughout the institution.

INTEGRATED LIBRARY SYSTEMS AND DATA WAREHOUSES

Most managers who wish to explore bibliomining will need to work with the technical staff of their integrated library system (ILS) vendors to gain access to the databases that underlie that system to create a data warehouse. The cleaning, pre-processing, and anonymizing of the data can absorb a significant amount of time and effort. Only by combining and linking different data sources, however, can managers uncover the hidden patterns that can help to understand library operations and users.

EXPLORATION OF DATA SOURCES

Available library data sources are divided in three groups for this discussion: data from the *creation* of the library, data from the *use of the collection*, and data from *external sources* not normally included in the ILS.

ILS Data Sources from the Creation of the Library System

Bibliographic Information

One source of data is the collection of bibliographic records and searching interfaces that represent materials in the library, commonly known as the Online Public Access Catalog (OPAC). In a digital library environment, the same type of information collected in a bibliographic library record can be collected as metadata. The concepts parallel those in a traditional library: take an agreed-upon standard for describing an object, apply it to every object, and make the resulting data searchable. Therefore, digital libraries use conceptually similar bibliographic data sources as traditional libraries.

Acquisitions Information

Another source of data for bibliomining comes from acquisitions, where items are ordered from suppliers and tracked until received and processed. Because digital libraries do not order physical goods, somewhat different acquisition methods and vendor relationships exist. Nonetheless, in both traditional and digital library environments, acquisition data have untapped potential for understanding, controlling, and forecasting information resource costs.

ILS Data Sources from Usage of the Library System

User Information

In order to verify the identity of users who wish to use library services, libraries maintain user databases. In libraries associated with institutions, the user database is closely aligned with the organizational database. Sophisticated public libraries link user records through zip codes with demographic information in order to learn more about their user population. Digital libraries may or may not have any information about their users, based upon the login procedure required. No matter what data is captured about the patron, it is important to ensure that the identification information about the patron is separated from the demographic information before storing this information in a data warehouse; this will protect the privacy of the individual.

Circulation and Usage Information

The richest sources of information about library user behavior are circulation and usage records. Legal and ethical issues limit the use of circulation data, however. This is where a data warehouse can be useful, in that basic demographic information and details about the circulation could be recorded without infringing upon the privacy of the individual.

Digital library services have a greater difficulty in defining circulation, as viewing a page does not carry the same meaning as checking a book out of the library, although requests to print or save a full text information resource might be similar in meaning. Some electronic full-text services already implement server-side capture of such requests from their user interfaces.

Searching and Navigation Information

The OPAC serves as the primary means of searching for works owned by the library. Additionally, because most OPACs use a Web browser interface, users may also access bibliographic databases, the World Wide Web, and other online resources during the same session; all of this information can be useful in library decision-making. Digital libraries typically capture logs from users searching their databases and can track, through "clickstream" analysis, the elements of Web-based services visited by users. In addition, the combination of a login procedure and cookies allow connecting user demographics to the services and searches they used in a session.

External Data Sources

Reference Desk Interactions

In the typical face-to-face or telephone interaction with a library user, the reference librarian records very little information about the interaction. Digital reference transactions, however, occur through an electronic format, and the transaction text can be captured for later analysis, which provide a much richer record than is available in traditional reference work. The utility of these data can be increased if identifying information about the user can be captured as well, but again, anonymization of these transactions is a significant challenge.

Item Use Information

Fussler and Simon (as cited in Nutter, 1987) estimated that 75-80% of the use of materials in academic libraries is in-house. Some types of materials never circulate, and therefore, tracking in-house use is also vital in discovering patterns of use. This task becomes much easier in a digital library, as Web logs can be analyzed to discover what sources users examined.

Interlibrary Loan and other Outsourcing Services

Many libraries using Interlibrary Loan and/or other outsourcing methods to get items on a "just-in-time" basis for users. The data produced by this class of transactions will vary by service, but can provide a window to areas of need in a library collection.

FUTURE TRENDS

Bibliomining can provide understanding of the individual sources listed earlier; however, much more information can be discovered when sources are combined through common fields in a data warehouse.

Bibliomining to Improve Library Services

Most libraries exist to serve the information needs of users, and therefore, understanding those needs of individuals or groups is crucial to a library's success. For many decades, librarians have suggested works; market basket analysis can provide the same function through usage data to aid users in locating useful works. Bibliomining can also be used to determine areas of deficiency and predict future user needs. Common areas of item requests and unsuccessful searches may point to areas of collection weakness. By looking for patterns in high-use items, librarians can better predict the demand for new items.

Virtual reference desk services can build a database of questions and expert-created answers, which can be used in a number of ways. Data mining could be used to discover patterns for tools that will automatically assign questions to experts based upon past assignments. In addition, by mining the question/answer pairs for patterns, an expert system could be created that can provide users an immediate answer and a pointer to an expert for more information.

Bibliomining for Organizational Decision-Making within the Library

Just as the user behavior is captured within the ILS, the behavior of library staff can also be discovered by connecting various databases to supplement existing performance review methods. While monitoring staff through their performance may be an uncomfortable concept, tighter budgets and demands for justification require thoughtful and careful tracking of performance. In addition, research has shown that incorporating clear, objective measures into performance evaluations can actually improve the fairness and effectiveness of those evaluations (Stanton, 2000).

Low use statistics for a work may indicate a problem in the selection or cataloging process. Looking at the associations between assigned subject headings, call numbers and keywords along with the responsible party for the catalog record may lead to a discovery of system inefficiencies. Vendor selection and price can be examined in a similar fashion to discover if a staff member consistently uses a more expensive vendor when cheaper alternatives are available. Most libraries acquire works both by individual orders and through automated ordering plans that are configured to fit the size and type of that library. While these automated plans do simplify the selection process, if some or many of the works they recommend go unused, then the plan might not be cost effective. Therefore, merging the acquisitions and circulation databases and seeking patterns that predict low use can aid in appropriate selection of vendors and plans.

Bibliomining for External Reporting and Justification

The library may often be able to offer insights to their parent organization or community about their user base through patterns detected with bibliomining. In addition, library managers are often called upon to justify the funding for their library when budgets are tight. Likewise, managers must sometimes defend their policies, particularly when faced with user complaints. Bibliomining can provide the data-based justification to back up the anecdotal evidence usually used for such arguments.

Bibliomining of circulation data can provide a number of insights about the groups who use the library. By clustering the users by materials circulated and tying demographic information into each cluster, the library can develop conceptual “user groups” that provide a model of the important constituencies of the institution’s user base which can fulfill some common organizational needs for understanding where common interests and expertise reside in the user community. This capability may be particularly valuable within large organizations where research and development efforts are dispersed over multiple locations.

In the future, organizations that fund digital libraries can look to text mining to greatly improve access to materials beyond the current cataloging / metadata solutions. The quality and speed of text mining continues to improve. Liddy (2000) has researched the extraction of information from digital texts, and implementing these technologies can allow a digital library to move from suggesting texts that might *contain the answer* to just *providing the answer*, extracted from the appropriate text or texts. The use of such tools risks taking textual material out of context and also provides a few hints about the quality of the material, but if these extractions were links directly into the texts, then context could emerge along with an answer. This could provide a substantial asset to organizations that maintain large bodies of technical texts because it would promote rapid, universal access to previously scattered and/or uncataloged materials.

CONCLUSION

Libraries have gathered data about their collections and users for years, but have not always used those data for better decision-making. By taking a more active approach based on applications of data mining, data visualization, and statistics, these information organizations can get a clearer picture of their information delivery and management needs. At the same time, libraries must continue to protect their users and employees from misuse of personally identifiable data records. Information discovered through the application of bibliomining techniques gives the library the potential to save money, provide more appropriate programs, meet more of the user’s information needs, become aware of gaps and strengths of their collection, and serve as a more effective information source for its users. Bibliomining can provide the data-based justifications for the difficult decisions and funding requests library managers must make.

KEY TERMS

Bibliometrics: The study of regularities in citations, authorship, subjects, and other extractable facets from scientific communication using quantitative and visualization techniques. This allows researchers to understand patterns in the creation and documented use of scholarly publishing.

Bibliomining: The application of statistical and pattern-recognition tools to large amounts of data associated with library systems in order to aid decision-making or justify services. The term "bibliomining" comes from the combination of bibliometrics and data mining, which are the two main toolsets used for analysis.

Data Mining: The extraction of non-trivial and actionable patterns from large amounts of data using statistical and artificial intelligence techniques. Directed data mining starts with a question or area of interest, and patterns are sought that answer those needs. Undirected data mining is the use of these tools to explore a dataset for patterns without a guiding research question.

Data Warehousing: The gathering and cleaning of data from disparate sources into a single database, optimized for exploration and reporting. The data warehouse holds a cleaned version of the data from operational systems, and data mining requires the type of cleaned data that lives in a data warehouse.

Integrated Library System: The automation system for libraries, combining modules for cataloging, acquisition, circulation, end-user searching, database access, and other library functions through a common set of interfaces and databases.

B

Online Public Access Catalog (OPAC): The module of the integrated library system designed for use by the public to allow discovery of the library's holdings through the searching of bibliographic surrogates. As libraries acquire more digital materials, they are linking those materials to the OPAC entries.

Bridging the Digital Divide in Scotland

Anna Malina
e-Society Research, UK

INTRODUCTION

Perceptions of the different meanings and issues surrounding the term *digital divide* have set the scene for policy development in various countries. In recent times, broader analysis of the meanings and problems have altered understanding, and a new range of initiatives to tackle perceived problems is being devised in the United Kingdom (UK) and its regions. In what follows, digital divide perspectives are outlined and action to close the divide in Scotland is discussed.

BACKGROUND

For some time now, the Information Society vision in many countries has been accompanied by knowledge of risk of exclusion and strategies to close the so-called "Digital Divide," often seen as a short-hand term to indicate significant inequalities in access across social groups, and in particular between those who have access to ICTs (i.e., the "haves" and the "have-nots" or those who do not have access) (Civille, 1995; Raab, 1996). EU directives (e.g., eEurope 2002 [2000] and eEurope 2005 [2002]) support the goal of cheaper and more widespread access. The 2002 goal is to achieve physical access to the Internet, and the next stage is to consider content to stimulate access. The hope is that the benefits that emerge as a result of access to modern information and communication technologies (ICTs) will be felt by regional and local economies and communities.

Extending access to ICTs will help ensure innovation, economic development, and the new economy (Tambini, 2000a). In discussing universal Internet access, Tambini (2000b) points to arguments that without widespread access, e-commerce would not be able to support greater innovation and entrepreneurship. In addition, the intense concentration on developing e-government could not be legitimised. Moreover, benefits said to be associated with the design of ICTs to improve efficiency, effectiveness, and transparency in public service delivery could not be realised. Norris (2001) and others note the views of pessimists who fear an escalation of existing inequalities, and optimists who hold that new ICTs have the potential to widen opportunities for more democratic participation. However, without universal Internet access, it is unlikely that wider forms of electronic participation and actions associated with e-governance and e-democracy could be supported. Additionally, distance learning and public education resources would not reach wider audiences or increase literacy levels.

BRIDGING THE DIGITAL DIVIDE IN SCOTLAND

The Scottish Household Survey shows that access to the Internet in Scotland is growing quickly. People who are excluded comprise the unemployed, those with low incomes, low levels of education, and poor literacy and numeracy levels. The Scottish Executive, the Scottish Parliament, the voluntary sector, and other organizations in Scotland have designed a range of initiatives to tackle problems associated with the digital divide. The Scottish framework is based on raising awareness, widening access, increasing skills, building support, developing content, and motivating and involving communities.

Scottish Executive and Scottish Parliament

Similar to the UK Government, the Scottish Executive (i.e., the devolved government of Scotland) is committed to achieving universal access to the Internet by 2005. The Scottish Executive initiative—Digital Scotland—set out to ensure that Scotland obtains and retains maximum economic and social advantage from the development of ICTs. Digital divide problems are associated with a lack of telecommunications infrastructure and with poverty, lack of awareness, and low skill levels (Digital Inclusion: Connecting Scotland's People, 2001). Emphasis has been placed on expanding Scotland's communication infrastructure to stimulate demand for broadband and to test innovative delivery technologies. A three-year Digital Champions programme[1] was set up to improve inclusive ICT provision in Social Inclusion Partnerships (SIPs) in deprived areas of Scotland. This project provides community professionals with local knowledge to engage local people in various initiatives in order to drive local ICT activities forward.

In 2002, a £3.2 million initiative was launched by the Social Justice Minister to create a network of 1,000 new Internet access points in areas where current public provision was still poor.[2] The Scottish Executive also promotes awareness of existing public access to the Web, and provides an online service to help people find the nearest access point.[3]

The Scottish Parliament's Web site[4] provides extensive information online. To help address problems of the digital divide, the Parliament worked with the public library sector to establish a network of 80 partner libraries throughout Scotland, many of which now provide public access to the Internet through freely available terminals.

With a key focus on the citizen, government portals across the UK are offering services that they suggest are relevant to life episodes. Closely linked to the UK Government Portal (www.ukonline.gov.uk) is the Scottish Government Portal that operates under the brand *Open Scotland*[5] to promote choice and public take-up of services.

Voluntary Sector Initiatives

In August 1999, com.com/holyrood, a public-private partnership between the Scottish Centre for Voluntary Organisations (SCVO) and British Telecom (BT), was given the task of installing 200 PCs into local halls and community centres throughout Scotland. However, access alone was not considered enough to address the digital divide, and SCVO also began to develop voluntary sector content. In June 2002, a Web portal[6] was launched to act as a single gateway to Scotland's voluntary sector. In addition, a lobby channel allowed voluntary organisations to conduct their own e-consultations. Moreover, online questions could be forwarded to Members of the Scottish Parliament (MSP).

Education and Learning Initiatives

The National Grid for Learning (NGfL) Scotland was set up by the Scottish Executive Education Department in September 1999 to connect all schools, colleges, universities, and libraries in Scotland to the Internet by 2002. A key objective of the NGfL Scotland Communities team[7] is to use ICT to improve opportunity, access, and quality of life for excluded groups, and to actively involve communities in worthwhile local projects. The communities channel of NGfL Scotland aims to supply information, advice, and assistance to all those providing support for ICTs in their community. In addition, NGfL Scotland's Connecting Communities Training Programme[8] promotes the effective use of ICT in community learning agencies across Scotland.

The Scottish University for Industry (SUfI) was set up to promote public/private partnership, commission research, draw on other analyses, and investigate the needs of market and client groups in Scotland. SUfI built on partnerships already existing in Scotland and worked closely with Highlands and Islands Enterprise and other partners to develop skills in using ICT. The subsequent development of a variety of IT centres in different locations of Scotland has provided Internet access and a learning environment for people to meet, to learn about new ICT, and to achieve new skills.

Scottish radio and television broadcasts were organised in late 1999 to promote learning directly and supporting the BBC's Webwise campaign, building on an earlier programme entitled Computers Don't Bite. Drawing from £200 million pounds allocated to support Community Access to Lifelong Learning (CALL) across the UK, the new Opportunities Fund (NOF) in Scotland was allocated £23 million pounds to support LearnDirect, an organisation providing public information about local learning centres.

Scotland is aiming to close the digital divide and to encourage people in deprived areas to acquire the key IT skills that are suitable to the demands of an Information Society.

Wired Communities in Scotland

During 2001, in an attempt to promote digital inclusion, a three million pound initiative outlined the intention to create two pilot digital communities in Scotland. The document, titled Digital Inclusion: Connecting Scotland's People (*Scottish Executive*, 2001, p. 22) outlines intention and funding for:

- the provision of entry level PCs, software, and Web access to up to 2,000 homes in each community;
- the development of links with school-based ICT and Web access initiative;
- the development of a community Web portal for each community with local content relevant to that community, including relevant online public and commercial services;
- the provision of training to increase the level of ICT and Web skills;
- the promotion to raise awareness of the benefits of the Web; and
- the creation of a network of local people to provide ongoing support.

The same report also outlines the aims of the digital communities Scotland project as follows:

- to use ICTs to help tackle social exclusion in these communities;

- to create a "critical mass" of Web users in each community;
- to contribute to achieving universal access to the Web;
- to increase the take-up of computers and the Web in disadvantaged households;
- to increase ICT skills in disadvantaged communities;
- to increase community involvement to develop local online content and a local support network; and
- to create partnerships with the private sector.

In late 2001, communities across Scotland were invited to submit bids to the Scottish Executive to receive funding and support to become digital communities. Towards the end of March 2002, the Scottish Executive selected two winning communities—one rural and one urban.

The Argyll Islands, the rural community selected, covers 13 of the 26 inhabited islands in the archipelago. A total of 2,145 households from a population of 4,290 was included. The digital communities submission for funding suggests that while the islands "are rich in biodiversity, culture, history, archaeology, renewable energy opportunities, and landscape, they suffer from many issues of deprivation and disadvantage, both caused and accentuated by their geographical isolation" . Physical and demographic characteristics of the islands combine to produce economic and social conditions constraining economic activity and growth. As such, the islands of Argyll are categorised as "fragile areas" by Highlands and Islands Enterprise and as "disadvantaged areas" by the Council's Economic Development Strategy (Argyll and Bute Council First Round Digital Communities Submission, 2002).

All local people in the Argyll Islands are expected to profit from new opportunities to use computers and access the Internet. The aim is to make it easier to communicate speedily and cheaply in regard to public services, to interact with peers, to telework, and to access health services and lifelong learning materials. Wherever possible, the intention is to include the business community of these islands as well as community groups. While some members of the community already have computer skills, the initiative is expected to extend training and support to any of those households that currently have computers but lack sufficient knowledge and training to use them to full advantage. In addition, the intention is to build e-services into a comprehensive community portal.

Bellsmyre, situated to the north of the town of Dumbarton, is the urban digital community selected for funding. Bellsmyre has 789 households and a population of 1,694 people. No telecommunications company had cabled the community, and at the time of the bid, Bellsmyre only had an analogue telephone infrastructure. The area is described in the First Round Proposal document as the most deprived within West Dunbartonshire.

At the time, people living in Bellsmyre had not yet responded to previous encouragement to train and use technology and, as a result, were considered in danger of being excluded from society even further. Technology is being taken to the people to promote the advantages of learning. Drawing from partnership arrangements, the key aim outlined in Bellsmyre's First Round Proposal is to help achieve the objectives set out in Scotland's digital inclusion strategy. It is envisaged that delivery of training and ICT services by Digital Champions and local community groups and agencies will help develop trust. It is hoped that attitudes toward ICT will improve, fear of technology will subside, confidence will improve, and the benefits of being connected to the Web will emerge. It is also hoped that attitudes toward learning will change and become more positive. A central aim is to ensure that levels of educational achievement will rise locally. Key aspirations are to reduce digital exclusion, create an ICT-skilled local population that will develop a routine taste for further learning and training and go on to employment or start up new businesses.

E-Democracy and the Digital Divide in Scotland

The UK government has established a Cabinet Committee to oversee e-democracy in the UK, and to develop a strategy for its development and rollout. An e-democracy charter divides the e-democracy domain into two clear fields: e-voting and e-participation. It is possible to design technology specifically to support local authorities by taking a creative, flexible, and democratic approach at local levels (Sisk, 2001). However, the ways in which technology might be developed and implemented to support better democratic participation in local areas have not been researched previously in Scotland. An added difficulty is that because each local authority is charged with representing multiple communities with diverse needs, the local authorities may need to use different e-democracy processes in different ways in different communities. This highlights a gap in knowledge about the numerous ways e-democracy systems could be tailored to suit the democratic needs of dissimilar communities. In addition, there is a matter of ensuring authentic participation of citizens in ways in which they are willing to be involved and that reflect their views and experiences about issues they feel are relevant in their own communities and beyond.

FUTURE TRENDS

A New Zealand report, "The Digital Divide – Examining the Main Characteristics that Influence Household Internet Connection in New Zealand" (2004), reflects international research in suggesting that the expansion of information and communication technologies is mainly utilised by households with higher incomes and by households whose members have formal educational qualifications. The report also found that "although the age of the youngest occupant, ethnicity, labour force status and geographic location played important roles in determining household Internet access, the most important variables identified as influencing household connectivity levels were household income, the level of educational qualification and household composition" (Chapter 3 Conclusion).

Research conducted by the Greater London Authority to outline a strategy to address the digital divide in London shows that while socioeconomic factors such as low income, low levels of education, low-skilled jobs, unemployment, and lack of technology skills are a barrier to the adoption and use of ICTs, sociopersonal aspects such as low levels of awareness, interest, understanding, and acceptance of ICTs are also very important (Foley et al., 2002).

A great deal of attention and policy and resource support over recent years has helped to ensure that excluded groups and communities living outside mainstream society are provided with different kinds of access to contemporary ICTs. However, Wilhelm (2000) questions whether or not the information under class can now be wholly defined in terms of access. Instead, he emphasizes broader contexts of information-seeking behaviour (i.e., media use patterns and cultural and environmental contexts). Drawing from Schon, Sanyal, and Mitchell (1999), he argues that these contexts will "provide a thicker description of the various shades of information and communications inequalities" (p. 70). Hague and Loader (1999) argue that experiences of using ICTs will vary enormously, since people do not generally share the same traits and since members of the public are very different in terms of gender, race, disability, class, location, and religion.

Others suggest that digital divide arguments should move away from issues of access alone. For example, Warschauer (2003) argues that increased emphasis should be put on action to ensure that people develop more meaningful use of technology within their own social arenas and daily practices.

CONCLUSION

Consideration of the Scottish context suggests that commitment to develop locally based ICT infrastructure and innovative new initiatives is fundamental in addressing problems associated with the digital divide. Critical evaluations of these initiatives would be invaluable, and it is crucial now for long-term research programmes to broaden understanding of meaningful routine use. Some researchers underline the importance of gathering empirical data relating to how and why people use ICTs in different settings (Malina & MacIntosh, 2003). Action research is suggested to assess the democratic requirements of those living in different kinds of communities, and to enable more meaningful design, development, and continuous assessment of ICT-based systems underpinning new democratic practices. It is suggested that this research approach could be applied initially to the two "digital communities" in Scotland—Argyle & Bute and Bellsmyre. In seeking to consult citizens, we must listen to their democratic needs and consider their perceptions. Research would help to improve the quality of citizenship and the level of democratic participation in local communities. The research work would also provide a framework to better appreciate the significance of technology in supporting e-democracy at local community levels and, in so doing, to contribute knowledge to strategy and planning policies and social and digital inclusion agendas to address problems of the digital divide in Scotland.

KEY TERMS

Digital Divide: Refers to individuals or members of communities and groups whose social, cultural, political, economic, or personal circumstances constrain access to electronic communications or limit benefit to their lives from contemporary electronic technologies.

Digital Inclusion: Strategies and actions to assure more equal access to digital technologies and Web facilities and to strengthen effective, meaningful, and beneficial use for all members of the public in their day-to-day lives.

Distance Learning: Learners are connected with educational resources beyond the confines of a traditional classroom, and instructed via computer-mediated communication and different types of electronic technologies that can overcome the constraints of distance, time, physical presence, or location that separate instructors and students. Learning may be synchronous or asynchronous.

e-Commerce: The buying and selling of commercial goods; the conduct of financial transactions using digital communications and electronic networks such as the World Wide Web; and aspects of sharing of business information, maintenance of business relationships, and provision of information services.

e-Democracy: The use of electronic communications to support and increase democratic engagement and deepen and widen citizen participation.

e-Government : The ability of government to design and use ICTs to interact internally and externally with government bodies, citizens, and businesses in order to deliver integrated electronic public services.

e-Governance: Communication by electronic means to place power in the hands of citizens to determine what laws need to be made and how these laws should be written.

Information and Communication Technologies (ICTs): While often meaning different things in different timescales, places, and contexts, ICTs describe all media and a mix of converging technology tools involved in the dynamic transfer and storage of analogue and digital data. In addition to Internet-based technologies such as computers, telephones, and networks, ICTs in a broad sense include digital television, cable and satellite technologies, and music formats (e.g., MP3), DVDs, and CDs. ICTs may be used to facilitate remote human interaction for good and evil purposes. In the context of this article, ICTs are used to increase human communication; broaden education, literacy, and knowledge; and enhance social, cultural, political, and economic capacity. It is hoped that this will help address problems attributed to the so-called digital divide.

B

Bridging the Growing Digital Divide

Ioannis Tarnanas
Kozani University of Applied Science, Greece

Vassilios Kikis
Kozani University of Applied Science, Greece

INTRODUCTION

That portion of the Internet known as the World Wide Web has been riding an exponential growth curve since 1994 (Network Wizards, 1999; Rutkowski, 1998), coinciding with the introduction of NCSA's graphically-based software interface Mosaic for "browsing" the World Wide Web (Hoffman, Novak, & Chatterjee, 1995). Currently, over 43 million hosts are connected to the Internet worldwide (Network Wizards, 1999). In terms of individual users, somewhere between 40 to 80 million adults (eStats, 1999) inthe United States alone have access to around 800 million unique pages of content (Lawrence & Giles, 1999), globally distributed on arguably one of the most important communication innovations in history.

Yet even as the Internet races ambitiously toward critical mass, some social scientists have begun to examine carefully the policy implications of *current* demographic patterns of Internet access and usage (Hoffman & Novak, 1998; Hoffman, Kalsbeek, & Novak, 1996; Hoffman, Novak, & Venkatesh, 1997; Katz & Aspden, 1997; Wilhelm, 1998). Looming large is the concern that the Internet may not scale *economically* (Keller, 1996), leading to what Lloyd Morrisett, the former president of the Markle Foundation, has called a "digital divide" between the information "haves" and "have-nots." For example, although almost 70% of the schools in this country have at least one computer connected to the Internet, less than 15% of classrooms have Internet access (Harmo, 1997). Not surprisingly, access is not distributed randomly, but correlated strongly with income and education (Coley, Cradler, & Engel, 1997). A recent study of Internet use among college freshman (Sax, Astin, Korn, & Mahoney, 1998) found that nearly 83% of all new college students report using the Internet for school work, and almost two-thirds use email to communicate. Yet, closer examination suggests a disturbing disparity in access. While 90.2% of private college freshman use the Internet for research, only 77.6% of students entering public black colleges report doing so. Similarly, although 80.1% of private college freshman use email regularly, only 41.4% of students attending black public colleges do.

Further, although numerous studies (CyberAtlas, 1999; Maraganore & Morrisette, 1998) suggest that the gender gap in Internet use appears to be closing over time and that Internet users are increasingly coming from the ranks of those with lower education and income (Pew Research Center, 1998), the perception persists that the gap for race is not decreasing (Abrams, 1997).

We now raise a series of points for further discussion. We believe these issues represent the most pressing unanswered questions concerning access and the impact of the digital divide on the emerging digital economy. This chapter is intended to stimulate discussion among scholars and policy makers interested in how differences in Internet access and use among different segments in our society affects their ability to participate and reap the rewards of that participation in the emerging digital economy. In summary, we have reviewed the most recent research investigating the relationship of race to Internet access and usage over time. Our objective is twofold: 1) to stimulate an informed discussion among scholars and policy makers interested in the issue of diversity on the Internet, and 2) propose a research agenda that can address the many questions raised by this and related research.

BACKGROUND AND PERSPECTIVE

Laugksch (1999) pointed out that scientific literacy has become an internationally well-recognized educational slogan, buzzword, catchphrase, and contemporary educational goal. The same applies to the case of digital divide. Courtright and Robbin (2001) contend that "the metaphor of the digital divide" — has become part of the national discourse of the United States, an abstract symbol that condenses public concerns about social inequality and evokes hopes for solutions related to the use of information technology. In addition, "the digital divide is a potent resource whose symbolic properties and communicative power have activated a wide array of participants in the policy debates about how to create a more just society."

According to Hoffman (2001, cf.: Arquette, 2001), the term *digital divide* was first used by Lloyd Morrisett who vaguely conceived of a divide between the information-haves and have-nots. However, the divide herein mainly is a gap of PC penetration in the early days of the Apple II in 1980 (Arquette, 2001). The term then grasped public's attention with the issuance of the first National Telecommunications and Information Administration (NTIA) survey on Internet adoption and use in the US in 1994 with the catchy title: *Falling Through the Net.* Since then, numerous articles, either popular or academic, on this issue have been published. According to a convenient sample of newspapers, journal articles, newswires and similar mass media sources in the Lexis-Nexis database from January 1999 to December 2000 (Arquette, 2001), the increasing rate of digital divide related articles hits almost 3000%.

In developing countries, digital divide is receiving similar social saliency. A quick search with the key words "digital divide" in one of Greece leading news Web site *Daily Online* (www.in.gr) shows that at least 500 articles somehow related to this term are available. On July 2001, a high-level forum on public understanding of information technology with the special topic of *Pay Attention to the Digital Divide* was held in Greece. A wide range of representatives, including governmental officials, IT experts, educators, social scientists and media practitioners, presented their viewpoints and comments on this issue. Digital divide has been incorporated into daily conversational discourse.

Ironically, while the term *digital divide* has frequently appeared in varied contexts, including academic writings, both the connotative and denotative meanings of it are confusingly incoherent. The presence of other similarly prevalent terminologies, such as digital equality, information equality, e-development, network readiness, etc., adds additional confusion. People seem to debate on the issue without a shared understanding of what is meant by the digital divide. As Arquette (2001) contends, the entire researcher community is plagued by a lack of definitional clarity of the concepts such as digital divide: "each researcher assumes other researchers use the same definitional frameworks for these terms while in fact there is no such shared meaning in nomenclature" (p. 3).

While the comment of Arquette (2001) mainly refers to the phenomenon in the English speaking world, the use of its minority counterpart of the term *digital divide* is also in a similar situation. For example, among more than 30 articles collected by the book *Pay Attention to the Digital Divide in Developing Countries* (Leng, 2002), no consistent conceptual definition is available across the writings. While some are talking about the Internet penetration divide among different social groups categorized by age, occupation and educational level, others refer the concept to an uneven development of e-infrastructure among different areas or nations. So, whenever the term digital divide is confronted, the following question can always be raised: *in terms of what*?

This chapter intends to introduce a new approach of operationalizing digital divide from the perspective of Developing Countries. We first make a brief review of different definitional perspectives of the term *digital divide*. Then a detailed introduction of National Informatization Quotient is presented which will be employed as the operational definition of the informatization level of a region. Finally we will investigate the geographical digital divide in Developing Countries in terms of NIQ.

CONCEPTUAL REVIEW

Conceptual definition involves verbal descriptions of the essential properties that are to be included in the intended meaning of a concept. In research practice, it often involves specifying the essential dimensions of a concept (McLord & Pan, 2002, p. 62). On the other hand, o*perational definition* involves procedures by which a concept is to be observed, measured, or manipulated. It details the rules, specific steps, equipment, instruments, and scales involved in measuring a concept (p. 65). In this section, we will briefly review the multiple conceptions around digital divide.

Digital divide is a fresh term not unfamiliar to communication scholars (Zhu, 2002). As early as 1970, a theory called *knowledge gap* (Tichenor, Donohue & Olien, 1970) was developed which has been one of the most active inquiry fields hereafter in communication studies. The supposition of knowledge gap mainly concerns the different knowledge possession through mass media by social groups with varied social-economic-status. In 1980s, with the development of ICTs, especially with the wide application of PC in diverse contexts, a divide between the information-haves and have-nots was sensitively observed and warned (Compaine, 2001). Since early 1990s, digital divide has gradually become a convenient label, or more precisely, a metaphor (Courtright & Robbin, 2001), in describing the inequality of possessing and using ICTs, especially the Internet connectedness.

The first group of definitions varies on the concrete referents of what digital means. In a narrow sense of the definition, digital divide is particularly referred to the inequality of Internet access and use among different social groups or localities. US Department of Commerce's (1995, 2001) Falling through the net reports represent the most influential version of the stream. Zhu (2002) also takes Internet penetration as the sole indicator of what digital means in his construction of digital divide index (DDI) while taking age, sex, education and occupation collectively as the categorizing factors. In short, in this stream of definitions, digital divide is operationalized to

Internet access/penetration divide categorized by demographics and social status factors.

However, to many people, the term *digital* means a wide range of ICTs other than the Internet. Arquette (2001) labeled it as the concept fit disjuncture in the studies of digital divide, i.e., to measure global digital equality in terms of teledensity or Internet penetration. Employing the so-called Information Intelligence Quotient (IIQ) analytical framework, he uses ICT infrastructure rather than a single ICT such as Internet or telephony as the subject of the "digital".

A second clue of conceptualizing the digital divide basically focuses on the meaning of "divide". Many different analytical perspectives on this concern are available. Jackel (2001) exemplifies some of these:

- a macro-level-comparison of the so-called First and Third world or a comparison of rich and poor countries;
- a comparison of differences in modern societies according to the level of integration in the labor market;
- a comparison of differences in modern societies according to education groups, gender and age, more general a comparison of generations;
- a specification of differences in modern societies according to communication skills;
- a comparison of different diffusion curves as a result of differing demands.

As can be seen, the dimensions identified by these perspectives are noticeably diverse.

Synthesizing the prior research on digital divide, Arquette (2001) proposed an organizational framework based on three dimensions of digital divide: ICS infrastructure, access, and use. ICS infrastructure refers to the technophysical means by which voice, audio, video and/or data communication circulates. The operationalization of the dimension involves the specification of sixteen indicators, including telephony penetration (wire line and wireless), Internet hosts, and costs of calls, etc. The second dimension is ICS access which focuses on the ability of persons interested in using the infrastructure (regardless of that infrastructure quality or quantity) to gain access to the infrastructure. Nineteen indicators are developed to operationalize the dimension. The third dimension of digital divide that Arquette (2001) specifies is ICS use. Use-based conceptualizations of digital divide are conceived in terms of how people employ the technologies. Another nineteen indicators are developed to measure the situation of this dimension of digital divide. In summary, IIQ is an aggregate meta-analytic framework for assessing the state of digital divide among different nations or regions.

A notable point implied by the IIQ is its consideration of the dimension of ICT use. In fact, access is not enough is becoming a recognizable consensus (e.g., Blau, 2002; Jackel, 2001; Nagaraj, 2002). In other words, merely connecting people and computers will not bridge the digital divide (Blau, 2002), and there's digital discrimination among the information haves, too (Nagaraj, 2002). Jackel (2002) labels the divide among ICT haves as the second level of "divide".

NIQ is a composite index comprised of 20 indicators in six dimensions. It is the operational definition of the National Informatization Level (NIL). In the remaining part of the article, the digital divide is discussed in terms of this NIL which is operationally defined as NIQ. The six dimensions of NIQ are:

- The development and application of information resources (IR): The indicators under this umbrella term include Radio and TV broadcasting hour/per 1,000 people; Bandwidth per person; Telephone use frequency per person; Total capacity of Internet data base.
- Information network construction (IN). There are four components in this dimension, including Total length of long distance cable; Microwave channels; Total number of satellite stations; Number of telephone lines per 100 people.
- The application of information technologies (IT): the indicators for this dimension include Number of cable TV stations per 1,000 people; Number of Internet users per 1 million people; Number of computers per 1,000 people; Number of TV sets per 100 people; E-commerce trade volume; Proportion of investment in the information industry by enterprises to the total fixed investment.
- Information industry development (II): there are two indicators designed to reflect the situation of this dimension: Added value contributed by the information industry to the total GDP; Contributions made by the information industry to the total GDP increase.
- Human resources of informatization (HR): there are two indicators for this dimension: Proportion of university graduates per 1,000 people; and Information index which refers to the proportion of expenditure other than fundamental consumption to the total expenditure.
- The environment for informatization development (EI). Two indicators are designed to measure the situation of the dimension: proportion of expenses for research and development of the information industry to the country's total budget in R&D; Proportion of investment on the infrastructural

development of the information industry to the country's total investment in capital construction.

Compared to other index used to reflect the digital divide or ICT development in a country or region, NIQ has several characteristics:

1. It is a multi-dimensional composite index. Therefore, NIQ is a comprehensive reflection of the state informatization level rather than the development of some particular ITs.
2. As for its application in assessing digital divide, the divide it evaluates is a geographical divide rather than informatization divide among different social groups or divides defined by other factors.
3. The index covers a wide range of the aspects regarding the informatization development. Particularly, NIQ emphasizes the importance of information industry in its structure of dimensions. The proportion of indicators related to information industry is notably high which, reflects the fact that NIQ will be a guideline for the promotion and adoption of IT in developing countries.

DEVELOPING A RESEARCH AGENDA

We now raise a series of points for further discussion. We believe these issues represent the most pressing unanswered questions concerning access and the impact of the digital divide on the emerging digital economy.

Computers in the Home

While previous research has shown that inequalities in Internet access in schools persist (Educational Testing Service, 1997, Sax et al., 1998), the research reviewed here suggests that inequalities in Internet access at home may be even more problematic. The role of access to the Internet at home needs to be much more clearly understood (Abrams, 1997). Whites are more likely to have access to the Internet and to have ever used the Web than Minorities and these gaps appear to be *increasing* over time. Probing deeply, we have discovered that among recent Web users, who by definition have access, the gaps in Web use have been *decreasing* over time. Over time, there appear to no or only slight differences between whites and Minorities in how recently they had used the Web, how frequently, or in their length of time online. Gaps in general Web access and use between Different minorities and whites appear to be driven by whether or not there is a computer present in the home. Access to a personal computer, whether at home, work, school or somewhere else, is important because it is currently the dominant mechanism by which individuals can access the Internet. We believe that access translates into usage. Overall, individuals who own a home computer are much more likely than others to use the Web. This suggests that programs that encourage home computer ownership (see, for example, Roberts, 1997) and the adoption of inexpensive devices that enable Internet access over the television should be aggressively pursued, especially for Minorities.

Morrisette (1999) forecasts that by the year 2003, over half of all households in the United States will have access to the Internet, but that PC penetration could stall at 60% of households. Research is necessary to understand what motivates individual-level adoption of home computers and related technologies, as well Internet adoption, both within and outside the home. Additionally, research is required to understand the long-term impact of home computer ownership on Internet access and use. Katz and Aspden (1997) investigated the role of social and work networks in introducing people to the Internet. The dominant three ways people were originally introduced to the Internet were 1) taught by friends or family, 2) learned at work and 3) self taught. Formal coursework was the *least* often mentioned way people were introduced to the Internet. Long term Internet users were most likely to have learned at work; for recent Internet users, friends/family and self-taught were equally important. These results reinforce the importance of the presence of a computer at home, or the opportunity to access the Web from locations other than the home, in stimulating Web use.

Insight into the importance of reducing this gap in Web use between whites and African-Americans is provided by Anderson and Melchior's (1995) discussion of *information redlining*. Information redlining signifies the relegation of minorities into situations where satisfying their information needs is weighed against their economic and social worth. From the minority point of view, this is both an access issue and a form of discrimination. The new technologies of information are not simply tools of private communication as is a telephone, or tools of entertainment as is a television. They provide direct access to information sources that are essential in making social choices and keeping track of developments not only in the world at large, but also within their immediate neighborhoods. Unless the neighborhoods are properly served, there is no way out of information redlining for most of these disadvantaged groups. Research on this topic is warranted.

There are also interesting differences in media use between whites and Minorities that also deserve further probing. For example, although the rate of home PC ownership among Minorities is flat or even decreasing, the rates of cable and satellite dish penetration are increasing dramatically for Minorities. At a minimum, these results suggest that Minorities may make better immediate prospects than whites for Internet access through cable modems and satellite technology.

Web Use Outside of the Home

In addition to gaps in home computer ownership, the implications of differential Internet access at locations outside the home, including school, the workplace and other locations needs to be clearly understood. Research suggests that additional access points stimulate usage. Further research is necessary to understand the impact of multiple access points on Web use, particularly for individuals who have no access at home. Public-private initiatives such as Bell Atlantic's efforts in Union City and Bill Gates announcement of a $200 million gift to provide library access to the Internet are a step in the right direction (Abrams, 1997). It has also been noted that "community networks and public access terminals offer great potential for minority communities" (Sheppard, 1997). Further, the recent roll-out of E-rate funds (Schools and Libraries Corporation, 1998) provides a significant opportunity for researchers to understand the factors important in stimulating Web usage among those least likely to have access.

School Web Use

The role of Web access in the schools, compared to other locations, needs to be clearly understood. Students enjoy the highest levels of Internet access and Web use, especially when there are computers in their households. However, white students are still more likely than Minority students to have access and to use the Internet, and these gaps persist over time. Indeed, our findings closely parallel statistics comparing student Internet use at private universities and minority public colleges (Sax et al., 1998). As a recent report by the Educational Testing Service (1997) makes clear:

- There are major differences among schools in their access to different kinds of educational technology.
- Students attending poor and high-minority schools have less access to most types of technology than students attending other schools.
- It will cost about $15 billion, approximately $300 per student to make all our schools "technology rich."

This is five times what we currently spend on technology, but only 5% of total education spending. Anderson and Melchior (1995) cited lack of proper education as an important barrier to technology access and adoption. Access to technology does not make much sense unless people are properly educated in using the technologies. Our data do not speak to the quality of the hardware/network connections, or the quality of information technology education that is provided by school.

Differences in Search Behavior

Reasons for the gap between different minorities and whites in Web search behavior need to be clearly understood. Such differences could have important implications for the ultimate success of commercial efforts online. White Web users are more likely to report searching for product or service-related information than Minorities. One possibility is that despite sites such as NetNoir and Black Entertainment Television, general purpose search agents may not be perceived as an effective way to locate Web content that is compelling to minority users (*New Media Week* 1997). This suggests the development of search engines and portals targeted to the interests of racial/ethnic groups.

Shopping Behavior

There appear to be no differences between different minorities and whites in the incidence of Web shopping. Is this because race doesn't matter for "lead users?" who are most likely to shop, or is this because commercial Web content better targets racial and ethnic groups than does non-commercial Web content? Previous research (Novak, Hoffman, & Yung, 1999) suggests that more skill is required to shop online than to search. However, as noted above, whites are more likely to search for information online than are Minorities. More generally, consumer behavior in the commercial Web environment is complex and only weakly understood. Further research is needed to explore fully the differences in consumer behavior on the Web and their implications for commercialization.

Multicultural Content

Studies investigating the extent of multicultural content on the Web are needed. Another possibility for the gap between different minorities and whites in Web search behavior is that there is insufficient content of interest to different minorities. *Interactive Marketing News* (1997) claimed that "while there are about 10 million sites on the Web, there are fewer than 500 sites targeted" to different minorities. However, others have commented on the multicultural diversity of the Web. Skriloff (1997) reported, "there are thousands of Web sites with content to appeal to other ethnic groups. Many of these sites are ready-for-prime time with high quality content, graphics, and strategic purpose."

Community Building

Are there different cultural identities for different parts of cyberspace? Schement (1997) notes that by the year 2020, major U.S. cities such as Los Angeles, Chicago, and New York will have increasingly divergent ethnic profiles, and will take on distinctive cultural identities. An important question is whether there are divergent ethnic profiles for areas of cyberspace. While the questions in the three IDS do not allow us to directly address this issue, our analyses provide some preliminary evidence of divergent ethnic profiles for various Web usage situations. For example, minorities appear to be more likely to use the Web at school and at other locations, and in some cases, are more likely to use the Web at work. How much of this is driven by the lack of a PC in the home and how much by other factors we have yet to hypothesize and investigate?

In addition to facilitating community building at the global level, the Web also facilitates neighborhood-level community building. Schwartz (1996) discusses how the Internet can be used as a vehicle for empowering communities. Anderson and Melchior (1995) raise the issue of the ways in which telecommunications can be used to strengthen communities. Thus, we should expect to find neighborhood Web sites emerging as an important aspect of cyberspace, and that these Web sites will parallel the ethnic profiles of the corresponding physical communities.

Income and Education

Income matters, but only after a certain point. Household income explains race differences in Internet access, use, home computer ownership and PC access at work. In terms of overall access and use, higher household income positively affects access to a computer. But at lower incomes, gaps in access and use between whites and Minorities existed and were increasing. Research is necessary to determine the efforts most likely to be effective to ensure access for lower-income people, especially Minorities. The situation is different with education. As with income, increasing levels of education positively influences access, Web use, PC ownership and PC access at work. However, whites are still more likely than Minorities to have access to and use the Internet, and own a home computer, and these gaps persist even after controlling for educational differences.

The policy implication needs to be carefully considered: To ensure the participation of all People in the information revolution, it is critical to improve the educational opportunities for Minorities. How this might best be achieved is an open research question.

CONCLUDING REMARKS

The consequences to civil society of the digital divide in Internet use are expected to be severe (Beaupre & Brand-Williams 1997). Just as A.J. Liebling observed for the freedom of the press (Liebling 1960), the Internet may provide for equal economic opportunity and democratic communication, but only for those with access. The United World economy may also be at risk if a significant segment of our society, lacking equal access to the Internet, wants for the technological skills to keep National firms competitive.

The broad policy implications for these findings should not be overlooked. By identifying those who are truly in need, policymakers can prudently and efficiently target support to these information disadvantaged. Only when this point is reached can *all* those who desire to access the Online Services be possibly accommodated. However, connectivity to all such households will not occur instantaneously; rather, there is a pivotal role to be assumed in the new electronic age by the traditional providers of information access for the general public — the public schools and libraries. These and other "community access centers" can provide, at least during an interim period, a means for electronic access to all those who might not otherwise have such access. Policy prescriptions that include public "safety nets" would complement the long-term strategy of hooking up all those households who want to be connected to the Online Services.

Bridging the Industry–University Gap through Action Research

Ned Kock
Texas A&M International University, USA

INTRODUCTION

Virtually every university in the US and overseas has seen a significant increase in demand for information technology (IT) courses and programs in the last 10 years (Greenspan, 1999; Monaghan, 1998; Ross, 1998). At the source of this demand is an ever-growing need for qualified IT professionals in most companies, whether the companies are in technology industries or not (Alexander, 1999; Andel, 1999; Trunk, 2000; Wilde, 1999).

Given the practical motivation above, one would expect university IT courses to be closely aligned with the industry's basic needs. Nevertheless, the gap between industry and academia in the field of IT (King, 1998; Kock et al., 2002; Richter, 1999) seems to be widening rather than contracting, which is evidenced by some symptoms: (a) students complaining about their lack of "real-world" IT experience when they graduate; (b) industry representatives pointing out that universities do not prepare students for the challenges and complexity of corporate IT management; and (c) faculty teaching topics that are related to their research yet far removed from the daily reality faced by IT professionals.

One way of addressing the problematic situation above is to establish industry-university partnerships. Such partnerships, particularly those involving research universities, have been commonplace for quite some time, and are arguably on the rise (Burnham, 1997; Wheaton, 1998). Irrespective of economic sector or industry, the vast majority of industry-university partnerships are of the *research partnership* type, which predominantly involves applied firm-specific research. In this type of partnership, funding from the industry partner is received in exchange for "intellectual horsepower" in the form of research services and technology transfer (Hollingsworth, 1998; Meyer-Krahmer, 1998).

A much less common type of industry-university partnership is what we refer here to as a *course partnership*, which gravitates around a regular university course (or set of courses) rather than a research project or program. In these types of partnerships, the industry partner agrees to sponsor one or more courses in which the students are expected to apply concepts and theory learned in class to the solution of some of the industry partner's key problems. Students benefit from the direct contact with the industry they are likely to join after they graduate as well as professional relationships they are able to establish during the course.

This article discusses a *course partnership* involving a large engineering and professional services company, and a public university, both headquartered in Philadelphia. An action research study of the course partnership is used as a basis.

Like typical action research studies (Checkland, 1991; Lau, 1997; Peters & Robinson, 1984; Winter, 1989; Wood-Harper, 1985), ours aimed at providing a service to the research clients (Jonsonn, 1991; Rapoport, 1970; Sommer, 1994) while at the same time performing an exploratory investigation of the effect of Web-based collaboration technologies on course partnerships. The research clients in question were the students and the industry partner. Also, in line with a subclass of action research, namely participatory action research (Elden & Chisholm, 1993; Greenwood et al., 1993; McTaggart, 1991; Whyte, 1991), one of the research clients, the industry partner, participated actively in the compilation and analysis of the exploratory research data, as well as in the interpretation of the findings.

BACKGROUND

Our study was centered on a different and arguably promising approach to implementing course partnerships that was recently proposed to address the problems outlined previously (Kock et al., 2000, 2002, 2003). The approach involves conducting certain courses, particularly senior undergraduate and graduate courses, in close partnership with companies. Such courses are designed so that the concepts and theory discussed in class are applied in team course projects geared at solving immediate problems at the company partner. Other fundamental characteristics of these course partnerships are:

- All team projects are conducted in one single organization. Letting student teams identify organizations they would want to work with, based on criteria defined by the instructor, usually leads to different student teams conducting projects in different organizations, and thus to significant discrepancies in project complexity, project scope, and organizational support across different student teams. These problems can have a negative impact on learning, and are considerably reduced when all team projects are conducted in one single organization.

- Potential projects are identified in advance. The identification of a potential project by student teams can take up to 5 weeks of a 14-week course. One may argue that this is acceptable, as long as concepts and theory are covered in the classroom during those initial 5 weeks. However, in addition to identifying a project, a student team also needs to learn about the organizational culture, key people, and specific business processes they will be dealing with. This can easily take up another 5 weeks, leaving little time for other key project activities (e.g., business process redesign and IT implementation). The solution to this problem is to identify potential projects in advance, prior to the formal start of the course, and distribute them among student teams in the first week of the course.
- Top management personally sponsors the course partnership. Often, when students are asked to come up with their own company-sponsored course projects, the individuals who sponsor the projects are not senior managers. As a result, a project sponsor may be reluctant or lack the authority to approve organizational changes or purchases of hardware and software necessary for a project to be effectively completed. These difficulties are mitigated when top management directly sponsors team projects.

It is important to note that course partnerships with these characteristics require a considerable amount of extra time and effort from the students and instructor, well beyond what is usually expected in traditional courses. In addition to applying the concepts and theory learned in class, students would also have to learn "on-the-fly" how to effectively deal with issues that are found in real-world projects (e.g., organizational culture and politics). The instructor, on the other hand, has to also take on project management, industry-university liaison, and inter-organizational team facilitation responsibilities, in addition to traditional course delivery and student mentoring duties.

IMPLEMENTING A COURSE PARTNERSHIP: TEMPLE UNIVERSITY AND DAY & ZIMMERMANN, INC.

The course partnership idea discussed previously has been implemented through a collaboration between Temple University, a large public university located approximately two miles from downtown Philadelphia, and Day & Zimmermann, Inc., a US$ 1.5 billion engineering and professional services company headquartered in downtown Philadelphia. The course was a pilot version of CIS650 - Process Design and Information Technology, a newly developed course in Temple's Computer and Information Science Department dealing with process analysis and redesign issues.

The course instructor (the author of this article) initiated the course partnership by sending a letter to one of the senior executives at Day & Zimmermann. In the letter, the course instructor inquired if the company would be interested in partnering with Temple University, providing details about the partnership. The partnership was approved after an initial meeting involving the course instructor and senior managers at the company.

The course project required students to analyze and redesign five of Day & Zimmermann's business processes using the concepts, theory and techniques taught in class. The course partnership and related project had direct support from Day & Zimmermann's Chief Information Officer (CIO) from the outset. A senior manager at Day & Zimmermann, who reported directly to the CIO, was assigned the responsibility of managing the project together with the course instructor. The project involved, directly and indirectly, over 30 Day & Zimmermann employees and 26 Temple students.

The students were split into five process redesign teams, which periodically met with key Day & Zimmermann employees at the company's headquarters in downtown Philadelphia. Each team analyzed and redesigned one process, generated three reports, and delivered an oral presentation to Day & Zimmermann management at the end of the course. The first report generated by each team contained a detailed description of the process targeted; the second a detailed description of the redesigned process and the rationale behind the redesign decisions; and the third a detailed analysis of IT solutions to enable the new (redesigned) process.

WEB SITE REMOVES OBSTACLES TO PARTICIPATION

Before the course partnership was started, two main obstacles had to be dealt with. First, Day & Zimmermann employees were expected to actively participate in the process redesign efforts. In order to do so, they had to understand the concepts and theory used by the students. Yet, most of the Day & Zimmermann employees likely to be involved in this project could not come to Temple to audit the course together with the students. Also, given that Temple students and Day & Zimmermann employees were not co-located, a great deal of their interaction would have to occur by means other than face-to-face meetings. The solution to overcome these two obstacles was the development of a password-protected Web site, which allowed Day & Zimmermann employees to access all the course material online. The Web site also supported interaction between them and Temple students through shared document areas, multimedia components, and discussion boards.

WAS THE COURSE PARTNERSHIP SUCCESSFUL?

The partnership was considered a success by Day & Zimmermann management and employees, as well as by Temple students. Managers emphasized the anytime/anyplace collaboration between Day & Zimmermann employees and Temple students enabled by the Web site as one of the key elements that made the course partnership a very successful collaborative effort.

Temple students emphasized the real-world experience as one of the most positive aspects of the course. Following is a representative comment by a student extracted from one of the anonymous course evaluation forms completed at the end of the course:

"The learning experience was very rich. The group project gave us hands on experience in applying the redesign techniques we learned in the course. It was a great experience to work with upper level IT management!"

Table 1 shows the average scores for several question/statements asked from the students in connection with the course. The question/statements were part of a standard course and faculty evaluation, and were answered anonymously.

Several students pointed out that the course required considerably more time and effort from them than most traditional university courses they had taken before. In spite of that, their anonymous evaluations of the course were very positive, as it can be seen in Table 1. The average answer to the question/statement "Overall, this is one of the best courses I have had at Temple" was 3.53, on a 0-to-4 scale. The average answer to the question/statement "Overall, I have learned a great deal from this course" was 3.41, also on a 0-to-4 scale.

An added benefit for Day & Zimmermann was the ability to identify young talent based on observation of business-relevant action (as opposed to the traditional analysis of resumes). Day & Zimmermann were able to observe a group of 26 students in action over a two-month period and identify several students whom they would like to consider hiring. This is not as easy to accomplish with other approaches for identifying new graduates for hiring, of which internships are perhaps the most popular. There are two key reasons for this. First, the number of interns that could be hired for a two-month period by an organization would typically be considerably smaller, thus significantly reducing the number of students that

Table 1. Course evaluation scores

Question/statement	Score
The objectives and requirements of the course were made clear.	3.82
The instructor clearly communicated the subject.	3.88
The instructor was open to questions and comments.	3.82
The instructor was accessible outside the classroom.	3.70
The instructor was impartial in evaluating my performance.	3.47
The instructor expected academic excellence from students.	3.47
Overall, the instructor did an excellent job teaching.	3.82
Overall, I have learned a great deal from this course.	3.41
Overall, this is one of the best courses I have had at Temple.	3.53

(Score = average score for the class regarding the question; Range: 0-4)

Day & Zimmermann managers would be able to observe in action during that period of time. Second, the tasks that the interns would be assigned to would not usually be nearly as complex and strategically relevant as those carried out in this course.

CONCLUSION AND LESSONS FOR FUTURE PARTNERSHIPS

The general perception at the end of the course partnership was that it had been an exciting and rewarding experience for all those involved. Students saw the course as a valuable experience that provided them with a unique view of IT management and which complemented the concepts, theory and techniques learned in the course and throughout their university program. Day & Zimmermann managers perceived the input provided by the students as very valuable and likely to lead to concrete business process improvements.

Also, a few lessons have been learned along the way that can be useful for universities and companies planning to implement similar course partnerships in the future. These lessons are summarized below.

- The course partnership should have two main co-project managers, one from academia and one from industry. As with most inter-organizational initiatives, the scope of management authority does not usually extend beyond organizational boundaries. Students will respond more quickly to requests by the instructor than to requests by a manager of the partner organization. Similarly, employees of the partner organization will respond more quickly to a request by someone who has formal authority within the organization than to a request by the instructor. Therefore, the instructor should share the responsibility of managing the project with a member of the partner organization who has enough formal authority to oversee all the team projects.
- The course partnership should include at least one purely social activity. Social activities allow for important information exchanges that would not normally occur in formal meetings. For example, prior to the final oral presentation by student teams at Day & Zimmermann, a pizza party (paid for by the company) was held in downtown Philadelphia. After the party, several people remarked that the personal knowledge they learned from informal conversations during the party was invaluable to them. The party was also seen as a "thank you" gesture by the partner organization to the students. Not only did this boost morale, but it also helped the students relax for the presentation the next day, as they got to know the people they would be presenting to at a more personal level.
- The business problems addressed through the course partnership should be "real" and of high relevance to the partner organization. Because students are involved, not professional consultants, the partner organization may be tempted to create "toy" problems to be solved through the course partnership, rather than address real and relevant business problems. The motivation for this may be the perceived risks linked to not accomplishing the goals of the project (e.g., wasted time, internal conflicts, and reluctance to engage in future organizational change efforts). The problem with this approach is that it is likely to relieve the students from any real responsibility and, at the same time, decrease the motivation for employees to get involved. A better alternative to reduce risk is to involve experienced consultants at critical points in the course partnership (the costs are relatively low since few consultant-hours are likely to be used).
- Partner organization employees should be asked to report on and make an oral presentation of their projects too. Course partnerships such as the one described here are, as the name implies, collaborative endeavors in which members of the two organizations involved should contribute evenly. Therefore, *key me*mbers of the partner organization should also be asked to make presentations about their projects. This is particularly important because, in some cases, despite full dedication from the students, a project may fail to accomplish its initial goals. And, a closer examination may indicate that the failure was not the students' fault, but that it was caused by lack of interest or commitment from the part of one or more employees. Employee reporting and presentations are useful in assessing whether this is the case, which in turn is important for appropriately grading the students' coursework. Moreover, the requirement to report and present their projects communicates to the partner organization employees that they are equally responsible for the outcomes of the project, which is likely to increase their level of commitment and dedication to the project.

The course partnership discussed in this article went well beyond the idea of having students conduct their course projects in real organizations, which is an approach adopted by many project-based courses around the world. It seems that the close cooperation between Temple University and Day & Zimmermann that characterized the course partnership presented here was the key reason for its success. This type of cooperation requires extra time and effort from everyone involved – students, instructor, company management and employees. Yet, the positive (tangible and intangible) outcomes of the partnership seem to easily outweigh its costs.

KEY TERMS

Action Research: Type of research approach in which the researcher attempts to improve the research client, which can be an organization, while at the same time generating relevant academic knowledge.

Co-Partnership Managers: The course instructor, on the university side, and a senior manager of the client organization, who jointly manage a course partnership project.

Course Partnership: Course-based industry-university partnerships, where a course is designed so that the concepts and theory discussed in class are applied in team course projects geared at solving immediate problems at the company partner.

Industry-University Gap: Disconnect between the knowledge and skill needs of industry practitioners and the knowledge and skills imparted on students by universities.

Process: Set of interrelated activities through which an organization transforms inputs into value-added outputs. Inputs and outputs can be tangible (e.g., materials, parts) or intangible (e.g., services, information) items.

Process Redesign: Approach to organizational improvement through transformation of business processes. The term refers to business process change approaches emphasizing gradual change (e.g., total quality management) or radical change (e.g., business process reengineering).

Research Partnership: Industry-university partnership involving collaboration in applied firm-specific research. In this type of partnership, funding from the industry partner is received in exchange for "intellectual horsepower" in the form of research services and technology transfer.

Web-Based Course Partnership: A course partnership in which a Web site is developed to serve as a central communication hub and document repository for the partnership.

Building and Management of Trust in Information Systems

Hungarian Academy of Sciences, Budapest, Hungary

INTRODUCTION

Thanks to the rapidly developing information and communication technologies, the complexity of networked organizations becomes very high, so the representation of their structure, the description of their operation, and their control needs new technologies and approaches. The availability of individuals independent from location and time means mobility, and that is an important attribute of today's society. This mobility can be achieved by using different types of wireless networks such as wireless wide area networks (WWANs—GSM, GPRS, and UMTS), wireless local area networks (WLANs, such as WiFi 802.11b, 802.11a), and wireless personal area (or Pico) networks (WPAN—Bluetooth, IrDA2).

In spite of the application of high-tech approaches, tools, and methodologies, there is a common point in all of the organizations; human beings make the most of important decisions, and they operate and use systems. According to experience, improper application of this human factor can make operation very inefficient, even in the case of technically advanced systems. The lowest level of connection among systems is made through protocols; the highest contact level is among decision makers and users, namely, human beings. A very important element of this human contact is trust. In a networked organization, trust is the atmosphere, the medium in which actors are moving (Castelfranchi & Yao-Hua Tan, 2001). Only trust can bridge the cultural, geographical, and organizational distances of team members (and even of firms) and keep them from turning into unmanageable psychological distances. Trust is the base of cooperation, the normal behavior of the human being in society. The ability of enterprises to form networked systems depends on the existing level of trust in the society and on the capital of society (Fukuyama, 1995). As the rate of cooperation is increasing in all fields of life, the importance of trust is evolving even faster.

Lack of trustworthy security services is a major obstacle in the use of information systems in private, in business (B2B [business to business]), as well as in public services. Trust is intimately linked to consumers' rights, like security, identification, authentication, privacy, and confidentiality. Secure identification, authentication of the users, and communication security are main problems in networked systems.

Information management (IM) is a fuzzy term covering the various stages of information processing from production to storage and retrieval to dissemination toward the better working of an organization, where information can be from internal and external sources and in any format. The role of trust in these processes is definitive as human-to-human and human-to-system communications form the base of information management.

BACKGROUND

Definitions of Trust

The word trust is used by different disciplines, so there are many definitions of the term fulfilling the demands of the actual theory or application. In everyday life, without trust, one would be confronted with the extreme complexity of the world in every minute. No human being could stand this, so people have to have fixed points around them. One has to trust in family members, partners, trust in the institutions of a society and its members, and trust within and between organization partners. The diversity of approaches is one reason that trust has been called an "elusive concept to define" (Gambetta, 1988, p. 213).

Trust can be defined as a psychological condition comprising the truster's intention to accept vulnerability based upon positive expectations of the trustee's intentions or behavior (Rousseau, Sitkin, Burt, & Camerer, 1998). Those positive expectations are based upon the truster's cognitive and affective evaluations of the trustee and the system and world as well as of the disposition of the truster to trust. Trust is a psychological condition (interpreted in terms of expectation, attitude, willingness, perceived probability). Trust can cause or result from trusting behavior (e.g., cooperation, taking a risk) but is not behavior itself.

According to Luhman (1979), trust can be viewed as a cognitive and social device able to reduce complexity, enabling people to cope with the different levels of uncertainty and sometimes the risks that, at different degrees, permeate our life. Without trust, an individual would freeze in uncertainty and indecision when faced with the impossibility to calculate all possible outcomes of a situation. Engaging trust automatically can reduce the number of decision nodes that are being analyzed and facilitate the decision-making processes. From a social perspective, trust permits the necessary knowledge sharing of delegation and cooperative actions.

The following components are included in most definitions of trust (Harrison, McKnight, & Chervany, 1996):

- the willingness to be vulnerable and to rely,
- confidence and having positive expectations and attitudes toward others, and
- interdependence and taking risks as necessary conditions.

Trust has different forms such as the following.

1. **Intrapersonal trust:** trust in one's own abilities (self-confidence) and a basic trust in others
2. **Interpersonal trust:** expectation based on cognitive and affective evaluation of partners in primary relationships (e.g., family) and nonprimary relationships (e.g., business partners)
3. **System trust:** trust in depersonalised systems and a world that function independently (e.g., economic system, regulations, legal system, technology); requires voluntary abandonment of control and knowledge
4. **Object trust:** trust in nonsocial objects; trust in correct functioning (e.g., in an electronic device)

Trust is a Multifaceted Construct

There is compelling evidence originating from the organizational research community to support the idea that trust is a many sided, complex construct. McAllister (1995) has proposed two critical dimensions: emotional trust and cognitive trust. Emotional trust is the development of noncalculating and spontaneous emotional bonds, and affects two or more people. Emotional trust is demonstrated through confidence and openness in sharing ideas, feelings, and concerns. Cognitive trust refers both to judgments of competence (predictably professional behavior) and reliability (the congruence between words and actions) about the other members of a team.

Represented Forms of Trust

There are two basic modeling approaches in describing trust: the cognitive approach (Castelfranchi & Falcone, 1999) and the mathematical approach (Marsh, 1994). In the case of applying cognitive models, trust is made up of underlying beliefs, and trust is a function of the value of these beliefs. The mathematical modeling approach ignores the role of underlying beliefs and uses a trust metric based on variables like perceived competence, perceived risk, utility of a situation for the agent involved, importance of a situation, and so forth. These models incorporate some aspects of game theory and the evolution of cooperation models. Both modeling approaches see trust as a variable with a threshold for action. When the value of the variable crosses the threshold, the agent executes an action. In the Marsh model, the action is cooperation; in the Castelfranchi and Falcone model, the action is delegation. The action is Boolean in nature; the agent either delegates or not, or the agent either cooperates or not.

Classifying the Meanings of Trust

Harrison et al. (1996) made a very deep and thorough analysis of the word trust from many aspects in their working paper. The goal of the paper was to develop a classification system for the types of trust, and to develop trust definitions and types that can be accepted by most disciplines.

In the following, the main groups of the classification system for trust constructs are given to better understand the definitional problem. Impersonal and structural trust refers to those definitions of trust that differentiate it from being a property or state of a person or persons. Dispositional trust means that trust is based on the personality attributes of the trusting party. Personal and interpersonal trust means that one person trusts another person, persons, or thing(s) in the situation.

Guided by the classification system, six related types of trust have been defined in the working paper. The six constructs are as follows: trusting intention, trusting behavior, trusting beliefs, system trust, dispositional trust, and situational decision to trust. Both cognitive and affective components are included in trusting beliefs, trusting intention, and trusting behavior. The six constructs cover the more common of the dictionary definitions of trust. This multidimensional view of trust provides a parsimonious way to organize measurable trust types while clearly distinguishing one type from another.

BUILDING TRUST

Connection of Trust and Information Management

Information technology management deals with the management of the different steps of information processing, and trust has a role where human beings are involved in this process. Human beings basically have two types of connections in these processes: human-to-human relationships through networks and human-to-computer-system communication through interfaces. In the first case, trust management of virtual teams can be analyzed; in the second case, special effects of computer interfaces and the role of security technologies in trust building and maintenance can be studied (Mezgár & Kincses, 2002). Information management has to take into consideration the aspects of the trust-building process to develop, modify, and influence information handling into the direction that increases trust of human beings participating in these processes.

Trust is More Than a Simple Technology

In building trust there are two approaches: the information technology approach and human-centered approach based on culture and morality. The information technology approach means that security has to increase by different architectures, protocols, certifications, cryptography, authentication procedures, and standards, and this increased security generates the trust of users. This means access control (passwords, firewalls) protects the integrity and privacy of messages, databases (cryptography), and the identification of users. Stressing the effectiveness of these technologies for humans (users) can cause trust in the systems based on this convincing action. Based on the technological approach, 100% security can never be obtained (there will be always security holes somewhere in the systems), so full trust cannot be guaranteed based on these mechanisms.

The human side of trust is more complicated. There was different research (e.g., Hoffmann, Novak, & Peralta, 1999) focusing on this side of trust. From this aspect, the user interface has the main role, that is, the menu structure and the messages sent for the user by the system. In the case that the user feels that the interface is easy to use, it is transparent; he or she can control the system (even with low-level computer knowledge), that is, the system is "user friendly." Through this he or she can be convinced that this is a trustworthy system.

It would be a mistake to think that applying only the human-centered approach would generate trust; the technological part has to be added as well (e.g., biometrical identification), so mainly, the structured integration of the two approaches can result in the expected level of trust.

Technical Side of Trust Building: Application of Security Mechanisms

Security is a very complex term. There is computer, communication, information system, physical, and a lot of other types of security. As an addition, these terms are overlapping each other in a lot of cases. Approaching security from the side of trust, security is the set of different services, mechanisms, and software and hardware tools for generating trust with pure technology. More generally, security is a condition that results from the establishment and maintenance of protective measures that ensure a state of inviolability from hostile acts or influences (FED, 2003).

The totality of protection mechanisms within a computer system, including hardware, orgware, and software, is responsible for enforcing a security policy called trusted computing base (TCB). The ability of a trusted computing base to enforce correctly a unified security policy depends on the correctness of all types of mechanisms within the trusted computing base, the protection of those mechanisms to ensure their correctness, and the correct input of parameters related to the security policy.

In network management, the security management covers the set of functions (a) that protects telecommunications networks and systems from unauthorized access by persons, acts, or influences, and (b) that includes many subfunctions, such as creating, deleting, and controlling security services and mechanisms; distributing security-relevant information; reporting security-relevant events; controlling the distribution of cryptographic keying material; and authorizing subscriber access, rights, and privileges (FED, 2003; Tipton & Krause, 1998).

The building blocks, elements of security, are the security services and the security mechanisms. The security services are the following (Schneier, 1996).

- **Access control:** protects against unauthorized use
- **Authentication:** provides assurance of someone's identity
- **Confidentiality:** protects against disclosure to unauthorized identities
- **Integrity:** protects from unauthorized data alteration
- **Nonrepudiation:** protects against originator of communications later denying it

The means for achieving these properties depends on the collection of security mechanisms that supply security services, the correct implementation of these mechanisms, and how these mechanisms are used.

Security mechanisms with crypto functions are the following (three basic building blocks are used).

- Encryption is used to provide confidentiality, and also can provide authentication and integrity protection.
- Digital signatures are used to provide authentication, integrity protection, and nonrepudiation.
- Checksums or hash algorithms are used to provide integrity protection and can provide authentication.

Human Side of Trust Building: Feeling of Trust

The feeling of security experienced by a user of an interactive system does not depend on technical security measures alone. Other (psychological) factors can play a determining role; the user's feeling of control can be one of these factors.

Trust is a dynamic process and it alters based on experience. The trusting process begins when an individual perceives indications that suggest a person or organization may be worthy of trust. These indications can include behaviors such as manners, professionalism, and sensitivity, and these forms are designed to represent trustworthiness. These formal claims to trustworthiness become strengthened over time and are eventually transformed into "character traits," such as dependability, reliability, and honesty. The research study of Cheskin (1999) identifies six fundamental factors that communicate trustworthiness in case of e-commerce Web sites.

- **Brand:** the importance of the company's reputation in the choice to do business with them
- **Navigation:** the ease of finding what the user seeks
- **Fulfillment:** the process the user experiences from the time a purchase process is initiated until the purchase is received to the user's satisfaction
- **Presentation:** ways in which the appearance of the site, in and of itself, communicates meaningful information
- **Technology:** ways in which the site technically functions
- **Seals of approval:** symbols that represent the companies that specialize in assuring the safety of Web sites

It has to be analyzed why people feel safe and secure and what causes these feelings. The hypothesis of D'Hertefelt (2000, p. 1) was, "The feeling of security experienced by a user of an interactive system is determined by the user's feeling of control of the interactive system." The more a user feels in control of an interactive program, the more the user will trust the site or the program. An interactive system that generates the user to feel in control has to be (a) comprehensible (the client needs to know what and how he or she can accomplish, and needs confirmation that it actually has been accomplished), (b) predictable (user has to know what is going to happen when clicking on a button or menu item), and (c) flexible and adaptable (the user will feel in control if he or she can choose the way a task is executed instead of having to figure out how the system requires it to be done).

The process of building trust is slow; trust is formed gradually. It takes quite a lot of time and repeated positive experiences (Cheskin, 1999). Online trust can be described as a kind of human relationship. The initial stage is that of interest and distrust; there has to be a motivation, a need, to get interested in the service, or coworking. In subsequent phases the trust will evolve or, in case of negative experiences, the cooperation will terminate.

Trust depends on the time span of cooperation and the type of connection as well. It can be stated that there are differences in the trust building process in short-term and long-term relationships. In case of short-term relationships (e.g., in a virtual organization), trust must be achieved quickly and then be maintained with no or rare face-to-face interaction. The members of these teams must assume that other remote team members are trustworthy, and then later on modify their assumptions according their positive or negative experiences.

In long-term relationships there are four factors that influence trust building (Rocco, Finholt, Hofer, & Herbsleb, 2001).

- The expectation of future interaction may motivate greater investment in building trustworthy relationships.
- Long-term relationships offer more time to establish trustworthiness through routines and culture.
- People have more communication channels, which may affect trust to the extent that participants have additional ways to clarify misunderstandings or to correct failures.
- Participants are interested in successful task performance, and trust formation may assume a higher priority.

TRUST AND INFORMATION MANAGEMENT

Devices, Services and Technologies for Trust Building in Information Management

As security, one important base of trust involves many topics—not only information security technology, but also the structure of the firms; the management techniques also have to follow the ongoing changes of the IC technologies. In case the security challenges are put into a broader, management-oriented interpretation, they can be classified into four categories according to Dhillon (2001).

- Establishing good management practices in a geographically distributed environment and yet being able to control organizational operations
- Establishing security policies and procedures that adequately reflect the organizational context and new business processes
- Establishing correct structures of responsibility, given the complex structuring of organizations and information-processing activities
- Establishing appropriate information technology emergency recovery plans

A solution for addressing trust is to build a chain of trust where each link is strong but also connects to its neighbor by verifying its trustworthiness. In particular, beginning with a priori grounding in a physically trustworthy base, each link of the chain checks signature-based trust tokens of its neighbor before the chain is allowed to carry any weight. Such a chain begins with processors and extends to operating systems, to applications, to interconnected protocols, and ultimately, to end users.

Trust management unifies the notions of security policy, credentials, access control, and authorization. An application that uses a trust-management system can simply ask the compliance checker whether a requested action should be allowed. Trust-management policies are easy to distribute across networks, helping to avoid the need for application-specific distributed policy configuration mechanisms, access control lists, and certificate parsers and interpreters (Blaze, Feigenbaum, & Lacy, 1996).

Virtual Teamwork and Trust Management

Today the different types of networked organizations need new types of cooperation as the members of the working teams are geographically (physically) separated; they use shared documents and communicate through e-mail and high quality audio and video channels. These teams are called “virtual teams” as they never meet personally and have no face-to-face contact. The work of teams without face-to-face contact is less effective and reliable based on the observation stated by Handy (1995, p. 46): “trust needs touch.” According to case studies, it is evident that trust of virtual team members is significantly lower than trust in conventional teams (Rocco et al., 2001). In other experiments where interaction was primarily via e-mail, very similar results were gained, as in geographically distributed teams (Jarvenpaa & Leidner, 1999)

The latest research shows if people meet before using computer-mediated communication (CMC), they trust each other, as trust is being established through touch. In case participants do not meet formerly but initiate various getting-acquainted activities over a network, trust is much higher than if they do nothing before, nearly as good as a prior meeting. Using chat forums to get acquainted is nearly as good as meeting, and “even just seeing a picture is better than nothing” (Zheng, Veinott, Bos, Olson, Gary, & Olson, 2002, p. 141).

Information Technology Tools for Generating Trust

Identification of a user or customer of an information system is a complex task. In computer science, the identifier is a string of bits or characters that names an entity, such as a program, device, or system, so that other entities can call that entity. In the context of information systems, the purpose of identification is very concrete: It is used to link a stream of data with a certain person, so the following definition can be given, “Human identification is the association of data with a particular human being” (Clarke, 1994, p. 1).

Information systems have tended to use codes rather than names as the primary identification mechanism. The most reliable mode to identify a person is to apply biometric techniques (Jain, Bolle, & Pankanti, 1999). The applied techniques in biometry systems in IT includes a physiological (fingerprint, iris, facial features, etc.) element or factor as well as a behavioral one (e.g., vocal patterns, typing rhythm). Biometric identification is preferred over current methods involving passwords and PINs (personal identification numbers) as the person to be identified is required to be physically present at the point of identification, so the person of the user is identified, not the device as in the case of PIN and password. The layered biometric verification (LBV) technology entails layering different biometric technologies into a complex identification process.

The main factor of trust is confidentiality that can be achieved by technologies that convert or hide the data or text into a form that cannot be interpreted by unauthorized persons. There are two major techniques to fulfill this goal: encryption and steganography. Encryption is transforming the message into a ciphertext, such that an enemy who monitors the ciphertext cannot determine the message sent (Schneier, 1996). Steganography is the art of hiding a secret message within a larger one in such a way that the opponent cannot discern the presence or contents of the hidden message (Johnson, Neil, Duric, & Jajodia, 2000). For example, a message might be hidden within a picture by changing the low-order pixel bits to be the message bits.

Generating Trust by Human-Computer Interfaces

Generally speaking, the goal of an interface is to interconnect two or more entities at a common point or shared boundary. As a communication- or information-system term, an interface is the point of communication between two or more processes, persons, or other physical entities. Interfaces are the key points for gaining the trust of the user or customer. They are the first connection points between the user and the system; identification of the users takes place at these points (e.g., password input, fingerprint reader, smart-card reader), so they have to be designed very carefully. In the design of both types of interfaces, ergonomic and psychological aspects are taken into consideration besides the technical ones.

Trusted Time

Trusted time is important in global network communication. Trusted time is essential to ensuring that the network and operations infrastructure run accurately, securely, and reliably, and that all relying applications execute with traceability that provides auditability to resolve disputes, avoid repudiation, and ensure legal enforceability of electronic business transactions. The auditable sourcing and synchronization of time involves a chain of trust.

FUTURE TRENDS IN INFORMATION TECHNOLOGY MANAGEMENT

Nearly all types of systems in all fields of the economy have become distributed and virtual structures appeared. The result is big structural and cultural changes in enterprises. A new communication technology appeared as well: the wireless technology. The management of these new systems has brought new aspects into focus also in the field of information management. The main advantages of wireless and mobile communication are that anybody from anywhere at anytime can make contacts. According to market researcher Gartner, 45% of the American workforce is using mobile technology of some kind, including laptops, PDAs (personal digital assistants), and new sensor networks (Gartner Symposium, 2003). By 2007, more than 50% of enterprises with more than 1,000 employees will make use of at least five wireless networking technologies.

Mobile devices became far more popular than it was estimated before, and thanks to the extremely fast development of electronic industry, these devices have grown into multifunctional tools. Mobile Internet rewrites many rules. People everywhere, in different positions, are using new services that are relevant to their personal needs and preferences and are accessible at anytime, anywhere. New terms are developing in all sectors of the industry, in finance, in the government, and in the society as well.

Information architectures, structures, business processes, and business models of enterprises have to be modified according to new information communication technology. Mobile technologies add new value in being continuously connected. Short response times assure the validity of information. Productivity is no longer restricted by place or time. Best of all, it is possible to experience new ways of communicating and sharing information. In an information- and communication-centered world, security and trust are exceptionally important as the value and strategic role of reliable information is extremely high. Information technology management systems and the managers themselves have to adapt to this fast, nonstop, changing environment. Smart cards, personal trusted devices, and secure agent architectures (Wong & Sycara, 1999) are some of the main elements in information technology that will change in the future.

CONCLUSION

The chapter has shortly introduced the main characteristics of trust and its connections between security services and mechanisms, and its role in information technology management. The importance of trust is increasing very fast as the main characteristic of the information and knowledge society is cooperation through computer and communication networks. As it is pointed out by different analyses based on real-life statistics, when users do not trust a system or service, they do not use it. The organizations have to adapt themselves to this requirement even by changing their culture or organization structures as well.

Integrated mobile technologies are speeding up this tendency as they offer mobility and freedom for citizens. Distributed information systems with different sizes are playing a definite role, but originating from their openness and flexibility, the information systems will always be a security risk. As absolute (100%) security and trust cannot be reached with pure information technology approaches, they have to be integrated with the human-centered techniques based on psychological methods.

There is a need for complex, flexible security systems that are user friendly and platform independent at the same time. The developments of hardware and software elements of such systems are going on and the potential users have to get acquainted with them. The managers of information technology have to adapt these technologies, tools, and devices into their systems to provide a high security and trust level that can induce trust in all humans involved in the different phases of the life cycle of information systems.

KEY TERMS

Biometry (synonym: biometrics): Generally, biometrics refers to the study of measurable biological characteristics. In computer security, biometric technologies are defined as automated methods of identifying or authenticating the identity of a living person based on his or her physiological (e.g., fingerprint, hand, ear, face, eye [iris or retina]) or behavioral (e.g., signature, voice, keystroke) characteristic. This method of identification is preferred over current methods involving passwords and PINs as the person to be identified is required to be physically present at the point of identification, so the person of the user is identified, not the device as in the case of PIN and password.

Encryption: Encryption is the transformation of plaintext into an apparently less readable form (called ciphertext) through a mathematical process. The ciphertext may be read by anyone who has the key that decrypts (undoes the encryption of) the ciphertext.

Layered Biometric System: Multilayer, layered, and multimodal biometric systems combine more than one physiological or behavioral characteristic for verification or identification. By promoting multilayered identification and authentication—that means parallel use of strong passwords, smart tokens, and biometrics—many significant security problems can be eliminated. The combination of multiple biometric methods such as voice and fingerprints, in conjunction with, for example, digital certificates and smart cards, offer the companies an ideal solution to provide a very high level of protection for their sensitive information.

Personal Trusted Device: People like smart, little equipment, tools that they can keep in their handsand bring permanently with themselves, so they can control them both physically and in time. According to the concept of the personal trusted device, they have to be personal, always carried by the user, small, cheap, battery powered, secure as a smart card, and they have a common user interface. Mobile phones can fulfill the role of a personal trusted device as mobile phones are well placed as identity tokens; they have dynamic authentication already proven in GSM, mass market, and secure communications. Mobile phones are (the only) mass-market smart card readers and they are highly personal. Users are usually very attached to their phones, and they can be made more personal by use of PIN or (later) biometrics.

Steganography: Steganography (literally meaning *covered writing*) dates back to ancient Greece. It includes a vast array of methods of secret communications that conceal the very existence of the message. In today's computer security, steganography is the science of hiding information by embedding messages within other seemingly harmless messages. Steganography works by replacing bits of useless or unused data in regular computer files (such as graphics, sound, text, HTML [hypertext markup language]) with bits of different, invisible information. This hidden information can be plaintext, ciphertext, or even images. Unlike encryption, steganography cannot be detected. Therefore, steganography is used to supplement encryption. An encrypted file may still hide information using steganography, so even if the encrypted file is deciphered, the hidden message is not seen.

Trust: Trust can be viewed as a cognitive and social device able to reduce complexity, enabling people to cope with the different levels of uncertainty and sometimes the risks that, at different degrees, permeate our life. Without trust, an individual would freeze in uncertainty and indecision when faced with the impossibility to calculate all possible outcomes of a situation. From a social perspective, trust permits the necessary knowledge sharing of delegation and cooperative actions (Luhman, 1979).

Trust Chain: A solution for addressing trust is to build a chain of trust where each link is strong but also connects to its neighbor by verifying its trustworthiness.

Trust Management: Trust management is a unified approach to specifying and interpreting security policies, credentials, and relationships; it allows direct authorization of security-critical actions. A trust-management system provides standard, general-purpose mechanisms for specifying application security policies and credentials. Trust-management credentials describe a specific delegation of trust and subsume the role of public key certificates; unlike traditional certificates, which bind keys to names, credentials can bind keys directly to the authorization to perform specific tasks.

Trusted Time: Trusted time is emerging as the industry's best practice. Trusted time is auditable, secure, available, warranted, accurate, and managed. Trusted time is essential to ensuring that the network and operations infrastructure run accurately, securely, and reliably, and ensure legal enforceability of electronic business transactions. The auditable sourcing, setting, and synchronization of time involve a "chain of trust" that is complex, requires time specialization, and involves multiple sources of risk.

Trustworthiness: Trustworthiness is the ability to attain and maintain a "trusted state," which is definable, measurable, validated, and demonstrable over time. Digital trustworthiness is a verifiable level of electronic process integrity, security, control, authenticity, and reliability that captures, preserves, retrieves, verifies, renders, and makes available in human readable form the essential transaction content, context, notice, intent, and consent to meet the electronic forensic-evidence requirements necessary for legal admissibility and regulatory compliance.

B

Building Educational Technology Partnerships through Participatory Design

John M. Carroll
The Pennsylvania State University, USA

INTRODUCTION

Educational technology provides many examples of how efficient software development and deployment is not enough. Teachers work in a complex and dynamic context in which measurable objectives and underlying values collide on a daily basis. Traditionally, teachers work in isolation from their peers; individual teachers have well-established personal practices and philosophies of education. Teachers have enormous discretion with respect to what goes on in their classrooms, yet are also routinely interrogated by supervisors, by parents and other community members, and by educational bureaucracies. This has led to an abiding tension in the culture of schools: Teachers' innovative practices are often not adequately acknowledged or valued, and at the same time, teachers often passively resist school reforms that are imposed top-down.

Technology is a particularly problematic element in the culture of schools. The isolation and discretion of the teacher's work environment requires that technology for classroom use be highly appropriate and reliable. Yet it is generally assumed that teachers are to be *trained* on new technologies, not asked to *define* what those technologies should be. From the teacher's standpoint, classroom technology often is itself the problem, not the solution. This culture of technologydevelopment in the schools has been singularly ineffective—film and radio in the 1920s, television in the 1950s, and computer-assisted instruction in the 1980s, among others, have been notable failures (Tyack & Cuban, 1995).

An alternative to merely efficient technology development is *participatory design*, the inclusion of users within a development team such that they actively help in setting design goals and planning prototypes. This approach was pioneered, and has been widely employed, in Europe since the 1970s, and now consists of a well-articulated and differentiated set of engineering methods in use worldwide (Carroll, 2000; Clement & Van den Besselaar, 1993; Muller, 2003; Muller, Haslwanter, & Dayton, 1997; Rosson & Carroll, 2002).

In 1994, a design collaboration was formed between Virginia Tech and the public schools of Montgomery County, Virginia. The objective was to develop and investigate a high-quality communications infrastructure to support collaborative science learning. Montgomery County is located in the rural Appalachian region of southwestern Virginia. In March 2000, one of its high schools was listed among the top 100 in the US by *Newsweek* magazine. However, in others, physics is only offered every other year and to classes of only three to five students. The initial vision was to give students in this diverse and dispersed school district access to peers through networked collaboration.

We felt it was critical for the teachers to contribute as collaborators in design analysis, implementation, deployment, testing, and refinement, and as leaders in the development of courseware and classroom activities that would exploit the software. For a classroom-technology partnership to succeed, the university researchers must eventually fade and leave the teachers to maintain and develop its achievements. In the end, the technology-development goals of this project were achieved, though this is not the topic of this paper (Isenhour, Carroll, Neale, Rosson, & Dunlap, 2000).

BACKGROUND

We analyzed our participatory engagement with the teachers as "developmental" in the sense of Piaget and Inhelder (1969) and Vygotsky (1978). We believe the teachers developed qualitatively different roles through the course of our collaboration. In some cases, these roles were suggested to them; in other cases, they defined and claimed new roles. But in all cases, these transitions exemplified the defining characteristics of *developmental change*: active resolution of manifest conflicts in one's activity, taking more responsibility, and assuming a greater scope of action. Each successive stage can be seen as a relatively stable organization of knowledge, skills, and attitudes that resolves the instigating conflict.

During the six years of this project, we distinguished four stages in our collaboration with the teachers. At first, the teachers were *practitioner-informants*; we observed their classroom practices and we interviewed them. Subsequently, the teachers became directly and actively involved in the requirements-development process as *analysts*. Later, the teachers assumed responsibility as *designers* for key aspects of the project. Finally, the teachers became *coaches* to their own colleagues within the public school system.

In a classic Piagetian example, a child in the preoperational stage perceives single dimensions of quantity. This produces conflicts: A given quantity of liquid poured from a short, wide container into a tall, thin container appears suddenly to be more, but of course cannot be more. These conflicts eventually precipitate a cognitive reorganization called the concrete operational stage, in which constant quantities are perceived as constant regardless of varying shapes and arrangements.

Developmental change in adults is of course more complex. The stages we describe are not singular competencies, but relatively complex ensembles of collaboration, social norms, tool manipulation, domain-specific goals and heuristics, problem solving, and reflection in action. They are social constructions achieved through enculturation, constituted by the appropriation of the artifacts and practices of a community (Vygotsky, 1978).

In the Piagetian notion of stages in child development, successive stages build upon the cognitive structures and enabled activity of prior stages, but ultimately replace those structures. A child who enters the concrete operational stage can no longer function at the preoperational stage. Adult growth, however, is not static achievement, but continual elaboration. The teachers are still practitioners whose classroom practices we regularly observe and whose classroom expertise we still interrogate; they seem to us and to themselves to be representative practitioner-informants. However, they are now *also* analysts and designers, and often coaches. Indeed, effective design coaches probably must be experienced designers, successful designers must be skilled analysts, and analysts must have attained significant domain knowledge (Carroll, Chin, Rosson, & Neale, 2000).

MAIN THRUST OF THE CHAPTER

Developmental theory explains transitions between stages as resolutions of conflict. Thus, the preoperational child's conflicting perceptions of quantity based on single dimensions, such as height and width, are resolved in the abstraction of quantity as an invariant in the concrete operational stage. For development to take place, the child must have attained the requisite competencies to experience the triggering conflict, and then be able to reconceptualize the situation in such a way that the conflict dissolves.

This analytical schema seems to fit the transitions between the stages of cooperation we identified. The general mechanism appears to be that successive increases in knowledge, skill, and confidence empowered the teachers to resolve conflicts by assuming successively greater scope of action and responsibility in the project. Early on, the teachers faced the conflict that their pedagogical concerns and perspectives would be adequately represented and fully considered by the group only if they themselves championed those concerns. This went beyond the practitioner-informant role they had played in the project up to then. But they were both motivated and competent to resolve this conflict by assuming the analyst role in the project.

Once the teachers were functioning as analysts in the project team, further conflicts and resolutions arose. The teachers experienced a conflict between their own analyses of system requirements and the current state of our project software and development plans. They resolved these conflicts by formulating their own design proposals, ultimately a radical reorientation of the project's vision of classroom activity. They became designers. Subsequently, the teachers recognized that they were the best qualified project members to train new teachers and to pursue specific curricular extensions of the project. They became coaches.

The teachers' behavior also reflects development *within* the four general stages we have described. For example, cognitive scaffolding (via examples, reflective prompts) was needed to engage the teachers in the novel and relatively abstract activity of design analysis. But as the project progressed, teachers spontaneously identified and presented design trade-offs to the group as a way to articulate personal positions. This is consonant with the general notion of learning as movement through a zone of proximal development (Vygotsky, 1978).

The designer stage also reflects several different levels of development. Initially, the teachers were able to collaborate with a research assistant in focused design sessions, cowriting scenarios of technology-mediated activities for their classroom. Later they banded together as a subgroup, pooling their goals and expertise to develop a scenario that specified a new vision of collaborative learning activities. Ultimately, each learned to function as an independent designer, envisioning and specifying activities optimized for their own teaching styles, objectives, and classroom environments. In their coach role, the teachers also worked first as a group, but subsequently recruited and mentored colleagues in a one-to-one fashion.

In sum, it appears that the transitions among stages were triggered by conflicts with respect to the teachers' role in the project. In each case, a series of scaffolded activities enabled them to attain the knowledge, skill, and confidence that led them to expand their role (Carroll et al., 2000).

FUTURE TRENDS

We originally committed to a long-term participatory-design method because we conjectured that such an approach would be crucial for success in this educational technology setting. We believe we could not have succeeded to the extent we have had we not made this commitment. Working from the national agenda for school reform, educational technology, and science education (AAAS, 1993; NTSA, 1992), and from our own initial vision of a "virtual school," we would have built the wrong system—we would not have had effective support from teachers. Little or nothing would have been sustained after the initial project funding ended.

Participatory design is fundamentally a process of mutual learning, and thus of personal development for participants. But it is often exemplified by rather singular and ephemeral learning interactions. Our study expands the scope of the design participants' personal development by examining a case of long-term cooperative design interaction, and by describing a developmental sequence of roles with constituent capacities and responsibilities.

Much research on participatory design has focused on relatively short-term collaborative relationships. This is especially true in North America, where many participatory-design techniques are directed at brief user-interface-design interactions of perhaps one hour (Muller et al., 1997). Such methods are both effective and democratic, but it seems unlikely that the experience of manipulating a user-interface mock-up during a brief participatory session can have a significant developmental effect on a person's knowledge, skills, self-confidence, or other professional capacities.

In our project, user-interface design per se was a secondary issue. We used brief participatory exercises, but this level of engagement was more a starting point than the objective of our work. More specifically, we wanted the teachers to have a significant voice in designing the functionality and the use of the virtual school, not merely its appearance. We needed to learn about pedagogical goals and practices, classroom management, school-system politics, the relationship of the community and the schools, and so forth.

Where participatory-design investigations *have* focused on longer term interactions, chiefly in Europe, these often involve extremely well-organized user groups with well-defined roles and prerogatives in the design process. In many cases, the users are represented by labor unions whose personnel provide legal representation of user interests in the design process. In these cases, there is sometimes a clear demarcation, even conflict, between the user (union) interests and management's technology strategy. Indeed, this is an important element of the context for many of these studies. Because the user role in many of these studies is both specified a priori and representative (versus individual), the personal development of user-designers is not a central issue. These case studies also typically involve situations in which the development and deployment of new information technology is a given, and the challenge is to define appropriate technology for the users and their activities (Bjerknes & Bratteteig, 1993; Bødker, Ehn, Kammersgaard, Kyng, & Sundblad, 1987; Merkel et al., 2004).

In the educational domain, the deployment of new information technology is far from given. Indeed, the introduction of new technology has historically almost always failed in school settings. One of the key questions for us was whether a concept for appropriate technological support could be developed at all.

The users in our domain are very loosely organized. As mentioned earlier, teachers traditionally work in isolation from peers; they manage their own work practices and environments (classrooms). The notion of a "user community" in this domain is almost ironic. Teachers unions in the US are also extremely weak and play no role in the introduction of classroom technology. Indeed, school administrations in the US rarely have technology strategies at all. Thus, unlike the European case studies, the issue is almost never one of recognized conflict, but rather finding a direction at all.

The teachers in our team do not represent other teachers; they are individuals who, as members of our team, have become teacher-designers. This is precisely why their personal development as designers is a central issue in our study. Of course, we do hope that they are representative teachers—allowing us to generalize our investigation to other teachers participating in similar development projects—but this is a separate issue. The point is that in our project, and unlike many long-term participatory-design efforts in Europe, the teachers act as individual professionals just as university researchers do.

CONCLUSION

The stages we have described here are specific to our project; they emerged through specific things that we did and are rooted in the specific goals of our project. At the same time, they suggest a schematic programme for developing cooperative engagement more generally. Most participatory-design work engages users at the practitioner-informant stage. This would seem to be an obvious and general starting point for any participatory-design collaboration. In our project, the teachers transitioned to the analyst stage through their inclusion in a requirements-analysis workshop and a significant process of iterative requirements development (Carroll, Rosson, Chin, & Koenemann, 1998). This is perhaps not typical of participatory-design practice, but it is a modest extension. Nevertheless, the teachers found it quite stimulating to be invited to objectify their own experience, to dissect it and not merely describe it.

KEY TERMS

Analysts: Users who collaborate with designers as domain experts analyzing constraints and trade-offs in existing and envisioned work practices are called *analysts*. This is the second stage in the developmental theory of participatory-design relationships between users and designers.

Coaches: Users who help other users participate in design work by coaching them are called *coaches*. This is the fourth stage in the developmental theory of participatory-design relationships between users and designers.

Designers: Users who collaborate with designers as domain experts envisioning new work practices and tools are called *designers*. This is the third stage in the developmental theory of participatory-design relationships between users and designers.

Developmental Theory: Theories of learning that involve growth and other qualitative changes in skills, knowledge, and capacities. Developmental theory is contrasted to accretive theories in which learning is conceived of as a matter of quantitative improvements—more knowledge or faster performance.

Educational Technology: Technology used in formal educational contexts, such as classrooms. Recent examples are television, personal computers, and the Internet.

Participatory Design: Design methods in which users (and other stakeholders) provide special expertise and play active and autonomous roles in design work.

Practitioner-Informants: Users who collaborate with designers as domain experts providing information about work practices are called *practitioner-informants*. This is the initial stage in the developmental theory of participatory-design relationships between users and designers.

Building Local Capacity via Scaleable Web-Based Services

Helen Thompson
University of Ballarat, Australia

INTRODUCTION

Information communications technology (ICT) has been identified as a key enabler in the achievement of regional and rural success, particularly in terms of economic and business development. The potential of achieving equity of service through improved communications infrastructure and enhanced access to government, health, education, and other services has been identified. ICT has also been linked to the aspiration of community empowerment, where dimensions include revitalizing a sense of community, building regional capacity, enhancing democracy, and increasing social capital.

In Australia, there has been a vision for online services to be used to open up regional communities to the rest of the world. Government support has been seen "as enhancing the competence levels of local economies and communities so they become strong enough to deal equitably in an increasingly open marketplace" (McGrath & More, 2002, p. 40). In a regional and rural context, the availability of practical assistance is often limited. Identification of the most appropriate online services for a particular community is sometimes difficult (Ashford, 1999; Papandrea & Wade, 2000; Pattulock & Albury Wodonga Area Consultative Committee, 2000). Calls, however, continue for regional communities to join the globalized, online world. These are supported by the view that success today is based less and less on natural resource wealth, labor costs, and relative exchange rates, and more and more on individual knowledge, skills, and innovation. But how can regional communities "grab their share of this wealth" and use it to strengthen local communities (Simpson 1999, p. 6)? Should communities be moving, as Porter (2001, p. 18) recommends (for business), away from the rhetoric about "Internet industries," "e-business strategies," and the "new economy," to see the Internet as "an enabling technology—a powerful set of tools that can be used, wisely or unwisely, in almost any industry and as part of almost any strategy?"

Recent Australian literature (particularly government literature) does indeed demonstrate somewhat of a shift in terms of the expectations of ICT and e-commerce (National Office for the Information Economy, 2001; Multimedia Victoria, 2002; National Office for the Information Economy, 2002). Consistent with reflections on international industry experience, there is now a greater emphasis on identifying locally appropriate initiatives, exploring opportunities for improving existing communication and service quality, and for using the Internet and ICT to support more efficient community processes and relationships (Hunter, 1999; Municipal Association of Victoria and ETC Electronic Trading Concepts Pty Ltd., 2000; National Office for the Information Economy, 2002).

The objective of this article is to explore whether well-developed and well-implemented online services can make a positive contribution to the future of regional and rural communities. This will be achieved by disseminating some of the learning from the implementation of the MainStreet Regional Portal project (www.mainstreet.net.au). To provide a context for this case study, the next section introduces some theory relevant to virtual communities and portals. The concept of *online communities* is introduced and then literature is reviewed to identify factors that have been acknowledged as important in the success of online community and portal initiatives.

BACKGROUND

In regional Australia, many Web-based initiatives have been premised on fear of external electronic commerce ventures adversely affecting local industry (McGrath & More, 2002, p. 50). Media and government reports have reinforced notions that those who ignore the adoption of electronic commerce will do so at their peril (Department of Communications Information Technology and the Arts, 2000). Recent research however identifies a movement beyond the "starry-eyed fascination with, and high expectations of, technology per se," with the focus now more pragmatically on how ICT can enable enhanced business and community processes and more effective organizational relationships (More & McGrath, 2003).

The term *online community* means different things to different people (Preece, 2000). In early definitions, the term described communication facilitated through bulletin boards (Rheingold, 1994, pp. 57-58). More recent definitions reflect the expansion of Web-based technologies and often link online communities with concepts of regional communities and local strengths (Keeble & Loader, 2001).

In Australia the terms *online community, regional portal, Web portal,* and *community portal* are often used more or less interchangeably. Web portals "provide focal points on the Web, places to start, places to go to find things" (Gronlund, 2001, p. 88). They have been identified as one strategy for encouraging regional participation in the information economy. For example, according to the Department of Communications Information Technology and the Arts (2001), a regional portal can achieve the online aggregation of potential and existing regional presence into a comprehensive portal, gateway, or regional Web site. In funding initiatives, preference has been given to projects that offer inclusive regional aggregation of business, government, and community services, and which provide interactive services to clients both in and external to the region.

Some definitions of online communities capture the concepts of both *communities of interest* and *communities of location,* and identify the role of encouraging communication and information sharing among members as important (McGrath & More, 2002). Australia's largest telecommunications provider describes online communities as providing a focal point for the provision of local regional information. In terms of functionality, these community portals generally incorporate local news services, local weather reports, a directory of community organizations, and features such as bulletin boards, discussion forums, a calendar of events, and transaction services (Telstra Country Wide, 2002).

To achieve optimum online collaboration, various issues require consideration. These include notions of community, trust and commitment, processes and structure, knowledge management, learning, and collaboration (More & McGrath, 2003). Some further factors more specific to the success of online community or portal initiatives are considered in the next section.

In forging and managing online collaboration, people issues rather than technological ones have been identified as the most challenging. "Certainly across a broad range of projects, many have come to realize that managing people, relationships, and business processes is harder than managing technology" (McGrath & More, 2002, p. 66). It is easy to underestimate the amount of planning and effort that is needed to build and sustain an online community; therefore care should be taken to avoid miscalculations. In particular, "overlooking the key role of the human facilitator is perhaps the greatest reason that online communities fail to meet the expectations of their designers" (Bernal, 2000, p. 4).

For many projects, collaboration is the key to survival, renewal, and growth, especially in regional areas "where the threat of global competitive dynamics often drove alliances" (McGrath & More, 2002, p. 67). Initiatives, however, with a broad geographical focus, can "encounter difficulties in establishing and maintaining cooperative relationships across multiple communities in their regions" (Simpson, 2002, p. 8).

"Many projects that have adopted a 'build it and they will come' approach have been doomed to early failure" (Simpson, 2002, p. 4). Developers need to work with community members to ensure that the goals of the site owner and the needs of community members are met (Preece, 2000). Good online services provide multiple levels of entry, many-to-many relationships, and rapid movement between the services and content of disparate providers (Local Government Association of Tasmania and Trinitas Pty Ltd., 2001).

Community members also need compelling reasons to use and return to an online community again and again. There will be a need to balance supply-side investment (access, technical platforms) and demand-side investment (content and services) (Local Government Association of Tasmania and Trinitas Pty Ltd., 2001).

"If you get this right—if you can identify and fill a need in the lives of your community members—you can go a long way on very little technology. If you miss this, no amount of technology is going to make you successful as an online community." (Kim, cited in Bernal, 2000, p. 3)

Engaging and relevant content are vital to increase uptake and sustained use of the Internet. Portal content management strategies should be *bottom-up* in their approach. This can be achieved by providing multiple opportunities for interaction and by providing permission-based access to software that allows members to produce content for their online community (Brumby, 2001; Telstra Country Wide, 2002).

Soft technologies are also essential in building user confidence and comfort with new technology. "Individualized awareness raising…training activities, and learner support are key elements in creating within the community the desire, motivation, and enthusiasm to trial and take up the technology" (Simpson, 2002, p. 7).

This review has highlighted a number of factors which can impact the success or otherwise of portal type initiatives. This background information provides a context for introducing the MainStreet case study in the next section.

MAIN THRUST OF ARTICLE

In May 1999 a collective of regional stakeholder organizations engaged the University of Ballarat to research the requirements and make recommendations on how the Central Highlands and Wimmera regions of Victoria could capture greater advantages from new information and communications technologies.

The research, documented in *Victoria's Golden West Portal Project Business Case* (Thompson, 1999), involved a number of different stages. These included confirming existing regional Web content, examining community portal developments, identifying portal tools, researching potential revenue streams, conducting focus group sessions, and other forms of stakeholder consultation.

The research report described how an environment could be established that would be conducive to the widespread adoption of electronic commerce. Specific recommendations included: establish a membership-based regional association with a specific focus on electronic commerce; establish infrastructure for a manageable and economically sustainable Internet presence in a way that would encourage the enhancement of community service and facilitate communities of interest and trading communities; and through a regional portal, achieve better Web content coordination, provide a valuable information source for residents, and also enhance efforts to promote all the attributes of the region.

The Chamber of Electronic Commerce Western Victoria Inc. (the Chamber) was established to facilitate the advancement of electronic commerce and implement the MainStreet portal project. Funding applications were prepared, and in November 1999 the MainStreet project secured funding of AUD 274,000 through Networking the Nation, with a further AUD 135,000 approved in May 2000. The University's Centre for Electronic Commerce and Communications (CECC) was then contracted to implement the project because it had the specialist skills necessary to develop the portal infrastructure and services.

Research had identified that many portal projects had produced 'static' or 'fixed' solutions. The MainStreet model, with the inclusion of a technical team as a critical element, was different, but the decision to have this team was significant in determining how the MainStreet project would evolve. The technical officer and part-time programmers would develop a portal framework based on the core services identified during the preliminary study. All tools would be selected or developed with non-technical end users in mind. The initial toolset would include event calendars; news publishing tools; online registration, payment, and product systems; and access to Web wizards and other Web publishing tools. This would be achieved by incorporating a range of in-house developments, with some integration of externally sourced product. The core services would create capacities to link regional Internet information and services, construct searchable directories, dynamically generate content like news and weather, distribute publishing and authoring rights, and promote community news and events.

The MainStreet project was actively promoted in the period leading up to its official launch in July 2000. This promotion was important as it helped to maintain interest in the project while technical developments proceeded behind the scenes.

During the early part of 2002, the MainStreet project attracted its first major client. Success in securing the Ararat Online project (www.ararat.asn.au) was attributed to involving regional stakeholders right from the project's beginning. Ararat's Economic Development Manager had participated in a range of activities, meetings, and focus group sessions. Through these activities he developed a strong understanding of how MainStreet offered Ararat something different that could be applied immediately to benefit his local community.

The Ararat Online project would include a range of elements with more than 80 businesses and community groups to benefit directly from an upgrade of their Web presence. They would also be given the opportunity to undertake training so that each organization would gain the skills to manage their own site. A further opportunity would be available for six businesses through an e-commerce mentoring program. Selected businesses would be assisted in the implementation of electronic commerce initiatives developed to match their particular business needs.

The value derived from the Ararat Online project was substantial. First, although the project did not represent a significant 'bottom-line' contribution in the context of the overall project budget, the investment of AUD 8,000 in a regional electronic commerce context represented a significant buy-in for the MainStreet product. Second, the Ararat Online project provided an opportunity to showcase the full product suite, its technical capabilities, the Web products, and the training and consulting services. Third, the project would help to address one of the early barriers: people in the target region had a very limited understanding of what a portal was. The Ararat Online project would provide a 'real' example, which it was hoped could be used to demonstrate the value and benefits that were associated with the efficient linking of Internet-based information and services in an easily searchable form. In other words, the Ararat Online project would establish the first 'before' and 'after' images. This proved to be a very powerful marketing mechanism for the project.

The project's technical team, however, had their task doubled—they were now expected to build not one, but two portals, and to deliver these within very short periods. They were successful in developing a way to replicate the MainStreet functionality through Ararat Online (www.ararat.asn.au) and later through projects with the

Birchip Cropping Group (www.bcg.org.au), Moorabool Shire (www.mconline.com.au), and Pyrenees Shire (www.pyreneesonline.com.au).

The original goal had been to establish MainStreet as the "point of first electronic contact for the region" (Thompson 1999, p. iv.). The vision was that people would find MainStreet, and from there be able to search and access information about a particular region or locate services of a particular type. What, however, was now understood was that 'communities' were much more motivated if the functionality of MainStreet could be delivered with local Web addresses and branding. Information could then be filtered up to the MainStreet umbrella so that client communities could be either accessed directly or through MainStreet. While this turned the original concept upside down, there was a strong indication that communities in the region were prepared to pay to both establish and maintain a service based on the 'replicable portal framework' developed through the MainStreet project.

FUTURE TRENDS

The MainStreet portal infrastructure and tools have since been replicated to suit a range of different clients, with this approach proving to be a very effective way of getting people actively engaged online. Appendix 1 contains a selection of URLs for clients including local governments, town-based communities, membership-based organizations, industry groups, and small and medium enterprises.

While a number of factors have been highlighted, the most successful and distinctive aspect has been the development of the replicable portal framework. It has been this capability that has been leveraged to cause increase in 'buy-in', participation, and ongoing investment in regional Web-based services. Members of 'geographic communities' and 'communities of interest' are able to work with CECC to design and implement sophisticated Web-based services, customized to meet their specific communication, promotional, and/or electronic commerce needs. Through this university/community partnership, initiatives are then sustained by putting community members in charge of the management of their online community. Local ownership and the sustainability of infrastructure and technical support services have been achieved by effectively aggregating regional demand for portal services.

The MainStreet project has made a significant contribution to the advancement of ICT and electronic commerce uptake in the Central Highlands and Wimmera regions of Victoria. Many individuals and communities have been assisted in advancing their uptake of electronic commerce as they update their community sites, publish event information and news items, or show others how to build simple Web sites. The level of functionality and services accessed is high and, because clients have strong ownership of their online activities, maintain their own Web-based information, and are committed to annually investing to maintain the portal infrastructure and services, the services can continue to be delivered after the initial seed funding period.

The MainStreet project has also supported and encouraged a staged uptake of electronic commerce, with a number of organizational clients becoming increasingly confident in both selecting and investing in electronic commerce solutions.

Services have also been customized to meet the needs of small groups such as Birchip Cropping Group, and also larger communities such as Moorabool, Ararat, and the Pyrenees Shire regions. This has overcome a barrier where under most models, the costs to establish (and sustain) a local portal have been substantial, and therefore prohibitive for small towns and community groups.

CONCLUSION

Through the MainStreet project, regional and rural communities have a greater ability to build on local strengths and capitalize on the opportunities that are provided by electronic commerce and ICT. Communities, however, just like businesses, require assistance in identifying the most appropriate online service for their particular circumstances. Policies that encourage communities to enter collaborative partnerships, and which leverage existing infrastructure, knowledge and learning, should thus be seen as preferable to the funding or establishment of discrete or stand-alone initiatives. Well-developed and well-implemented online services can make a positive contribution to the future of regional and rural communities. Case studies such as the one presented in this article are effective in illustrating the impacts, influences, and challenges that can be experienced in operationalizing and sustaining online communities in a regional and rural context.

ACKNOWLEDGEMENTS

The author acknowledges Brian West from the University of Ballarat who has been generous in the provision of advice and encouragement that greatly assisted in the preparation of this work.

KEY TERMS

'Bottom-Up' Approach: Development approach founded upon the principle that communities are better placed to coordinate and integrate efforts at the local level.

Case Study: The intensive examination of a single instance of a phenomenon or where one or just a few cases are intensively examined using a variety of data-gathering techniques.

Community Informatics: A multidisciplinary field for the investigation of the social and cultural factors shaping the development and diffusion of new ICT and its effects upon community development, regeneration, and sustainability.

Community Portal: Online initiative often developed through participative processes which aims to achieve better coordination of relevant Web-based information and provide communication services for community members.

Regional Development: The act, process, or result of actions to grow, expand, or bring a regional place to a more advanced or effective state.

Web Portal: Focal points on the Web which provide a place to start. Web portals facilitate the location of information by incorporating the strengths of search engines and additionally provide more efficient access to information by categorizing it into easily recognizable subcategories or channels.

Building Police/Community Relations through Virtual Communities

Susan A. Baim
Miami University Middletown, USA

INTRODUCTION

Over the past two decades, police departments around the globe have been involved in a slow, but steady transition from call-based policing to community-oriented policing. The former approach, while effective at closing cases once a crime has occurred, does little to develop crime prevention partnerships between officers on the beat and the citizens of local communities. Community-oriented policing serves to increase awareness of issues and potential problems before they occur, thus assisting police departments to provide a more proactive approach to stopping crime within their communities.

One of the greatest difficulties in developing effective community-oriented policing programs is establishing solid, two-way communications links between police officers and the populations that they serve. Information flow to the police and suggestions back to the citizenry often fall victim to the same constraints—lack of time to interact effectively and lack of a ready-made mechanism to deliver the information in a timely manner. To reduce or eliminate these constraints, interactive police department Web sites and virtual communities (that involve both police officers and citizens) can provide actionable and measurable performance increases in the efficiencies and the effectiveness of community-oriented policing efforts. Although the IT hardware, software, and design expertise needed to create interactive Web sites and virtual communities are readily available, online efforts at community-oriented policing will remain more of a theoretical interest than a broad-scale application until police departments truly understand the needs and the wants of the citizens within their local communities.

This article explores a service-learning approach for use in a university classroom that combines IT applications with current research practices in the use of citizen satisfaction surveys conducted for local police departments. Examples are drawn from three primary-based research studies involving police departments that are turning away from call-based policing practices and proactively moving toward community-oriented policing practices.

BACKGROUND

Descriptions of community-oriented policing efforts may be found in the literature as early as the 1960s, although the majority of papers published date from the mid-1990s to the present day. Successful community-oriented policing programs began to emerge as departments returned to fundamental cop-on-the-beat policing that put officers back in close contact with citizens in their neighborhoods and in their places of business (Sissom, 1996). The knowledge gained from the early community-oriented policing efforts was used to improve departmental training efforts and also used to focus police officers more closely on crime prevention techniques. Community-oriented policing practices have continued to evolve in more recent studies where most authors focus on how the police can better identify specific issues that are divisive within their respective communities (Culbertson, 2000; Vincent, 1999; Woods, 1999; Rohe, Adams & Arcury, 2001).

Community-oriented policing programs rely heavily on current and ongoing issues of citizen concern received from both the police departments and the citizens of the communities served. The basic premise of community-oriented policing involves both sides becoming very familiar with each other's needs, wants, and expectations, and then forming a true community partnership to create a safe environment for citizens to live and work. Police officers are, in a sense, being asked to enroll in a police version of a basic marketing course in order to learn how to sell this new approach to the residents of their communities (Cummings, 2001). Residents, long accustomed to seeing police officers only when an emergency has been reported, can represent a tough sell for police officers in terms of forming proactive crime prevention citizen partnerships. Additionally, many police departments, themselves, may believe that the extra time and effort necessary to create community-oriented policing programs is not worth the increased costs, given the difficulties in measuring the perceived benefits of crime prevention programs. Crime, itself, is measurable and actionable in terms of police performance. For example, the widespread incorporation of computerized emergency call systems (e.g., 911 in the United States and similar systems in other nations) has given police departments ready access to tools capable of tracking performance measures such as call volume, time from call to officer arrival, clearance rate of calls, and so forth (Siegel, 1999). Particularly for police departments that score well on these measures and are rewarded appropriately by their city councils and/or their citizenry, the impetus to move toward more time-consuming and less easily quantified community-oriented policing objectives appears to be small. Like many governmental agencies, operational change in police departments tends to be extremely slow and very difficult to implement.

Regardless of these prevalent views, however, one finding that all parties seem to agree on is that the proper incorporation of new computer-based technologies will help police departments get closer to the citizens that they protect and serve. Computer-based technologies also help the individual officer solve crimes at the same time. An excellent example of such a technology is the mobile laptop computer now found in a high percentage of patrol cars (Greenemeier, 2002; Couret, 1999). Officers in the field now have access to virtually the same information as their office-based counterparts, and they can get at that information in real time without the translation losses associated with working through a radio dispatcher. Frequent reliance on the Internet and e-mail for sharing information and communicating between local police departments and other external police agencies also adds to the active network in use by the majority of police departments today. Given the significant improvements in computer technology, the timing is right for police departments to begin to implement community-based policing practices.

The design and development of efficient and effective "customized" community-oriented policing programs clearly places a burden on police departments to solicit, collect, analyze, and interpret data from their citizenries in order to make wise choices regarding the scope and size of any program that is set up. Obtaining high-quality data can be a formidable task, due to the diversity of the population to be sampled and due to the fact that not all respondents share the same expectations regarding active participation in crime prevention with their local police departments. It is with this background framework in mind that modern IT techniques, combined with current research practices, can significantly boost the ability of all parties to communicate and to share information that is critical in moving a police department from call-based policing practices to community-orientated police practices.

SURVEYS, INTERACTIVE WEB SITES, AND VIRTUAL COMMUNITIES

Police departments often lack not only the knowledge of what citizens might respond favorably to in terms of interactive Web sites or virtual communities, but also to the expertise that is needed to conduct unbiased research surveys among their constituencies to generate the required data input. Citizen satisfaction surveys are becoming highly efficient and effective tools for a variety of city government purposes with credible studies cited in the literature over the past several years (Kearney, Feldman & Scavo, 2000; Oleari, 2000). Often, such citizen surveys, conducted among random samples of the community's population, will be highly revealing of the type of information needed to set up initial Web site and/or virtual community structure(s).

To generate useful data that can drive the development of interactive Web sites and virtual communities, it may be necessary to enlist the services of professional researchers. Given large citizen populations, researchers may want to choose conducting either a mail or an online survey. If neither format is selected, they then need to develop a survey instrument, a process plan, and a timeline for conducting the survey, and at the conclusion of the survey, an unbiased set of concrete, actionable, and meaningful recommendations on how to put the data to use. Unfortunately, hiring a professional research firm can cost thousands of dollars that taxpayers cannot afford to spend given today's tight city budgets. A workable alternative, therefore, is to "hire" university students (under the direction of an instructor knowledgeable in current research techniques) who want to have a "hands-on" educational experience that benefits themselves, their university, and their local community in a service learning setting.

The three citizen satisfaction surveys described in this article were conducted following a traditional mail survey format. Table 1 briefly summarizes the city locations, numbers of surveys sent and returned by respondents (including response rate), and the dates that the research studies were conducted over the past few years. In each case, the study was run collaboratively with a police department in Southwestern Ohio (all looking to implement community-based policing practices in their communities) and an undergraduate Marketing course at Miami University. Students in each of the courses developed the database (in Excel or in Access), handled all of the data tabulation, and analyzed the results under the guidance of the author (as instructor of the courses).

Table 1. Citizen satisfaction studies (mail surveys) involving local police departments

City	No. of Surveys Sent	No. of Surveys Returned	Response Rate	Date Conducted
Middletown, Ohio	2,000	636	32%	Spring 2000
Oxford, Ohio	1,857	522	28%	Spring 2001
Trenton, Ohio	1,600	478	30%	Spring 2001

Since future citizen satisfaction surveys of this type may be conducted using Internet-based survey instruments in situations where there is reason to believe that a sufficient concentration of "online" respondents is available, citizen respondents were asked to provide data on their Internet usage and their previous access to city and/or police department-sponsored Web sites. Data were also collected on the desirability and projected usage level of advanced interactive Web services, in case these types of services should be offered by police departments at a later date. Selected data are summarized in Table 2.

A careful examination of the data generated across all three surveys reveals several important findings for police departments that may desire to set up interactive Web sites and/or virtual communities to enhance police/community relations. These findings were generated by examining the cross-tabulations of the questions noted in Table 2 with various demographic parameters tracked in the surveys and also the respondent verbatims related to Web site usage. Results are summarized qualitatively in Table 3.

- In all three communities surveyed, personal Internet connectivity varied with age group. Older residents were less likely to have Internet access at home, and they did not appear to make up for this lack by using Internet access at work or public Internet access at libraries or other similar locations.
- Among residents with Internet connections, most users felt comfortable using Internet sites as casual observers or to download information, but only a small percentage of individuals were comfortable sending personal information online. Subsequent questions revealed that this reluctance could be attributed to the desire to keep personal information secure—regardless of any printed claims regarding "secure" Web sites or other online privacy statements relayed by Internet providers.
- Even among residents who felt comfortable with two-way communications online or with using interactive Web sites, it is evident that traditional communication mechanisms would have to be maintained in order to meet all needs, especially as they relate to police departments. Most residents believe that traditional means of communication are a "safety net" that must be used when electronic communications go down.

Police departments seeking to increase citizen participation in community-oriented policing efforts through the incorporation of electronic communications mechanisms such as interactive Web sites and/or virtual communities may face a similar situation as outlined above. While it would be too simplistic to state that the general citizenry will not accept such efforts, it is imperative to acknowledge that a significant percentage of city residents may be reluctant to participate in online communications at the present time. As such, it is critically important for those involved in setting up interactive Web sites and/or virtual communities to bear in mind that it may take time for these initiatives to "catch on" and that a keen eye

Table 2. Citizen satisfaction studies—Internet usage

City	No. of Surveys Returned	Percent of Respondents Using the Internet	Percent of Internet Users Accessing City and/or Police Web Sites	Percent of Internet Users w/Interest in an Upgraded Police Web Site
Middletown, Ohio	636	40%	29%	13%
Oxford, Ohio	522	81%	28%	3%
Trenton, Ohio	478	66%	15%	48%

Table 3. Key findings regarding citizens' use/desire to use the Internet for police services

- In all three communities surveyed, personal Internet connectivity varied with age group. Older residents were less likely to have Internet access at home, and they did not appear to make up for this lack by using Internet access at work or public Internet access at libraries or other similar locations.
- Among residents with Internet connections, most users felt comfortable using Internet sites as casual observers or to download information, but only a small percentage of individuals were comfortable sending personal information online. Subsequent questions revealed that this reluctance could be attributed to the desire to keep personal information secure—regardless of any printed claims regarding "secure" Web sites or other online privacy statements relayed by Internet providers.
- Even among residents who felt comfortable with two-way communications online or with using interactive Web sites, it is evident that traditional communication mechanisms would have to be maintained in order to meet all needs, especially as they relate to police departments. Most residents believe that traditional means of communication are a "safety net" that must be used when electronic communications go down.

is essential to make the Web sites attractive (with frequent updates) for casual and/or new Internet users.

John Hagel and Arthur Armstrong contend that there is "nothing more uninviting to passing Web traffic than a community without members" (1997, p. 134). Interpreting this comment in the context of community-oriented policing is straightforward. To attract proactive, involved citizens, interactive Web sites and virtual communities must offer something of value—something to cause these citizens to check back frequently, to offer suggestions, and to take away information that is valuable and that cannot be obtained as easily through alternative means. In bringing interactive Web sites and/or virtual communities to fruition, it may be advantageous to encourage members of the police department to participate vigorously and frequently—especially as the sites are first introduced. Some citizens may take a "watch and see" attitude before beginning to participate in online community-based policing efforts. The presence of helpful and interesting information from the police department may help draw these citizens from the mode of casual observer to the mode of full-partner participant.

The technology required to offer interactive Web sites and virtual communities is well established, and it will not be addressed specifically in this article. Police departments have numerous choices in how to achieve these goals, ranging from employing the services of professional Web site and virtual community design/support organizations, to "bootlegging" efforts from members of the city workforce and/or police department who are proficient at computer operations. What is mandatory, however, is the list of criteria given in Table 4.

- The Web site and/or virtual community must be in operation 24/7. Long periods of inactivity or excessive "down" periods must be avoided.
- Police officers and/or a department spokesperson(s) must monitor the Web site(s) frequently and actively participate in the citizen/police partnership.
- Continuous solicitation of new members will keep the Web site(s) fresh and productive.
- Police departments must not become discouraged if it takes a relatively long period for the concept to "catch on" in their communities.

Many police departments have a preliminary foundation on which to build an interactive Web site or a virtual community since they already have a police department Web site in place. (Among the three Ohio cities surveyed, Middletown, Oxford, and Trenton, all have police department Web sites or Web pages in an overall directory of city services.) Even if these sites exist only to provide a brief overview of the departments' operations, they can serve as a starting point to build citizen involvement. The key for the developer charged with expanding a basic Web site into an offering capable of engaging the local citizenry in community-oriented policing is to recognize that marketing the partnership process and the end result of the project (in terms of actionable and measurable performance indicators) will be as critical as executing the technical details of the assignment. Considered to be one of the true Internet pioneers, Howard Rheingold stated in an interview that the three most critical things that a developer must determine before beginning a project of this type are: 1) how the site will be marketed, 2) what is expected in return for visits by potential members, and 3) what technologies will be needed to put the site into proper operation (Moore, 2001).

While interactive Web sites can provide a forum for police officers and citizens to exchange information, in general these exchanges are likely to be highly discreet in nature—involving only one citizen and one police officer

Table 4. Criteria for successful use of interactive Web sites and virtual communities

- The Web site and/or virtual community must be in operation 24/7. Long periods of inactivity or excessive "down" periods must be avoided.
- Police officers and/or a department spokesperson(s) must monitor the Web site(s) frequently and actively participate in the citizen/police partnership.
- Continuous solicitation of new members will keep the Web site(s) fresh and productive.
- Police departments must not become discouraged if it takes a relatively long period for the concept to "catch on" in their communities.

or department representative at a time. The real opportunity to magnify the positive benefits of community-oriented policing will occur as groups of citizens and officers begin to communicate on a frequent basis. If this is handled electronically, the communications may evolve into a highly functional virtual community. Police departments are well positioned for such an effort because police officers need to interact with the citizenry in order to keep a finger on the pulse of the community. Citizens, on the other hand, often have trouble interacting with the police unless an emergency has occurred. The mindset is that police officers are incredibly busy and that they do not have time to "just chat," when it is actually through such interactions that community-oriented policing makes its mark.

Police departments will need to go the extra mile in establishing virtual communities because individual citizens, or even groups of business people, will be unlikely to set up a virtual community infrastructure with sufficient credibility to attract widespread participation. Police departments may want to borrow guidelines on community participation from authors such as Rachel Gordon, who has published an extensive discussion on "hints for success" in virtual community interactions (Gordon, 2000). Privacy and confidentiality concerns must also be properly addressed. Even though an interactive Web site or a virtual community is considered to be a public forum, clear statements regarding the collection and use of information are warranted (Sheehan, 2002; Sheehan & Hoy, 2000; Milne & Culnan, 2002). Finally, police departments should also keep in mind that they are not setting up interactive Web sites and virtual communities in order to run for-profit businesses. As such, the goal is not to extract data from citizen participants in order to judge how to market revamped and/or new police services. Rather, the goal is to generate critical information and upgrade the ability of both sides to deal with the process of maintaining an environment in which all citizens feel safe to live and work (Brewer, 2000; Wood, 2000).

FUTURE TRENDS

Community-oriented policing is here to stay. For the three Southwestern Ohio communities studied, the benefits of the process far outweigh the anticipated costs and extra effort put forth by their police departments. Data consistently showed that community-oriented policing programs would be greatly appreciated by citizens and business owners alike. Nevertheless, time pressures and resource constraints still continue to plague police departments in the same manner as they do other for-profit businesses, non-profit organizations, and governmental agencies. The key to successful implantation of community-oriented policing efforts thus becomes finding efficient and effective ways to interact with the public at large. Fortunately, the rapid increase in Internet connectivity and the general upswing in personal e-mail and Web usage provide a suitable vehicle for police departments to use in establishing better communication links with the citizenry.

It is highly likely that police departments will continue to increase their presence online in a variety of formats. The relevant issues requiring future study are primarily application oriented and not rooted in the basic technologies of setting up Web sites and/or offering access to virtual communities. Fortunately, police departments can ride the coattails of IT developers who are already generating continuously more advanced Internet communications technologies for business and industrial clients. This is not to say, however, that engaging the citizenry of a community to communicate with the police online is an easy or well-understood proposition. The state of the art today is one of relatively infrequent successes. Solid, two-way communications take time and money to implement, and both issues are at a premium in most police departments—regardless of whether those communications take place through traditional channels or in an online format.

Citizen satisfaction surveys, conducted through a mail survey format as described in this article or conducted in a fully online research mode, are likely to grow in importance as police departments continue to focus more energy on meeting the specific needs and wants of their communities. In terms of service learning at the university level, surveys of this type are natural service learning projects for post-secondary students in business, sociology, criminal justice, and other similar majors where a quantitative and qualitative study of police/citizen interactions is of value. Educators are likely to find students highly willing to participate in such work, and police departments eager for the unbiased "third-party" perspective that a well-run research study can provide.

Future research should focus on identifying more precisely what information citizens would value receiving through interactive Web sites and/or virtual communities. Individuals charged with developing interactive Web sites and/or virtual communities for police and citizen use would also be well advised to consider surveying police officers to better elucidate their department's needs and wants before beginning the design process. Collectively, the issues surrounding the "true" needs and wants of citizens in a local community transcend the technical aspects and challenges of mainstream research in information technology to include additional aspects of public policy, criminal justice, and citizens' rights. Citizen satisfaction surveys are, nevertheless, one form of practical application toward the future direction of applied information technology solutions.

CONCLUSION

Interactive Web sites and virtual communities represent two of the most innovative ways to generate meaningful, two-way dialogs over the Internet. As the technologies for connecting multiple Internet users in these manners mature, information technology researchers and developers can turn significant attention toward solving the specific application problems posed by unusual clients. Connecting the citizenry of a community with their police department in an efficient and effective manner is just one of a growing number of novel applications made possible by advanced Web site design and virtual community hosting technologies. As community-oriented policing efforts continue to grow in the coming years, it is highly likely that the efforts of information technology professionals will play a critical role in their success—making all of us feel safer at home and at work.

KEY TERMS

Call-Based Policing: Traditional policing approach whereby officers respond to emergency calls for assistance and address crimes and other situations after the fact.

Citizen Satisfaction: Term coined to describe the overall approval rating of services received by citizens within their communities. A 100% rating indicates total satisfaction with services received. Ratings may be taken "per service" or represent satisfaction with an entire government structure.

Community-Oriented Policing: Contemporary policing approach that builds relationships between police officers and the citizens of a community on an ongoing basis. Crime prevention is stressed as a partnership approach before an actual emergency situation(s) develops.

Interactive Web Site: A Web site or page configured so as to invite correspondence between the user and the originator/sponsor of the site. Such sites go beyond passively providing information to those who browse the site. Customarily, there are options to complete online surveys, send e-mail to the sponsor, request specialized or personalized response(s), and so forth.

Internet Privacy: Concerns expressed by Internet users regarding the security and confidentiality of information transmitted electronically. Government agencies and business/industry professional groups share responsibility to address Internet privacy concerns.

Internet-Based Survey: A contemporary survey technique through which researchers may obtain respondents' opinions via online survey processes. Respondents may either be asked to go to a Web site to complete a survey (Web-based) or the survey questionnaire may be e-mailed to the respondents (e-mail-based) for them to complete and return electronically.

IT Applications: Research and development work performed to create a situation-specific bridge between new or existing IT hardware and software technologies and the information needs/wants of a customer. The combination of proper hardware, software, and tailored application delivers a well-rounded IT solution for the customer's problem.

Mail Survey: A traditional survey technique in which a multi-part survey questionnaire is mailed to a randomized sample of individuals (within a larger population) who are asked to complete the questionnaire and return it to the survey researcher for tabulation and analysis.

Service Learning: Educational projects structured to take students out of the traditional lecture-based classroom and involve them in "real-world" problem-solving opportunities of importance to their communities. Students apply theories learned in their classroom studies in a practical manner that generates a completed work product for one or more clients, while helping to cement in students' minds the usefulness of the theoretical concepts under study.

Virtual Community: An online forum or discussion group through which members may interact either in real time or asynchronously. Most virtual communities use discussion groups and message boards that are accessible online to all members. Members correspond by posting messages back and forth within the forum. Membership in a virtual community indicates that the user shares one or more common interests with others in the same forum.

Business Model Application of UML Stereotypes

Daniel Brandon, Jr.
Christian Brothers University, USA

OVERVIEW

The UML (Unified Modeling language) has become a standard in design of object-oriented computer systems (Schach 2004). UML provides for the use of stereotypes to extend the utility of its base capabilities. In the design and construction of business systems, the use of stereotypes is particularly useful stereotypes, and this article defines and illustrates these.

UML STEREOTYPES

“Stereotypes are the core extension mechanism of UML. If you find that you need a modeling construct that isn’t in the UML but it is similar to something that is, you treat your construct as a stereotype” (Fowler & Kendall, 2000). The stereotype is a semantic added to an existing model element and diagrammatically it consists of the stereotype name inside of guillemots (a.k.a., chevrons) within the selected model element. The guillemot looks like a double angle bracket (<< … >>), but it is a single character in extended font libraries (Brown, 2002). The UML defines about 40 of these stereotypes such as “<<becomes>>”, “<<include>>”, and “<<signal>” (Scott, 2001). However, these 40 standard stereotypes are not particularly useful in business models and do not add the meaning necessary for automatic code generation in a UML CASE tool.

One common general use of the stereotype is for a metaclass. A metaclass is a class whose instances are classes, and these are typically used in systems in which one needs to declare classes at run time (Eriksson & Penker, 1998). A similar general use is for powertypes. A powertype is an object type (class) whose instances are subtypes of another object type. Figure 1 shows an example of the use of stereotypes for powertypes (Martin & Odell, 1998).

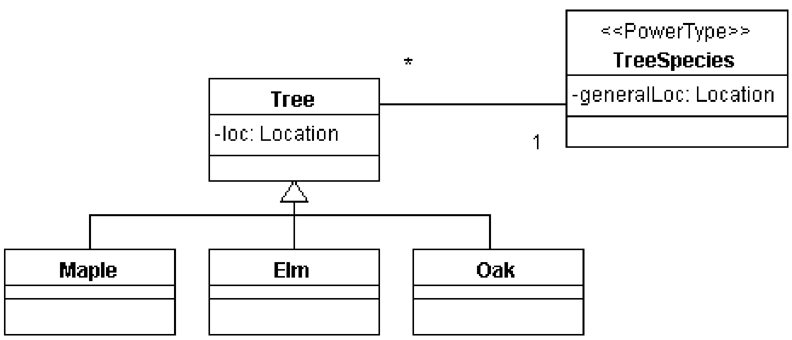
USER DEFINED STEREOTYPES FOR BUSINESS SYSTEMS

In the design of business systems we have found some stereotypes that were useful, and two stereotypes that are extremely useful. When defining stereotypes it is necessary to describe (Eriksson & Penker, 1998):

1. on which (UML) element the user-defined stereotype should be based;
2. the new semantics the stereotype adds or refines; and
3. pne or more examples of how to implement the user-defined stereotype.

A common use of stereotypes in business systems is for interfaces as found in Java or CORBA; this is shown in Figure 2. An interface typically has public functionality but not data (unless holding data for global constants). The class model element has been modified with the “<<interface>>” notation. This is commonly used for

Figure 1.



UML CASE products that do not have separate interface symbols or where these symbols do not allow data (i.e., global constants).

Still another common stereotype usage in business systems is to clarify or extend a relationship. Figure 3 shows a stereotype called “history” which implies a “many” cardinality for history purposes, that is, each person has zero or one current employers but may have many employers in terms of the employee’s history. It may imply some common functionality upon code generation such as (Fowler & Kendall, 2000):

```
Company Employee::getCompany(Date);
```

CODE WRITING AND GENERATION

Most modern UML CASE (Computer Aided Software Engineering) products can generate “skeleton” classes from the UML class diagrams and possibly other diagrams. For business systems design, we need to write the code for our classes (usually implemented in Java or C++) based on both the Structural Model (UML Class Diagram) and the Dynamic Model (UML Activity Diagram). This process is shown in Figure 4. It is very important that consistency between the two diagrams is achieved.

Many such CASE products allow the user to write their own “class generation scripts” in some proprietary scripting language or in a general scripting language (i.e., Python). With user defined stereotypes, the user can

Figure 2.

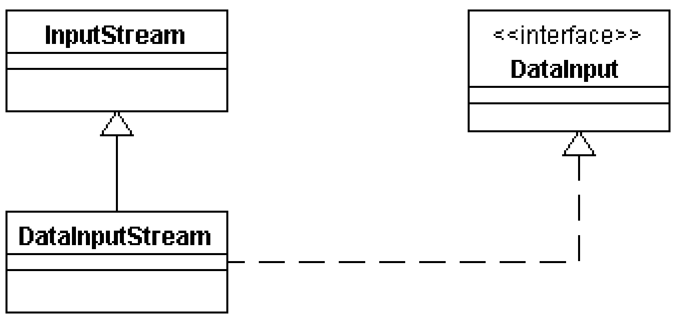


Figure 3.

Figure 4.

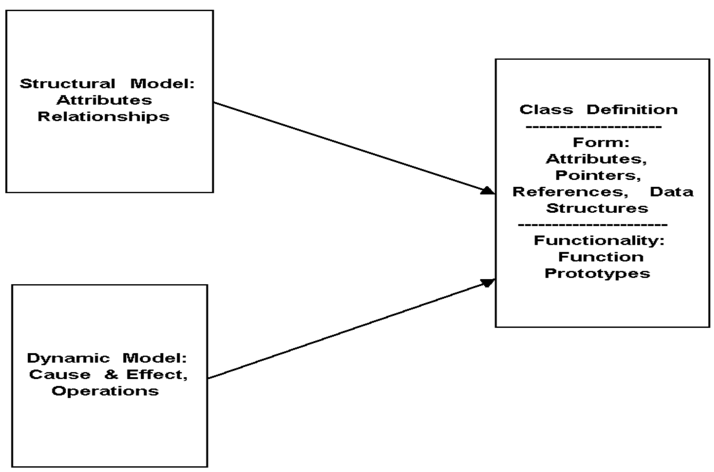

Figure 5.

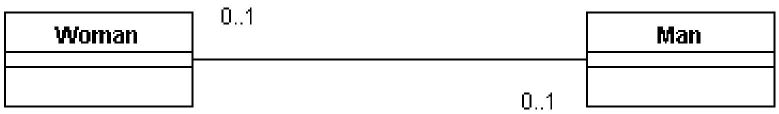

Figure 6.

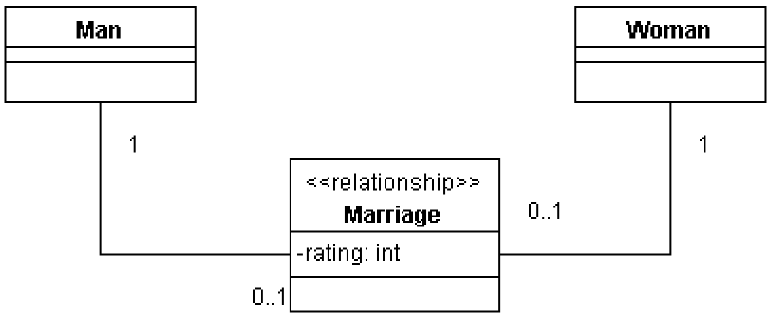

modify the class generation script code to use their stereotypes as needed.

RELATIONSHIP OBJECT TYPES

As an example, consider a simple association between two object types. Often these simple relationships need to be modeled as object types because these relationships have data content and/or functionality. Figure 5 shows a simple association between two object types representing the relationship "current marriage". If we need to maintain an attribute on each marriage (such as rating), then we can more effectively represent the relationship as an object type as shown in Figure 6. Here we use the "relationship" stereotype to indicate that this object type is a relationship; and the code generation can use a more appropriate class representation. Others authors have suggested other notations for relationship object types such as "placeholders" (Martin & Odell, 1998), and UML suggests using the dotted line from a standard object type (class) to the relationship line. But implementing these other diagramming techniques in code generation is difficult and has ambiguity problems.

ACTIVITY DIAGRAMS

A UML Activity Diagram is a state diagram in which most of the states are action states, and most of the transitions are triggered by the completion of these action states. This is the case in most models of business systems. Activity diagrams identify action states, which we call operations (Martin & Odell, 1998), and the cause and effect between operations. Each operation needs to belong to an object type, at least for a C++ or Java implementation. Operations may be nested, and at some point in the design the operations need to be defined in terms of methods. The methods are the processing specifications for an operation and can be so specified in lower lever activity diagrams, pseudo code, or language specific code. Note that the term "methods" may cause some confusion here since in programming terminology, a method is a function defined within a class and it is invoked upon an object (unless it is a static method).

Drawing Methodology

Figure 7 shows a typical UML activity diagram for a simple ordering process. The operations are represented in the ovals and the arrows show the cause and effect scenario or the "triggers". In this diagram, there are two "fork/join" model elements, and the use of "conditional branch states" is also common. Each of the operations must be associated with a particular object type. The standard way to do that in this UML type diagram is to use "swimlanes", and these are the vertical lines shown in Figure 7.

There are two problems with the standard representation as shown in Figure 7. The first problem is that, as the system gets more complex (more object types and

Figure 7.

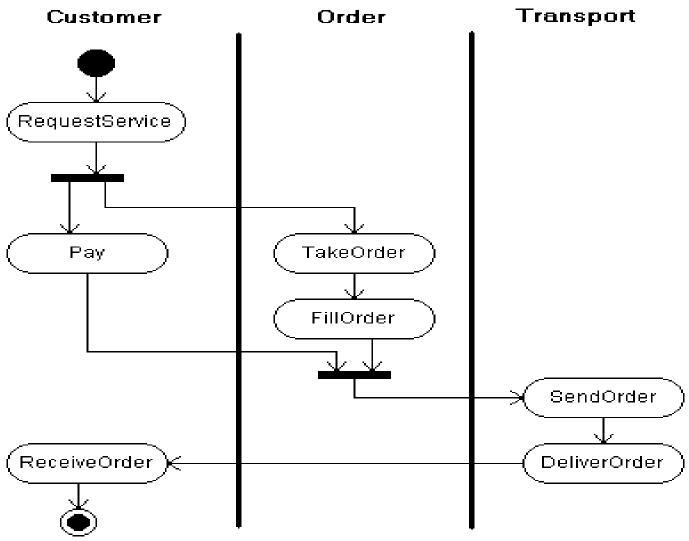

Figure 8.

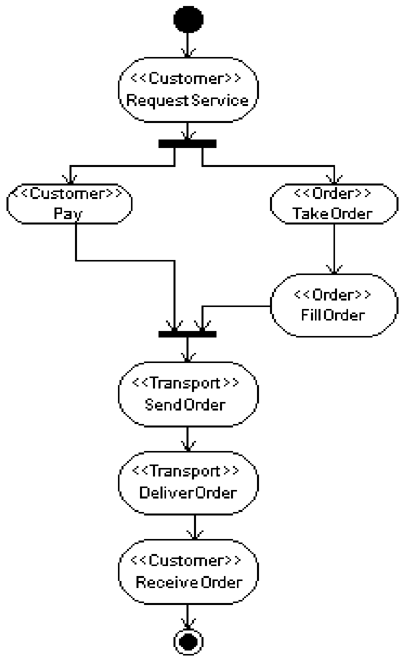

operations), it is very difficult to draw in swimlanes. The second problem is that code generation is very difficult in UML CASE products since you have to scan the geometry of the drawing to find out which operations lay in which swimlanes. A solution to the above problems with standard UML activity diagrams is to use a stereotype for the operation element to indicate the object type (class) owning that operation. Figure 8 shows the same systems as Figure 7 drawn with the "operation owner" stereotype.

Model Consistency

The use of these UML stereotypes allows a greater degree of consistency checking of business models. A final business system design will involve several UML diagram types. For example business systems typically have static structural diagrams (UML Class Diagram) and dynamic diagrams (UML Activity Diagram). These diagrams must be consistent with one another, in particular:

1. The object types (shown with the operation stereotype notation) that contain the operations in activity diagrams must be included on the structural diagrams.
2. The operations shown in the activity diagrams (along with the object types identified with the stereotype notation) must be included as operations in the same object type on the structural diagrams.

For a UML business system example (including implementation in C++), the reader is referred to the full book chapter on this subject (Brandon, 2003).

FUTURE TRENDS

As UML becomes more accepted for general use in the design of business systems, we could expect to see more universal stereotypes being formulated. Eventually, libraries of these stereotypes should become generally available and UML tool vendors would include support for these libraries in their products.

CONCLUSION

UML stereotypes can be very useful in designing business systems. For example, the use of a "relationship" stereotype is helpful in static structural models (UML Class Diagrams) and the use of an "operation owner" stereotype is most helpful in dynamic models (UML Activity Diagrams). These stereotypes aid in both the design/drawing phase and in the implementation (coding) phase of the overall system construction.

KEY TERMS

Activity Diagram: An UML diagram showing operations and triggers between operations; a diagram which shows system dynamics via cause and effect relationships. An activity diagram is a state diagram in which most of the states are action states, and most of the transitions are triggered by the completion of these action states.

CASE: Computer Aided Software Engineering.

Class: A program construct representing a type of thing (abstract data type) which includes a definition of both form (information or data) and functionality (methods); the implementation of the design concept of "object type".

Composition: A new class in an objected programming language that is composed of other classes.

Dynamic Model: A UML model describing dynamic behavior such as state changes, triggers, and object type operations.

Encapsulation: The ability to insulate data in a class so that both data security and integrity is improved.

Framework: A software foundation which specifies how a software system is to be built. It includes standards at all levels both internal construction and external appearance and behavior.

Function: A programming construct where code that does a particular task is segregated from the main body of a program; the function may be sent arguments and may return arguments to the body of the program.

Implementation: The code placed inside of methods. For some languages, this code is pre-compiled or interpreted.

Include: Some code stored separately from the main body of a program, so that this code can be used in many programs (or multiple places in the same program).

Inheritance: A feature of object-oriented languages that allow a new class to be derived from another class (a more general class); derived classes (more specific classes) inherit the form and functionality of their base class.

Interface: The specification for a method ("what" a method does); how that function is called from another program. Interfaces are provided in source form as opposed to implementations which are secure. This allows one to use a method without regard for "how" that method is coded. It also allows multiple implementations of the same interface.

Libraries: A group of functions and/or classes stored separately from the main body of the main program; an "include" file consisting of functions and/or classes.

Metaclass: A class whose instances are classes.

Method: A function defined inside of a class, a processing specification for an operation.

Object Type: A specification of a type of entity, both structure (attributes) and operations (functions) are specified for object types; the notion of object type is a design notion being implemented as a "class".

Operation: A process related notion in UML; operations cause state changes in objects.

Packages: Similar to a library, but just containing classes.

Patterns: A software library for a common business scenario. A framework may be a design framework (possibly expressed in UML [Unified Modeling Language]) or an implementation framework (possibly in C++, Java, or PHP).

Polymorphism: The ability of object-oriented programs to have multiple implementations of the same method name in different classes in an inheritance tree. Derived classes can override the functionality defined in their base class.

Relationship: A connection concept between object types. There are several types of relationships including: aggregation, composition, association, and inheritance (generalization/specialization).

Reuse: Reuse (software) is a process where a technology asset (such as a function or class) is designed and developed following specific standards, and with the intent of being used again.

Separation: The separation of what a method does (interface) from how the method does it (implementation).

Stereotype: The core extension mechanism of UML.

Structural Model: An UML model describing static structure (relationships and properties).

Trigger: One operation invoking another operation; a call from one method to another method within the same or different object type (class).

UML: Unified Modeling Language

Business Model Innovation in the Digital Economy

Chung-Shing Lee
Pacific Lutheran University, USA

INTRODUCTION

Most Internet ventures failed because they did not have viable business models and sustainable long-term strategies. Their business models failed to satisfy the two fundamental questions associated with the characteristics of the Digital Economy (Lee & Vonortas, 2004):

- Does your organization's business model follow the fundamental economic principles of the Digital Economy? That is, what is the underlying economic logic that explains how your organization can deliver value to customers at an appropriate cost?
- Does your organization's business model capitalize on the "disruptive attributes" of the Digital Economy? That is, how can you organization capture the full benefits of the Internet innovation?

These two fundamental questions lead business executives to consider several strategic questions regarding the implementation of an innovative business model in the Digital Economy.

- What are the functions and components of a viable business model in the Digital Economy?
- What are the disruptive attributes of the Internet innovation and how does an organization capitalize on them for competitive advantage and profits?
- What are the differences between the traditional organizational transformation process and the value creation process in the Digital Economy?
- How do transaction costs and network effects in the Internet economy change a company's competitive position?
- How do the cost and revenue structures in the Digital Economy differ from in the traditional industrial economy?

BACKGROUND

A business model is the method of doing business by which a company can generate revenue to sustain itself (Rappa, 2003; Turban, King, Lee & Viehland, 2004). It describes the basic framework of a business. It also tells what market segment is being served (who), the service that is being provided (what), the means by which the service is produced (how) (Chaudhury & Kuilboer, 2002), and how it plans to make money long term using the Internet (Afuah & Tucci, 2003, p. 51).

A firm's business model should also spell out how the company is positioned in the value chain or within the business ecosystem. Weill and Vitale (2001) define an e-business model as a description of the roles and relationships among a firm's consumers, customers, allies, and suppliers that identifies the major flows of product, information, and money, and the major benefits to participants. Timmers (1998) defines business model as an architecture for the product, service, and information flows, including: a description of the various business actors and their roles, a description of the potential benefits for the various business actors, and a description of the sources of revenues.

A business model consists of multiple components and performs different functions. A "new economy" business model requires four choices on the part of senior management, argued by Rayport and Jaworski (2001). These include the specification of a value proposition or a value cluster for targeted customers; a scope of marketspace offering, which could be a product, service, information, or all three; a unique, defendable resource system, that is, the associated resource system to deliver the benefits; and a financial model, which includes a firm's revenue models, shareholder value models, and future growth models. In a similar effort, Chesbrough and Rosenbloom (2002) identify the functions of a business model as: 1) to articulate the value proposition; 2) to identify a market segment; 3) to define the structure of the firm's value chain; 4) to specify the revenue generation mechanisms(s) for the firm; 5) to describe the position of the firm within the value network; and 6) to formulate the competitive strategy to gain advantage over rivals. Other efforts to bring together the various lines of thought and to establish a common denominator for the business model discussion include Alt and Zimmermann (2001) and Dubosson-Torbay, Osterwalder, and Pigneur (2002).

Rappa (2003) identifies nine basic Internet business models: brokerage, advertising, infomediary (e.g., recommender system, registration model), merchant, manufacturer (direct marketing), affiliate (provide commission for online referrals), community (voluntary contributor model or knowledge networks), subscription, and utility (e.g., pay by the byte). In addition, Turban et al. (2004) also identify several types of Internet business models, including name your price, find the best price, dynamic brokering, affiliate marketing, group purchasing, electronic tendering systems, online auctions, customization and personalization, electronic marketplaces and exchanges, supply chain improvers, and collaborative commerce.

In order to sustain a successful business venture, a viable business model should address a number of issues and the dynamics of the respective elements which include: what value to offer customers (strategic goals and value proposition); which customers to provide the value to (scope of offerings); how to price the value (pricing); how much and who to charge for it (revenue models); quantity of resources required and the associated costs to provide the value; what strategies, structures, and processes need implementing to offer value; and the legal issues that may influence the general vision of the business model (Alt & Zimmermann, 2001). In addition, in order to prosper in e-commerce, a firm's Internet business model must capitalize on the "disruptive" attributes and characteristics of the Internet or Digital Economy to enable it to offer innovative solutions and value to customers.

BUSINESS MODEL INNOVATION

Although the changes made possible by the Internet are strategic and fundamental (Ghosh, 1998), the underlying technologies are not radically different from the existing technologies that support business operations. Computing and communication technologies, which are the technological foundations for the Internet, have both been improved incrementally over the past few decades. Bower and Christensen (1995) argue that the technological changes that damage established companies are usually not radically new or difficult from a technological point of view. However, the Internet is considered a disruptive innovation to many businesses. It is disruptive to the traditional way of doing business in that it is transforming the rules of competition and inventing new value propositions and business models. The successful implementation of a viable business model in the Digital Economy requires a paradigm shift. In moving toward e-commerce as an enabler, a business executive must be able to identify the disruptive nature of the innovation and then capture the benefits. Table 1 lists several disruptive attributes of the Internet and e-commerce identified by Lee (2001). Organizations in the Digital Economy must understand and capitalize on the disruptive attributes of the Internet and e-commerce to transform their business models for success.

Business model innovation in the Digital Economy is the use of new knowledge (both technological and market) that capitalizes on the disruptive attributes of the Internet to design and implement an innovative way of offering products or services that customers want. Examples of successful business model innovations that were able to capitalize on some of the disruptive attributes of the Internet include channel innovation (e.g., Dell's build-to-order virtual integration model), process innovation (e.g., Boeing virtual design and e-procurement PART page), customer experience innovation (e.g., Schwab), auction and reverse auction model (e.g., eBay and Priceline), online virtual community (e.g., iVillage), customer-relationship (e.g., Yahoo!), and affiliate network (e.g., Amazon).

VALUE CREATION IN THE DIGITAL ECONOMY

In a competitive market environment, businesses exist to create value for their customers. To understand how a business creates value, a simple "input-transformation-output" model can be utilized to describe the process of value creation. In the Industrial Economy, inputs to a value creation process are raw materials or all of the necessary physical inputs that are required to produce the finished products or services. Outputs are finished products or intermediate goods used as inputs to another transformation or value creation process. Information, such as design and engineering know-how as well as production methods and procedures, is applied to facilitate the "physical" transformation process, which involves one or more of the four value-adding activities: alter, transport, inspect, and store (Meredith & Schaffer, 1999). Management's focus is to make the transformation process more efficient by implementing techniques such as lean manufacturing, total quality management, and business process re-engineering. In contrast, input to the value creation process in the Digital Economy is information (e.g., customer profiles and preferences, i.e., the digital assets, as well as production and distribution status) that firms gather, organize, select, synthesize, and distribute (Rayport & Sviokla, 1995) in the transformation process to provide individual customers a bundle of customized solutions. In the Digital Economy, information is a source of value, and every business is an information business (Earl, 1999). Since physical and digital economies co-exist within a firm or supply chain, management should go beyond concentrating on improving the

B

Table 1. Summary of disruptive attributes of the Internet and e-commerce

Open Platform. Internet provides an open and nonproprietary platform for communication and collaboration. The open source movement in software development (e.g., Raymond, 1999) has contributed to Internet-enabled collaboration and free information sharing.

Network Effects. Network effects exist in the industrial economy (e.g., regular telephone service) but are much stronger in the Digital Economy. For knowledge-intensive products, such as software operating systems, characterized by high upfront costs, network effects, and customer groove-in (Arthur, 1996), achieving a critical mass of installed customer base is vital for success.

Connectivity and Interactivity. E-commerce enables close connections with customers and among supply chain or business ecosystem partners' information systems. The benefits include real-time pricing, flexible products and services versioning, gathering customer information, and a very low cost for the distribution of information goods.

Information Sharing and Exchange. In the Digital Economy, the traditional trade-off between richness and reach in information exchange no longer exists (Evans & Wurster, 1997). Information can reach many customers or business ecosystem partners through the Internet without sacrificing the richness of the contents.

Prosumption. *Prosumption* (Tapscott, 1996) is the term to describe the convergence of design with development process, and the production of goods and services by customers in the e-commerce environment. Internet-enabled collaborations can reduce both concept-to-design and design-to-production cycle times.

Digital Assets. Digital assets are information about customers (e.g., purchasing patterns and profiles). A firm that exploits the Internet should build and utilize its digital assets in order to provide customer value across many different and disparate markets. In the Digital Economy, information is a source of revenue, and every business is an information business (Earl, 1999). A firm should use information to create new businesses and/or reinvent customer relationships through the implementation of a virtual value chain (Rayport & Sviokla, 1995).

Cost Transparency. The vast amount of information about prices, competitors, and features that is readily available on the Internet helps buyers "see through" the costs of products and services (Sinha, 2000).

Industry Scope. Value generated in Internet-enabled business transcends traditional industrial sectors. A firm or business ecosystem (Gossain & Kandiah, 1998) or business Web (Tapscott, Ticoll & Lowy, 2000) must provide unique (and customized) "solutions" (as opposed to single product or service) to individual customers.

Speed and Frequency of Changes. Change is fast and frequent in the Digital Economy. Firms in every industry must learn to adapt quickly to changing business and economic environments. Arthur (1996) states that adaptation in a turbulent environment means watching for the next wave that is coming, figuring out what shape it will take, and positioning the company to take advantage of it.

Virtual Capacity. The advance in network and storage technologies gives customers the feeling that it has infinite virtual capacity to serve them (Afuah & Tucci, 2003). General online merchandise stores (e.g., Amazon.com) and all-purpose business-to-business mega exchanges can offer enormous variety without building huge physical display areas that rack up costs and alienate many shoppers. In addition, virtual communities have infinite capacity for members to participate in discussions and sharing of information anywhere and anytime for as long as they want.

transformation process itself, to focus on leveraging information assets and capitalize on the disruptive features of the Internet and e-business to create more value for the customers. Table 2 compares the transformation processes, and Table 3 presents organizational goals and value creation strategies to assist business executives in designing and implementing a viable business model in the Digital Economy.

COST AND REVENUE MODELS

Rather than searching for the single dominant effect or cost advantage that will provide a long-term sustainable competitive advantage for a company, companies wishing to take full advantage of the disruptive power of Internet commerce must understand the underlying economic logic of the Digital Economy (Lee & Vonortas, 2004). There are four cost factors: scale, scope, switching costs, and transaction costs from both the demand and supply sides that must be examined to determine the viability of the business model.

Internet commerce and virtual value chain have redefined the concepts of economies of scale, allowing small companies to achieve low unit costs in markets dominated by big companies. In addition, online mega store or exchange models are able to spread fixed costs over a larger customer base and offer a wide selection of goods. On the demand side, marketing strategies in markets in which strong network effects exist must be designed to influence customer expectations in order to achieve a critical mass of users.

In the Digital Economy, companies can not only identify and take advantage of the economies of scope in production and distribution, they can also redefine economies of scope by drawing on a single set of "digital assets" to provide value across many different and disparate markets (Rayport & Sviokla, 1995). The combination of demand-side scale and scope economies reinforces network effects in the Digital Economy. For example, Amazon and Yahoo! are able to expand their scope of offerings to provide customers a package of "solutions" across numerous industrial sectors due to the ability to exploit its large installed based of customers.

In the Digital Economy, strategies to increase trading partners' and customers' switching costs include prosumption (e.g., Dell's direct order model), virtual communities (e.g., fool.com), an extranet that allows partners access trade-specific information (Riggins & Rhee, 1998), and developing a strong trust relationship with the end-customers by participating in business ecosystems (Gossain & Kandiah, 1998) or b-Webs (Tapscott et al., 2000).

The Internet has dramatically reduced the costs of many kinds of market transactions. It could prove easier and cost effective to disaggregate many value-creating activities out to the open market so companies can concentrate on their core competences. Companies must also reduce customers' (transaction) costs of doing business with them by making it easy for customers to obtain and

Table 2. Comparison of organizational transformation and value creation processes

	Traditional Economy	**Digital Economy**
Input:	raw materials	Information in digital form
Transformation: (Value Creation)	inspect, alter, transport, and, store	Gather, organize, select, synthesize, and distribute
Output:	Intermediate or finished products/services	Knowledge-or solution-based services
Roles of Information:	A supporting element that facilitates the physical transformation process	A source of value that enable that enables firms to offer new value propositions
	It serves as the connection between the various value-adding stages within a supply chain	Real-time information enables supply chain integration, collaboration, and synchronization

Table 3. Organizational goals and value creation strategies in the Digital Economy

INPUT

Organizational Goals:

- Design innovative products and services to meet customer's latent needs
- Reach the critical mass by building an installed base of customer
- Take advantage of the network effects to build a successful e-business

Management Strategies:

- Increase collaboration throughout the product design process
- Synchronize product design requirements within a supply chain or business ecosystem in the early stages of the development process
- Leverage knowledge capital critical to the design process through external linkages (e.g., alliance partners, research labs and universities)
- Achieve demand-side economies of scale by increase installed customer base's collective switching costs
- Reduce customer's transaction costs (i.e., make it easy for customers to do business with you)

TRANSFORMATION VALUE ACTIVITIES

Organizational Goals:

- Improve efficiency and effectiveness of business or supply chain transformation process
- Match the performance of the physical activities to the digital world

Management Strategies:

- Sustaining innovation approach: Apply conventional management techniques (e.g., lean manufacturing and total quality management) to improve process efficiency
- Achieve production economies of scale and scope
- Disruptive innovation approach: Take advantage of the lower transaction costs in the digital economy to redesign organizational structures and to reconfigure value creation systems

OUTPUT

Organizational Goals:

- Create numerous innovative knowledge- or solution-based products and services
- Provide a package of solutions to satisfy or exceed customer's expectations

Management Strategies:

- Transform value proposition by taking advantage of the network effects and demand-side economies of scope, i.e., leverage on a single set of "digital assets" to provide many solutions to individual customers
- Increase user's (or buyer's) switching costs by offering value across many different and disparate markets
- Influence users' decision-making process through the use of extranet and Web-based collaborative planning tools
- Look beyond costs as the sole arbiter of value

compare product-related information, identify customer decision process, and be able to provide assistance.

Internet commerce provides companies with new sources of revenues via opportunities to offer new "customized" services or solutions in addition to, and sometimes independent of, the traditional products or services sales. In the Digital Economy, pricing can be done in real time. Product can even price below unit cost (in the long run) as long as other e-commerce revenue models, such as online advertising and referral fees, are sustainable. Internet business models also offer companies new opportunities to test prices, segment customers, and adjust to changes in supply and demand. They can create enormous value in the process because online pricing allows companies to make adjustments in a fraction of the time and to profit from even small fluctuations in market conditions, customer demand, and competitors' behavior (Baker, Marn & Zawada, 2001).

Finally, Tapscott et al. (2000) and Gossain and Kandiah (1998) argue that in the new business ecosystems or b-Webs, customers perceive greater value in one-stop shopping with a known and trusted company. Customers receive "a package of solutions" that satisfies their explicit and implicit needs, rather than purchasing individual products from different vendors. For example, Internet companies, such as Amazon.com, Edmunds.com, and Marshall Industries, are perceived as a single "trusted" source to offer complementary products and services provided by their ecosystem partners to end-customers.

MANAGERIAL IMPLICATIONS

This article identifies major elements and provides specific guidelines to assist organizations in designing an innovative business model in the Digital Economy. A viable business model in the Digital Economy must transform value propositions, and organizational structures and systems to enhance value creation (see Tables 2 and 3). It must be able to take advantage of the Internet network effects and other disruptive attributes (see Table 1) to achieve and sustain a critical mass of installed base of customer. A viable business model in the Digital Economy must also develop trust relationships with business ecosystem partners and customers through virtual communities to reduce their costs of doing business with the company, and to increase their costs of switching to other vendors. Companies must build and maintain a large set of digital assets and leverage them to provide value across many different and disparate markets. Finally, companies must identify customers' latent needs and transform their business models from a product- or component-based model to a knowledge- or solution-based model.

FUTURE TRENDS

Future research on the analysis, design, development, implementation, and controlling of business model innovation in the Digital Economy include, but are not limited to the following areas:

- Analytical and architectural frameworks for new business models
- Models and modeling techniques
- Specific details and guidelines for business model innovation
- Specific industry perspectives on business models (e.g., converging of technologies and industries, media industry, and communication industry)
- Sustainable business models for digital contents, mobile commerce, collaborative commerce, peer-to-peer architecture
- Trust and business model innovation in business ecosystems

CONCLUSION

A viable business model must follow the fundamental economic principles outline in this article (i.e., costs and revenue models). Most important, an innovative business model in the Digital Economy must capitalize on the disruptive attributes of Internet commerce. E-business initiatives can be implemented as a sustaining innovation to enhance the current way of doing business (i.e., focus primarily on improving the efficiency of organizational transformation). In such case, companies fail to identify and capitalize on many of the Internet's opportunities. Business model innovation in the Digital Economy requires business planners and strategists to recognize and capture the full benefits of the disruptive characteristics of the Internet and e-commerce.

KEY TERMS

Business Model: The method of doing business by which a company can generate revenue to sustain itself (Rappa, 2003).

Digital Assets: The information (in digital form) a company collected about its customers. Companies that create value with digital assets may be able to reharvest them through a potentially infinite number of transactions (Rayport & Sviokla, 1995).

Digital Economy: The economy for the age of networked intelligence (Tapscott, 1996). The Digital Economy is also a knowledge economy. Information, in all its forms becomes digital, is the input of organizational transformation or value creation process.

Disruptive Innovations: Innovations that typically present a different package of performance attributes—ones that, at least at the outset, are not valued by existing customers. The performance attributes that existing customers value improve at such a rapid rate that the new innovation can later invade those established markets (Bower & Christensen, 1995). Innovations are disruptive when the current organization lacks the necessary models of competitive architecture and organizational capabilities, and are therefore unable in critical ways to do what must be done (Miller & Morris, 1999).

Economies of Scale: *Supply-side economies of scale*—Reductions in unit costs resulting from increased size of operations. *Demand-side economies of scale*—The value of a technology or product increases exponentially as the number of users increase (network effects lead to demand-side economies of scale).

Economies of Scope: *Supply-side economies of scope*—Cost of the joint production of two or more products can be less than the cost of producing them separately. *Demand-side economies of scope*—A single set of digital assets can provide value for customers across many different and disparate markets.

Network Effects or Network Externalities: A technology or product exhibits network externalities when it becomes more valuable to users as more people take advantage of it (Katz & Shapiro, 1986).

Switching Costs: Investment in multiple complementary and durable assets specific to a particular technology or system (Tirole, 1988).

Transaction Costs: Costs associated with contractual relationships in a market economy, such as costs that the consumer or the producer pays to make the market transaction happen.

B

Business Modeling with Client–Oriented Requirements Strategy

María Carmen Leonardi
UNCPBA, Argentina

INTRODUCTION

Rational unified process (RUP) (Jacobson, Booch, & Rumbaugh, 1999) is an iterative, incremental and use case driven methodology. RUP starts the software development with the requirements capture stage, taking into account that *"the major challenge is that the customer, who we assume to be primarily a non-computer specialist, must be able to read and understand the result of requirements capture. To meet this challenge we must use the language of the customer to describe these results"* (Jacobson et al., 1999, p. 113). As requirements are originated from the system's context, RUP proposes the definition of it through a business model, more concretely, a *business use cases model* and a *business objects model*. There are several approaches to enhance this first stage of the RUP development. In this article, the author describes the most important proposals and briefly presents her strategy that defines a set of activities and heuristics to define a UML conceptual object model starting from stakeholder oriented requirements models. These models describe the overall context in which the software will be developed and operated, known as universe of discourse (Leite & Leonardi, 1998). The strategy enhances traceability (Pinheiro, 2000) between requirements and RUP models.

BACKGROUND: BUSINESS MODELING IN THE CONTEXT OF RUP

As mentioned earlier, RUP proposes a business model to define the organization without defining any explicit techniques or strategy to guide the construction of it. There are some works that present different proposals to enhance this stage, taking into account different starting points and perspectives. In this section, the author briefly describes the most important.

From the RUP/UML and business technology community, there are some proposals to model the organization. The work of Eriksson and Penker (2000) presents a combination of techniques to model the business with UML organization models representing processes, events, resources, goals, business rules and general mechanisms. The business architecture and its elements are represented from four different views: business view, business process, business structure and business behavior. They propose a set of UML business extensions to represent those concepts using the standard UML extension mechanisms. The authors propose three categories of business patterns to describe common modeling solutions during the business modeling: resource and rules patterns, process patterns and goals patterns. In Barros, Duddy, Lawley, Milosevic, Raymond, and Wood (2000), an interesting proposal is presented extending UML in order to define the organizational enterprise model for systems that will be implemented using distributed objects technology. This model is described in terms of processes, entities, lists and events of the business. Finally, in Marshall (1999), some key concepts of an enterprise and their components are modeling. Specifically, they define the purpose, processes, entities and organization of the enterprise with standard UML diagrams.

From the requirement community, one of the most important works is Santander and Castro (2002). This strategy allows the definition of use cases starting from the i* organizational model. This strategy captures organizational requirements to define how the system fulfills the organization goals, why it is necessary, what the possible alternatives are and what the implications to the involved parts are, all of them represented by the two i* models. The approach presents some guidelines to develop use cases from these models. This approach is a goal-based methodology useful for RUP software requirements definition phase since it generates use cases for the software system.

Although it is not directly related to RUP business modeling, one of the most important works in generating conceptual object-oriented specifications from natural language is the strategy presented in Juristo, Moreno, and López (2000). This strategy consists of analyzing natural language-based descriptions (expressing the problem to be solved) from a syntactic and semantic perspective in order to identify the key elements of the object-oriented conceptual model (modeling the problem in the computer). The proposal is a semi-formal model that lets organizations systematically produce object-oriented models. It is based on two components: a mathematical component that defines formal rules to identify the elements of the object-oriented conceptual models from the natural language structures; and a method that guides the analyst in the development of such models, by means of the definition of a set of defined steps.

A CONSTRUCTION PROCESS OF THE RUP BUSINESS MODEL BASED ON STAKEHOLDER-ORIENTED REQUIREMENTS MODELS

During the early stages of development, when the interaction with the stakeholders is crucial, the use of natural language-oriented requirements engineering techniques seems necessary in order to enhance communication. These techniques are very useful to obtain a first specification of the universe of discourse that will be easily validated with the stakeholders and will be the basis for a development. Therefore, the necessity of integrating stakeholder-oriented requirements models and strategies to enhance the construction process of the business model keeping the RUP philosophy of using the customer language is highlighted. Stakeholder-oriented models are based on natural language, therefore the communication between engineers and stakeholders are facilitated. The author presents a strategy based on heuristics that guide the construction of the RUP starting from the stakeholders-oriented requirements models. Due to space reason, the author does not present the full strategy, which may be found in Leonardi (2003). The section is organized in three subsections: one to present the stakeholder-based models, the second presents the construction process and finally, in the third, its use is discussed.

Stakeholder-Oriented Requirements Models

The models presented in this section are well-known, used and accepted by the requirements engineering community (Leite et al., 1997; Leite & Leonardi, 1998). In this proposal, they are used as the first models to obtain a RUP business object model. The models are: language extended lexicon model, scenario model and business rules models.

- **Language Extended Lexicon:** The language extended lexicon (LEL) (Leite et al., 1997) is a structure that allows the representation of significant terms of the universe of discourse. The purpose of the lexicon is to help understand the vocabulary and its semantics, leaving the comprehension of the problem for a next step. It unifies the language allowing communication with the stakeholder. LEL is composed of a set of symbols with the following structure: *symbol name* “ word or phrase and set of synonyms; *notions* defining the denotation of the symbol; and *behavioral responses* describing the symbol connotation. In the description of the symbols, two rules must be followed simultaneously: the “closure principle” that encourages the use of LEL symbols in other LEL symbols forming a graph, and the “minimum vocabulary principle” where the use of symbols external to the application language is minimized. LEL terms define objects, subjects, verbal phrase and states. Figure 1 shows the heuristics to define each type of symbol.
- **Scenario Model:** A scenario describes situations of the universe of discourse (Leite et al., 1997). A scenario uses natural language as its basic representation, and it is connected to LEL. Figure 2

Figure 1. Heuristics to represent LEL terms

Subject	Notions: who the subject is.
	Behavioral responses: register actions executed by the subject.
Object	Notions: define the object and identify other objects with which the former has a relationship.
	Behavioral responses: describe the actions that may be applied to this object.
Verb	Notions: describe who executes the action, when it happens, and procedures involved in the action.
	Behavioral responses: describe the constraints on the happening of an action, which are the actions triggered in the environment and new situations that appear as consequence.
State	Notions: what it means and the actions which triggered the state.
	Behavioral responses: describe situations and actions related to it.

describes the components. In Leite, Hadad, Doorn, and Kaplan (2000), the scenario construction process is described.

- **Business Rule Model:** We define business rules as statements about the enterprise's way of doing business, reflecting business policies (Leite & Leonardi, 1998). Organizations have policies in order to: satisfy the business objectives, satisfy customers, make good use of resources, and conform to laws or general business conventions. The business rule model distinguishes between functional rules and non-functional rules. *Functional rules* are general policies regarding organization functionality. Non-functional rules are divided in *macrosystem rules* that describe policies that constrain the behavior and structure of the organization and *quality rules* that are demands of the organization on the characteristics of its processes or products. Rules are built following some syntax patterns, in which the main components must be a LEL symbol. In Leonardi, Leite, and Rossi (1998), the authors describe the construction process.

THE CONSTRUCTION PROCESS OF THE RUP BUSINESS MODEL

Once the models are constructed and validated with the stakeholders, they have to be manipulated in order to be mapped to a RUP business model, more concretely a business use case model and a business object model. The strategy is organized in four stages, defining for each one a set of heuristics that guide the definition of the different models enhancing traceability. The stages are:

- **Business Use Cases Model Definition:** The business use case starting from the scenario model is described; each scenario will be a business use case. As there is a well-defined process for the scenario construction, the use cases obtained are a representative and validated group defining the behavior of the main actors of the organization.
- **Business Classes Identification and Definition:** The proposed heuristics in this stage guide the identification of the classes starting from the LEL symbols, taking into account the taxonomy of these symbols in order to define them as classes or responsibilities (see Figure 1). It is important to remark that when the universe of discourse is analyzed, active and passive entities can be distinguished. This distinction is reflected in the classification as actor or resource considered in the scenario model and as object or subject considered in the LEL. As business classes define the universe of discourse, they will have the same distinction. Therefore, primary and secondary classes can be considered. Although from the object-oriented paradigm there is no distinction between the kind of objects, heuristics, to define them, are different because inside the universe of discourse, they have different semantics; the primary classes are those that represent active entities, and the secondary classes are the ones that represent passive or resources entities. Therefore, we propose different heuristics for defining them: primary classes are defined from the subject LEL terms and some of the verbal phrase LEL terms; and secondary classes are derived principally from object LEL terms. Responsibilities of the classes are defined taking into account the behavioral responses of the corresponding LEL terms. As each business use case is a detailed description of a particular situation, it is used to complete the responsibilities and collaborations between the classes that appear in it as LEL terms. This is possible due to the traceability between LEL terms and classes. Finally, the functional business rules model is utilized to add more responsibilities to the defined classes or to create new ones if the relevance of a set

Figure 2. Components of scenario

Title: identifies a scenario.
Objective: describes the purpose of the scenario.
Context: defines geographical and temporal locations and preconditions.
Resources: identify passive entities with which actors work.
Actors: detail entities actively involved in the scenario.
Set of episodes: each episode represents an action performed by actors using resources.

Note: Notions of c*onstraint* and e*xception* are added to some of the components of a scenario: a *constraint* refers to non-functional requirements and may be applied to context, resources or episodes. An *exception*, applied to episodes, causes serious disruptions in the scenario, asking for a different set of actions which may be described separately as an exception scenario.

of related business rules justifies the creation of a new class to represent them.

- **Business Object Diagram Definition:** Once the classes and their responsibilities have been identified, structural aspects of the classes are modeled (methods, attributes, relationships) defining a UML object diagram. Attributes are defined taking into account the notions of the corresponding LEL terms. Methods are derived from the previously defined responsibilities; the heuristics consider the possibility of split responsibilities in several methods or group some of them into a single method, with the aim of enhancing the quality of the interface of the defined classes. LEL terms corresponding to the defined classes are analyzed in order to define inheritance, part-of and associations relationships between them. A set of heuristics is also defined to attach non-functional rules to the involved class. Rules are modeled as OCL expressions (Warmer & Kleppe, 2003) associated to methods, attributes or associations. The business object diagram defines the universe of discourse, and as such, it does not present software limits, leaving this task for the analysis stage where the actors of the system are defined and the use cases of the software system are identified from the business use cases.
- **Business Use Cases Model Realization:** The next step is to describe the *business use cases* based on the previously defined classes. Business use cases realizations may be defined by means of interaction diagrams (collaboration or sequence) or activity diagrams. The heuristics may be used as an informal validation mechanism, because by applying them, the business use cases are "executed", and the engineer may analyze if the defined classes and their responsibilities perform the behavior of them.

Analyzing the Use of the Strategy

The strategy was used in several case studies. From this experience, some advantages of it are mentioned:

- Natural language allows communication with stakeholders, enhancing models validation.
- LEL and business rules models allow engineer to define objects from a global perspective, enhancing the specific behavior defined in a use case.
- From the object-oriented perspective, this strategy improves the analysis phase, by the incorporation of stakeholder-oriented techniques.
- From the requirements perspective, this strategy extends the requirements capture phase to the definition of an object-oriented conceptual model that allows engineer to visualize the problem in terms of objects, the same concept that he will use in the rest of the development process. A conceptual object model is obtained that serves as a basis for RUP oriented development, reducing the gap between analysis and design phases allowing that transition between conceptual modeling and design phase results in a more natural process (Kotonya & Sommerville, 1998).
- This strategy identifies and maintains the trace relationships generated by the application of the heuristics, allowing traceability between the RUP business model and LEL, scenarios and business rules models. It also defines internal RUP models traces and internal requirements models traces. Each trace relationship links two or more model components, defining its semantics, that is, the origin component, the source, cardinality and the kind of relationship between the components.

The main difficulties found during the application of the strategy are:

- One of the most significant problems is the level of detail of the specifications. Depending on the level, more or less classes can be found. But, this problem is inherent to specifications, independent on a particular strategy.
- It is very important to deal with the redundancy between the LEL, business rules and scenarios to avoid translating it to the object model.
- As the strategy generates a lot of traceability information, it is necessary to define what trace relationships are managed, since if all of the possible links are generated, the maintaining will be tedious, time consuming and labor-intensive.

FUTURE TRENDS

Integration between business modeling, requirements engineering techniques and the rest of the software development steps are essential. It is necessary to define some strategy to guide in the translation of the requirements models to an architectural model, in order to obtain a first description of an adaptable architecture that reflects the non-functional and functional requirements. New proposals are emerging from different areas with the objective of working in the integration (*STRAW*, 2003). Moreover, research must be set in the context of the OMG model driven architecture (MDA, 2004), to define business models that can be used as the computer independent model (CIM) and requirements model that can be used as the platform independent model (PIM) integrated to a completely MDA software development.

CONCLUSION

In this work, the author presented a brief survey of proposals that enhance the first stage of RUP development where the RUP business model is defined through the business use cases and the business-objects models. The author also presented her strategy based on well-known and used stakeholder-oriented requirements models to define this model. This strategy is compatible with the aims of RUP of enhancing the interaction with the customer by the use of easy reading and understanding models (Jacobson, Booch, & Rumbaugh, 1999). As use cases model is the key model of RUP, our strategy has incorporated them by means of scenario representation, but it has also added complementary models to enhance the knowledge of the business organization. LEL model and the business rules model also increase the abstraction degree of object-oriented modeling, allowing engineers to define objects from a global perspective, enhancing the specific behavior defined in a use case. The strategy proposes a set of heuristics to guide in the manipulation of the great quantity of information generated by the requirements models to define the RUP business model. A trace mechanism is defined in order to enhance traceability between models.

KEY TERMS

Business Model: A model of a company that shows the company's function in the world, what it does, how and when. It is designed to serve the needs of one or more types of handlers, and it should contain the information these handlers need " no more and no less (Marshall, 1999).

Conceptual Model: A mental model that allows understanding and simplification of the problem. The purpose of domain modeling is to contribute to an understanding of the system's context, and thereby also to understanding of the system's requirements as they originate from this context. The system's internal way of solving this problem will be dealt with in the analysis, design and implementation workflows (Jacobson, Booch, & Rumbaugh, 1999).

Rational Unified Process: A use case driven, architecture-centric, iterative and incremental software development process that uses UML to describe the artifacts (Jacobson, Booch, & Rumbaugh, 1999).

Requirements: Defined during the early stages of a system development as a specification of what should be implemented. They are descriptions of how the system should behave, application domain information, constraints on the system's operation, or specifications of a system property or attribute. Sometimes they are constraints on the development process of the system (Kotonya & Sommerville, 1998).

Requirements Traceability: The ability to define, capture and follow the traces left by requirements on other elements of the software development environment and the traces left by those elements on requirements (Pinheiro, 2000).

Stakeholder: People or organizations who will be affected by the system and who have a direct or indirect influence on the system requirements. They include end-users of the system, managers and others involved in the organizational processes influenced by the system, engineers responsible for the system development and maintenance, customer of the organization who will use the system to provide some services, external bodies such as regulators or certification authorities (Kotonya & Sommerville, 1998).

Unified Modeling Language (UML): A standard graphical language for visualizing, specifying, constructing, and documenting the artifacts of a software-intensive system (Booch, Rumbaugh, & Jacobson, 1999).

B

Business Process and Workflow Modeling in Web Services

Vincent Yen
Wright State University, USA

INTRODUCTION

In large organizations, typical systems portfolios consist of a mix of legacy systems, proprietary applications, databases, off-the-shelf packages, and client-server systems. Software systems integration is always an important issue and yet a very complex and difficult area in practice. Consider the software integration between two organizations on a supply chain; the level of complexity and difficulty multiply quickly. How to make heterogeneous systems work with each other within an enterprise or across the Internet is of paramount interest to businesses and industry.

Web services technologies are being developed as the foundation of a new generation of business-to-business (B2B) and enterprise application integration (EAI) architectures, and important parts of components as grid (*www.grid.org*), wireless, and automatic computing (Kreger, 2003). Early technologies in achieving software application integration use standards such as the common object request broker architecture (CORBA) of the Object Management Group (*www.omg.org)*, the distributed component object model (DCOM) of Microsoft, and Java/RMI, the remote method invocation mechanism. CORBA and DCOM are tightly coupled technologies, while Web services are not. Thus, CORBA and DCOM are more difficult to learn and implement than Web services. It is not surprising that the success of these standards is marginal (Chung, Lin, & Mathieu, 2003).

The development and deployment of Web services requires no specific underlying technology platform. This is one of the attractive features of Web services. Other favorable views on the benefits of Web services include: a simple, low-cost EAI supporting the cross-platform sharing of functions and data; and an enabler of reducing integration complexity and time (Miller, 2003). To reach these benefits, however, Web services should meet many technology requirements and capabilities. Some of the requirements include (Zimmermann, Tomlinson & Peuser, 2003):

- *Automation Through Application Clients:* It is required that arbitrary software applications running in different organizations have to directly communicate with each other.
- *Connectivity for Heterogeneous Worlds:* Should be able to connect many different computing platforms.
- *Information and Process Sharing:* Should be able to export and share both data and business processes between companies or business units.
- *Reuse and Flexibility:* Existing application components can be easily integrated regardless of implementation details.
- *Dynamic Discovery of Services, Interfaces, and Implementations:* It should be possible to let application clients dynamically, i.e., at runtime, look for and download service address, service binding, and service interface information.
- *Business Process Orchestration Without Programming:* Allows orchestration of business activities into business processes, and executes such aggregated process automatically.

The first five requirements are technology oriented. A solution to these requirements is XML-based Web services, or simply Web services. It employs Web standards of HTTP, URLs, and XML as the lingua franca for information and data encoding for platform independence; therefore it is far more flexible and adaptable than earlier approaches.

The last requirement relates to the concept of business workflow and workflow management systems. In supply chain management for example, there is a purchase order process at the buyer's side and a product fulfillment process at the supplier's side. Each process represents a business workflow or a Web service if it is automated. These two Web services can be combined into one Web service that represents a new business process. The ability to compose new Web services from existing Web services is a powerful feature of Web services; however, it requires standards to support the composition process. This article will provide a simplified exposition of the underlying basic technologies, key standards, the role of business workflows and processes, and critical issues.

WHAT ARE "WEB SERVICES"?

The phrase "Web services" has been defined in many different ways (Castro-Leon, 2002; Ambrosio, 2002). In the working draft of Web Services Architecture (W3C, 2003), it is defined as:

"…a software system designed to support interoperable machine-to-machine interaction over a network. It has an interface described in a machine-processable format (specifically WSDL). Other systems interact with the Web service in a manner prescribed by its description using SOAP-messages, typically conveyed using HTTP with an XML serialization in conjunction with other Web-related standards."

A simplified Web service architecture based on this definition is conceptually depicted in Figure 1.

Main features of Web services are that services (Burner, 2003):

1. Expose programmable application logic.
2. Are accessed using standard Internet protocol.
3. Communicate by passing messages.
4. Package messages according to the SOAP specification.
5. Describe themselves using WSDL.
6. Support the discovery of Web services with UDDI.
7. Are loosely coupled.

WEB SERVICES TECHNOLOGIES

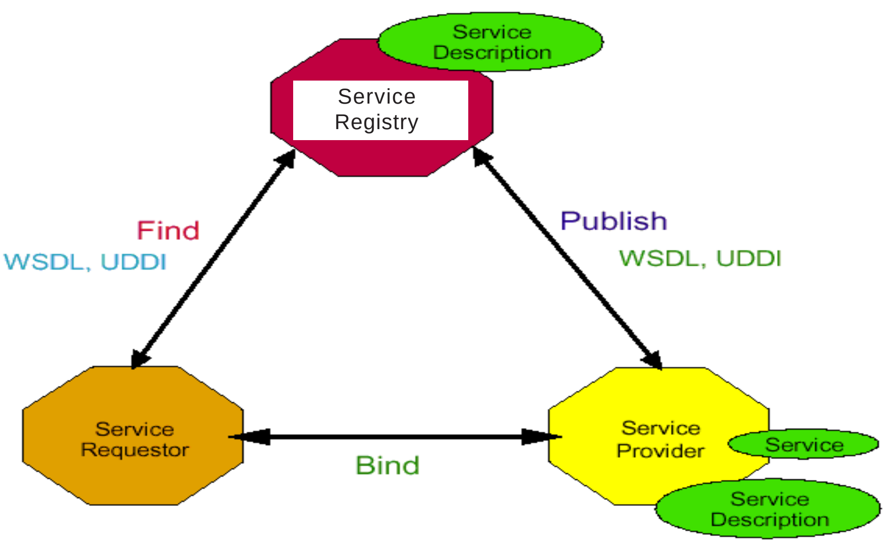
Three XML-based protocols—one for communication, one for service description, and one for service discovery—have become de facto standards (Curbera et al., 2002). They are:

- SOAP (the Simple Object Access Protocol) provides a message format for communication among Web services.
- WSDL (the Web Services Description Language) describes how to access Web services.
- UDDI (the Universal Description, Discovery, and Integration) provides a registry of Web services descriptions.

Another area of importance in Web services is the capability of constructing new composite Web services from existing Web services. Many standards in this area are being developed (Van der Aalst, 2003), for example, Business Process Execution Language for Web Services (BPEL4WS) by IBM and Microsoft (Fischer, 2002). It is not clear if there will be a common standard. However, regardless of the differences among vendor groups, the composition of Web services uses the concept of business processes and workflow management.

As noted earlier in this article, the development and deployment of Web services do not require a particular platform, nevertheless most Web services development

Figure 1. A simplified Web services architecture (W3C, 2003)



is being accomplished today using either Microsoft .NET or Sun Microsystems' J2EE specifications (Miller, 2003). It is not clear which of the two competing platforms is most suitable for the developers and their future directions (Miller, 2003; Williams, 2003).

THE ROLE OF BUSINESS PROCESSES AND WORKFLOW MODELING IN WEB SERVICES COMPOSITION

The need to integrate software components within and across companies is to economically re-use components for supporting business processes automation. A business process such as borrowing a book from a library may involve: 'check user identification', 'enter call numbers', and 'generate a receipt' activities. Each activity in the business process is a piece of work and is performed according to a sequence defined by business rules. That is, a business process contains a workflow (Allen, 2000).

The Workflow Management Coalition (Norin & Shapiro, 2002) defines the *business process* as:

"…a set of one or more linked procedures or activities which collectively realize a business objective or policy goal, normally with the context of an organizational structure defining functional roles and relationships."

Workflow management is further defined as:

"…the automation of a business process, in whole or part, during which documents, information, or tasks are passed from one participant to another for action, according to a set of procedural rules."

To understand complex business processes, workflow modeling techniques provide logical descriptions of the flow of activities that achieves the goal of the process. Companies compete to provide workflow-based tools for Web-service integration (Ganesarajah & Lupu, 2002). Such tools allow developers to use the concept of workflow to build complex business processes from Web services. Since a complex business process contains a large number of activities, managing the execution of these activities, (e.g., monitoring the workflow progress, sending activities to the right servers, and scheduling activities for execution) can be critical. The advent of the workflow management system or the workflow engine software is to serve this purpose.

Existing methods for creating business processes are not designed to work with cross-organizational components and Web services platforms (Peltz, 2003). This gives rise to multiple Web services standards for business process modeling and execution (Van der Aalst, 2003). However, regardless of standards, the composition of Web services requires the modeling (and construction) of a Web service from one party perspective and the interaction among each involved party. This is accomplished by using business process and workflow modeling in two aspects: 1) specifying internal details of the composition to offer an executable business process, and 2) planning the message sequences between parties and sources. The former is called *orchestration* and the latter is called *choreography* in creating business processes from composite Web services (Peltz, 2003).

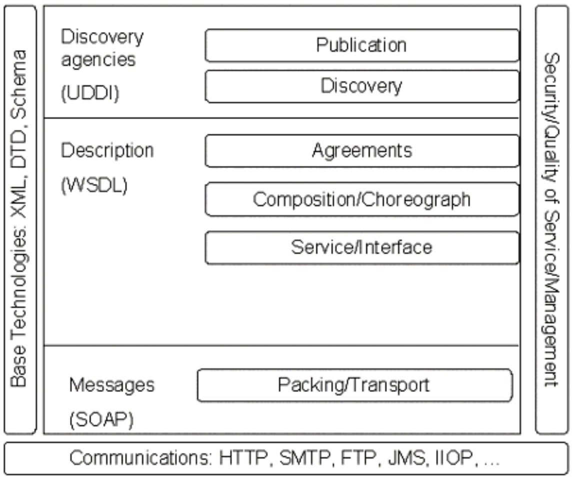
OUTSTANDING AND CHALLENGING ISSUES IN WEB SERVICES

Web service technology is still emerging, and researchers are still developing important functionalities for meeting technical and business requirements. Although some Web service standards such as SOAP, WSDL, and UDDI have been widely accepted, others such as Web services composition language are being developed by many organization and industry groups (Van der Aalst, 2003). These languages build upon the concept of workflow management systems to allow for orchestrating a group of required Web services in support of a business process. Due to real-world demands for more complex business problems integration, many companies and standards organizations have built extensions to the core specifications. Unfortunately, few of these extensions are interoperable. To resolve this problem and ensure application interoperability and extensibility, the W3C (2003) is developing a formal Web service architecture. There are different competing approaches (Kleijnen & Raju, 2003) to this problem, notably, the ebXML specifications suite, an independent technology for business-to-business integration (Patil & Newcomer, 2003). Additional challenges lie in XML and Web services security standards (Naedele, 2003). Obviously, the creation and support of Web service standards for mission-critical applications is a challenging, complex, and time-consuming process. Figure 2 adapted from W3C (2003) shows more completely the critical service areas of Web services.

A brief explanation of some Web service architectural components follows:

- *Packing/Transport:* This is the message layer that packs information into messages and transports it between parties.
- *Service/Interface:* Describes operational interfaces of a Web service.

Figure 2. A Web service architecture



- *Composition/Choreography:* Describes how services interact with each other in business processes.
- *Agreements:* The service level agreement defines the specific performance, usage, costs, and so forth, and the business level agreement defines a contractual agreement between the two business partners in business engagement using Web services.
- *Security Management and Quality of Service:* Describes reliability and security characteristics.

Each component has varying degrees of achievement by industries and standard setting organizations. However, standards are not enough to realize the great expectations of Web services. Langdon (2003) describes several key inhibitors of Web services adoption, including the lack of complementary service providers for metering, accounting, and billing services; the lack of ready-to-use Web services from either internal sources or third parties; and the lack of third-party support of how to decompose an automation problem and how to deliver it.

CONCLUSION

Web services involve many technologies and standards. Although a very young field, it has made tremendous progress in the last two years. Software vendors like Microsoft's .NET and Sun's J2EE have tools for Web services development. However, the field has many challenging issues, with standards being one of them. This article provides an overview of Web services in general and the role of workflow in developing a Web services application in particular. Since workflow modeling in the composition of Web services utilizes knowledge of business processes, that is where MIS professionals should be actively involved.

KEY TERMS

EAI: Projects involving the plans, methods, and tools aimed at modernizing, consolidating, and coordinating the computer applications and data in an enterprise.

Grid Computing: A form of distributed computing that involves coordinating and sharing computing, application, data, storage, or network resources across dynamic and geographically dispersed organizations.

HTML (Hypertext Markup Language): A standard language for representing text, formatting specifications and hyperlinks.

HTTP (Hypertext Transfer Protocol): The standard for requesting and transmitting information between a browser and a Web server.

Java/RMI: A Java application programming interface known as remote method invocation.

Protocol: A set of rules and procedures governing transmission between two points in a network.

URL (Universal Resource Locator): A text string used as a reference to a Web resource. A URL consists of a protocol, a host name, and a document name.

XML (Extensible Markup Language): An extension of HTML that is being extensively used for transmitting data/information on the Internet.

Business Processes and Knowledge Management

John S. Edwards
Aston Business School, UK

INTRODUCTION

Knowledge has been a subject of interest and enquiry for thousands of years, since at least the time of the ancient Greeks, and no doubt even before that. "What is knowledge" continues to be an important topic of discussion in philosophy.

More recently, interest in *managing* knowledge has grown in step with the perception that increasingly we live in a knowledge-based economy. Drucker is usually credited as being the first to popularize the knowledge-based economy concept, for example, by linking the importance of knowledge with rapid technological change in Drucker (1969). Karl Wiig coined the term knowledge management (hereafter KM) for a NATO seminar in 1986, and its popularity took off following the publication of Nonaka and Takeuchi's book *"The Knowledge Creating Company"* (Nonaka & Takeuchi, 1995). Knowledge creation is in fact just one of many activities involved in KM. Others include sharing, retaining, refining, and using knowledge. There are many such lists of activities (Holsapple & Joshi, 2000; Probst, Raub, & Romhardt, 1999; Skyrme, 1999; Wiig, De Hoog, & Van der Spek, 1997). Both academic and practical interest in KM has continued to increase throughout the last decade.

In this article, first the different types of knowledge are outlined, then comes a discussion of various routes by which knowledge management can be implemented, advocating a process-based route. An explanation follows of how people, processes and technology need to fit together, and some examples of this route in use are given. Finally there is a look towards the future.

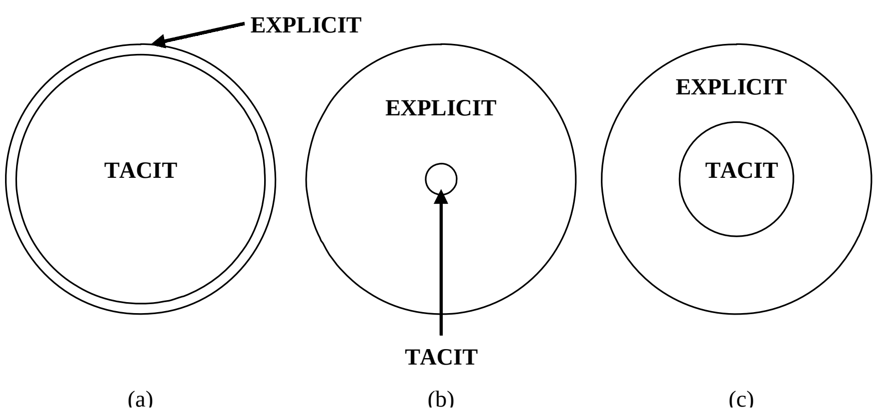
BACKGROUND

Types of Knowledge: Tacit and Explicit

Nonaka and Takeuchi's book (1995) popularized the concepts of tacit and explicit knowledge, as well as KM more generally. They based their thinking on that of Michael Polanyi (1966), expressed most memorably in his phrase "we know more than we can tell".

It is, however, most important to realize that tacit and explicit knowledge are not mutually exclusive concepts. Rather, any piece of knowledge has both tacit and explicit elements, as shown in Figure 1. The size of the inner circle represents the proportion of tacit knowledge: the "tacit core" at the heart of the knowledge that we "cannot tell". Figure 1(a) shows a case where the knowledge is almost entirely tacit, as in riding a bicycle. Figure 1(b) shows mainly explicit knowledge, where the tacit core is very small, for example, how to process a claim for travel expenses in an organization. Figure 1(c) shows an intermediate case, such as making a piece of furniture, where

Figure 1. The relationship between tacit and explicit knowledge



substantial amounts of both tacit and explicit knowledge are involved.

The Role of KM Systems

KM systems represent a deliberate, conscious attempt to manage knowledge, usually in an organization. Hansen, Nohria, and Tierney (1999) identified that there are two fundamental KM strategies, codification and personalization. Codification concentrates more on explicit knowledge (often relying very heavily on information technology), personalization more on tacit knowledge. Again, it is important to realize that these are not mutually exclusive, and that a strategy combining elements of both is likely to be the most successful.

ROUTES TO IMPLEMENTING KM

Many organizations have found it difficult to implement knowledge management systems successfully. Identifying "who", "what", and "why" – who is involved in knowledge management, what knowledge is being managed, and why is it being managed – can be problematic. The routes they have attempted to follow can be put into five generic categories, which will now be described.

Knowledge World Route

A substantial amount of the literature on knowledge management addresses knowledge at the level of the whole organization, or in a "world of knowledge" that is not specifically linked to the activities that a particular organization carries out. On an abstract level, such discussion of knowledge management can be extremely valuable. However, it has weaknesses in terms of practical implementation. For example, it is necessary not only to understand how individuals learn, but also how they learn in a given organization, and how the organizational systems may help or hinder the individual's learning process. The same issue applies even more forcefully to group learning, since the organization provides a crucial element of the group's context.

The practical focus in Nonaka and Takeuchi (1995) was very much on knowledge creation. As a result, organizations attempting to follow their principles for other aspects of KM, such as sharing or retaining knowledge, have sometimes found it difficult to make a specific connection from abstract ideas about knowledge to what the organization actually does, or could do, or should do. Often only the "why" is present, not the "who" or even the "what". Something more concrete is needed.

IT-Driven Route

This route assumes that the fundamental requirement is for the codification of as much knowledge as possible. Advocates of this approach sometimes refer to this as "extracting" the knowledge from the people who possess it; see for example Johannsen and Alty (1991). This is an inadvisable term to use, for two reasons. First, it is logically incorrect; their knowledge is being *shared*, not extracted. The people still have the knowledge after the "operation" has taken place. Second, it gives the people the wrong impression – that their knowledge is being taken away. This is not a recipe to encourage their cooperation. For an organization of any size, such a codification task evidently requires IT support, and the thrust of this route is that once the "correct" form of IT support for managing knowledge has been chosen, it is simply a matter of a great deal of hard work.

This technology-driven route only works well in a limited range of situations where the "what" questions are most important, for example, where the main KM task is managing the knowledge held by a company in the form of patents. In other circumstances, it may not achieve any improvement in knowledge management at all. One example of this from the author's experience is of a heavy manufacturing firm. Knowledge management in this organization was seen solely as an information systems issue; the KM group was part of the information systems department. The "solution" was seen in terms of the implementation of a knowledge sharing system based on Lotus Notes™. However, there was no real consideration as to who would share what knowledge or for what specific purpose. Consequently, the eventual use of the installed IT was poor; the only really successful use was by the knowledge management project team itself, where the "who" and "why" questions had been properly addressed, as well as the "what" questions.

Functional Route

An alternative route that has the potential to address the "who", "what" and "why" questions is to organize the implementation around the existing organizational structure. The most commonly found structural elements intended to facilitate learning and knowledge sharing in organizations are departmental groupings based on functions. These have clear advantages in terms of what might be termed professional development and allegiance. Davenport and Prusak (1998) report examples of successful knowledge transfer between groups of surgeons, and groups of tunneling engineers, among others. However, this functional route also has the disadvantage that it encourages the compartmentalization of knowledge. This problem can only worsen over time, as specialisations multiply and sub-divide. In addition, professional divisions can actively prevent sharing of knowledge. It has, for example, taken decades for hospital doctors in the UK National Health Service to allow other professionals such as pharmacists and physiotherapists to participate in decision-making about treatment of individual patients on an equal footing. On a wider scale, modern Western medical science has come to separate "diet" and "drugs", at least until the very recent past, in a way that Chinese medicine, for example, never has done. The problems of running an organization in this manner, and the "functional silos" mentality that tends to result, were recognized by authors such as Hammer (1990) as part of the business process reengineering movement, when KM was in its infancy.

Therefore, although the functional route to implementation will allow some improvement in KM, progress may be limited by the characteristics of the existing structure, and in the worst cases (for example, where transferring knowledge between functions is the greatest KM issue in the organization) this route may be counter-productive.

People-Centric Route

A people-centric route to KM is the essence of the Hansen et al. (1999) personalization strategy. By definition, such an approach, appropriately implemented, will answer all the "who" questions that might be involved in KM. Thus in organizations where there is general consensus on "what" knowledge is important and "why" it needs to be managed, such a route should prove effective.

However, as was mentioned in the previous sub-section, organizations have become increasingly diverse in their activities, and in the range of specialized knowledge that they need to access. This means that consensus even on what knowledge the organization has, never mind what is important, may be difficult to achieve. On the one hand, it may not be easy for a particular specialist to fully appreciate "what the organization does". Equally, even the most conscientious senior manager will find it literally impossible to understand all the expertise and knowledge possessed by the specialists in his or her organization. To repeat the quotation from Hewlett Packard CEO Lew Platt (Davenport & Prusak, 1998, p. xii), "If HP knew what HP knows, we would be three times as profitable."

Business Processes Route

The managers in an organization have to translate the goals of any strategic program or initiative – whether on knowledge management or something else – into practical, implementable reality. In other words, to connect with "what the organization does". Various management thinkers have presented models of this, for example:

- Porter's (1985) value chain,
- Earl's (1994) view of core processes, the ones that are done directly for external customers,
- Beer's (1985) "System Ones", the systems that make the organization what it is,
- Core competences/competencies as espoused by Hamel and Prahalad (1994).

Although there are some significant differences between them, their common theme is that the effectiveness – indeed, the competitive advantage – of organizations depends not on how they are structured, or on what resources they have, but on what they *do*. In the terminology of this article, this means their underlying business processes. Note that the term *business* processes is used throughout, but such processes exist equally in not-for-profit organizations.

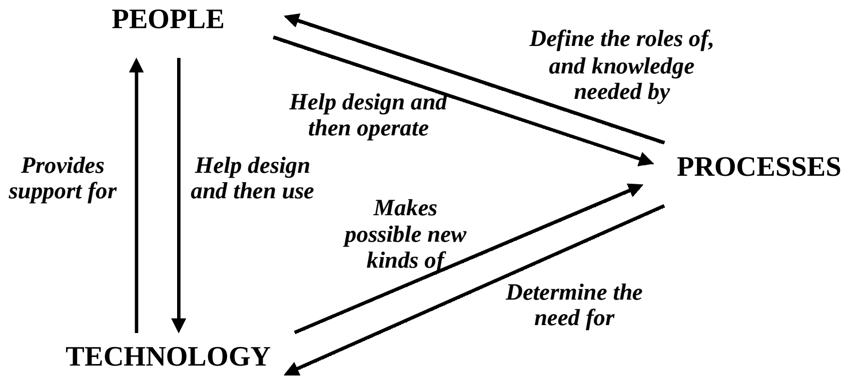
Business processes possess five characteristics that justify their use as a foundation for knowledge management in organizations.

1. Business processes have identifiable customers, whether internal or external. Knowledge is of little relevance unless put to use for a customer of some kind.
2. Business processes cut across organizational boundaries. Knowledge does not need to, and does not, obey the artificial boundaries within an organization.
3. Business processes consist of a structured set of activities. Choosing the appropriate way to structure activities is an important part of the knowledge.
4. Business processes need to be measured. Without some form of measurement as a comparison, knowledge cannot be validated.
5. While the parts of a business process are important, the overriding requirement is that the overall process works. Valid knowledge in an organizational context must take a holistic view.

An additional argument (Braganza, 2001) is that viewing knowledge management in terms of an organization's processes gives a much-needed *demand-side* view of

B

Figure 2. People, processes and technology in a KM system



knowledge. This is complementary to the supply-side view of knowledge that stems, for example, from considerations "of data leading to information leading to knowledge". Beer and Earl particularly concentrate on this demand-side perspective. Beer indeed goes even further, to include the informal processes and activities of the organization as well as the more formalized ones.

Completing this argument for a greater use of the business processes route, the knowledge that an organization requires must, logically, be related not just to what that organization does, but also to how it does it. Thus, people in organizations should think about this knowledge, and how to manage it, by reference to that organization's business processes.

PEOPLE, PROCESSES AND TECHNOLOGY

From the earlier discussion, it may be seen that, whichever route is chosen, effective KM requires the consideration of both tacit and explicit knowledge. The need is to coordinate people, processes and technology successfully. The interaction of these three elements is shown in Figure 2.

Not only does a knowledge management system consist of more than technology, it is important to realize that the technology used to support KM does not have to be "KM software". Recent studies have found that generic software such as e-mail or an Intranet may be at least as important as specific software (Edwards, Shaw, & Collier, 2004 (to appear); Zhou & Fink, 2003).

KM BY A BUSINESS PROCESSES ROUTE

As it has so far been less frequently attempted than the other routes, some examples of organizations that have implemented KM by a business processes route will now be given.

Unisys (Wizdo, 2001) have embarked upon a company-wide knowledge management initiative with an explicit process focus. Its objectives include:

- Accelerating the speed and scope of organisational learning,
- Decreasing the time it takes to reach critical mass in new markets,
- Uniting cross-boundary groups,
- Increasing innovation in product and process.

Wizdo identifies three increasingly ambitious categories of "transformation" in business: efficiency, innovation and re-invention. The Unisys knowledge management program regards a focus on processes as essential in achieving the two "higher" categories.

Objective Corporation (Fisher, 2001) changed most of their processes over a period of some five years. They found that such an emphasis not only improved knowledge management within the business, but also had a significant impact on the performance of the business itself. In this case, it was most likely the effect of a coherent training programme, with an emphasis on understanding, increasing the overall organisational performance through the people involved operating more effectively.

Both of these examples involved substantial use of information technology. However, that does not have to be the case. The author's group has been working with a component manufacturer in the aerospace industry, whose KM initiative also has an explicit process focus. Typically, their manufacturing processes use a machine operated by one person. The operators' choice of the best way to retain and share knowledge does not use IT at all (except for a word processor). The agreed best operating procedure, with illustrations, is put on a laminated sheet of paper mounted near the machine, which includes the names of the people who had contributed to designing the procedure. A suitable pen is provided to annotate the laminated sheet. At regular intervals, office staff come round to produce a revised version of any of the "Standard Operating Sheets" that have been annotated.

FUTURE TRENDS

A further justification for the use of business processes as the foundation for implementing knowledge management is that they are now becoming part of the mainstream of management thought. For example, the latest version of the ISO9000 family of standards for Quality Management Systems, including ISO9001: 2000, is constructed on the basis of a "process approach". The ISO9000 term *realisation process* is equivalent to Earl's core process or Beer's primary activity as discussed earlier. Significantly, the latest editions of strategic management textbooks (Johnson & Scholes, 2001) typically discuss the business process view of organizations, whereas earlier ones did not.

It seems clear, therefore, that the business processes route to implementing knowledge management is likely to become more common in future, and that this will encourage the development of ever more appropriate information technology for supporting it. Equally, new information technologies will enable new types of process. Intelligent agents, smart cards and "picture phones", for example, all offer different possibilities for supporting KM which have only just begun to be considered.

CONCLUSION

This article has considered the implementation of knowledge management systems by looking at five different generic routes towards achieving it: knowledge world, IT-driven, functional, people-centric and business processes. While each of these routes has some merits, it has been argued that the business processes route offers potential for the greatest integration between knowledge management and "what the organization does". It is, thus, likely to be increasingly common in the future.

KEY TERMS

Business Process: A structured, measured set of activities designed to produce a specified output for a particular customer or market (Davenport, 1993, p. 5).

Business Process Reengineering: The fundamental rethinking and radical redesign of business processes to achieve dramatic improvements in critical, contemporary measures of performance, such as cost, quality, service and speed (Hammer & Champy, 1993, p. 32).

Demand-Driven View of Knowledge: A view of knowledge stemming from the requirements of the organization; for example, what knowledge is needed to carry out a particular activity and how can it be applied?

Explicit Knowledge: Knowledge that has been (or can be) codified and shared with others.

Knowledge Management: Supporting and achieving the creation, sharing, retention, refinement, and use of knowledge (generally in an organizational context).

Knowledge Management Software: Software specifically intended for knowledge management, such as data mining and "people finder" software.

Knowledge Management System: A combination of people, processes and technology whose purpose is to perform knowledge management in an organization.

Supply-Driven View of Knowledge: A view of knowledge stemming from the knowledge itself rather than its uses. Often related to a continuum data-information-knowledge.

Tacit Knowledge: Knowledge that is difficult or impossible to express, except by demonstrating its application.

B

Business Strategy, Structure and IT Alignment

Petros Theodorou
Technological Educational Institution of Kavala, Greece

INTRODUCTION

The structure of production during the last decade has been changed radically. The importance of design, flexibility, quality, and dependability increased. The main motive behind that restructuring seems to be the qualitative and quantitative diversification of demand (regulatory, technology, and other issues can be mentioned as well). The diversification of demand forced production to be more flexible in order to accommodate the environment's variations. Information systems (IS) proved to be a perfect 'partner' for the enterprise who wants to move along at this pace: to increase competitive advantage and retain its competitive position in the market. The capabilities of information technology (IT) for increasing competitive advantage forced management to consider IT in the strategic planning process and to consider IT not as a mere tool of bolts and nuts, but as a strategic partner. The key for the successful IT-IS adoption is the strategic IT alignment model. According to this, IT should be aligned with organizations' structure and employees' culture in order to avoid resistance and increase core competence at the strategic level. But the strategic options offered by advanced IT investments are not appraised by using the usual hard financial criteria. Instead, Black and Scholes developed a financial formula to valuate derivative financial products and open the road to valuate options offered by real investments. Thus, the application of Black and Scholes' formula offers an opportunity to valuate financially strategic IT investment.

The importance of alignment among IT-business structure and strategy-environment is increased strategically, but the relationship among all those variables is complicated. Generally, in the classical strategy school, strategy is determined by environmental uncertainty. Structure (as well as technology) should follow the needs of strategy, and advanced information technology must be aligned with business strategy and structure. This alignment is a prerequisite for the creation of competitive advantage. Information technology is a key element of structure to bypass environmental uncertainty. In this model, other contingencies like size, age of organization, political forces, regulatory framework, and so forth must be taken into account as the interaction among all those factors forms the alignment model.

BACKGROUND

The concept of alignment has been widely examined in strategy and organizations' theory literature, underlying the contingency theories and constituting the groundwork of management of technology and strategy of information systems. Strategic alignment and strategic fit have been among the top concerns of business executives (Rodgers, 1997; Brancheay, Janz & Wetherbe, 1996) and the core concept in the normative models. Alignment literally means an arrangement of groups or forces in relation to one another. The determination of those forces is an important aspect of strategic alignment research. The following aggregate variables are commonly found in many alignment models: environment uncertainty, business structure, information technology (IT), and business strategy. Among those variables, Miles and Snow (1984) determine strategy as the basic alignment mechanism, and organizational structure and management processes as the internal arrangements. In the classical school of strategy, environment has the most important role as a determinant of strategy. Structure follows the alterations of strategy, while the role of IT is collateral. Strategy follows environmental variations and determines the structural form. IT as a part of structure follows strategy as well. In contrary to this view, Mintzberg and Quinn (1996) proposed a bottom-up approach that is free of the 'environmental biased' (Theodorou, 1997). Practical experience shows that variables which should be aligned are interrelated in a multidimensional way; but for the sake of simplicity, a simple bivariate approach is usually used among:

environment↔strategy, structure↔strategy, IT ↔strategy and IT↔structure.

Moreover, it should be mentioned that the concept of alignment in business strategy has two dimensions (Horovits, 1984; Reich & Benbasat, 1999)-the intellectual (interrelated IT and business plans) and the social dimension (understanding and commitment of participants). Furthermore, alignment is more an ongoing process and not a stable state, thus sustainability can be gained only by continuous efforts. No strategy is universally superior, irrespective of the environmental or organizational context (Venkatraman, 1989). A flexible structure that follows demand capable to produce in low volume, low cost, and high quality needs long-term investment. Strategic alignment enables enterprises to avoid over-simplicity while targeting competitive and distinctive advantage assisting to dominate in competition (Drago, 1999). According to that concept, business strategy should evolve while taking into account the impact of IT. On the other hand, if information technology is applied without taking into account the strategic targets of cost, design, quality, flexibility, and dependability, then only operational benefits will be created without any impact on competitive advantage.

Generally the strategic alignment problem has multiple dimensions, but the main determinants are the following: environmental uncertainty, business structure, IT and business strategy. Except for the previously mentioned variables, we could refer business culture, managerial knowledge/processes and individual roles, the regulatory issues, political forces, and so forth. The alignment model should consider among other contingencies the impact of industry and competitive change (particularly under the influence of IT and the generic strategies in the strategy portfolio), the strategic changes induced by IT that affect the reengineering of internal and external value chain, the IT capabilities that shift or expand the business scope and domain, and finally, the size and the age of the firm. In the “management in ’90s” research framework, Morton (1991) illustrates some of the various aspects of the firm that must be considered in the alignment process. In this model, strategic fit is defined by looking at the IT potential to shape and support business strategy; alignment at the organizational level is defined by looking at organizational infrastructures and processes. Thus, four perspectives of alignment arise: the strategy execution, the technology, the competitive potential, and the service level. Moreover, four alignment mechanisms are identified: value management, governance, technological, and organizational capability. Misfit and misalignment is responsible for why many IT applications are not meeting expectations and do not cover the needs of the company.

MAIN THRUST OF THE ARTICLE

As previously mentioned, the concept of strategic alignment has various dimensions. The most important according to the bivariate approach are business strategy, business structure, information technology, and business environment. Thus, the interrelation among those variables captures the purpose of the alignment model. The external environment is characterized as dynamic, if the firm experiences often exogenous changes, such as: product design by competitors, variability in time of deliveries (by suppliers), high growth in market share, changes in relative market share, changes and innovation in information technologies adapted by competitors or offered in the marketplace, and so forth. Every source of uncertainty which the firm realizes from the external environment (capable to affect competitive advantage) is a main drive to reconsider the alignment mechanism. Through strategic analysis the firm realizes (if possible) the changes in the external environment to take action realigning the business structure in order to reply to competition. Information technology in this context offers the flexibility needed for quick and efficient response. Thus, the relation of information technology and business strategy and structure is of vital importance. Following, we will present the strategy-IT and structure-IT alignment.

Strategic Alignment of Advanced IT

An important aspect of strategy and IT alignment was to correspond the strategic content with IT capabilities, in other words, IT to strategic objectives, and examine how they are affected. That topic is basically investigated in strategic information system literature where matrix models developed in order to determine strategic alignment. Porter’s work comprised the basis for the development of strategic information systems even though his model is more familiar in strategic management literature. Neumann (1994), in his book about strategic information systems, denotes that Porter’s model of ‘5-forces’ is the framework of frameworks. Specifically, regarding the strategic objectives, Porter attempted a generalization of specific strategic targets, the so-called generic strategies, which are: cost, differentiation, and focus (niche) strategy. Furthermore, Wiseman (1998) extended that logic by adding the strategic targets of alliance, growth, and innovation. Generally, business strategy should take into account IT in order to generate strengths and attain opportunities that increase competitive advantage. Competitive advantage from IT can be derived by taking into account the opportunities that can be exploited from the 5-forces model; for example, how can the firm: build barriers to entry, build switching costs, change the basis of competition, change the balance of power in suppliers relationship, and generate new products? Moreover, the sustainability issue raised the importance of business strategy and IT integration. Strategic information systems literature tried to explain alignment among strategy and IT with the use of matrix models. Synnot made a composition of the Boston Consulting Group’s matrix and Porter’s generic strategies in order to identify IT strategic options and achieve strategic alignment. A well-known model for the attainment of strategic opportunities criticized for over-simplicity is the Strategic Grid Matrix developed by McFarlan (1984). The empirical research of Hirschheim (1982) indicates that regardless of the 'simplicity problem', an important benefit that arises is that the model forms the basis for a dialogue among management. Thus this model is helpful for consensus and agreement, which is a significant part of social alignment. An important upgrade of strategic grid was made by Ward (1987), who extended the hermeneutic capability of the model by incorporating IS/IT planning (for a composition of strategic grid and Ward matrix, see Theodorou, 2003). Based on this matrix, Parson (1983; also see Ward, Griffiths & Whitmore, 1994, p. 251) discussed alignment among generic and IT strategies. Parson's generic IS/IT strategies include: centrally planned, leading edge, free market, monopoly, scarce resource, and necessary evil. The conclusion is that an organization will need to adopt a full range of generic strategies if it is to manage an extensive portfolio (Ward et al., 1994). Parson attempted a classification of IT applications according to the organization's functions and Porter's generic strategies. An important set of generic strategies is also found in manufacturing strategy literature. Based on the distinction made by Skinner (1985, pp. 78, 80, 88), Swamidass and Newell (1987), Adam and Swamidass (1989), and Swink and Way (1995), strategy is determined by priorities, and priorities determine the strategic direction. As can be seen from this literature, the generic business and IT strategies have been split up to more than five competitive priorities, and those priorities can be further split up to many tactics (for a more detailed analysis, see Theodorou, 1996b). The basic priorities are: design, cost, quality, flexibility, dependability, and innovation (Theodorou, 1997). Theodorou used a Likert scale to estimate the priorities of a firm, and further to detect the impact of IT using VACOR algorithm and based on the ROIC criterion. It was observed that higher performing firms follow the target of flexibility as a first-order priority, and late in the list was cost. That doesn't mean that cost was not of interest, but on the contrary, that the cost target for those firms was achieved (Theodorou, 2001). Kathuria and Igbaria create a matrix in order to correlate organizations' structure (from a functional view) with strategic priorities and IT, bypassing the limits of a two-dimensional approach. In this approach IT technologies and priorities are aligned according to the business functions (Kathuria & Igbaria, 1997).

Structural Alignment of Advanced IT

The theme of fit and alignment is central to any contingency model developed by organization theorists. Structure should be aligned with environment, taking advantage of IT capabilities. The target is to shape new forms of structure flexible enough to respond quickly to environmental threats and opportunities (Morton, 1995). Flexibility enables structure to interface with environmental uncertainty while taking advantage of IT potential. Venkatraman's (1989) statistical conceptualization 'opened' the field of empirical research in testing strategic alignment, introducing the concepts of moderation, mediation, matching, covariation, profile deviation, and gestalt. Ivary (1992) references that the mediation perspective dominates in research, but omits the criterion of performance. Fiedler, Grover, and Teng (1996) attempted a taxonomy of IT in relation to structure without a performance criterion. Brown and Magill (1994) refer to the gestalts approach for the identification of the form of centralization. Furthermore, Bergeron, Raymond, and Rivard (2001) found that moderation and matching perspective confirm the performance implications for the structure-IT pair under the strategic IT management approach. Generally, it can be seen that the prevailing concepts in structure-IT fit are: the matching, mediation, and moderation perspective. Those concepts, according to Raymond, Pare, and Bergeron (1995), can be presented as follows:

Matching: ((structure⇔IT)⇒Performance)
Mediation: (IT⇒structure⇒Performance)
Moderation: (IT⇒(structure⇒Performance))

Theodorou (1997) used performance as a criterion variable for structural variable analysis and determined IT-structure fit, using the moderate perspective for certain contingencies. In this model '21' (structural) variables try to grasp elements of structure in order to determine the structural design (organizational form) of the enterprise. Structural clusters were determined using VACOR algorithm. The impact of IT was estimated using the Newton Raphson algorithm and neural networks. It was concluded that the matching approach confirmed that high-performing organizational subunits matched a decentralized and differentiated structure with non-routine (flexible) technology (Theodorou, 1997; Theodorou & Dranidis, 2001). Once the firm makes strategic choices on IT, matching structures must be defined if the resulting performance is to be high (Raymond et al., 1995). If structure is to be defined in a more detailed mode, then the main structural variables and parameters should be determined (Theodorou & Dranidis, 2001).

FUTURE TRENDS: ALIGNMENT A REAL OPTION

Generic options are embedded in business strategy and business structure choice. As presented previously, the generic options regarding the strategic priorities can be conceptualized in cost, quality, dependability, and flexibility (for an extended discussion, see Theodorou, 2003). Additionally, business structure can take various forms (Mintzberg & Quinn, 1996). Theodorou and Dranidis (2001) developed a neural network system to determine business structure according to a set of structural variables, where different combinations provide different structural forms. Thus, options are embedded in structural design as well as in strategic priorities. Information technology must be aligned with business strategy and structure according to the demands of the external environment. Theodorou (2004) developed a DSS to determine the alignment mechanism for the above-mentioned variables. Strategic and structural options must be aligned within the external environment, taking advantage of information technology capabilities. Balasubramanian, Kulatilaka, and Storck (2000) noticed the importance of the relation among the real options and the alignment. They developed an approach using business capabilities from operating drivers and real options. According to this capability-based approach, valuation is contingent on market conditions and the degree of success in attaining the capabilities set as target (Balasubramanian et al., 2000).

But even if this framework can work well, in cases of IT applications with certain impact on sales (like e-commerce), it is not clear how it can be applied in IT applications with only operational benefits, where sales impact is superficial and only cost benefits can be encountered. In the case of the alignment model, a performance criterion (like ROIC or better a factor describing many performance estimates) can be employed in order to test if business structure, strategy, and information technology are aligned. Then the real options approach can be used on this criterion in place of exercise and spot price. Usually, analytical methods are used in a real options approach and are based upon the Black and Scholes formula, to estimate the options of abandonment, growth, and postponement (Kim & Sanders, 2002). In the classical approach the price of the asset (spot and exercise) is replaced with the NPV of the project. A basic step in that estimation is to derive the standard deviation from shocks in exogenous factors. In the case of the alignment model, standard deviation is estimated from shocks in strategic priorities and structural variables.

Reversibly, in the case of Black and Scholes, variance is derived from shocks on the financial variables (like prices, interest rates, etc.). The variability of choice in strategic priorities and structural variables produce variance in the strategic alignment model, and this is transferred in the criterion of performance which is applied in the option formula, in order to estimate the options of abandonment, growth, and postponement. The alignment model estimates the various strategic and structural options that can be found in the real context of an enterprise (Theodorou, 2004). The difficulty in IT valuation (and mainly in systems that automate operations such as CAM and MRPI) is that we can not estimate the currency inflows of the system. Alternatively, in the case where operational benefits, through cost reduction, can be encountered (like a database), two things can be done: a) discount the free cash flows, or b) estimate the strategic impact of efficiency on market share and estimate the MIRR on the differential revenues.

Generally, despite those two solutions, the mechanism of the alignment model with a performance factor can be proven more efficient and appropriate for implementation and valuation, as it takes into account all the available options in relation to business strategy and structure. Only under that concept can the benefits of information technology be fully valuated.

CONCLUSION

Firms, nowadays, operate in an uncertain environment, due to the qualitative and quantitative diversification of demand. Firms are targeting in small niches, trying to serve specific market needs. In this circumstance, the need for a flexible structure and strategy to bypass environmental uncertainty is increased. Information technology proved to be a good ‘partner’ to attain the strategic targets of this new environment. Computer-aided design, finite element analysis, concurrent engineering, and other techniques help to decrease the time to market and the cost of the new product’s design. Computer-aided manufacturing, DNC, and CNC machines enable the decrease of setup cost and produce economically smaller lots (batches) in order to serve smaller market niches, attaining economies of scope. Materials requirement planning for the West and just-in-time systems for the East automate the orders of material, and cut cost and time to market. Most of those systems (for a classification, see Theodorou, 2003) were integrated and popularized as MRPII or ERP in intranets or through the Internet.

The integration of those systems, along with the human factor, led to the emergence of strategic alignment theory. Alignment and fit seems to be very important in decreasing resistance and increasing competitive advantage. Key elements for the alignment to be considered by any firm are external environment, business strategy, business structure, and information technology. Business strategy should be aligned with the external environment and incorporate the information technology capabilities in the strategic plan. Information technology should fit with business structure and vise versa in order to serve specific strategic targets and priorities, like cost, quality, dependability, design, and so forth. Also, from the successful IT and business structure fit, strategic advantages can be created in an emerging pattern capable of influencing environment and strategy. It should be mentioned that alignment is not a stable state since environment is continuously changing, and strategy should accommodate respectively. Other contingency factors have to be taken into account like the age of the organization, the size, the culture, the power, as well as other historical factors specific for each enterprise.

A new challenge is opened for the application of the alignment model in the financial valuation of advanced IT systems. Hard financial measures proved incapable of evaluating the strategic impact and strategic role of those systems. Based on the alignment model, a proper choice of strategic priorities and structural variables can be made in relation to environmental uncertainty in order to create competitive advantage. Structural equation modeling opens the ground for an application. Structural variables and strategic priorities are the main latent variables that offer the options to be aligned under the performance criteria. Then, the performance factor can be used to estimate the options of abandonment, growth, and postponement based on the Black and Scholes formula.

KEY TERMS

Information Technology Competitive Advantage (ITCA): The increased profitability and market share by a better positioning due to strategy and structure selection based on the alignment model.

Information Technology Fit: The best relation that can be achieved in a strategic alignment model among information technology, business structure, and business strategy.

Strategic Alignment Model: A model to help appropriate selection of strategic priorities and structural variables. Incorporates a dynamic interaction among business strategy, structure, information technology, and environment, while taking into account the most important contingencies like: the age, the size, the culture, etc.

Strategic Information Systems: Information systems that increase competitive advantage in a long-term horizon, with more than operational benefits, such as better positioning and increase in market share.

Structural Design: Forms of structure derived by optimal combinations of structural variables with information technology and business strategy in a way that increase competitive advantage.

Structural Variables: The most important elements of structure (variables) that characterize and form the structural design (span of control, levels of hierarchy, level of standardization, etc.).

Cache Management for Web-Powered Databases

INTRODUCTION

In recent years, the World Wide Web, or simply the Web (Berners-Lee, Caililiau, Luotonen, Nielsen, & Secret, 1994), has become the primary means for information dissemination. It is a hypertext-based application and uses the hypertext transfer protocol (HTTP) for file transfers.

During its first years, the Web consisted of static hypertext markup language (HTML) pages stored on the file systems of the connected machines. When new needs arose, e.g., database access, it was realized that we could not afford in terms of storage to replicate the data we want to publish in the Web server's disk in the form of HTML pages. So, instead of static pages, an application program should run on the Web server to receive requests from clients, retrieve the relevant data from the source, and then pack the information into HTML or extensible markup language (XML) format. Even the emerged "semistructured" XML databases that store data directly into the XML format need an application program that will connect to the database management system (DBMS) and retrieve the XML file or fragment. Thus, a new architecture was born: in the traditional couple of a Web client and a Web server, a third part is added, which is the application program that runs on the Web server and serves data from an underlying repository that, in most cases, is a database. This architecture is referred to as *Web-powered database* and is depicted in Figure 1. In this scheme, there are three tiers: the database back-end, the Web/application server, and the Web client.

BACKGROUND

Due to the existence of *temporal locality* in Web request streams, we can exploit the technique of *caching*, that is, temporal storage of data closer to the consumer. Caching can save resources, i.e., network bandwidth, because fewer packets travel in the network, and time, because we have faster response times. Caching can be implemented at various points along the path of the flow of data from the repository to the final consumer. So, we may have caching at the DBMS, at the Web server's memory or disk, at various points in the network (i.e., proxy caches), or at the consumer's endpoint. Web proxies may cooperate so as to have several proxies to serve each other's misses. All the caches present at various points comprise a *memory hierarchy*. The most important part of a cache is the mechanism that determines which data will be accommodated in the cache space and is referred to as the cache *admission/replacement policy*.

Requests for "first-time accessed" data cannot benefit from caching. In these cases, due to the existence of *spatial locality* in request streams, we can exploit the technique of preloading or *prefetching*, which acts complementary to caching. Prefetching may increase the amount of traveling data, but on the other hand, it can significantly reduce the latency associated with every request.

The role of a cache is to store temporally a set of objects that will most probably be requested by its clients. A cache replacement policy assigns a value to every cached object, called *utility value (UV)*, and evicts from cache the object with the least utility value. The aim of the replacement policy is to improve the cache's effectiveness by optimizing two performance measures: the *hit ratio* and the *cost-savings ratio (CSR)*. The former measure is defined as:

$$HR = \sum h_i / \sum r_i$$

and the latter is defined as

$$CSR = \sum c_i * h_i / \sum ci * r_i$$

where h_i is the number of references to object i satisfied by the cache out of the r_i total references to i, and c_i is the cost of fetching object i in cache. The cost can be defined either as the object's size s_i or as the downloading latency c_i. In the former case, the CSR coincides with the byte–hit ratio (BHR); in the latter case, the CSR coincides with the delay-savings ratio (DSR).

Figure 1. Architecture of a typical Web-powered database

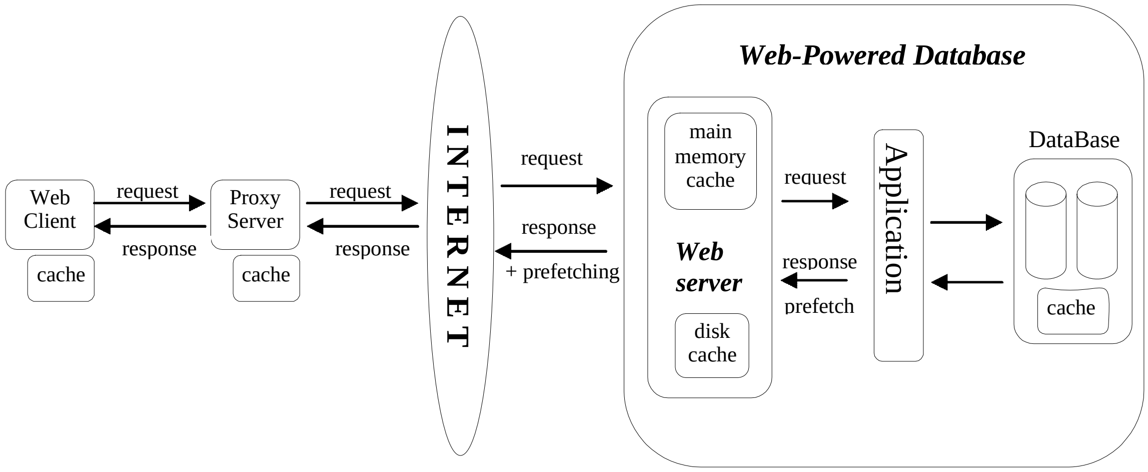

Table 1. A list of factors differentiating Web caching from traditional caching

1. Variable Object Size
The Web object's size varies considerably. It ranges from a few bytes (e.g., small HTML or text files) to several megabytes (e.g., large multimedia files). In contrary, the objects that move through the levels of the caching hierarchy in operating systems or database systems have fixed size, which is equal to the size of a disk block.

2. Variable Fetching Cost
The cost (time penalty) for retrieving a Web object varies significantly. Different objects may have different fetching costs, because they differ in size or in their distance from the client (in terms of network hops). Moreover, the same file may have different fetching costs at different time instances, depending on the server (e.g., heavy load) and network conditions (e.g., congestion).

3. The Depth of the Web Caching Hierarchy
Because caching can happen nearly anywhere, including on the server, on the user's machine, at Internet service protocols (ISPs), at telecommunication companies, at the peering points of national networks, etc., the depth of this hierarchy is significantly larger than the respective depth in computer systems. The large depth of this hierarchy significantly affects the characteristics of the request stream.

4. The Origin of the Web Request Streams
The requests seen by the Web caches, especially by the proxies and the reverse proxies, are not generated by a few programmed processes like the request streams encountered in traditional computer systems. They mainly originate from large human populations with diverse and varying interests.

CACHING IN WEB-POWERED DATABASES

Web cache replacement (Katsaros & Manolopoulos, 2002) is one of the most important areas of Web caching for several reasons. First, studies have shown that the cache HR and BHR grow in a *log-like fashion* as a function of cache size (Breslau, Cao, Fan, Phillips, & Shenker, 1999). Thus, a better algorithm that increases HR by only several percentage points would be equivalent to a several-fold increase in cache size. Second, the growth rate of Web content is much higher than the rate with which memory sizes for Web caches are likely to grow. Finally, the benefit of even a slight improvement in cache performance may have an appreciable effect on network traffic, especially when such gains are compounded through a hierarchy of caches. There are several factors that distinguish Web caching from caching in traditional computer architectures (see Table 1).

The majority of the replacement policies focus on the first two factors. The main drawback in the design of these policies is that they do not achieve a balance between HR and CSR. Some of them are called *recency-based policies* and favor the HR, e.g., the Greedy Dual-Size (Cao & Irani, 1997), the Size-Adjusted LRU (Aggrawal, Wolf, & Yu, 1999), whereas some others are called *frequency-based policies* and favor the CSR (BHR or DSR), e.g., LRV (Rizzo & Vicisano, 2000), LFU-DA (Diley & Arlitt, 1999), and LNC-R-W3 (Shim, Scheuermann, & Vingralek, 1999). Notable exceptions are the LUV (Bahn, Koh, Noh, & Min, 2002), GD* (Jin & Bestavros, 2001), and CRF (Katsaros & Manolopoulos, 2004), which try to combine recency and frequency. The drawback of LUV and GD* though, is the existence of some manually tunable parameters. CRF is a self-tunable policy that gracefully combines recency and frequency and addresses all the particularities of the Web caching environment.

PREFETCHING IN WEB-POWERED DATABASES

Prefetching is employed in order to cure caching's shortcomings. An effective and efficient prefetching scheme should maximize the number of cache hits due to its action and at the same time minimize the incurred cost due to the prefetched objects. This cost may represent cache space, network bandwidth, server overloading, etc. Although the implementation mechanism of prefetching is very important, the core issue in employing a prefetching scheme is the deduction of future object requests.

In general, there exist two alternatives for the deduction of the future client requests. The first is termed *informed prefetching*, and the second is termed *predictive prefetching*. In Table 2, we explain why the former is not appropriate for the Web environment.

A predictive prefetching algorithm is based on the notion of Markov predictors. Let $T_r = \langle tr_1, \ldots, tr_k \rangle$ be a sequence of consecutive requests (called a transaction) and $S = \langle d_1, \ldots, d_n \rangle$, $n \leq k$ be a sequence of accesses, which is a subsequence of T_r. Given a collection of nTr transactions, where the sequence S appears fr(S) times, then the appearance probability *P(S)* of S is equal to *P(S)* = fr(S)/nTr.

If $S = \langle d_1, \ldots, d_n \rangle$ is a sequence of accesses, then the conditional probability that the next accesses will be to $d_{n+1}, \ldots, d_{n+m}$ is $P(d_{n+1}, \ldots, d_{n+m} | d_1, \ldots, d_n)$, and it equals the following:

$$P(d_{n+1},\ldots,d_{n+m} \mid d_1,\ldots,d_n) = \frac{P(d_1,\ldots,d_n,d_{n+1},\ldots,d_{n+m})}{P(d_1,\ldots,d_n)}$$

Given a collection of transactions, rules of the form

$$d_1, \ldots, d_n \Rightarrow d_{n+1}, \ldots, d_{n+m} \tag{1}$$

can be derived, where $P(d_{n+1}, \ldots, d_{n+m} | d_1, \ldots, d_n)$ is not less than a user-defined value T_c. $P(d_{n+1}, \ldots, d_{n+m} | d_1, \ldots, d_n)$ is

Table 2. Informed and predictive prefetching

Informed Prefetching Can be applied in cases where the client program knows exactly the resources the client is going to request and reveals them into the cache (Patterson, Gibson, Ginting, Stodolsky, & Zelenka, 1995). Informed prefetching is actually a scheduling policy subject to a set of constraints regarding cache space, timeliness of prefetching, and available bandwidth. It requires the communication bandwidth between the applications and the cache to be stable. Thus, it can be implemented only in cases where the cache is embedded into the application, e.g., databases and operating systems.
Predictive Prefetching How will future references be deduced if not revealed by the client program? The only possibility is to take advantage of the spatial locality present in Web request streams. Spatial locality captures the coreference of some resources. The remaining issue is to "quantify" spatial locality, that is, to discover the dependencies between references for different data. Such dependencies can be discovered from past requests and can be used for making predictions about future requests.

the confidence of the rule. The left part of the rule is called the *head* and has size equal to *n*, whereas the right part is called the *body* and has size equal to *m*. The dependency of forthcoming accesses on past accesses defines a *Markov chain*.

Definition of a *n - m* Markov Predictor

An n - m Markov predictor calculates conditional probabilities $P(d_{n+1}, \ldots, d_{n+m}|d_1, \ldots, d_n)$ between document accesses and discovers rules of the form (1), which are used to predict future accesses.

A predictive prefetching algorithm is defined as a collection of n - 1, n - 2, …, n - m Markov predictors. Existing predictive Web prefetching mechanisms can be categorized into three families.

The algorithms of the first family use the concept of the *dependency graph* (DG) (Padmanabhan & Mogul, 1996; Jiang & Kleinrock, 1998). The DG has a node for each object that has ever been accessed and an arc from node X to node Y, if and only if Y was accessed within w accesses after X and the same client did both accesses. DG maintains the number of accesses to each node X and the number of transitions from X to Y. It calculates conditional probabilities $P(d_i|d_j)$ for all d_i, d_j belonging to a transaction. Therefore, DG discovers rules of the form $d_i \Rightarrow d_j$, or equivalently, it uses a 1-1 Markov predictor.

The algorithms belonging to the second category are based on the notion of a *k-order PPM predictor* (Fan, Cao, Lin, & Jacobson, 1999). A k-order PPM predictor maintains j - 1 Markov predictors, for all $1 \le j \le k$ (k is a user-specified constant). It employs Markov predictors that have the constraint that the preceding j requests must be consecutive in the request stream. These Markov predictors calculate conditional probabilities of the form $P(d_{n+1}|d_n), \ldots, P(d_{n+1}|d_{n-k+1}, \ldots, d_n)$ and determine the corresponding rules, which have head sizes equal to 1,2, …, k.

A generalization of the above two families was presented in Nanopoulos, Katsaros, and Manolopoulos (2003). That scheme uses *n - m* Markov predictors that calculate conditional probabilities of the form $P(d_{n+1}, \ldots, d_{n+m}|d_1, \ldots, d_n)$, though the document accesses need not be consecutive. Moreover, the maximum head size *n* and the maximum body size *m* are not set by the user but are adaptively estimated by the data.

FUTURE TRENDS

We all know that the Internet, and consequently the Web, faces performance problems. Performance problems arise in any of the following three general areas:

1. Web server processing delays
2. Internet delays
3. “Last-mile” delays (delays between the subscriber and the Internet, e.g., due to a slow dial-up modem connection)

The idea in alleviating these problems is to make content delivery from origin servers more “distributed,” moving some of their content to the “edge” of the Internet. Based upon this idea, the content delivery networks (CDN) emerged recently. CDN are designed to take advantage of the geographic locations of end users. Rather than serving content from the origin Web site, the content distribution model makes copies of “key” content on multiple content delivery servers sites distributed through the Internet, close to the users requesting that content.

A CDN, running on thousands of servers distributed across the Internet, contracts with content providers to deliver their content. A CDN addresses efficiently the aforementioned performance problems:

1. With the “hottest” content “outsourced,” the load on the origin server is reduced.
2. The connection from a local content delivery server is shorter than between the origin Web server and the user, thus reducing latency.
3. Because many users share the CDN servers, this service greatly increases the hit ratio.

The deployment of large-scale CDNs brings some new challenges to caching. One very important issue is that of object placement, that is, the selection of the edge servers where an object should be stored (Tang & Chanson, 2002). This problem could also be seen in combination with that of object replacement (Korupolu & Dahlin, 2002). Another very important issue is related to maintaining the coherency of the cached objects, especially in the case that these objects are dynamically generated (Tang & Chanson, 2004).

Prefetching is also challenging in the context of CDN because of the huge number of clients served. To deal with this problem, the cache satellite distribution systems (Armon & Levy, 2004), CSDS for short, have emerged as a technology for feeding the caches with the information clients are expected to request, ahead of time. In such a system, the participating caches periodically report to a central station about requests received from their clients. The central station selects a collection of Web documents that are “pushed” via a satellite broadcast to the participating caches, so that upon a future local request for the documents, they will already reside in the local cache and will not need to be fetched from the terrestrial network.

CONCLUSION

Web-powered databases have emerged to support numerous Web applications, like e-commerce systems, but due to the large number of visitors they attract, they face serious performance problems. To reduce or even alleviate such problems, the techniques of caching and prefetching have been employed. The different physical characteristics of the Web objects, the existence of hyperlinks, and the nature of the Web caching hierarchy call for different caching and prefetching solutions than those investigated in traditional operating and database systems. The present article recorded the most critical factors that affect the design of caching and prefetching policies for Web-powered databases and surveyed the major families and their representatives for these policies.

KEY TERMS

Caching Proxy: A caching proxy or proxy server or proxy is a server that acts as an intermediary between a client and a content server. It intercepts the requests of the client and checks whether it can serve the client from its own cache, and if not, it forwards the requests to the content server.

Capacity Miss: This miss occurs because the cache cannot accommodate all requested objects.

CDN (Content Distribution Network or Content Delivery Network): This is a network of cache servers owned by the same Internet Service Provider that delivers content to users on behalf of content providers. CDN servers are typically shared, delivering content belonging to multiple Web sites, though all servers may not be used for all sites.

Compulsory Miss: A compulsory or cold-start miss occurs in the first access to a Web object.

CPN (Capacity Provisioning Network): This is a network of cache servers owned, operated, and coordinated through capacity trading by different Internet Service Providers. Unlike CDN, with the purpose of replicating content from specifically contracted content providers, CPN's goal is to cache whatever content users access from around the world of content servers. Qualitatively, a CDN services the supply side of content distribution; a CPN services the demand side.

Flash Crowd Problem: It occurs when the request load overwhelms some aspect of a Web site's infrastructure, such as the front-end Web server, network equipment or bandwidth, or the back-end transaction-processing infrastructure. The resulting overload can crash a site or cause unusually high response times.

Spatial Locality: Describes the effect that when an object is referenced, its "nearby" objects will tend to be referenced soon. The notion of "nearness" can include the minimum number of hyperlinks that link the two objects, or it can describe semantic nearness.

Temporal Locality: Describes the effect that an object, which has just been referenced, has a high (or increased) probability of being referenced again in the near future. Formally: let $p_i(k)$ denote the probability that, following a reference to object i, the next reference to object i occurs within k references. We say that a particular object shows temporal locality of reference if there exists a $k > 0$ such that $p_i(k) > 1 - (1 - 1/n)^k$.

Case-Based Learning in Computer Information Systems

Morgan Jennings
Metropolitan State College of Denver, USA

Charles H. Mawhinney
Metropolitan State College of Denver, USA

Janos Fustos
Metropolitan State College of Denver, USA

INTRODUCTION

How can we retain computer information systems (CIS) students? A decline in enrollment similar to that which occurred in the 80's (Mawhinney, Callaghan, & Cale, 1989) is the motivating factor for this question. A google™ search on declining enrollments in information systems brings up reports supporting this trend. DePaul University, for example, had increased undergraduate enrollments "in all colleges but the School for New Learning and the School of Computer Science, Telecommunications and Information Systems" (DePaul University, 2003). A report from the California Community College system listed the top 15 curricular areas of declining FTE's (Perry, 2003); Computer and Information Science and Computer programming made the list. Our own Computer Information Systems (CIS) and Computer Science programs have fewer students enrolled.

BACKGROUND

A recent comparison study (Jennings, Mahwinney, & Fustos, 2003) confirmed past research (Mawhinney et al., 1989) indicating that students perceive that an IS career provides less work-place interaction than they desire. Lack of understanding regarding an IS career is not uncommon. As Mawhinney et al. (1989) and von Hellens and Nielson (2001) found, students believe that CIS entails working alone and requires a high level of math. Because of the scarce or inaccurate knowledge regarding a CIS degree or career, students may avoid CIS programs.

In addition to a lack of understanding related to what an IS worker does in his/her job, retaining students within entry-level college IS courses is a problem (Myers & Beise, 2001). Many students feel they are computer literate until they enter an IS program. The skills that they possess and the skills needed within an IS degree are likely to be disparate (Easton & Easton, 2002; Karsten & Roth, 1998). Rather than a sink or swim attitude on the part of colleges and universities, time spent coaching and encouraging students on relevant computer skills for the IS degree may help them feel confident and able to complete the program (Compeau, Higgins, & Huff, 1999). This means more than showing students the benefits of technology or how to use a computer. It may require providing meaningful and relevant learning situations in which to use the technology (Venkatesh, 1999) that are similar to actual work-related scenarios (Gallivan, 2000).

Without an accurate picture, it is difficult for students to understand the work-style of information system professionals. The content of CIS courses is technically-oriented and many students struggle with the content, usually in isolation. This, however, belies the business environment where employees usually work together on projects. Learning should take place in a similar environment. In addition, research suggests that there is a synergistic learning effect within group environments (Ryan, Bordoloi & Harrison, 2000; Savery & Duffy, 1995). For example, better understanding of a system and development of more accurate mental models was found in a group environment (Gallivan, 2000). An unconstructive aspect of such a learning situation is that negative comments may affect the attitude of group members (Gallivan, 2000), or "group think" may stifle creativity.

MAKING THE CASE

Given that the team or group-based projects approach is a ubiquitous part of a career in this field, authentic learning environments could provide students with a more realistic model of the IS field. With authentic learning environments, the necessary information technology skills are embedded in the learning process. Also embedded in the learning process are the soft skills that managers say are lacking in employees, such as problem solving, communicating effectively and working in group environments. (Lee & Trauth, 1995; Todd, McKeen, & Gallupe, 1995).

There is a body of research and theory on the importance of providing authentic and relevant learning environments. This is often within the context of constructivism, an umbrella term that identifies a learning philosophy. Constructivism gained wide-spread acceptance in the educational technology discipline in the early nineties (Duffy & Jonassen, 1991; Lebow, 1993; Savery & Duffy, 1995; Vanderbilt Cognition and Technology Group, 1990), although it has been in existence in different forms for decades. It is gaining acceptance within information systems and computer science education as well (Ben-Ari, 2001; Boyle, 2000). The Web, in particular, has provided a platform where collaborative learning environments can be supported (e.g., Shang, Shi & Chen, 2001; Vat, 2001).

Cases (Harvard Business School, 2003; Potvin, 2000) or problem-based learning (PBL) (Barrows, 1993, 1985), situated cognition (Duffy & Jonassen, 1991), learner centered (Henson, 2003) and cooperative learning and anchored instruction (Vanderbilt Cognition and Technology Group, 1990) are some of the terms or models that fit within a constructivist paradigm. While some aspects may vary, the overriding principles include active engagement, collaboration and personal relevance. The reasons for learning are embedded within rich, authentic contextually relevant environments (Harvard Business School, n.d.; Lebow, 1993). The outcome is the ability to reason and problem-solve ill-structured situations. These types of environments are more likely to develop ownership on the part of the students involved (Savery & Duffy, 1995) and may promote what Agarwal & Karahanna (2000) call cognitive absorption and Jennings (2002) calls cognitive aesthetics.

The Harvard Case Method (Harvard Business School, 2003) and PBL are probably the most well known examples. Neither Harvard cases nor PBL are new concepts. The Harvard Case Method originated in 1913 (Harvard Business School, 2003). The objective of the case method was to enhance judgment and decision-making capability and it is widely used because of its success (Harvard Business School, 2003; Potvin, 2000). Problem-based learning was developed in the mid 50's for medical education (Savery & Duffy, 1995) and like the Harvard Case Method, provides a student with a problem that they must solve. Most often, when a student resolution has been reached, it is compared to the solution of the company or physician from which the case originated, although this is not always the situation. Whether or not a comparison is made, the goal is for students to acquire the knowledge and skills to solve problems in their respective fields.

Constructivist models are designed for ill-structured material and provide relevant, engaging, authentic contexts from which to draw conclusions. Teachers (or facilitators) are mentors and guides who challenge students to problem-solve; they model higher order thinking skills (Barrows, 2003; Savery & Duffy, 1995). These models all include interaction between peers which is a successful means to engage students (Vanderbilt Cognition and Technology Group, 1990).

They are however, not particularly easy to implement because of the time commitment and the difficulty in distilling a problem into an appropriate case or authentic environment in which to anchor instruction. The problems for Harvard cases come from the business world, such as a company implementing an e-business model. It can take between 1-4 months to develop a case and Harvard Business School (HBS) considers four factors when devising a case (Harvard Business School, 2003):

1. The issues on which the case will focus;
2. The analysis required on the part of students to address those issues;
3. The data required in the case to perform that analysis satisfactorily; and
4. Where the data can be obtained.

Two sites that provide many free cases are the Idea Group Inc. Web site (http://www.idea-group.com/cases_pp/login.asp) and the HBS Web site (http://harvardbusinessonline.hbsp.harvard.edu/b02/en/cases/cases_home.jhtml). Idea Group has information systems cases while HBS provides general business cases. In addition, the following links (retrieved February 12, 2004) have either example cases/problems or information regarding this type of learning environment.

- Multidisciplinary case-based learning for undergraduate students: http://www.blackwell-synergy.com/links/doi/10.1034/j.1600-0579.2000.040404.x/abs/
- The Center for Problem-Based Learning (PBL) at Samford University:http://www.samford.edu/pbl/
- University of Delaware (a list of links): http://www.udel.edu/pbl/others.html
- Problem-Based Learning: An Introduction: http://www.ntlf.com/html/pi/9812/pbl_1.htm

Another potential source for cases is a college's local business community. Working with a local company to develop a case provides a unique opportunity for students to interact with the company. Student feedback strongly indicates that this opportunity increases the relevance, engagement and desire to implement a worthwhile solution to a problem.

While Harvard cases are based on actual business situations, the conditions developed for problem-based learning come from well-formulated, realistic problems that mirror real-world situations. The following instructional principles (Savery & Duffy, 1995) provide a context from which to create appropriate problems:

1. Anchor all learning activities to a larger task or problem.
2. Support the learner in developing ownership for the overall problem or task.
3. Design an authentic task.
4. Design the task and the learning environment to reflect the complexity of the environment they should be able to function in at the end of learning.
5. Give the learner ownership of the process used to develop a solution.
6. Design the learning environment to support and challenge the learner's thinking.
7. Encourage testing ideas against alternative views.
8. Provide opportunity for and support reflection on both the content learned and the learning process.

Objectives for a problem include specific content learning. Student evaluation can be completed through peer and self-evaluation as well as traditional testing based on the objectives. Traditional testing may help alleviate an instructor's concerns regarding individual student learning.

FUTURE TRENDS

It is not enough to simply provide a case or problem to be solved. In order for this paradigm to work, students must become a team and team building must be taught. Wells (2002) uses Katzenbach and Smith's definition of team work: "A team is a small number of people with complementary skills who are committed to a common purpose, performance goals, and approach for which they hold themselves mutually accountable."

A cursory review of articles indicates that many faculty members are using a team approach in their courses. Fewer, it seems, include instruction on how to be a team member. As team work becomes prevalent within the college curriculum, we will likely see more instruction in team building. Without it, students often perceive group work with disdain: With guidance on team building, students are more positive in regard to the experience (Wells, 2002).

Companies have high expectations for CIS graduates (Shawyunm, 1999). It behooves us as educators to provide the business community with students who have had realistic CIS experience, which authentic learning environments provide. Team building concepts could be taught in the ubiquitous entry-level computing course so that students have the skills to work effectively in groups throughout their college term and careers.

CONCLUSION

We discussed the concepts of teamwork, using authentic problems or cases and how this type of model could be applied to courses in an undergraduate CIS program. Using this type of environment in CIS college programs would provide students with real-world skills and an accurate understanding of CIS. With authentic learning environments and team building instruction, the technology and soft skills are embedded in the learning process. By using this learning approach CIS majors experience interesting and varied problems during their student tenure. They enter the work force with immediately usable skills and a realistic understanding of their career of choice.

KEY TERMS

Active Learning: As a group, earners read, write, discuss, or are otherwise engaged in solving problems. Students engage in such higher-order thinking tasks as analysis, synthesis, and evaluation.

Anchored Instruction: Learning is anchored in a real world context. Within this context, learners engage in different activities to solve a problem, such as math calculations or geographic coordinates to travel across a continent or sale a ship.

Cognitive Apprenticeships: Students work in teams on projects or problems with close scaffolding of the instructor. Cognitive apprenticeships are representative of Vygotskian "zones of proximal development" in which student tasks are slightly more difficult than students can manage independently, requiring the aid of their peers and instructor to succeed.

Constructivism: A theory of learning and knowing that holds that learning is an active process of knowledge construction in which learners build on prior knowledge and experience to shape meaning and construct new knowledge (Lambert & Walker, 1995). Important concepts include: (a.) students are active rather than passive learners, (b.) students take responsibility for learning as an individual and within a social setting, (c.) learning must be embedded in contexts that have real-world relevance.

Harvard Case-Based Learning: Students are given a realistic case relevant to the course (information systems, accounting, management, etc.). Students work through the case, in or out of class and decide what should be done. They then meet with the entire class, or in groups and discuss and resolve the case.

Problem-Based Learning: Students are confronted with a well chosen, ill-structured problem that mirrors real-world problems. Students define problems, identify what information is needed and engage in solution generation and decision making.

Situated Cognition: A "situated cognition" theory of knowledge is characterized by the principle that the activity in which knowledge is developed and deployed is not separable from learning and cognition. Rather it is an integral part of what is learned (Brown, Collins & Duguid, 1989).

Census Data for Health Preparedness and Response

Jane L. Garb
Baystate Medical Center, USA

Richard B. Wait
Baystate Medical Center, USA

INTRODUCTION

The epidemiologist works with researchers in various disciplines as well as public and private health practitioners who are responsible for maintaining and improving the health of the population. Health is defined as "a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity"(WHO, 1948). The role of the epidemiologist is to provide information on the extent, etiology and risk of disease or injury. Key to this role is knowledge of the location, size and demographic makeup of the population at risk for developing disease or injury. By integrating this information with the location of cases as well as risk factors, epidemiologists can make a vital contribution to disease and injury prevention, intervention and response. This applies both to endemic or "usual" levels of both chronic diseases like cancer or heart disease and infectious diseases like pneumonia or influenza, and injuries like gunshot wounds or motor vehicle accidents. It also applies to disease epidemics or outbreaks like SARS; attacks by biological or chemical weapons such as Anthrax, ricin or sarin; and inadvertent natural or technological disasters including earthquakes, transportation disasters or widespread power interruptions. This chapter explores the types of census data for disease surveillance, prevention and intervention.

BACKGROUND

Sources of Geographic and Population Data

The decennial census (*Census 2000*, 2001) and American Community Survey (*American Community Survey*, 2003; *Meeting 21st Century Demographic Data Needs Implementing the American Community Survey: May 2002*, 2002) are the major sources of population data in a GIS. The census is conducted every 10 years. It provides a complete count of the U.S. population based on the census "short form" given to every individual. In addition, it provides detailed socioeconomic and demographic information for individuals, families, and households and selected information about housing, based on the "long form", given to a 1/6 sample of the population.

The American Community Survey (ACS) is an ongoing survey by the U.S. Census Bureau on an approximate 2.5% sample of the population, with over-sampling for small governmental units such as American Indian Reservations. Data is collected monthly and reported annually using detailed demographic and economic questions from the Census long form, with additional questions such as those on grandparents as care-givers. Currently the American Community Survey is limited to an annual survey of 700,000 households in 31 sites across country. However, full implementation will begin in 2004. The first data products for the smallest areas and populations will be available in 2009. Once data products are produced for a population group or area, they will be updated each year (*American Community Survey Operations Plan*, 2003). ACS survey quality measures are high, and these help compensate for somewhat smaller sample size and larger confidence intervals of the ACS compared to the decennial census long form (Griffin & Obenski, 2002).

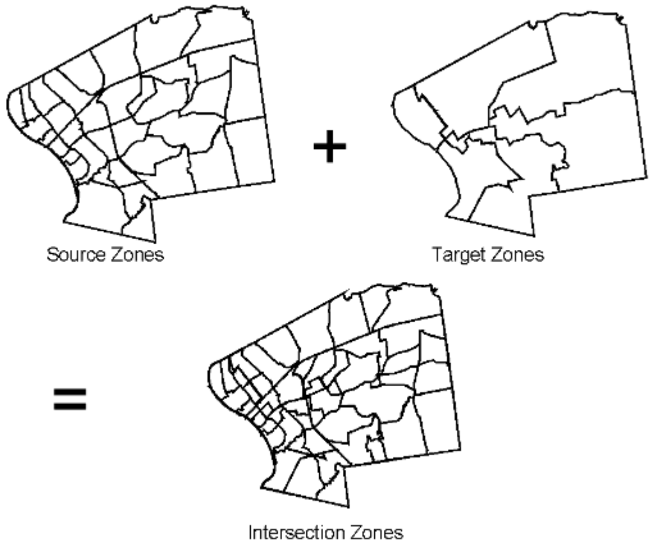
Census geographic data products are in the form of "TIGER"files (*TIGER/Line Files, Redistricting Census 2000*, 2001) which consist of street centerlines and address ranges as well as boundaries for census geographic units such as census tracts, block groups, cities and town boundaries, counties and regions.

All of these data products for the entire U.S. are publicly available from the Census Bureau Web site (http://www.census.gov) or on CD for a minimal price.

Daytime Population Estimates

The ACS holds the most promise for current population estimates because of its ongoing nature. However, other sources of daytime population estimates show utility when combined with additional data. The Census Transportation Planning Package (CTPP) (*Census Transportation and Planning Package (CTPP)*, 2003) by the Department of Transportation is a special tabulation of Census

Figure 1. Components of areal interpolation



2000 data (long form responses) that includes information according to place of work, place of residence and travel between home and work. Discussions are underway about CTPP products that would be based on ACS data.

Another survey is the Longitudinal Employer - Household Dynamics survey (LEHD) (*Longitudinal Employer - Household Dynamics*, 2003), based on a partnership between the Census Bureau and currently 10 states. This survey integrates state administrative data and census data products. It includes place of residence and place of work for workers by age, sex, and industry. Also an ongoing survey, it has ties to the ACS, which will improve its accuracy and potentially provide extremely accurate estimates of daytime populations in the future. Neither of these latter two surveys is fully implemented at this point, and this will depend on future congressional funding.

Data Integration in a GIS

We can integrate census data with health data in a GIS for prevention, intervention and response to diseases in all forms. This can be done for *endemic* or usual levels of chronic diseases like cancer or infectious diseases like pneumonia or influenza; infectious disease *epidemics* or outbreaks like the recent SARS epidemic; or sudden *attacks* with biological or chemical weapons. Census data allows us to perform critical GIS functions essential to mapping and analysis of spatial data in health.

To begin with, census geographic TIGER files are used as reference files for geocoding case or event locations. Census boundaries in these files are used in data aggregation of geographic areas and in the GIS function known as polygon overlay, where two map layers are overlaid on one another. This is the basis for a critical method necessary for utilizing census data for health called areal interpolation (Goodchild & Lam, 1980).

Both ACS and decennial census data are available only in aggregate form for fixed geographical units. These units – census tracts, block groups, counties – are administrative units used by the census to aid in census data collection, or by political entities to apportion representation and govern. However, the most useful geographic units for health applications, in which data are often available – neighborhoods, school districts, hospital service areas, and so forth – do not coincide with the census geography for which population counts are available.

Since 9/11, the scope of health has extended from preparedness against naturally occurring diseases and chronic conditions to biochemical weapons. The unique geography required for using census data in routine healthcare is even more of a challenge in the case of a bioterrorist attack, where the appropriate geographical units – police sectors, drainage sub-basins or the plume resulting from a chemical or biological release – may be unpredictable, and different depending on the nature of the biochemical weapon used.

Areal interpolation (AI) becomes a key method for addressing the challenge of estimating the population for the geography of healthcare. It starts with original geographic units for which data such as population counts is known. These are called "source zones" (see Figure 1). Units for which population counts or other information is unknown but desired, in this case, neighborhoods, schools districts, and so forth, are called "target zones".

A GIS can calculate the intersection of these two layers through the polygon overlay operation. The result is "intersection zones". The population totals or other attribute data for the source zones are allocated to each of the intersection zones according to one of several available statistical methods of varying complexity (Bracken & Martin, 1989; Burrough, 1986; Flowerdew & Green, 1994; Flowerdew, Green, & Kehris, 1991; Flowerdew & Openshaw, 1987; Green, 1988, 1990; Lam, 1983; Langford, Masser, & Unwin, 1989; Langford & Unwin, 1994; Martin & Bracken, 1991; Mugglin, Carlin, & Gelfand, 2000; Mugglin, Carlin, Zhu, & Conlon, 1999; Tobler, 1979). Then the population totals for the intersection zones are aggregated into the target zones. AI methods rely on the GIS primarily for calculating the area of the intersection zones. The simplest methods allocate the population into each intersection zone based on the proportion of the source zone area represented by the intersection zone (areal weighting) or whether the center of the target zone falls within the source zone (point-in-polygon). The LandView project (Census, 2004) of the U.S. Census Bureau provides easy-to-use software employing the latter type of method. Although these methods are relatively easy to calculate, they assume that the population is evenly distributed across the source zone, which is not usually the case. The more sophisticated AI methods do not make this assumption, but assume rather that the population is clustered around roads, houses, night-time lights, according to soil type or elevation, and so forth. The population is allocated into the target zones according to the presence of these factors. The LandScan Global Population Project (Laboratory) employs some of the latter methods in the process of estimating affected populations on a world-wide basis.

Using areal interpolation, census population data can be available for geographical units which are relevant to healthcare. Some examples of such units are hospital service areas, community health service areas, neighborhoods, school districts, police sectors, and water service areas. This allows much greater flexibility in using census data in health. The assumptions of the areal interpolation method used, its computational complexity and the degree of estimation accuracy needed must be kept in mind when choosing the appropriate areal interpolation method for a particular purpose.

Disease Surveillance and Community Profiles

We can assess the risk of disease to particular populations in a community by calculating disease rates. Rates tell us how prevalent endemic diseases are or what the risk is of getting the disease in an epidemic or biochemical attack. A rate is composed of a numerator divided by a denominator. For endemic or epidemic diseases, hospitals or public health departments have the numerators for disease rates – they know how many cases of disease there are and where they are located. For example, for "reportable" infectious diseases, physicians report cases

Figure 2. Rate of violent incidents by police sector in Springfield, MA

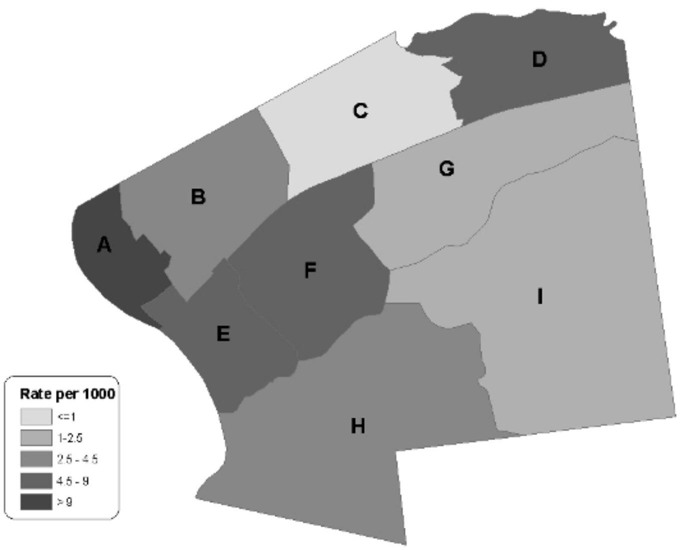


Figure 3. Time course of Shigellosis epidemic in Springfield, MA

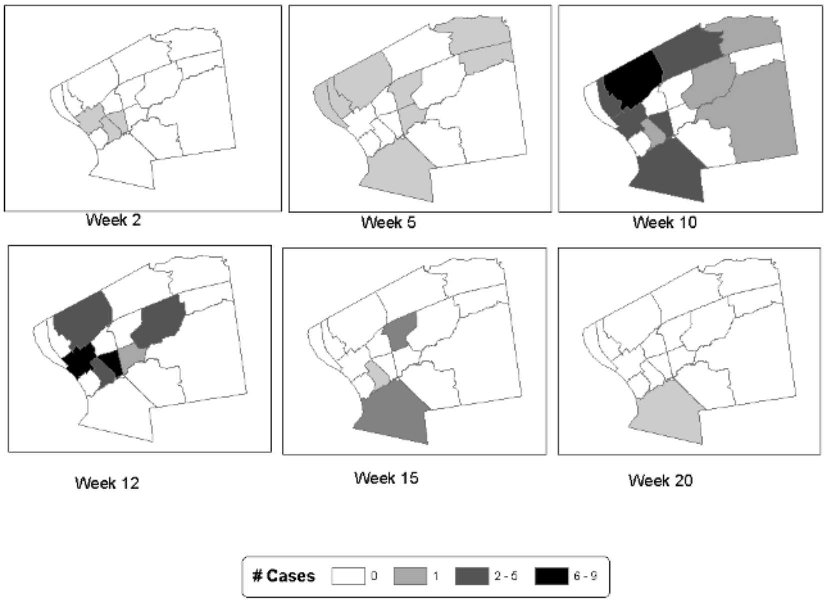


to their local or state public health department, who then sends this information to the Centers for Disease Control. Incidence and prevalence rates for these diseases are published in local and state public health reports, and nationally in the *Morbidity and Mortality Weekly Report* (CDC). Many hospitals maintain disease registries for chronic diseases such as cancer, heart disease or neurological disorders. This data is often sent to state or national disease registries. Some of this data can obtained by directly contacting state public health departments.

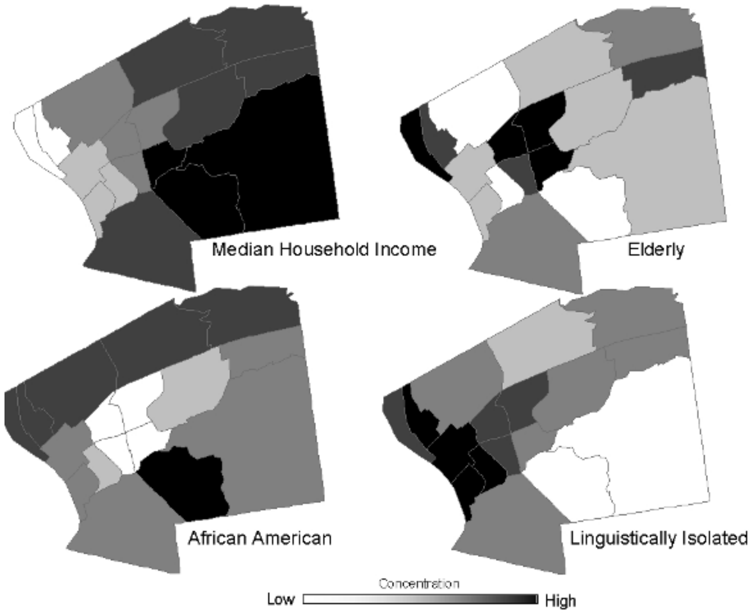
As discussed earlier, these types of data are usually available only in aggregate form, summarized as incidence rates for arbitrary geographic units like zip codes, which do not coincide with census geographic units.

Census data provides the denominators for these rates, so, through AI if necessary, we can estimate the risk of disease in our community for all residents or for different geographic areas or population subgroups. The map in Figure 2 is an example of how disease rates can be displayed for cancer surveillance. It represents the prevalence of late stage breast cancer in Springfield, Massachusetts – the number of existing cases of late stage disease for every 10,000 women by *neighborhood*. In this example, the exact location of breast cancer cases was obtained from the two hospital cancer registries in Springfield which represent 95% of reported cases in the city. Population totals by neighborhood were estimated from census block data using areal interpolation. This map is called a "choropleth" or color-coded map. The color intensity indicates the level of disease. The darker the shade, the higher is the risk of late stage breast cancer and visa versa.

Disease incidence rates can also be displayed temporally in a series of maps, to follow the course of disease over time. The time frame can be days or weeks for an epidemic or bioterrorist attack, or years for chronic diseases. This information on disease surveillance can be used to direct medical resources for intervention or prevention of endemic diseases or emergency treatment for the victims of an epidemic or biological attack. Figure 3 illustrates how GIS was used to combine local public health data on case locations with census population estimates to plot the course of a local shigella epidemic over time.

Census data also provides *both* numerators and denominators for demographic and economic rates, which allows us to visualize the socioeconomic character of a community. Figure 4 shows population concentrations for linguistically isolated, elderly, and African American residents as well as the distribution of median household income in Springfield using GIS software ArcGIS (ESRI, 1999a). In the case of a biological attack, identifying demographic subgroups known to be at increased risk could direct efforts to prevent the spread of the biological agent. For example, in a mass vaccination effort against smallpox, geographic areas with high concentrations of

Figure 4. Socioeconomic profile of Springfield, MA



the elderly could be targeted for the first wave of vaccination. In the event of a chemical weapon attack, areas with high concentrations of linguistically isolated residents would require foreign-language communication of emergency instructions.

Putting endemic disease rates and demographic rates together and mapping them in a GIS, we can visualize how the current geographic pattern of disease relates to demographic and economic patterns in the community. Pattern similarities between disease rates and census demographic rates indicate a possible relationship between the two. This forms the basis for hypotheses to be tested with spatial analysis.

Techniques such as spatial regression (Bailey & Gatrell, 1995) can be used to identify significant socioeconomic and demographic risk factors for disease – characteristics of population subgroups that put them at increased risk for disease. In this type of spatial analysis, census tracts, blocks, neighborhoods or other geographic areas become the unit of analysis. Disease rates in the different geographic areas are compared. Census population and housing characteristics are tested to see if they are related to the geographic distribution of disease. This type of analysis accounts for spatial proximity of geographic areas.

We can use the results of this type of analyses to design intervention and prevention programs for endemic diseases. It directs us to community groups with which to partner in implementing educational and outreach programs, and indicates what social and cultural factors should be taken into account in order to design more effective programs.

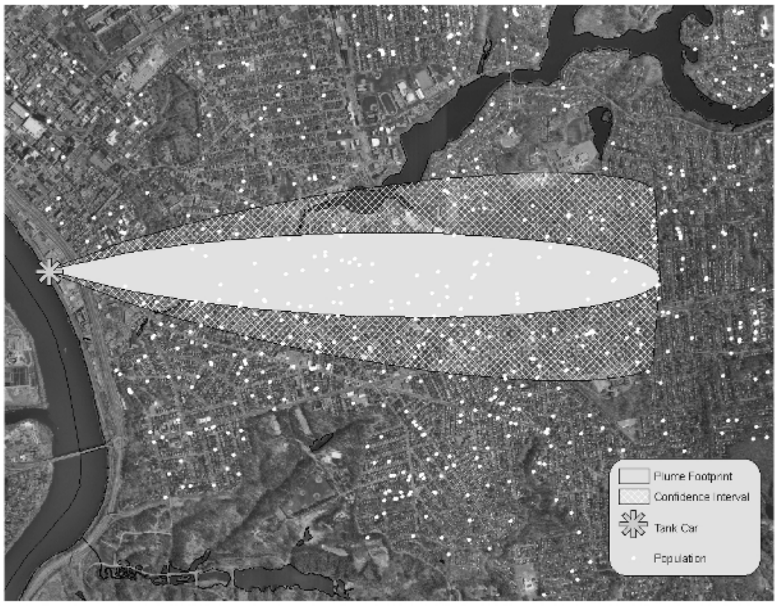
FUTURE TRENDS

Locating Affected Populations for Disaster Response

An increasingly important consideration in the context of homeland security and public health is determining the geographic location and size of the population at risk of exposure to biochemical weapons or other weapons of mass destruction. Special-purpose shareware programs such as ALOHA (Areal Locations of Hazardous Atmospheres, 2003), HAZUS (HAZUS(Hazards U.S.), 2003) or CATS (ESRI, 1999b) which model the dispersion of toxic chemicals, can be combined with areal interpolation methods in a GIS to help in this challenge.

For example, in a disaster drill at Baystate Medical Center in conjunction with the City of Springfield, a fictitious railroad tank car containing ammonia was hit by a terrorist attack and exploded. In addition to causing mass casualties at the site of the explosion, a plume of ammonia gas was released into the air. ALOHA was used to calculate the size and location of the plume of ammonia gas that was released based on knowledge of elevation and current wind and temperature conditions. This was

Figure 5. Footprint of amonia gas plume overlaid on population distribution in the affected area



mapped and overlaid on a map of the population distribution of the area, based on current American Community Survey data (Figure 5). The areal weighting method was used to estimate the size of the population affected by the plume which would likely be in need of medical care. This method was chosen because quick calculations could be computed and re-computed on-the-fly to accommodate the shifting plume, giving rough population estimates sufficient to determine the magnitude of response necessary. Without our calculations, hospital administrators were estimating about 10-12 casualties. Our calculations showed that the population inside the plume was approximately 25,000. In this case, ease-of-computation was more important than having the most accurate population estimates.

CONCLUSION

Census data has several key uses for the epidemiologist. TIGER/line files are integral to the GIS functions of data aggregation, address geocoding, areal interpolation. Population counts from the decennial census and the American Community Survey provide denominators for disease rates and show community demographic profiles which can be used in disease surveillance as well as the analysis of socioeconomic factors in disease, program design and locating high-risk populations in a disaster or disease epidemic. This article has provided some practical applications of how the epidemiologist can combine census and health data in a GIS in order to promote and protect the health of our population on a continual basis as well as in times of crisis.

KEY TERMS

American Community Survey: An ongoing survey conducted by the U.S. Census Bureau, which collects detailed demographic and socioeconomic information on a sample of the population.

Areal Interpolation: A method of estimating counts or quantities for one configuration of geographic units (target zones) based on known counts from a different configuration of the same geographic space (source zones).

Choropleth Map: A color-coded map, also referred to as a "thematic" map, in which geographic areas are portrayed in different hues or intensity according to their value on some quantity being displayed.

Disease Rates: The level of disease in a given time period, population and geographic area. It represents the proportion of disease cases in the exposed population or population-at-risk.

Endemic: The usual level of disease in a geographic area in a given period of time

Epidemic: An excessive level of disease in a geographic area in a given period of time

Geographic Information System (GIS): "A computer-based set of tools for capturing, (collecting), editing, storing, integrating, analyzing and displaying spatially referenced data" (Bailey & Gatrell, 1995).

Health: A state of complete physical, mental and social well-being and not merely the absence of disease or infirmity (WHO, 1948).

Spatial Regression: A spatial analytic technique modeling the relationship of various factors to the geographical distribution of some attribute measured on a continuous scale.

Certifying Software Product and Processes

Hareton Leung
Hong Kong Polytechnic University, Hong Kong

INTRODUCTION

Software certification can not only greatly improve the overall quality of software; it can also help to control the cost of software development. Because software has traditionally been perceived as intangible, it has commonly been certified on the basis of the thoroughness of its development methodology. Certification of the development process is based on the assumption that the development process can assure that the developed product complies with specifications. However, software can also be certified at the product level. In this chapter, we will present a process model that captures the essential aspects of process and product certification (Silva, 2002).

BACKGROUND

Software can be certified at two levels: *process certification* and *product certification*. Process certification evaluates the process against a standard or model process to which it should conform. In Europe, the most popular process evaluation model is ISO9001 (Cianfrani, 2001). In America the focus of process quality improvement and evaluation is a process *maturity* model such as the Capability Maturity Model for Software (SW-CMM) and the Capability Maturity Model Integration (CMMI) (Chrissis, 2003; Humphrey, 1995; Paulk, 1993). Yet another example of process certification is Bootstrap from Europe (Card, 1993).

Product certification involves directly assessing the equivalence of key attributes of software at the level of its specifications (specified service), and its behaviour (actual service). A software product can be characterised by its functional and non-functional attributes. Examples of product certification include the Department of Defense Y2K certification process (DoD) and the Hong Kong Article Numbering Association Software Certification Program (Hong Kong Article, 1987).

CERTIFICATION MODELS

We first present two certification models, one for process certification and the other for product certification. We then present a generic certification model for both process and product certification. There are two key participants in the certification process, each playing a different role: the certification body and certificate applicant (or the software developer).

For the presentation of the certification process, we have adopted the IDEF0 notation (Klingler).

ProCess Certification (PCC)

Figure 1 shows the five major stages of the Process Certification (PCC) model.

PCC-0: Review of Certification Guidelines

The certification body studies the process requirements, analyses the relationships between the process requirements and the certification model, and identifies important requirements. It then issues and publishes the certification guidelines. An applicant will then study the certification model and process requirements and from that gathers important information about the implementation of the process. The applicant then includes the certification requirements in the production process before the process assessment.

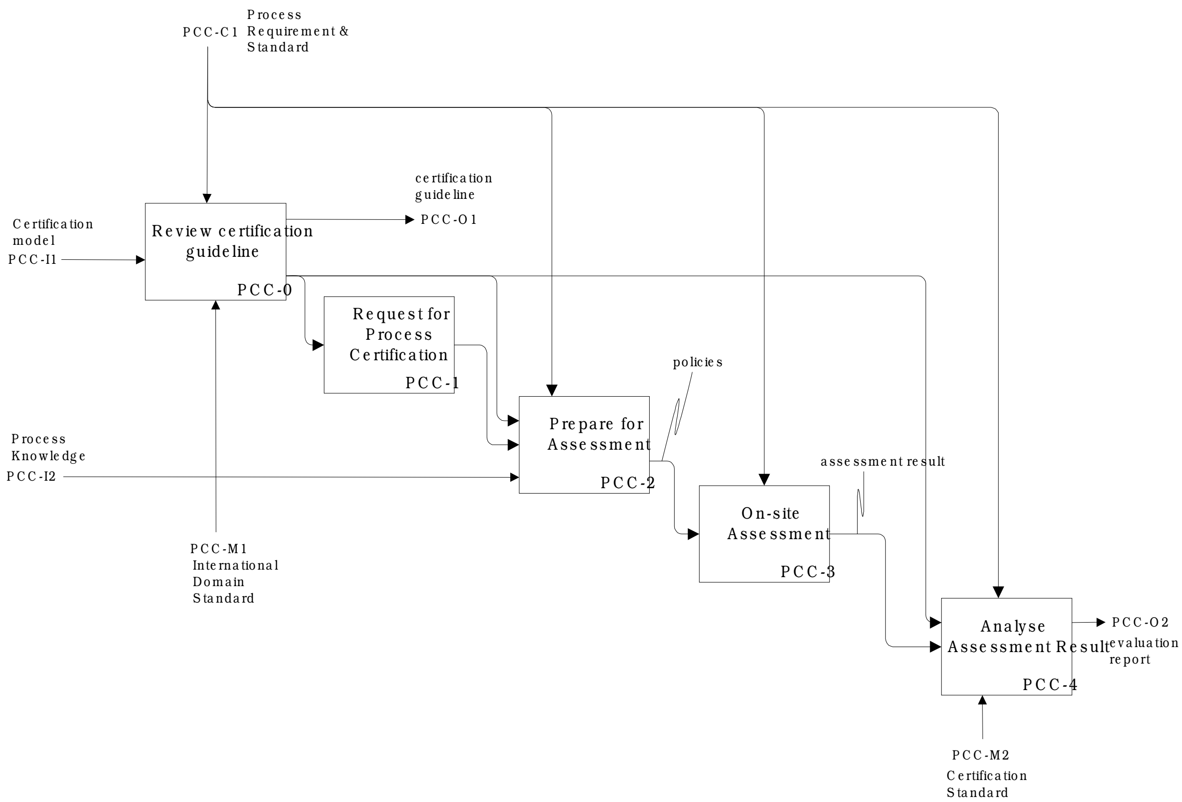
PCC-1: Request for Process Certification

After implementing the certification requirements in its production process, the applicant will apply to have the production process certified and will submit an application form to the certification body. The certification body will process the certification request and generate an application number to identify each certification.

PCC-2: Preparation for Assessment

The certification body will prepare the assessment guidelines and certification requirements to assess the applicant's production process. The body may familiarise the applicant's staff with the certification process by providing a pre-assessment service and audit training. The applicant's staff should ensure that the production processes fulfil the requirement of certification. The applicant then requests that the process be certified.

Figure 1. PCC model



PCC-3: On-Site Audit

The certification body will send assessors to the applicant's development site. Assessors will follow the assessment and certification guidelines to collect the process information and assess the applicant's production process. The applicant's staff should provide the necessary information to help assessors assess the production process. Finally, the assessors should produce an assessment report.

PCC-4: Analysis of Assessment Results

The certification body evaluates the assessment result to determine whether the production process passes the assessment and then returns the final result to the applicant. The applicant should analyse the assessment result to identify areas for improvement. Generally, to ensure that it keeps pace with the environmental and technological changes, the certification body should evaluate its certification guidelines after each certification.

Left-hand columns of Table 1 summarize the process stages of the PCC model.

ProDuct Certification (PDC)

Like the PCC model, the ProDuct Certification (PDC) model also consists of five major stages. The right-hand columns of Table 1 summarise the process stages of the PDC model.

The PCC and the PDC models not only both have five stages, they are also very similar in other ways. Indeed, although they differ in some details, most of their procedures have the same purposes and provide similar functions. For example, PCC-0, PCC-1, and PCC-4 are similar to, respectively, PDC-0, PDC-1, and PDC-4. The key difference between these models is that PCC focuses on the software production process, while PDC focuses on the software product.

Other specific differences between the PCC and PDC models are as follows.

Table 1. PCC model and PDC model description

	PCC Model *Certification body*	*Applicant*	**PDC Model** *Certification body*	*Applicant*
	PCC-0: *Review*	*Certification guideline*	**PDC-0:** *Review*	*Certification guideline*
	Gather the certification model information to issue, update and maintain certification guidelines.	Study the process requirement, and process certification model. Apply to the production process.	Gather all the domain knowledge, the industrial practice; issue and maintain a certification guideline.	Study the entire domain requirement, and domain certification model.
Input	Certification model	Certification model	Certification model	Certification model
Control	Process requirement	Process requirement	Domain requirement	Domain requirement
Support	International process standard	Nil	International domain standard	International domain standard
Output	Certification guideline	Quality policy	Domain certification model	Quality policy
	PCC-1: *Request for*	*Process certification*	**PDC-1:** *Request for*	*Product certification*
	Process the applications	Submit an application	Process the applications	Submit an application
Input	Certification guideline	Application form	Domain certification model	Quality policy
Control	Nil	Nil	Nil	Nil
Support	Nil	Nil	Nil	Nil
Output	Application no.	Certification process request	Application category	Certification request
	PCC-2: *Prepare for*	*Assessment*	**PDC-2:** *Prepare for*	*assessment*
	Help the applicant to produce documentation.	Implement quality policy, pre-assess before real assessment.	Study the certification guideline, arrange the certification schedule.	Study the certification guideline, prepare for the certification.
Input	Certification guideline	Certification guideline memo	Application category	Certification guideline
Control	Process requirement	Nil	Domain requirement	Domain requirement
Support	Nil	Nil	Nil	Nil
Output	Assessment schedule	Quality policy & documentation	Assessment material & schedule	Assessment schedule
	PCC-3: *On-site audit*		**PDC-3:** *Perform*	*Assessment*
	Perform on-site audit to assess the applicant's production processes.	Cooperate with the assessor to assess the production processes.	Following the assessment guideline, assess the product.	Submit the product and the product documentation.
Input	Assessment guideline	Company policies	Assessment material	Product and product information
Control	Process requirement	Process requirement	Domain requirement	Nil
Support	Nil	Nil	Nil	Nil
Output	Assessment result	Production processes information	Assessment result	Product and product information
	PCC-4: *Analyse*	*assessment result*	**PDC-4:** *Evaluation*	*assessment*
	Evaluate the assessment result.	Analyse the assessment result and identify improvement.	Evaluate the assessment result and generate an assessment report	Analyse the assessment result and identify improvement.
Input	Assessment results	Assessment result & its process	Assessment result	Assessment result & its product
Control	Process requirement	Process requirement	Domain requirement	Domain requirement
Support	Certification standard	Nil	Certification standard	Nil
Output	Evaluation result	Improvement list	Evaluation result	Improvement list

In the stage "Preparation for Assessment" PCC (PCC-2) requires the preparation of the assessment guidelines in order to assess the process. The corresponding stage of PDC requires only the preparation of assessment material in order to assess the product.

PCC-3 and PDC-3 differ in the assessment criteria that they use in the assessment stage. PCC involves some degree of subjectiveness, as the assessment is partly dependent on the assessors. In contrast, PDC often uses objective criteria based on the test execution result. Another difference is that as PCC requires that assessors appraise the staff's working procedures and the production methodologies, the process is assessed at the development site. PDC, however, will assess the product in a special laboratory, which is not usually at the applicant's own development site.

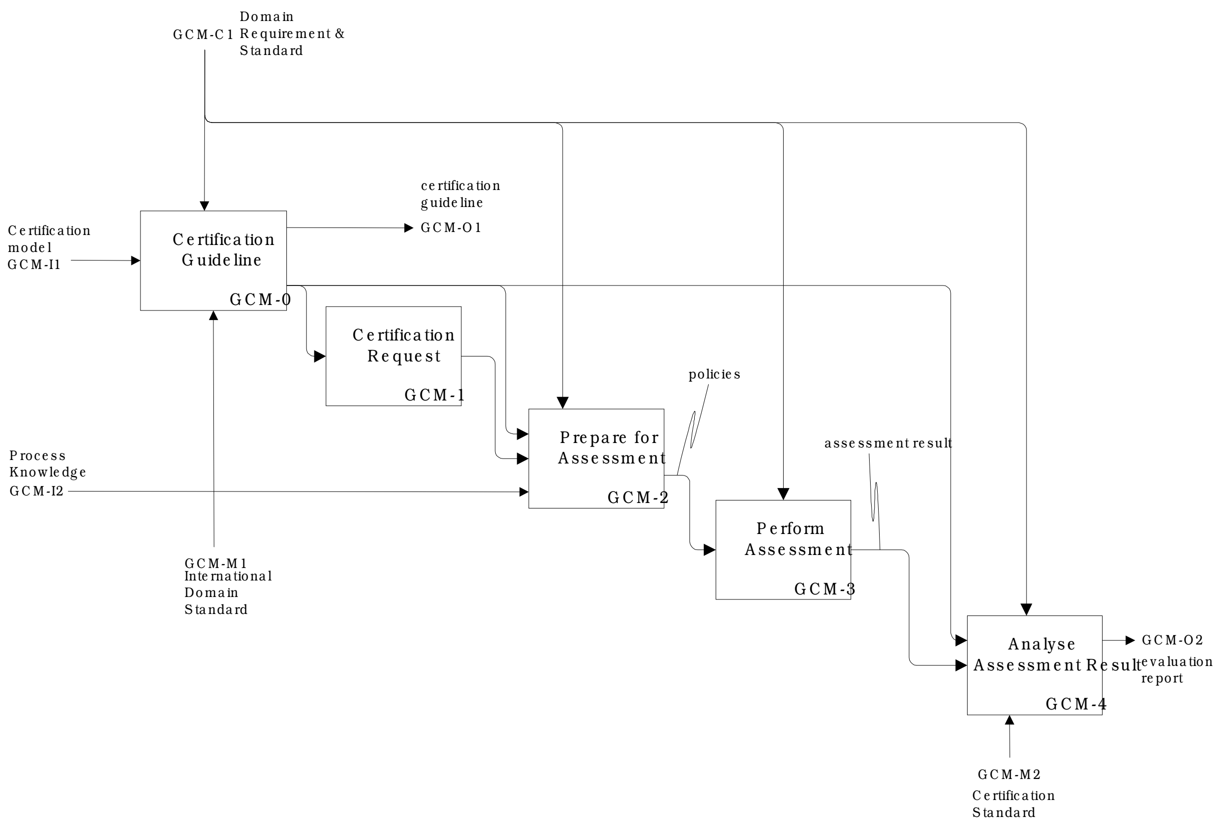
A Generic Certification Model (GCM)

A Generic Certification Model (GCM) for both process and product certification processes has been developed, as shown in Figure 2. The GCM is a natural and obvious adaptation of both PCC and PDC. Its model description is given in Table 2. GCM consists of five stages: establishment of certification guidelines, request for certification, preparation for assessment, performance of assessment, and analysis of assessment results.

FUTURE TRENDS

One area that has not been addressed in the general certification process model is the tailoring requirements. As some companies have their own specific needs and requirements, it would be advantageous that a tailoring

Figure 2. GCM



guideline be developed so that the GCM model can be adjusted to ease its adoption.

Newer process models, such as the project management processes promoted by the Project Management Institute (PMI, 2004) and various system outsourcing models proposed in the literature, are gaining acceptance. These new processes will have a positive impact on the final quality of a software system. We need more studies to understand the effect of implementing these models.

CONCLUSION

This article describes a general certification process model that includes both process certification and product certification. GCM captures the essence of most certification schemes and can be used as a basis for the development of various kinds of process and product certification methods. As the GCM components are reusable, they can increase the efficiency and effectiveness of the development of new certification methods. GCM can also serve as a basic checklist to ascertain whether a certification method has all the key elements required for carrying out certification. GCM has been evaluated by matching it against several process certification and product certification schemes (Leung & Li, 2002).

KEY TERMS

Assessment: The process of comparing the actual measurements of the characteristics of interest with the specifications of those characteristics.

BOOTSTRAP: BOOTSTRAP is a European method for software process assessment and improvement. It enhanced and refined the Capability Maturity Model (CMM) developed at the Software Engineering Institute (SEI) for software process assessment, and adapted it to the European software industry.

Certification: A procedure by which a third party gives written assurance that a product, process or service conforms to specified characteristics. Certification involves assessment.

CMMI: The Capability Maturity Model Integration (CMMI) models are an integration of best practices from proven process improvement models, including the SW-CMM, EIA731, and the Integrated Product Management CMM. They are tools that help organisations improve their ability to develop and maintain quality products and services.

IDEF0 Notation: Boxes within the diagram depict the sub-activities of the activity named by the diagram. Arrows between boxes depict availability of work products to activities. Arrows entering the left side of a box are inputs to the activity. Arrows exiting the right side of a box are outputs from the activity. Arrows entering the top of a box are controls that regulate the activity, and those entering the bottom are mechanisms that support the activity.

ISO9001: The ISO 9001 is an international standard that specifies the requirements of a quality management system. It is applicable to any organisation regardless of product, service, organisational size, or whether it is a public or private company.

SW-CMM: The Capability Maturity Model for Software (SW-CMM) describes a framework that software organisations can use to determine their ability to develop and maintain software. Its use can lead to organisational improvement. SW-CMM can be applied by acquisition organisations to select software contractor.

Challenges in M–Commerce

M-COMMERCE

E-commerce activity is growing exponentially, and it is revolutionizing the way that businesses are run. In Asia, there is now an explosion of mobile wireless services. The number of 3G users in Korea has surpassed 1 million while in Japan it has grown from 50,000 in 2001 to 2 million in 2003. Mobile e-commerce (m-commerce) makes business mobility a reality; mobile users can access the Internet at any time, from anywhere and from their shirt pockets/purses using ubiquitous inexpensive computing infrastructure. It is estimated that the m-commerce market will grow to over USD200 billion by 2005 (Abbott, 2002). There are many definitions of m-commerce. One definition consists of all or part of mobile wireless services ranging from mobile phone networks to wireless local area networks. However, the service provided by mobile phone systems has achieved huge success. Mobile phone users originate from all walks of life and include almost all age groups, from teenagers to retired people. It creates a new method of personal communication without location constraints. Instead of briefly describing all mobile wireless services, we will concentrate on the mobile phone and PDA related to mobile telecommunication. Hence, m-commerce is defined as electronic commerce carried out in handheld devices such as the mobile phone and PDA through a mobile telecommunication network.

E-commerce is characterized by e-marketplaces, online auction systems which act as the intermediary between buyers and sellers, whereas, m-commerce is personalized and ideal for access to location-based services. Many new business models have been established around the use of mobile devices. Mobile devices have the characteristics of: portability, low cost, more personalization, global positioning system (GPS), voice, and so forth. The new business models include micro payment and mobile payment, content distribution services and business services. Figure 1 illustrates m-commerce applications. Because of their existing customer base, technical expertise and familiarity with billing, mobile telephone operators are the natural candidates for the provision of mobile and micro payment services. Micro payment involves small purchases such as vending and other items. In other words, the mobile phone is used as an ATM card or debit card. Consumers can pay for purchases at convenience stores or buy train tickets using their mobile phones.

Content distribution services are concerned with real-time information, notification (e.g., bank overdraft), using positioning systems for intelligent distribution of personalized information by location; for example, selective advertising of locally available services and entertainment. Real-time information such as news, traffic reports, stock prices, and weather forecasts can be distributed to mobile phones via the Internet. The information is personalized to the user's interests. By using a positioning system, users can retrieve local information such as restaurants, traffic reports and shopping information. Content distribution services with a greater degree of personalization and localization can be effectively provided through a mobile portal. Localization means to supply information relevant to the current location of the user. Users' profile such as past behavior, situation and location should be taken into account for personalization and localized service provision. Notification can be sent to the mobile device too. Mobile network operators (MNOs) have a number of advantages over the other portal players (Tsalgatidou & Veijalainen, 2000). First, they have an existing customer relationship and can identify the location of the subscriber. Second, they have a billing relationship with the customers while the traditional portal does not. MNOs can act as a trusted third party and play a dominant role in m-commerce applications. In addition, the mobile phone has become a new personal entertainment medium. A wide range of entertainment services are available, which consist of online game playing, ring tones download, watching football video clips, live TV broadcasting, music download and so on. Unsurprisingly, adult mobile services and mobile gambling services are among the fast growing services. According to Juniper research, the total revenue from adult mobile services and mobile gambling services could be worth US$1billion and US$15billion respectively by 2008 (Kwok, 2004). Law regulators have to stay ahead of the fast growing development.

Businesses also need to think across traditional boundaries in e-commerce. Interaction among businesses, consumers, and smart appliances creates a lot of new opportunities: first, appliance-to-appliance, that is, appliances interact with an automatic service scheduler; second, appliance-to-business can deliver smart appliance repair alerts; third, business-to-appliance can deliver remote activation of smart appliances. For instance, the built-in sensors in a car will inform the repair service which part is broken. M-commerce also has a great impact on business applications, especially for companies with remote staff. Extending the existing Enterprise Resource Planning (ERP) systems with mobile functionality will provide remote staff, such as sales personnel, with real-time corporate and management data. Time and location constraints are reduced and the capability of mobile employees is enhanced. The logistic related business also benefits from the use of mobile inventory management applications. One interesting application is "rolling inventory" (Varshney & Vetter, 2002). In this case, multiple trucks carry a large amount of inventory while on the move. Whenever a store needs certain items/goods, a nearby truck can be located and just-in-time delivery of goods can be performed. M-commerce offers tremendous potential for businesses to respond quickly in supply chains.

CHALLENGES IN M-COMMERCE

M-commerce has a number of inherent complexities as it embraces many emerging technologies: mobile wireless systems, mobile handheld devices, software, wireless protocols, and security (Ojanperä & Prasad, 2001). These technologies have rapid product cycles and quick obsolescence. M-commerce, which is more complex than e-commerce, faces a number of challenges see Figure 2. The challenges are:

(i) The delay in 3G mobile network operators (MNO) in implementing their systems infrastructure. The success of m-commerce in Japan changes the concept of "free" Internet to "paid" Internet. Users are willing to pay for the service. MNOs anticipate a huge profit in taking control of the backbone of m-commerce – the wireless infrastructure. In addition, MNOs also play a dominant position in providing m-commerce applications. This has created an unreasonably high expectation from the services. Big companies in Europe, such as Deutsche Telecom, France Télécom, Spain's Telefünica and the UK's Vodafone, spent an estimated USD125 billion to USD150 billion on 3G licenses (Garber, 2002). Many of them are burdened with high debts.

(ii) With the exception of Asia, there is a lack of interest in 3G mobile phone systems. The Western European market has reached saturation point, where mobile possession rate is close to 100% in some countries.

Figure 1. M-commerce applications

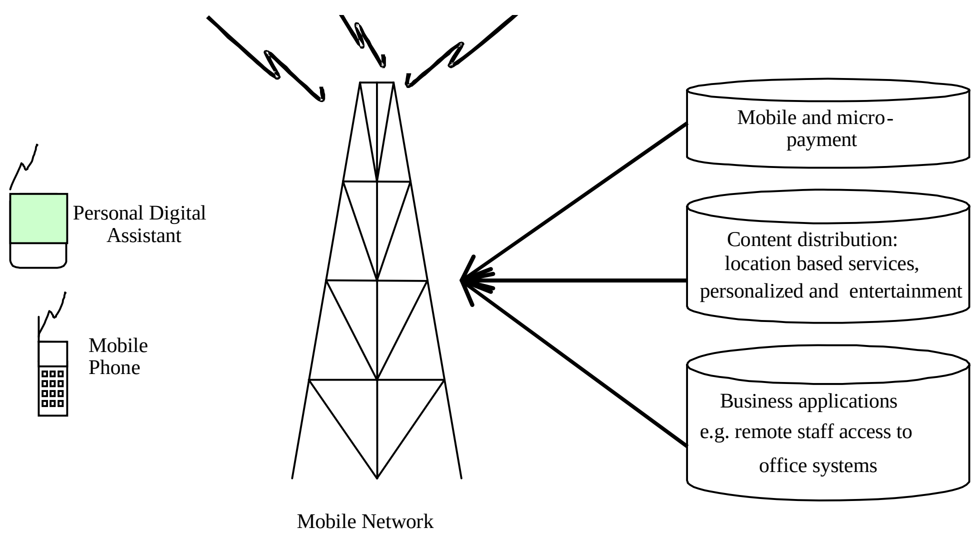

Figure 2. Challenges in m-commerce

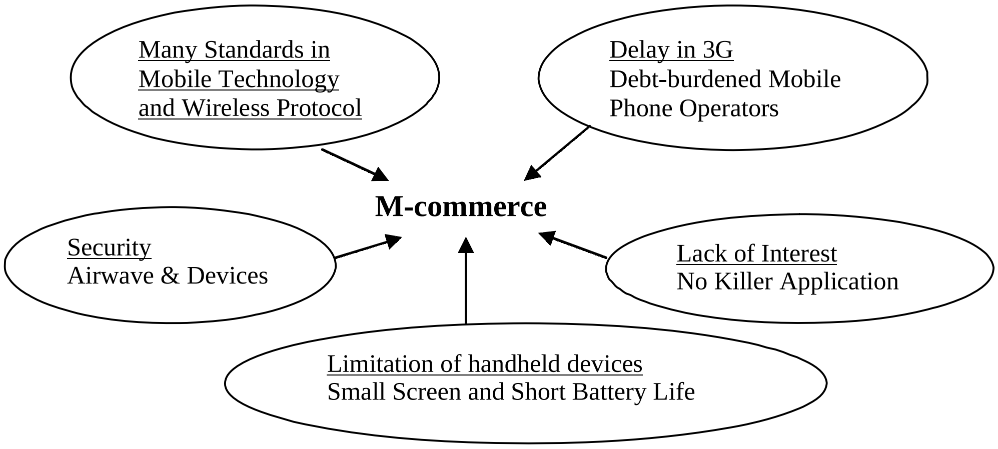

In addition, mobile users have "upgrade fatigue", that is, they are reluctant to upgrade their mobile phones. A report from the World Market Research Center, released in May 2002, predicted that 3G sales are likely to be sluggish because of a lack of consumer interest in new services. The research done by the mobile consultancy group Detica also warned that there is no single "3G killer application" that will entice large numbers of people to embrace 3G. In 2002, the mobile phone business pushed very hard on picture messaging, which requires new expensive handsets. The response has been poor. The mobile revenue mainly comes from the voice calls and SMS messaging.

(iii) An immature market with many standards. 3G standards have some commonalities, but they are not fully compatible with each other at the air interface (radio-transmission) level. This produces uncertainty for the success of global roaming and hence limits the creation of mass-market volumes for terminals and infrastructure. In addition, the spectrum problem in the US casts a shadow over global roaming. The Department of Defense occupies the spectrum band needed for 3G services. After September 11th, the U.S. military is unlikely to give up the spectrum. This introduces further technical difficulties. The advances in technology have resulted in a convergence of the functions of mobile phone and PDA devices. The sophisticated mobile phones are commonly equipped with PDA-functionalities such as a large screen and easier methods of input, for example, pen with touch screen. On the other hand, the high-ended PDAs are more compact – thinner and lighter than their predecessors. Furthermore, they are affordable and packed with many features, such as: large bright screen, handwriting recognition software, media player software, good user interface, slots for different types of memory and various wireless technologies – Wi-Fi, Bluetooth and infra red. The market for handheld devices is different from the personal computer (PC) market. For instance, Nokia not only produces phone hardware but is also involved in developing the Symbian software (the operating system of mobile phone) together with other phone manufacturers such as Motorola. Each device comes with its own proprietary operating system. Many standards are competing with each other. However, this situation is changing as Microsoft and Linux are both involved in creating operating systems for handheld devices – that is, mobile phones and PDAs. Microsoft joined the competition by rolling out two operating systems, Pocket PC2002 and the smartphone system for PDAs and mobile phones respectively in 2002. Both systems can be synchronized to a desktop PC, a convenience for business users. Linux, the open-source code, has two popular versions of embedded Linux for handheld devices: MontaVista Linux and uLinux. The participation of Microsoft and Linux in the handheld devices market will have an impact on the dominant position of Symbian.

(iv) Security. Mobile communications offer users many benefits such as portability, flexibility and increased productivity. The most significant difference between wired networks and mobile communication is that the airwave is openly exposed to intruders. The intruder eavesdrops on signaling and data connections associated with other users by using a modified mobile phone. In addition, their small size, relatively low cost, and mobility means that they are likely to be lost or stolen. Sensitive information such as the "private-key" is thus vulnerable (Karygiannis & Owens, 2002). A 3G mobile device, when connected to an IP network, is in the "always-on" mode. Both this "always-on" mode and bluetooth's "on" mode make the device susceptible to attack. Moreover, it also provides the opportunity to track a user's activity, which may be a violation of privacy.

(v) The limitations of handheld devices. Technological developments will increase the computing power and storage in handheld devices. However, insufficient battery life and power consumption will impede the potential growth of m-commerce even when 3G is widely available. At present, the battery life is very short (e.g., two to four hours for surfing) and the small screen is another limitation. PDA's have a larger screen (13cm*8cm) whereas the screen of a mobile phone is 7cm*5cm, which poses difficulty when surfing the Web. A low power, inexpensive, high-resolution colour display would seriously increase the growth of m-commerce.

On the other hand, Wi-Fi, wireless area local networks, which allow users to surf the Internet while moving, are proliferating at astonishing speed on a global scale. Worldwide retail chains like Starbucks and McDonald's offer wireless Internet access to their customers. It offers a fast and stable connection; the data rate is several times faster than 3G. The WiFi is an important, new and disruptive technology to mobile telephone technology, and it may be a watershed for all other m-commerce investments by telecom and content providers in the world of the mobile Internet (Lamont, 2001). In making use of this technology, mobile phone manufacturer (Nokia) and wireless network manufacturer (Cisco) have been working together closely to produce the Wi-Fi phone. A USA mobile telecommunication operator has integrated a network of Wi-Fi hotspots with the existing mobile network systems. In such a way, the tariff of accessing the mobile Internet will be reduced to a budget price. More handheld device users will surf the Internet through their compact mobile phones or PDAs when on their move. At the time of writing this article, WiMax (Worldwide Interoperability for Microwave Access), a wireless broadband connection in wide area network (WAN), is at the stage of discussing standards (Cherry, 2004). When this technology is standardized and ready for deployment, will it pose a big threat or offer an opportunity to mobile phone operators in the future?

CONCLUSION

The mobile Internet is ideal for particular applications and has useful characteristics that offer a range of services and content. The widespread adoption of mobile commerce is fast approaching. In business, the order of the day is "change". Winning customers in today's highly competitive and demanding world is the key to survival. The mobile world is changing the logic of business; businesses have to implement effective strategies to capture and retain increasingly demanding and sophisticated customers. Business needs to think critically about how to integrate the mobile Web to the wired Web, this needs careful strategic thought, as not all applications are appropriate; businesses that take the correct decisions will control the future.

KEY TERMS

2.5 Generation Wireless Service (2.5G): 2.5G changes wireless service to a packet-switched service that dramatically increases transmission speeds. It describes the state of wireless technology and capability usually associated with General Packet Radio Services (GPRS) - that is, between the second and third generations of wireless technology.

Global System for Mobile Communications (GSM): A world standard for digital cellular communications using narrowband time division multiple access (TDMA). It is the standard most commonly used in Europe and Asia, but not in the United States.

i-mode: The packet-based service for mobile phones offered by Japan's leader in wireless technology, NTT DoCoMo. The i-mode protocol uses compact HTML (cHTML) as its markup language instead of WAP's Wireless Markup Language (WML) to provide mobile phone voice service, Internet and e-mail.

Man-in-the-Middle: The intruders set up a base station transceiver with a modified phone and put themselves in between the target user and a genuine network. The intruders have the ability to eavesdrop, modify, delete, re-order, replay, and send spoof signaling.

Short Message Service (SMS): Has grown very rapidly and is very popular in Europe. SMS messages are two-way alphanumeric paging messages up to 160 characters that can be sent to and from mobile phones.

The First Generation (1G): The systems are analog, circuit-based, narrowband and are suitable for voice communication only.

The Second Generation (2G): Based on circuit-switched technology where each call requires its own cell channel, which makes transmission of data quite slow. 2G services include Code Division Multiple Access (CDMA), Time Division Multiple Access (TDMA), and GSM (Global System for Mobile Communication (GSM).

The Third Generation (3G): Will bring wireless transmission speeds up to 2Mbps, which permits high-quality wireless audio and video. It comprises three primary standards: W-CDMA (wide-band code division multiple access), CDMA2000, and TD-CDMA (time division CDMA).

Wireless Application Protocol (WAP): An open, global specification that empowers mobile users with wireless devices to easily access and interact with information and services instantly. The WAP is a standard for providing cellular phones, pagers, and other handheld devices with secure access to e-mail and text-based Web pages.

Wireless Fidelity (Wi-Fi): A popular term for 802.11b, a wireless local area network (WLAN) specified by the Institute of Electrical and Electronic Engineers (IEEE) and is based on the Ethernet protocol and CSMA/CA (carrier sense multiple access with collision avoidance) for path sharing. Wi-Fi supports a range of about 150 feet and data rates up to 11mbps.

Worldwide Interoperability for Microwave Access (WiMax): Called 802.16 in industry standard, a wireless broadband connection in wide area network (WAN). It offers fast wireless data communications over distance up to about 30 miles.

Challenges in Quality of Service for Tomorrow's Networks

Luiz A. DaSilva
Virginia Polytechnic Institute and State University, USA

INTRODUCTION

The original communication networks were designed to carry traffic with homogeneous performance requirements. The telephone network carried real-time voice, with stringent latency bounds, and therefore used circuit-switched technologies with fixed bandwidth allocated to each call. Original data networks were used for electronic mail and file exchange, and therefore employed packet switching and provided best-effort service.

Soon, however, it became clear that economies would accrue from utilizing a common network infrastructure to carry diverse kinds of traffic. Packet switching is now often employed for both real- and non-real-time traffic. This creates a problem: If the same network is to carry flows with diverse performance requirements, it is crucial that it support mechanisms to differentiate among these flows. For instance, real-time applications such as voice and video should be protected when competing for resources with nonreal-time applications such as file transfer or e-mail. Table 1 illustrates some of the quality of service (QoS) requirements of different classes of applications.

The desire to meet the needs of a broad range of applications that coexist in the same network is the primary motivation for the development of QoS mechanisms and architectures.

BACKGROUND

The concept of QoS arises from the need to allocate resources in order to maximize perceived quality on the basis of intrinsic application requirements (such as low latency for real-time voice), pricing (higher service quality for those willing to pay more), or policy (such as preferred access to network resources for users with mission-critical applications). A discussion of how pricing and policies relate to QoS can be found in DaSilva (2000a) and Flegkas, Trimintzios, and Pavlou (2002), respectively.

Either deterministic or probabilistic QoS guarantees may be associated with a given flow. When the network guarantees that the flow will be allocated bandwidth of at least B bits per second at every router on the source-destination path, it is providing a deterministic guarantee. On the other hand, if at least p% of packets belonging to the flow are guaranteed to encounter delay of less than D seconds, the network is providing a probabilistic guarantee.

It is important to note that QoS is not synonymous with performance. In the context of computer networks, the term QoS often implies that some sort of differentiation is made among disparate users. A variety of mechanisms are employed to this end. These include admission control, policing, congestion control, bandwidth reservation, marking, and classification. We briefly discuss each of these mechanisms next.

Table 1. QoS requirements of different classes of applications

Application	QoS Requirements
IP telephony	Low delay (on the order of ~ 100 ms)
Web surfing	Acceptable throughput
Streaming media	Low delay variation (jitter)
Networked virtual environments	Low delay in support of interactivity, high bandwidth in support of high-quality graphics
Online backup	High throughput, low packet losses (i.e., few retransmissions)
E-mail	High tolerance to delay, low to moderate data rate requirements

The decision of whether to accept a new call or flow is referred to as *admission control* (Breslau, Knightly, Shenker, Stoica, & Zhang, 2000); the objective is to ensure that the network can accommodate all of its current traffic flows with the desired QoS even after the new flow is accepted. In circuit-switched networks, incoming calls that cannot be accommodated are blocked; in packet switching, the flow may be denied access or the packets associated with it may be marked as lower priority and dropped when congestion occurs. This leads to *congestion control*; traffic supported by today's integrated networks tends to be bursty, and the admission decision is generally not made based on peak traffic conditions. It is therefore possible, even after admission control, that the network may experience congestion at times. Frost (2003) presents a study of the effects of temporal characteristics of congestion on user-perceived QoS. Measures to alleviate congestion include the dropping of packets at congested routers, as well as implicit or explicit signaling to the source to reduce its transmission rate. These measures may take into account QoS requirements, for instance, by requesting that one source reduce its transmissions while another (more critical) source is allowed to maintain its current rate.

Policing refers to measures taken by the network to ensure that the traffic being offered by a user conforms to a preagreed traffic contract. Excess traffic can be simply dropped at the ingress router or marked for best-effort delivery. Conversely, users may employ *shaping* to ensure their traffic conforms to preestablished parameters such as maximum data rate or maximum burst length. *Bandwidth reservation* may be used in packet-switched networks to provide minimum guarantees as to bandwidth availability to a flow. This requires a signaling phase to precede the transmission of packets, during which each router on the source-destination path agrees to reserve a portion of the available bandwidth to be used by the flow. Queuing and scheduling mechanisms such as weighted fair queuing are implemented by routers in order to meet such guarantees. Unlike in circuit switching, reserved bandwidth that is not being used by the reserving flow is generally made available to other flows through the use of work-conserving scheduling. To support service differentiation, packets are often *marked* using preassigned bit sequences in the packet header; this allows routers in the path to recognize the packet as part of a given flow and *classify* it accordingly (Gupta & McKeown, 2001).

QoS mechanisms can be provided at different layers of the protocol stack as well as by the application and the middleware (DaSilva, 2000b). At the physical and data link layers, prioritization, forward error correction, code, and slot assignment can be adopted for service differentiation. For instance, in random-access local area networks, nodes must back off in case of collision, picking an interval before they are allowed to attempt retransmission; by enforcing different back-off intervals for different nodes, we can achieve prioritization in access to the channel at times of heavy traffic. Scheduling, shaping, admission, and flow control are some of the mechanisms described above that may be adopted at the network layer. Middleware is sometimes developed to take care of classification of flows and marking of packets, and generation of resource-reservation requests. The application itself may employ prefetching and caching of information to improve performance experienced by selected users.

Asynchronous transfer mode (ATM) is one mature example of a packet-switched network providing QoS differentiation. In ATM, this is achieved by defining multiple service categories with associated QoS guarantees and traffic conformance definitions (Giroux & Ganti, 1999). Due to the ubiquity of the Internet protocol (IP) and current interest in real-time traffic using this protocol (voice over IP, for instance), recent research has focused on how to support QoS over the Internet (Armitage, 2000; Firoiu, Le Boudec, Towsley, & Zhang, 2002).

FUTURE TRENDS

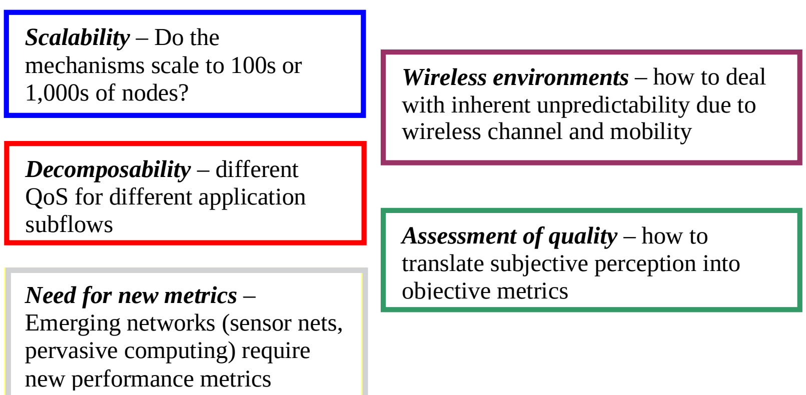
An important challenge in providing QoS differentiation in packet-switched networks has to do with the *scalability* of such mechanisms (Welzl & Muhlhauser, 2003). Stringent QoS guarantees require that all network nodes store information about individual flows in order to make scheduling decisions. While this is reasonable in an intranet, with a limited number of flows and complete control over the network by a single administrative unit, those types of approaches do not scale well. In particular, in the Internet, a core router may be routing packets belonging to many thousands of flows at any one time, and maintaining state information about each flow is infeasible. Stateless approaches achieve better scalability: They classify packets into a finite, reasonably small set of classes, marking each packet accordingly, and associate probabilistic service guarantees with each class. The Internet Engineering Task Force (IETF) has been studying QoS architectures for the Internet for several years. Any major change to the IP suite is, of course, always controversial (one must only look at the time it is taking for the widespread adoption of IPv6 for another example of the resulting inertia). While several important developments resulted from these working groups (Blake, Black, Carlson, Davies, Wang, & Weiss, 1998; Zhang, Deering, Estrin, Shenker, & Zappala, 1993), the ultimate goal of having QoS widely available in the Internet remains elusive.

Providing QoS guarantees in mobile wireless environments is another great challenge. The wireless medium is inherently subject to performance fluctuations due to fading, shadowing, noise, and interference. While techniques such as forward error correction, diversity, and power control reduce such fluctuations, it is still difficult to provide meaningful performance guarantees. Mobility compounds the problem. Still, third-generation (3G) cellular systems and beyond are providing differentiated service, including high-speed data service in addition to traditional telephony. In wireless local area networks (WLANs) such as IEEE 802.11, service differentiation will be achieved through prioritized (but, in most cases, still random) access to the wireless channel (Gu & Zhang, 2003). Physical-layer approaches to support QoS investigated in the literature include waveform selection and power control. These can be combined with slot assignment, prioritization, or other mechanisms for medium access control. QoS in mobile ad hoc networks is the subject of much research; the lack of infrastructure in such networks adds a layer of complexity to the problem (Chakrabarti & Mishra, 2001). In an ad hoc environment, it is difficult to guarantee the existence of a path between source and destination, much less the quality of communications using that path.

When link quality degrades or the network becomes congested, it is important to ensure that the inevitable QoS degradation occur in a graceful manner. We call an application *decomposable* if its data stream can be divided into two or more substreams that the application values differently. For instance, all quantized data is decomposable in the sense that the most significant bits of each sample are of greater "value" (in terms of the fidelity of the reconstructed signal) than the least significant ones. Similarly, albeit at a different level, multimedia applications are also decomposable: Each of the different components of a multimedia application (video, audio, image, text, animation) presents a different sensitivity to available bandwidth, as well as to delay and jitter, and each contributes differently to the perceived quality of the application. Both explicit and implicit adaptation may be employed during times of overload in order to minimize degradation of QoS as perceived by end users. In explicit adaptation, the application itself, upon receipt of feedback information from the network, reduces its transmission rate by transmitting only substreams that it considers most valuable. In implicit adaptation, the application negotiates different traffic contracts for each of its substreams; in times of overload, the network honors QoS assurances while discarding information in substreams for which only best-effort service has been negotiated. An early example of the latter is provided in Petr, DaSilva, and Frost (1989). There has also been some work in providing graceful performance degradation by taking advantage of the different impacts of the loss of intra, predictive, and bidirectional frames in Moving Pictures Experts Group (MPEG). However, taking into account application valuation of transmitted data in order to achieve graceful QoS degradation remains an open area of research.

An important open question is how to value the information that gets transmitted. The success of a QoS-enabled network should ultimately be assessed in terms of end-user perception of quality. Several of the QoS mechanisms deployed today act on a single layer of the protocol stack (say, the network or the data link layer) or on a single link in the path from source to destination. There has only been limited success in understanding how the deployment of differentiated scheduling or prioritization mechanisms at the different layers affects the end-to-end performance experienced by an application. Even more difficult is to translate user perception of quality (for instance, fidelity of video or audio, immersion in a networked virtual environment, satisfaction with an e-commerce experience) into metrics that are readily understood and optimized, such as throughput and av-

Figure 1. Some of the open areas of research in quality of service



erage delay. Subjective testing, one approach to assess user perception, is a lengthy and costly process that does not always generalize well.

In some emerging technologies, such as sensor networks and pervasive computing, traditional metrics (throughput, delay) do a poor job of characterizing performance. We need to define metrics that accurately assess how well the network fulfills its objective. For example, technology transparency is one of the desired features of pervasive computing environments, and performance metrics for the network should reflect how well this objective is achieved.

Figure 1 summarizes some of the current challenges in network quality of service.

CONCLUSION

A decade ago, networks that carried voice and data traffic were called *integrated networks*; today, *converged networks* is the more widely used term, and the diversity of traffic that must be carried increased significantly. Service differentiation is of vital importance if we are to ensure that a real-time video conference can share bandwidth with a massive file transfer (for instance, generated by an online backup job) and have both experience acceptable performance given the resources available in the network.

Although support for QoS in the Internet is taking longer than anticipated, most believe that it will eventually happen. In local networks and technologies at the edge of the internetwork, QoS support has been standardized faster. A recent example is IEEE 802.11e, which adds QoS features to the existing IEEE 802.11a and 802.11b standards for wireless LANs.

Significant challenges remain, including, among others, the scalability of QoS mechanisms for Internet deployment, application-layer QoS assessment, and support for QoS in mobile and ad hoc environments.

KEY TERMS

Assured Forwarding (AF): A per-hop behavior defined in DiffServ. AF provides different levels of forwarding assurances depending on available resources, the current number of flows in that AF class, and the drop precedence associated with the IP datagram.

Converged Networks: Networks that carry diverse types of traffic, such as real-time voice and video, Web browsing, traffic generated in grid computing, networked virtual environments, and so forth.

Differentiated Services (DiffServ): Architecture for QoS differentiation in the Internet. It employs marking of IP datagrams to associate packets to predefined per-hop behaviors. The DiffServ architecture is described in the IETF RFC 2475.

Expedited Forwarding (EF): A per-hop behavior defined in DiffServ meant to provide a "virtual leased line" type of service with guarantees on delay and jitter.

Multiprotocol Label Switching (MPLS): Associates "labels" to flows in an IP network. Each router on the end-to-end path makes scheduling and routing decisions for a packet based on the contents of its label.

Per-Hop Behavior (PHB): Describes, within the DiffServ framework, how traffic belonging to a particular behavior aggregate should be treated in each network node.

Policing: Mechanism by which the network determines whether offered traffic meets the specifications in the service agreement; excess traffic may be dropped or marked as noncompliant. Policing is typically implemented at the entry point to a network.

Policy: Set of rules specifying the level of access to network resources to which a user or application is entitled.

Prioritization: Certain packets or data flows may be given higher priority in accessing the medium or in being queued for transmission.

Resource Management: Set of mechanisms to efficiently control and allocate scarce network resources (often bandwidth) to users and traffic flows.

Scalability: The degree to which a protocol or algorithm can be extended to an increasing number of users or network nodes and continue to function properly.

Shaping: Users or applications may shape traffic to comply with prespecified parameters such as maximum data rate or maximum burst length. Leaky bucket and token bucket algorithms are often used for traffic shaping.

Virtual Private Network (VPN): A virtual network constructed for users within a single administrative unit (e.g., a company or university), making use of public communication links. Encryption and bandwidth guarantees may be supported over a VPN.

Work-Conserving Scheduling: A work conserving scheduler allows the link to go idle only when there is no packet, of any service class, awaiting service.

Change Process Drivers for E-Business

INTRODUCTION

The main focus of this article is a study of the transformation processes occurring in industry and business at large. It deals with the social and economic challenges and it explores the new concepts arising from an unprecedented technology revolution. In addition it sets the scene for a new era of industrial capitalism.

BACKGROUND

Over the last decade of the 20th century a large number of companies faced the future with trepidation while others lacked a good strategy (Ashkenas, 1997; Kidd, 1994; Possl, 1991). Many changes had taken place, including Just In Time (JIT) manufacturing and logistics, lean manufacturing (Womack et al., 1990), shorter product life cycles (Davenport, 1993), more intelligent approaches to IT (Drucker, 1992; MacIntosh, 1994; Nonaka, 1998), and costing (Ansari et al., 1997; Wilson, 1995), but making money was becoming more and more difficult. It was a time and climate for dramatic new approaches (Drucker, 1994; Goldman et al., 1995; Warnecke, 1993) with greater agility. New technologies were replacing old at a faster rate and information technology provided better management and control vision, albeit on a limited local scale (Arguello, 1994; Leachman et al., 1996; Makatsoris et al., 1996). And, push to pull manufacturing (Mertins, 1996) distinctly changed the approach to customers and service. Moreover, increased competitive and economic pressures resulted from the global reach of customers, manufactures and service providers keen to exploit the wealth of opportunities in both global markets and differences in worldwide regional markets (Bitran et al., 2003). Even players only operating in local markets (Bologni et al., 1996; Bonfatti & Monari, 2004; Zabel et al., 2000) could not resist the tide of change. As a result, many companies and economies (Hutton, 1995) were in a state of upheaval and as a consequence some fell by the wayside. This was a climate in which there was an uncertain outcome, and it was into this melting pot that the Internet and the World Wide Web (WWW) were to produce an environment for a much-needed revolutionary change in industrial approach. Later, broadband for landline and also wireless networking provided a much needed speedier access.

Businesses looked to the wider horizons and the dynamics of their supply chains as well as their markets to discover new ways of working with both customers and suppliers to grow and remain viable. The diverse industrial, commercial and operational practices and processes needed to be remolded. These targeted the collaborative aspects of external relationships to the advantage of company performance and the creation of new opportunities. This resulted in more and more use of new forms of communication and available multi-media. In this unsettled environment, once fear of change had been forced into the background, chaos became the domain of creative experimentation (Weiland-Burston, 1992). It is during this period of confusion and anxiety that the process of metamorphosis is taking place.

A surge of new software tool ideas have helped, including Enterprise Resource Planning (ERP) and Supply Chain Management (SCM) (Chang et al., 2001), Customer Relationship Management (CRM) (Greenberg, 2002), electronic commerce (e-commerce), electronic business (e-business) (CEC, 2000) and new forms of enterprise, amongst many others. These have stimulated the reformation of business attitudes to the flow of goods, services, information and knowledge (Bouet & Martha, 2000; Hardwick et al., 1996; Introna, 2001; Johnston, 2001; Richards et al., 1997; Zobel & Filos, 2002).

THE CHALLENGE

ICT (Information and Communication Technologies) tools and systems are important enablers (CEC, 2000) in the change process. They have played and will continue to play a major role in the emergence of new ways of conducting business and improving the economics of business. However, open global standards, protocols and interfaces, interoperable applications and platforms, trusted and sustainable infrastructure and compatibility between business practices have to be achieved before interconnection for broader based business is fully realized (Frick, 2000; Kidd, 2001).

The necessary social changes to business (McCarthy, 1996) are at least as significant as ICT. A web-like organizational network has emerged from the more loosely coupled supply chains. The value network and virtual enterprise permit new forms of communication, participation, leadership, and decision making to develop. In turn these create new economic balances, shared learning and procedures geared to people rather than institutions, in which ICT allows the collapse of space and time (Duttas, 2001; Franke, 2001). There is also resistance to change to be overcome (Deloitte & Touche, 2000; Hunziker & Sieber, 1999).

Three basic aspects to change have emerged, before smarter business is accomplished, to drive the change process and they are developing in parallel to carry business forward to the future:

- Organization: How organization and inter-company relations are developed to ensure greater collaboration; here meant as working jointly together, co-operating and co-ordinating, trusting each other, sharing information and knowledge where appropriate and refining the skills in the organization to cope with the economics, strategic aims, day-to-day operations and service excellence.
- ICT: How tools and systems are created, developed and introduced to ensure open, effective and efficient dynamic engagement between companies, using all the appropriate communication channels

Table 1. Some challenges to organizations

- Lack of awareness by very large sections of the business community:
    - How best to educate and train staff
- Lack of trust for successful e-business.
- Insufficient partners in an e-market.
- Lack of perceived benefit.
- Inequitable benefits:
    - How economics and risk are shared, which also takes into account a judgement of fairness.
- Lack of good business models.
- Limitation of collaboration to tier n suppliers.
- Needs to accelerate the business performance targets: for example--
    - Reduction of time to market;
    - Better precision for just-in-time production and logistics;
    - Provision of faster innovation cycles;
    - Working capital efficiency;
    - Increased resource utilization across the whole network;
    - Improvements to distributed inventory management;
    - Creation of new metrics for value network performance improvement.
- Demand for specialty products in small batches through intelligent automated production planning and logistics systems.
- Demand for astute fast mobile complex service engineering.
- Inter-company collaborative design of high-quality complex products.
- Lack of a standard business model for collaborative business.
- Lack of ability to manage and control large equipment/product integration produced in value networks to meet the necessary performance targets.
- Needs to meet the demand of mass customization and personalization through detailed models and processes and smart, agile order processing.
- Ability of companies to conceptualize a value network that is advantageous to them and to identify requirements for new skills, new metrics and changes to be made.
- Needs to have the ability to use shared knowledge and interpret shared information effectively among partners in a value network.
- How much transparency there should be between partners in a value network.
- Belonging to many value networks at the same time.
- Lack of standard business processes.

Table 2. Some challenges for ICT

• Lack of a cost-effective and affordable, real-time worldwide communication of complex business information to serve the globally distributed nature of business.
• Lack of interoperability between systems and applications.
• Lack of multi-lingual facilities.
• Lack of an affordable end-to-end high quality seamless integration.
• Lack of integrated workflow.
• Free flowing information flow in an end-to-end, timely and secure manner.
• Right economics for ICT suppliers.
• Lack of smart applications and good decision assistance tools for collaborative business.
• Need for data capture and filter systems that communicate in real time pertinent information to all partners in the value network.
• Knowledge sharing and usage across the value network.
• Cognitive decision making.
• Tracking individual ordered products from source to consumer and providing a succinct record of such. Human health in the human food chain is a critical issue.
• Development of intelligent agents as electronic proxies for individuals.
• Serve the special needs of SMEs.
• How to respond against unplanned/unexpected event with less cost.

Table 3. Some challenges for the business environment

• Too many standards developers and lack of co-ordination with sources of new work.
• Slowness of standards take-up by commercial ICT developers.
• Legal challenges:
• Contract law;
• Cross-border provision of services;
• Protection of intellectual property rights;
• Privacy;
• Consumer protection;
• Electronic payments.
• Regulation.
• Security:
• Trust;
• Cyber crime;
• Fraud;
• Unauthorized access;
• Computer attack.

open to them as necessary and of preferred choice. This applies both in business networks and supply chains and also in the marketplace, where new opportunities may be found. Such opportunities include competencies, products and services that may be useful to help create, enlarge or reduce value networks. Tools service amongst others co-operative planning, distributed event driven decision making and tracking.

- Environment: How exclusivity may be stripped away to provide global trade opportunities for all in the world of electronic trade not only buying but also selling to any region or nation irrespective of differences in language, culture or local laws or regulation.

Some of these challenges are outlined in Tables 1 to 3.

FUTURE TRENDS

Consolidation of ideas and rethinking of strategy has been helped not only by a political will (CEC, 2002; Timmers, 2002) and further research and development (CEC, 2003), but also by the economic down-turn[1] as well as a greater respect for the economics of change amongst all the industrial players.

ICT providers and consultants to date have provided much of the impetus for industrial change but industry has now to fully engage with strategic plans. One of the challenges highlighted in European statistics is that less than 20% of SMEs[2] had put in place any CRM or SCM software. Change through national incentives, joint projects and education through regional clusters of companies in the same industry sector is being encouraged.

Europe, one of the world's largest trading blocks, has a vision in line with the Lisbon objectives and eEurope for a Single European Electronic Market, SEEM (SEEM, 2002; SEEM, 2003), in contrast to today's separate and unconnected e-markets that serve different industrial or value network goals. It will solve many of the challenges illustrated previously and a research initiative for 2003 has been carefully orchestrated and heralded (CEC, 2003). Current CEC research has provided many strategies for future manufacturing (Geyer et al., 2003), as well as delivering results for biometrics (IBG, 2003) of particular relevance to future authentication, and specific industrial supply chain innovations. Other publications suggest that in the near future every single object will be connected to the Internet through a unique wireless address identifier allowing complete life cycle tracking (Datta, 2004; Murray, 2003; Sarma et al., 2000). A roadmap for intelligent agent research is also available (SEEM, 2002).

Studies and analysis of organizational webs (Tatnall & Gilding, 1999), value (Zobel & Filos, 2002) and inter-node relationships (Underwood, 2002) and new methodologies for design of networks (Soares et al., 2003) amongst many others have helped to develop the social processes in complex organizations and their symbiosis with new business systems. And the semantic Web may help to foster greater understanding between organizations (Berners- Lee, 2001).

In Europe the ICT Standards Board is set up to coordinate activities and sees that there is no duplication in the standards activities of European Standards Organizations (ESOs) and has provided input to standards (CENELEC, 2002). UN/CEFACT, OASIS, Open Source, and RosettaNet are working toward interoperability and effective processes for global e-business. Moreover, key industrial players through the organization, Open Mobile Alliance, OMA (SEEM 2002), are using interoperability and open standards as catalysts to ensure that mobile services develop more openly.

The European Union is acting to clarify its legislation and to provide new regulatory means for SEEM. A lot has already been dealt with and most of the issues should be cleared in the years up to 2005 (CSIRT, 2002; SEEM, 2002).

CONCLUSION

Metamorphosis will not be completed overnight and it will take many years before the process is finished. It is expected that a new end state for global business is characterized by: an expanding global economy; greater collaboration in smarter value networks; versatile virtual organizations; better deployment of knowledge; greater dynamism; versatility and unhindered opportunities in markets; highly dynamic processes; new standards of customer service excellence; better use of both capital and human resource; and better decision making. This will be brought about through better designed and correct deployments of ICT for structured, trusted and secure electronic exchanges between companies. Technological advances will continue unabated to feed the desires for improvement. Also, applications and tools will continue to improve with aids for helping organization building, revising or creating new inter-business processes, as well as providing aids for flexible sizing for smart collaborative value network configurations. Universal standards will make integration between applications and distributed databases and knowledge bases both easier and cheaper. And new telecommunications technology will improve both the speed and the volume of information flow per unit time from anywhere at any time. The workforce and end customers will experience a new way of living and fulfillment. The basic novelty of our age is the spirituality of consumerism and voracious appetite for information. How these may be blended with an increasing capacity for sympathy and mutual understanding will inspire both ways of life and collaborative business.

KEY TERMS

Broker: A broker is a manager of a virtual enterprise. A broker acts as an intermediary with the buyer of goods or services. A broker may also manage and control the ICT and provide educational services to small and medium enterprises, SMEs, or micro-companies.

Electronic Business, E-Business: Electronic business is any form of business or administrative transaction or information exchange that is executed using information and communications technology, ICT. This may be transaction performed in a peer-to-peer fashion between companies or organizations or with a customer. Electronic business impacts on the way business is perceived.

Electronic Market, E-Market: An electronic market is a market free from inhibiting constraints and affordable for all businesses in any shape, form or size and to allow them to easily take part in e-business with beneficial returns. It is a market in which trust, security and dependability apply and in which regulatory and legal issues are unified. It is a market where buyers and sellers ubiquitously execute business transactions online. These may include searching and identifying competence, ability to identify the right product or service together with quality, price and quantity, and virtual auctions. It is also based on an open, secure and reliable collaborative platform for knowledge exchange, joint product design, production planning and logistics in stable customer-supplier relationships.

Hub Company: A hub company is a lead company in a supply chain or value network that organizes and manages the work for end products and/or services. This is, for example, an automotive manufacturer, an aircraft manufacturer, a clothing manufacturer, or major food supplier. These are usually large companies but can be small if the end product is in building construction, for instance. Usually the manufacturing and services chain is complex and contains many sub-products that have to be drawn together with processes and services to meet design to manufacture targets and delivery excellence. In a value network the tier *N* suppliers are part of the collaborative network. It is to be noted that communication in the old economy was EDI and in the new economy will be fully open system interoperable ICT.

Intelligent Software Agent: An intelligent software agent acts at speed over the electronic communication channel on behalf of human individuals or companies as their proxy; it is a program acting on behalf of another person, entity, or process. An intelligent software agent is an autonomous program that is capable of perceiving and interpreting data sensed from its environment, reflecting events in its environment and taking actions to achieve given goals without permanent guidance from its user. Agents have to have the intrinsic ability to communicate, cooperate, coordinate, negotiate and ability to learn, as well as have the capability to evolve through their interactions with other agents. Agents can be standalone or be part of a multi-agent system.

Metamorphosis: In application to economies of companies it is a process of change from an existing but obsolete way of doing business to a new form but non-predestined state.

Smart Organization: A smart organization is a further evolution of value networks and virtual corporations through use of more advanced business models taking account of human ICT symbiosis and utilizing more intelligent applications and tools for collaborative work and holistic development of both product and service engineering.

Supply Chain: In its basic form is a buyer-centric chain or network of independent companies that are loosely inter-linked by activity along a manufacturing, servicing and distribution channel of a product service specialty, from sources of raw material to delivery to an end customer. Supplementary to this supply chain management is a set of approaches utilized to integrate suppliers, manufacturers, warehouses and retail stores and so on. Consequently merchandise is produced and distributed in right quantities, and to right locations at the right time, to minimize system-wide costs while at the same time satisfying service level requirements.

Value Network: This term is ambiguous, as the analytical perspective colors its meaning. Nevertheless, the value network in general terms evolves from a supply chain through mutual use of ICT and more closely linked collaboration and mutual dependency between the partner organizations or independent companies. Collaboration means electronic communication via extranet, or Internet, co-operation and co-ordination of work flow, information and knowledge exchange, negotiation and dynamic trading and joint decision-making. Value is derived through the exchanges with partner organizations in the network and its shared knowledge. The value network also aims to deliver the highest value to the end consumer and to its stakeholders

Virtual Enterprise/Virtual Corporation: A virtual corporation or enterprise is formed from a pool of competencies and capabilities resulting from a club of pre-qualified partners that may be expanded or contracted through the mutual desires of the club. The management body for a virtual enterprise selects partners, from the pool of competence available, to provide products or comprehensive services to any industry in direct competition to single companies or other virtual enterprises. It is necessary to have strong collaborative relationships between partners in the club. The virtual enterprise may exist only on a temporary basis to take market chances, for example tendering. It may also exist for a longer term for optimization of a value network to service a market need.

ENDNOTES

1 Economic down-turn in the global economy in the first years of the 21st century.

2 SMEs together with micro-companies account for 70% of employment in Europe.

Changing Trends in the Preparation of Print Media

Mark Snyder
Clemson University, USA

INTRODUCTION

Traditionally, the main purpose of printing is to generate reproductions in quantity. Before printing existed, scribes reproduced manuscripts by hand. Frank Romano, in the foreword of *Pocket Guide to Digital Prepress*, tells the story of a monk who, shortly after Gutenberg's development of cast-metal movable type sparked the advent of printing, authored an essay titled "In Praise of Scribes." The essay advocated the continuation of copying manuscripts by hand because of the character-building values it instilled in the scribes. The ironic part of the story is that the monk decided to have his manuscript printed. The moral that Romano teaches us is that the monk "was caught in the paradox of transitioning technologies" (1996, p. iv) and that a similar situation is taking place as digital technology revolutionizes the printing industry. The objective of this section is to provide some historical perspective and background of printing technology, particularly in the area of preparing media for printing (prepress), and then identify current issues in the field as well as future trends that are developing.

BACKGROUND

Movable type existed before the time of Gutenberg. However, the concept of mass-reproduction of graphic images was not fully realized until Gutenberg created metal type and adapted a wooden screw-type olive press to invent printing around 1450 A.D.

Typesetting remained the primary form of "prepress" work for about the next 500 years. The industrial revolution brought several technological advancements to the printing industry and, in the middle of the twentieth century, phototypesetting became the norm for generating type. Artwork was assembled into paste-ups to be "shot" on a camera, and many people were involved in the process of getting a job ready for press. Designers, photographers, copywriters, proofreaders, editors, typographers, paste-up artists, camera operators, color separators, strippers, and platemakers all were occupations supported by this process.

The "imagesetter," a device developed around 1980, represents a transitional technology that uses digital information and a laser to create an analog product—film. At the same time, page-layout software was developed that allowed the merging of text, line art, and digital photographic images into a layout. Output the page layout from a computer to an imagesetter, add the ability to electronically separate colors, and we have process-color films that are already positioned, thus eliminating the need for several workers.

More recently, platesetters and other "direct-to-plate" technologies have eliminated film from the process. Now, even offset lithographic presses are available with platemaking systems right on the press. A file can be sent from the computer directly to the press. The invention of the silicon chip, and associated digital technologies, has virtually eliminated the majority of the occupations listed earlier.

In fact, "desktop publishing" makes it possible for one person to be all of the above and the printer too. Many do-it-your-selfers proceed to create printed matter, regardless of the fact that they have little or no experience with typography or formal layout and design principles. The result is typically less than pleasing to the graphics professional's eye.

Today, the majority of professionally printed jobs are created using computers. Often they include a mix of text, line art, and photographic images. All of these types of "copy" are typically created using different software applications that have evolved to become very powerful each in their own way. Once all of this various copy is generated, it can be merged using an electronic page layout application. This is the heart of professional digital prepress.

Digital technology, along with highly skilled personnel, has made it easy to do tasks that were once challenging. The rapidly increasing processing power of computers, coupled with ingenious software tools and useful peripheral devices, has enabled the printing industry to make improvements in speed and quality. But it has also increased the likelihood of mistakes and poor design. The technology continues to advance, but so do the problems that need to be solved.

ISSUES, CONTROVERSIES, AND PROBLEMS

Because the technology is readily accessible to non-professional designers, a lot of unprofessional design work is being submitted to printing companies. While many of those who submit a job to a printer will claim that it is "ready to go," unfortunately this is usually not the case. A preflight technician reviews data sent to a printer to make sure that all artwork, fonts, file formats, and so forth are included and will work with the systems at that printing firm. Other concerns that a preflight technician might delve into would include checking whether a job meets size limitations, whether trapping issues are resolved, imposition, and if finishing and bindery requirements are met.

Though most professional graphic designers have enough experience that they are familiar with the common issues related to preparing art and text for printing, sometimes they actually go beyond the limits of what can be achieved. While graphic designers and printers don't always see things the same way, they do know that they need each other—and their ability to communicate will have to continually improve as digital prepress technology advances. Since the traditional occupations held by craftsperson's such as typesetters, paste-up artists, color separators, and strippers are virtually obsolete, "designers are taking on more and more of the prepress process themselves" (Agfa, 1994, p. 1).

Most jobs, even jobs submitted by professional designers, rarely make it through a preflight check successfully the first time. Bob Atkinson, an electronic prepress consultant, claims that "only about 15% of clientele-supplied files are actually ready to output without problems. The other 85% have one or more problems—some are minor and hardly noticeable in the final piece; others have more serious problems that will jam an imagesetter or other output device or, worse, produce an unacceptable print job that the client won't pay for" (2001, p. 1).

The most common mistakes in jobs that are submitted to printers are problems that relate to fonts. And, like fonts, any graphics files that are placed into a page layout file must be included with a job. Nested files can also create a lot of problems when trying to output a job to films or plates.

File formats are another puzzle needing to be figured out. In its educational brochure titled *An Introduction to Digital Color Prepress*, Agfa Corporation stated, "bitmapped images may be saved improperly and print poorly when placed into page-layout…applications." The company continued: "to overcome these problems, a variety of graphics file formats have been devised which link text, graphics, and separation capabilities among different programs and computer platforms" (1997, p. 24). Understanding which file formats are appropriate for the planned end-use is important. Photos scanned on desktop scanners have proven to be a problem area for printers. Not many can answer the question "at what resolution should I scan this picture?"—that is because it depends on a few different variables. If we plan to use the images in printed media, we need to know what resolution we are capturing with that digital camera.

The key to the resolution issue is understanding halftones and the line screens that are being used for printing halftone images. A halftone converts a regular photographic image (referred to as continuous tone) into dots of various sizes. When printed on white paper, this provides the illusion of tones (grays or various colors). The line screen specifies the number and frequency of these dots. Even if a client submits a file at the right resolution, they may set screen frequency, angle, and dot shapes incorrectly which will cause problems with halftone images.

Trapping is actually an old concept that is just handled differently with digital technology. The general idea is that we want two adjacent colors to overlap just slightly when printing so it does not leave a white space if it is printed slightly out of register.

Color management is perhaps the most vexing and perplexing problem facing design and printing professionals today. The issue of color begins with the original art or image that is captured and continues all the way through the process of creating the printed piece. Ingram, a professor of graphic communications, stated, "a color management system is a set of tools that permits consistent and predictable color reproduction. This includes all equipment in the production workflow having an impact on the color files as they move from one device to another" (2001, p. 26). The people involved in this process must have an understanding of color theory and how to make different devices generate color the same way. In many cases, designers and digital prepress departments do not use color management, and simply rely on experience and/or guesswork to approximate color matching.

One of the most significant, and yet simplest problems with jobs today are typographic errors that seem to slip by and get printed on the final product. Traditionally, jobs went through the hands of many people in the process of getting printed. Now, the chain of human workers that touch a job has become so short that many minor errors go unnoticed. Direct-to-press technology now makes it possible for jobs to go right from a designer's computer to a press. While this is more efficient than in the past, it also enables us to make mistakes faster than before!

SOLUTIONS AND RECOMMENDATIONS

Starting from the design stage, perhaps the most important concept for a designer to remember is that printing is primarily all about the reproduction of large quantities of media. Designing something that requires handwork makes mass reproduction difficult. In most cases, this is the type of issue that causes a design concept never to be realized.

If we design with the fewest number of fonts possible—without compromising the design itself—and use more common fonts, we will save a lot of time. Otherwise, designers need to be organized, and include all fonts and linked graphics files into a folder that contains everything for that job. Preflighting will likely turn up some problems, and it is the designer and/or client's responsibility to either provide missing resources, correct errors, or approve charges for correction by the printer.

Capturing images with a digital camera or scanning them at the proper resolution is essential to generating quality bitmapped images. Following the Nyquist Theorem for digital sampling of analog information, we typically try to sample at 1.5 to 2 times the screen frequency, or lines per inch, at which we intend to print the image. This should be multiplied by the scaling factor for the job**.** Using images captured at lower resolutions will impair the quality of the reproduction, and image files with higher resolutions than necessary will be too big and require excessive processing time.

Printing companies are beginning to see value in offering training to their customers and designers that send them problem files. Many are also providing Web sites that explain how to capture images at the proper resolution, upload files, use preferred file formats, prepare graphics files, and so forth. These specifications are typically customized to meet the requirements of the equipment owned by the printing company.

Outputting files with stochastic screening is an alternative to conventional halftones. This technique eliminates the possibility of moiré, an optical phenomenon that occurs when screens overlap at close angles, and provides excellent reproduction of details in a printed image. Stochastic screening is available for postscript output devices. "The film separations can be proofed using conventional methods and plates can be printed on standard Web and sheetfed offset presses" (Agfa, 1997, p. 17).

Digital data transmission has improved the way that customers transport jobs to printers. In the past few years, companies that use the Internet to provide private network services for the printing industry have emerged. File transfer services are big time savers, but they still don't eliminate the fact that all needed files, fonts, and links must be included in a job folder.

Digital workflows for the printing industry have improved during the past five years. Sean Riley stated in *Package Printing* magazine: "One often overlooked stage that printers have begun to explore in an effort to improve workflow, and therefore costs, is the prepress facet of the industry. Improvements in prepress workflow and/or data transmission have been available for quite a while now but [printers] have been slow to take advantage of these opportunities" (2002, p. 14).

Proprietary systems that automate the digital prepress workflow are offered as packages by vendors who also manufacture equipment such as platesetters. Trapping, color management, and raster image processing (RIPing) can all be quickly and easily accomplished via seamless solutions on powerful workstations.

Open Prepress Interface (OPI) is another digital workflow solution that improves prepress performance by minimizing the amount of data handled while generating page layouts. OPI servers employ an extension to Postscript "that automatically replaces low-resolution placeholder images with high-resolution images" (International Paper, 2000, p. 224). Basically, the OPI server reduces the amount of information traveling over a local area network until needed for output.

Color management is another process that has improved digital prepress. "At this point it is apparent that moving to a color managed workflow is not a simple process handled by a single individual. A color managed workflow includes everyone in the color reproduction food chain" (Ingram, 2002, p. 29). It is a scientific approach to what is thought of as the domain of an artist—color. It does not achieve perfect results, but it is amazing to see how much of an improvement there is over a non-color managed environment.

Proofing is another area that benefits from color management. It is rarely advisable to use soft proofs (viewing from a monitor) for contractual color approval. It is better to choose a proofing system that utilizes media similar to the finished product and is known to match output from press systems through a color-managed workflow. Printers favor proofing systems that produce colors using a subtractive colorant system that produces some type of dots to approximate halftone systems.

FUTURE TRENDS

One trend in the printing industry is a shorter route from design to press. Digital prepress peripheral systems, such as scanners and imagesetters, are being bypassed by digital cameras, direct-to-plate, and direct-to-press systems. As these systems become more automated, and direct-to-press technology evolves, it seems possible that the printing press will soon be under control of the prepress department of printing companies and viewed as just another output device.

Digital printing is a new category in the hierarchy of printing processes. One way to identify digital printing processes "is to refer to any printing device that inputs a digital data stream and outputs printed pages as a *digital printer*, and then further distinguish between printers that first build a physical master from which multiple copies are printed and those that do not" (Cost, 1997, p. 79).

Digital printing devices fall into one of the following five categories: photographic, thermal, ink jet, dye sublimation, and electrostatic. The advantage of digital printing is that it is used for reproducing smaller numbers of reproductions more cost effectively. "Virtually every market analyst places flexographic printing growth second only to that of digital printing" (Hogenson, 2002, p. 1). The development of high-quality color digital printing devices has made digital printing the fastest growing printing segment today.

Digital printing brings the realization of a completely digital workflow.

Another technology that is simplifying digital workflows is Portable Document Format (PDF). Huff and West report that "the goal of a PDF workflow system is to deliver electronic files to a film or plate recorder, or to a digital press or printer, with a minimum amount of operator intervention" (2000, p. 42). PDF files are independent of authoring and system software, so they can be opened on any platform. "PDF files serve as a digital master throughout the entire continuum of communication—from posting on the Web to outputting on a press" (Agfa, 1998, p. 1).

Printers especially like what PDF has to offer them. "For print-on-demand service providers, PDF erases many of the current variables introduced by the variety of platforms, application programs, and printers involved in any corporate system" (Young, 1998, p. 57). Perhaps the biggest advantage of using PDF for prepress is embedded fonts and graphics; prepress operators will no longer need to spend time spent searching for missing image files (Snyder, 1999, p. 35). If your document can be "distilled" into a PDF file, it is likely to be output with no problems.

Variable data printing is another trend that is taking advantage of the speed of digital processing. This type of printing produces products that can be individually customized. Most variable data printing is fast, low-quality ink-jet marking, but higher-quality systems that can print bitmap images do exist—although they are slower and targeted for short-run markets. Variable address data can be simply added on to preprinted forms and then shipped. Customized labels are another popular example of this technology. In variable data printing, database management becomes part of the responsibilities of digital prepress personnel. As digital printing technology advances, variable data processing will become faster and more commonplace.

CONCLUSION

In 1978, F.W. Lancaster, a noted library futurist, authored a book titled *Toward Paperless Information Systems* in which he raised, and answered, the question, "Will paper be as important in the information systems of the year 2000 as it is today? Almost certainly not" (p. 1). This has proven to be true in most library systems—paper is not as important as it used to be—but it is still there. Further into his book Lancaster generalizes his vision to ponder a broader perspective. He stated, "The paperless society is rapidly approaching, whether we like it or not" (p. 166).

Yet, the same technology has also made it possible to produce more printed media and packaging than before. According to Mercker, "The so-called paperless society that was projected to evolve with the computer age has actually led to a 40 percent increase in office printing in the United States." He also estimates that paper production will increase by 30 percent to keep up with global demands (1999, p. 1).

Packaging is the second-fastest growing print market. Fruscione reported that growth in the flexographic printing industry in the United States and Mexico has been tremendous because of digital prepress and computer-to-plate advancements. "Flexographic printing held 22 percent of all printing volume last year and 70 percent of the packaging industry" (2000, p. 2).

Publishing is another area that has improved with the use of computers. In the 1960s and 1970s, magazines were published with a colorful cover and black text inside. Process-color images were difficult to reproduce in a magazine and were considered something special. That has changed to the point where, today, most magazines are printed in full color from front to back. Realistic color images are now taken for granted.

A review of the history of printing should point out that a very gradual evolution in printing processes occurred during the course of about 500 years until, in the late twentieth century, digital technology revolutionized the industry. Since then, the process of creating print media has undergone rapid changes and technological advancements that have brought new problems, and new solutions, to the forefront. Ultimately, it seems that we have arrived, as Gutenberg did, at another technological crossroad. Much of what is done in digital prepress today can be repurposed for use in a variety of media forms. Although printing was the primary form of graphic communication for hundreds of years, it is now simply one of a number of ways to output digital information.

KEY TERMS

Desktop Publishing: Creating pages for print media using a standard home or office computer and commercial software, and then outputting them on a simple desktop printer.

Direct-to-Plate: Technology that enables digital layouts to be sent directly to a system that images plates appropriate to the printing process being used.

Flexography: A printing process that uses a raised, or relief-type, image on a flexible photoploymer or rubber plate. Commonly used for printing corrugated and flexible packaging, newsprint, and other media.

Halftone: A method to reproduce photographic images in printed media by creating a pattern of dots that change in size to create the perception of lighter and darker tones.

Imagesetter: An output device used primarily to generate films for the production of printing plates.

Nyquist Theorem: An equation to determine appropriate resolution when scanning an image digitally for graphic reproduction. The equation multiplies the desired printed halftone dot lines per inch (LPI) by 1.5 to 2 times, and then multiplies that value by the percentage of magnification of the reproduction from the original size of the artwork.

PDF (Portable Document Format): A file format that is capable of transferring designs across many different forms of media. PDF files are universal and independent of the computer systems they are on.

Postscript: A text-based page description language developed by Adobe Systems, Inc. that uses precise methods to communicate text and images to an output device.

Stochastic Screening: A method to reproduce photographic images in printed media by creating a random placement of very small dots that change in frequency to create the perception of lighter and darker tones.

Variable Data: Information that changes on sequential pages being output from a printing device.

Chief Knowledge Officers

Richard T. Herschel
Saint Joseph's University, USA

INTRODUCTION

A chief knowledge officer (CKO) is a senior executive who is responsible for ensuring that an organization maximizes the value it achieves through one of its most important assets-knowledge. Knowledge is often defined as information exercised for problem solving, understanding, and benefit. By adopting a CKO, firms formally recognize that knowledge is an asset that needs to be captured, disseminated, and shared to enhance firm performance and value creation. And most of all, they realize it is an asset that must be managed. Knowledge management is seen as essential, because firms today are valued in part on market perceptions of expertise as expressed through their processes, products and services (Choo, 1998).

The "intangibles" that add value to most products and services are knowledge-based — for example, technical know-how, product design, marketing presentation, understanding the customer, personal creativity, and innovation. Critical success factors for organizations today – the need for speed, management of complexity, a sense of history and context, effective judgment, and organizational flexibility — are all related to and dependent upon organizational knowledge (Herschel & Nemati, 2001).

Hence, the fundamental objective of a CKO-driven knowledge management program is to maximize return of investment of intellectual capital expended in the creation and delivery of the firm's products and services. To ensure continuous improvement, knowledge management programs must continuously pursue ongoing organizational learning so as to repeat successes, minimize repeating past failures, and to instill best practices and improve innovation. David Skyrme (2003) reports that the benefits of these programs can be quite significant. He cites the following examples:

- Dow Chemical has realized $125 million through better exploitation of its patent portfolio.
- Texas Instruments has saved investment in a new plant by sharing knowledge of best practice from its existing plants.
- Knowledge management at BP Amoco delivered $260 million to their bottom line in 1998.
- From 1997-2000, Ford Motor Company saved $914 million, mainly due to knowledge management programs.
- Chevron's knowledge management practices have enabled it to save $650 million since 1991.

BACKGROUND

The role of a CKO is to develop the firm's knowledge infrastructure, to promote knowledge capture, storage, and distribution, and to act as a symbol that employees look to for guidance in a knowledge management culture. Bontis (2002) states that a CKO can help a firm to leverage its intellectual capital by:

- promoting stability in a turbulent business environment,
- enabling the speedy delivery of products and services,
- creating high efficiency in the knowledge value chain by sharing of resources and realization of synergies, and
- enabling the separation of work so that specialization is feasible.

The CKO job description can encompass a number of responsibilities. For example, the CKO might be responsible for leading executive management to develop an enterprise knowledge strategy, validating this strategy across the enterprise, and then ensuring that its evolution complements and integrates with business strategy. The CKO may also be charged with setting priorities and securing funding for knowledge management (KM) programs as well as defining policies for security, usage, and maintenance of intellectual capital. Depending on the organizational culture, the CKO may also act as the chief advocate for KM as a discipline — walking and talking the program throughout the enterprise and assisting executives and senior management in building and communicating personal commitment and advocacy for KM (Davenport & Prusak, 1998).

In any scenario, the CKO must at least be responsible for managing and administering the day-to-day activities of the KM program and the KM infrastructure. This means overseeing the development of KM technology and information exchange architecture and assessing specific knowledge needs of business processes. Moreover, the CKO must ensure the integration of KM into employees' job activities, into key processes, and across communities of practice. They should also lead the development of formal programs that foster knowledge sharing and innovation, define expectations for individual and community participation in the KM program, and ensure participation and knowledge contribution by all levels of experts (including executive management). In addition, they should create a process to measure benefits and progress against program goals including competitive advancements, knowledge created, innovations, cost savings, speed of response, development of experts, sharing and participation, and then communicate achievements and shortcomings of the program. Finally, the CKO should manage relationships with external providers of information and knowledge and negotiate contracts with them (Harris, 1998).

While CKO job descriptions vary among firms, David Skyrme (2003) states that most CKO responsibilities include:

- developing an overall framework that guides knowledge management,
- actively promoting the firm's knowledge agenda within and beyond the company,
- overseeing the development of a knowledge infrastructure for the firm (e.g., via procedures and technology), and
- facilitating connections, coordination, and communication to enable knowledge exchange.

In a White Paper published at its Web site, DestinationKM (2000) states that identifying the need for a knowledge management officer or CKO and choosing that person may be among the most difficult endeavors a company undertakes. They argue that one way to approach these decisions is to ask at what stage in the corporate evolution a company recognizes the need for a knowledge management officer. Often, they claim, this realization comes after failures that affect the viability of a company. For example, companies that rely exclusively on paper trails and file cabinets to retain customer information could lose information, fail to note valuable customer characteristics and misrepresent the financial activity of the business. In many cases, they assert, company owners and top executives have been unaware of problems until they begin to lose customers and suffer dramatic losses in revenue. Other companies report implementing knowledge management and/or establishing a CKO position after competitors have hired away key employees who take the company's product knowledge, customer knowledge and confidential information with them.

DestinationKM states that identifying candidates for the CKO position can happen in a number of ways. In some cases, the potential CKO may already be part of the organization that utilizes knowledge management to improve business processes, but the CKO title or official position does not exist. For example, if a chief financial officer or senior business executive is already on board, the knowledge management role may become part of that individual's title and responsibility. Because business leaders tend to look in the direction of higher-ranking personnel and forward-thinking company officials to fill the CKO post, Destination KM asserts that it is not unusual for a member of the top management team to be sought for this role because these individuals have extensive knowledge of the company and already hold significant responsibilities

Davenport (1994) claims that to be successful, certain personal characteristics are critical for the CKO. These characteristics include:

- deep experience in some aspect of knowledge management, including its creation, dissemination, or application,
- familiarity with knowledge-oriented companies and technologies, such as libraries and groupware, and
- the ability to set a good example by displaying a high level of knowledgeability and success.

In a study of CKOs, TFPL (1998) finds that the majority of CKOs tend to possess these attributes. Their research shows that most CKOs emerge from planning teams and that they possess one of three main backgrounds – information technology (IT), human resources, or a core business function. But, TFPL notes, their common strength is their understanding of the organization and its business drivers, combined with an ability to take a holistic view of the company, and to understand the mix of hard and soft skills necessary to create, sustain and utilize the knowledge base.

MANAGING DIFFERENT FORMS OF KNOWLEDGE

A CKO's implementation of knowledge management programs often depends on his or her attitudes about explicit knowledge and implicit knowledge.

Explicit knowledge is defined as knowledge that can be expressed formally using a system of symbols, and can therefore be easily communicated or diffused. It is either object-based or rule-based. It is object-based when the knowledge is codified in strings of symbols (e.g., words, numbers, formulas) or in physical objects (e.g., equipment, documents, models). Object-based knowledge may be found in examples such as product specifications, patents, software code, computer databases, technical drawings, and so forth. Explicit knowledge is rule-based when the knowledge is codified into rules, routines, or standard operating procedures (Choo, 1998; Nonaka & Takeuchi, 1995).

CKOs preoccupied with explicit knowledge apparently tend to promote the use of technology to enable information distribution and sharing. Technologies that CKOs can employ in the explicit knowledge management process include text storage and retrieval systems, databases, expert systems, Lotus Notes groupware, and intranets. While use of technology to facilitate explicit knowledge transfer is a major concern for these organizations, Schreiber and Carey (2003) note that the interplay between task complexity, experience effects, and the type of data employed can affect its success.

Organizational members perform their work and make sense of their world using implicit knowledge as well. Implicit knowledge is knowledge that is uncodified and difficult to diffuse. It is hard to verbalize because it is expressed through action-based skills and cannot be reduced to rules and recipes. Implicit knowledge is learned through extended periods of experiencing and doing a task, during which the individual develops a feel for and a capacity to make intuitive judgments about the successful execution of the activity. Implicit knowledge is vital to the organization because organizations can only learn and innovate by somehow leveraging the implicit knowledge of its members. Despite its being uncodified, implicit knowledge can be and is regularly taught and shared. It can be learned by example. Implicit knowledge becomes substantially valuable when it is turned into new capabilities, products, or services (Choo, 1998).

It is important to note that implicit knowledge serves a critical role in the innovation process. It facilitates problem definition, problem solving, and predicting the outcomes of potential solutions (Nonaka & Takeuchi, 1995). However, it is often problematic to express implicit knowledge in a manner that others understand and hence formal intellectual exchanges as well as apprenticeships should be used to tap implicit knowledge. In two experiments examining the exchange of implicit knowledge, Herschel, Nemati, and Steiger (2001, 2003) find that the use of knowledge exchange protocols to structure the delivery of implicit information results in better understanding and retention by those with whom implicit knowledge is shared.

CKOs who emphasize implicit knowledge seem to spend a great deal of their time enabling, facilitating, and promoting informal dialogues. These CKOs appear to accept the premise that managing implicit knowledge means accepting chaos, ambiguity, and uncertainty and they feel that capturing implicit knowledge is expensive because it can only be revealed through conversations. For these CKOs, technology cannot be a driving force in implicit knowledge management because it lacks the media richness of face-to-face conversations — though some CKOs do promote video conferencing, because it enables non-verbal communication (Earl & Scott, 1999).

A decision by a CKO to emphasize one type of knowledge over another is often based more on pressures to produce demonstrable results than on the logic of facilitating organizational "knowing". However, such a strategy can be problematic. Choo (1998) and Nanaka and Takeuchi (1995) contend that failing to deal with both forms of knowledge and the conversion of one form to the other adversely impacts the effectiveness of knowledge management efforts. They argue that both forms of knowledge are critical, as is the interaction between them. These knowledge management experts believe that if a CKO sidesteps this issue, the CKO is inevitably compromising the long-term success of the knowledge management effort itself.

RESOLVING THE CKO CONTROVERSY

Twenty-five percent of Fortune 500 companies have a CKO and 80% of Fortune 500 companies have a knowledge management staff. Moreover, 42% of Fortune 500 companies anticipate appointing a CKO within the next 3 years (Flash, 2001).

Nevertheless, there are firms who believe the CKO function is not needed. Many of them feel that having a CKO is the wrong way to harness corporate know-how. Instead, these firms prefer a more grassroots approach, in which a team of knowledge management experts works closely with — or even as part of — the business units (Cole-Gomolski, 1999).

CKOs are often supposed to straddle business and information technology (IT) with a mandate to convince workers that it is good to share information and to work with IT to build applications to support such sharing. The problem is that some companies find that putting more control of knowledge management in the hands of end users themselves makes it an easier sell because knowledge sharing happens within business units. These firms believe that centralizing knowledge management under a CKO sends out the wrong message (Cole-Gomolski, 1999).

In firms where CKOs exist, Pringle (2003) notes that many of these have survived by judiciously distancing themselves from the original "craze," while still exploiting knowledge management concepts. This oftentimes means that CKOs do not talk about knowledge management per se. Instead, the CKO pursues activities that encourage employees to talk to one another or that allow workers to reuse already existing materials or information. Pringle notes that these CKOs typically imbed knowledge management activities within performance management systems that give staff members the incentive to learn and to share their expertise. That is, assessments of employee sharing of information efforts as well as demonstrable learning activities become an integral part of employee annual performance reviews.

Earl and Scott (1999) argue that appointing a CKO is indeed one way of galvanizing, directing, and coordinating a knowledge management program. However, they also feel that it is unlikely to be sufficient in itself; nor is it likely to be universally necessary. They concede that some organizations are investing in aspects of knowledge management without appointing a CKO. They believe that knowledge management, like total quality management, will become embedded in organizations and knowledge will become an obvious imperative source of value creation and competitiveness. In this scenario, all members of firms will own and drive knowledge management and, hence, the importance of and need for a CKO may decline.

FUTURE TRENDS

Contingency theory is useful in explaining company behavior relative to CKO adoption and deployment. Contingency theory states that desired organizational outcomes — such as performance — are the consequence of "fit" or match between two or more factors (e.g., strategy, culture, structure, tasks, environment and leadership style). The best way to organize depends upon the characteristics and the interplay between these factors (Scott, 1987).

Hence, the role of a CKO in a particular organization may inevitably depend on organizational factors. For example, in mature, knowledge-sharing organizational cultures, the CKO function may not need to be formalized as a distinct management position. However, in other firms, the relationship between knowledge management and other factors may not be as well integrated. In these firms, a CKO may be needed to act as a driver for organizational change. The point is that the focus of knowledge management will continue to vary significantly from one organization to another, and therefore so may the required leadership skills.

A multi-client study conducted by The Delphi Group revealed that, in practice, knowledge leadership spans a broad domain of positions and types of individuals. However, regardless of the differences in title or organizational placement, knowledge leaders appear to exhibit similar qualifications. The most notable have hybrid business/information technology experience, at least 10 years (and often much more) of line-of-business experience, an entrepreneurial attitude and a relatively high level of interest in career definition and development. They also display acumen in corporate communication throughout the formal hierarchy reflected in most organization charts, as well as in the informal networking that occurs in communities of practice or the "corporate underground". It is through all these channels that knowledge leaders may introduce methods and systems to match knowledge seekers with knowledge providers (Capshaw & Koulopoulos, 2004).

Hence, there does appear to be some common ground about what it will take to manage knowledge programs. In a recent survey at various companies, McKinsey (2004) asked CKOs for their views about make-or-break factors when it comes to managing knowledge. Although the CKOs had different experiences, all concurred that success will depend on two things: first, on the ability of senior management to agree about what it hopes to gain from managing knowledge explicitly and from creating a performance culture (which raises the demand for knowledge) and, second, on how well the CKO develops and executes a knowledge-management agenda.

CONCLUSION

According to Tom Davenport (1996), CKOs often oversee efforts to use technology for knowledge capture and distribution. However, CKOs must also foster sharing of implicit knowledge, which is less amenable to technology transfer. In this instance, CKOs must facilitate an organizational climate of knowledge sharing by encouraging such behaviors as mentoring and open dialogue. Hence, CKOs have three critical responsibilities: creating a knowledge management infrastructure, building a knowledge-sharing culture, and making it all pay off. Because of the complexity of the CKO job, these individuals necessarily need to have extensive knowledge of the company and already have significant organizational responsibilities.

KEY TERMS

Chief Knowledge Officer (CKO): A senior level executive responsible for managing a firm's knowledge management initiative.

Contingency Theory: States that desired organizational outcomes — such as performance — are the consequence of "fit" or match between two or more factors (e.g., strategy, culture, structure, tasks, environment and leadership style). The best way to organize depends upon the characteristics and the interplay between these factors.

Explicit Knowledge: Knowledge that can be expressed formally using a system of symbols, and can therefore be easily communicated or diffused. It is either object based or rule based.

Implicit Knowledge: Knowledge that is uncodified and difficult to diffuse. It is hard to verbalize because it is expressed through action-based skills and cannot be reduced to rules and recipes. Implicit knowledge is the same as tacit knowledge.

Intellectual Capital: Can be divided into three categories:

- *Human Capital* - that in the minds of individuals: knowledge, competences, experience, know-how, and so forth
- *Structural Capital* - "that which is left after employees go home for the night": processes, information systems, databases and so forth
- *Customer Capital* - customer relationships, brands, trademarks and so forth

Knowledge Exchange Protocols: A method of structuring tacit knowledge sharing so as to make its conversion to explicit knowledge more efficient. It emphasizes the use of dialogue segmenting accompanied by structural content headings to deliver implicit content.

Knowledge Management: A program for managing a firm's intellectual capital by systematically capturing, storing, sharing, and disseminating the firm's explicit and tacit knowledge.

Knowledge Management Architecture: The technology and procedural platforms employed by a firm to enable knowledge capture, sharing, retention, and distribution.

Citizenship and New Technologies

Peter J. Smith

Elizabeth Smythe
Concordia University College of Alberta, Canada

BACKGROUND

Not long ago globalization had only one face, that of a restructured capitalist economy employing new information technologies to operate on a global scale (Castells, 2000). According to this interpretation of globalization, the global is represented as space dominated by the inexorable and homogenizing logic of global markets (Steger, 2002). In this neoliberal model, the market replaces the state and the individual, the community thus posing a bleak future for citizenship.

Today, however, this one-dimensional view of globalization no longer holds sway. Transnational protests over the proposed Multilateral Agreement on Investment (MAI) and the meetings of the World Trade Organization (WTO) in Seattle are now seen as critical moments that speak to a new critical citizen activism that relies heavily upon new technologies and means of horizontal communication to operate on a global scale (Khagram, Riker & Sikkink, 2002; Ritchie, 2002). These means of communicating have provided an alternative voice and capacity to mobilize those excluded from an increasingly narrow spectrum of public discourse.

INTRODUCTION

This article examines this other side of globalization, in particular, the development of new processes and means of communicating and organizing which have enabled new forms of expression and connection among citizens which are not easily controlled by states and ruling elites. It does so by using two case studies of the failed attempt to negotiate the MAI at the Organization for Economic Cooperation and Development (OECD) in 1995-1998 and the failed effort to launch a new round of trade negotiations at the WTO Ministerial meetings in Seattle in 1999. These are good cases since both were based on a set of core neoliberal values shared by state elites of the 29 OECD member countries and the dominant members of the WTO. Despite having virtually no access initially to mainstream media and limited resources, a broad coalition of non-governmental organizations (NGOs) were able to challenge these elites and organize an effective opposition to the MAI and the Seattle meeting.

GLOBALIZATION, NEW INFORMATION TECHNOLOGIES, AND GLOBAL CIVIL SOCIETY

To understand how globalization might empower citizens, we must recognize that the information revolution made globalization possible. As Kobrin notes, "The emerging global world economy is electronic, integrated through information systems and technology rather than organizational hierarchies" (Kobrin, 1998, p. 362). However, while the information revolution breaks down hierarchies, it facilitates the creation of new power structures, redistributing not only economic, but also political power. Where economic globalization appears to be closing public spaces for state-centered citizenship, it may be opening them up elsewhere.

As a number of studies have indicated, information and communication technologies (ICTs), especially the Internet, have become important means of communication for many NGO networks (Warkentin, 2001; Smythe & Smith, 2003). Indeed, the Internet has been compared to the 'Swiss Army Knife' of political advocacy and organization (Hillwatch, 2001). This is because the Internet has become a multi-faceted tool providing civil society organizations with a number of advantages including:

- The facilitation of internal communication and provision of services to members—Strategy discussions and input of members at a distance are all made easier.
- The opening up of new public spaces for civil society organizations—The Internet can be used to educate the broader public about public policy and frame policy debates.
- The production, dissemination, and sharing of large amounts of information—Small, resource-poor organizations can, via the Internet, quickly and easily access research done by the organizations that do have these resources.

- The facilitation of public participation and mobilization—Thanks to the Internet civil society, organizations can quickly inform, organize, and mobilize their supporters.

The Internet thus possesses a variety of features that promote citizen engagement at a global level. The most frequently cited examples of how forces in civil and global civil society have combined to resist the traditional closed-door, top-down, multilateral processes are the MAI and the ministerial meeting in Seattle, and its failed attempt to launch the Millennium Round of trade negotiations (Ayres, 2003).

WHY THE MAI AND SEATTLE CASES?

Why use these two campaigns to empirically examine the argument about globalization's impact on citizens, democracy, and states? Primarily because many have argued that the root of the constraints states currently face in their capacity to make policy is globalization (McBride, 2003). The MAI, for example, was clearly designed and intended to limit state discretionary authority to discriminate between domestic and foreign investment in regulation.

Similarly, the expansion of areas of economic activity covered by trade rules have led to concerns that the WTO's rules are severely constricting the scope of state policies in favor of markets and corporations. If ICTs have facilitated contestation of globalization, it should be most apparent in the case of organizations like the OECD and the WTO.

The methodology used in examining these cases involved a variety of tools, including the analysis of thousands of Web pages and sites, and detailed interviews with a number of the organizations most actively involved in the campaigns, including participant observation in Seattle with an accredited NGO, along with the standard review of primary and secondary sources available.

THE MAI AND THE INTERNET

The MAI negotiations, formally launched in May, 1995 at the OECD Ministerial meeting, were drawn out over three-and-a-half years and ended in failure on December 2, 1998. While, at first, negotiations progressed rapidly in matters of general principles, they began to stumble in the winter of 1997 over the question of which economic sectors or state policies would be exempted from these general principles. Around the same time a draft of the February 1997 draft negotiating text was leaked and ended up very quickly on the Web sites of two public policy advocacy groups in North America. Once the text became known, public pressure—facilitated by the Internet—began to mount in a number of countries. In mid-October 1998, the French government, under pressure from the Green and Communists within its coalition, withdrew from the negotiations (Riché, 1998), thereby ending any real hope of agreement.

How important was the Internet in the politicization and mobilization against the MAI? To answer this question the authors began by surveying the presence on the Internet of MAI Web sites in February and March 1999, less than three months after the cessation of negotiations

Table 1. Web sites by type of sponsoring organization

Type of Group Sponsoring Site	Number of Sites	Per Cent of Total Sites
Public policy advocacy	53	15.1%
Political parties and MP sites	45	12.8
Media organizations	37	10.5
Government agencies—all levels	35	10

Canadian Center for Policy Alternatives (Ottawa)	12	10
Stop MAI–Australia	12	10

on December 2. Many of the Web sites had not been updated and were still on the Net a year later; the survey is broadly indicative of what citizens searching for information would have found, for example, in the winter of 1998, when public debate about the MAI was at its height.

Given that much of the anecdotal discussion about the Internet and the MAI claimed that the Web was mostly a tool of NGOs, the authors were surprised by the number of Web sites sponsored by members of legislatures, political parties (in most case, opposition parties), media organizations, governments, business and other organizations. Interviews suggested that many of the media and government Web sites followed in response to those of the advocacy, environmental, and development NGOs.

The authors also tried to get a sense of the countries where organizations were located which were active on the Web. The data indicated, not surprisingly, that the United States had the most Web sites, 31.9% of the 400 coded. However, the relatively large number of Canadian sites (17.6% of total) is striking and reflective of both the high level of connectedness in Canada and of the controversy the agreement generated in that country.

How is information linked and shared on the Web? Commentators have pointed to two aspects that make it a speedy and effective way to share and gather information—these are the use of hypertext links, and the extent to which information may be reproduced and shared in a variety of Web sites based around the world. As Table 2 indicates, virtually all of the Web sites had links (650) to other sites that provided information.

As indicated, 10 organizations accounted for over half of all of the hypertext links that appeared on the 400 Web sites. Virtually all of the other sites are North American, with the dominance of Canadian sites.

Interviews indicated that NGOs were strikingly similar in the way that they used the Internet, and what variation there was often reflected their size or restrictions on their activities dictated by their funding sources. Virtually all of the organizations used a Web site, e-mail, and a listserv as part of their anti-MAI activities. Web sites were generally targeted at a broader public than just a group's main membership. Their main function was to provide a means of gathering and sharing information and mobilizing those concerned about the agreement.

In the end, did the Internet really have an impact on the resulting failure of the negotiations? Interviews indicated that while none of the NGOs felt that the Internet campaign alone was responsible for the defeat of the MAI, all felt that the Internet campaign set the terms of public debate over the MAI.

THE CASE OF SEATTLE: THE ROAD TO THE WTO MINISTERIAL MEETING

The MAI and the WTO-Seattle case have direct links in the concern of many NGOs that the failed attempt to negotiate investment rules at the OECD would simply migrate to the WTO if a few powerful actors had their way. It is also linked in the lessons learned by both NGOs and governments and organizations like the WTO about the power and potential of ICTs. But concerns about the WTO in the globalization process also have roots in the earlier rounds of trade negotiations. The last and most significant was the Uruguay Round. It created the WTO in 1995 and left its members two key issues, services and agriculture, with built-in mandates for further negotiations.

The likelihood for severe conflict among WTO members meeting in Seattle was already very high given the presence of agriculture on the agenda. There was also

evidence of real discontent on the part of many developing countries who, now, along with economies in transition, vastly outnumbered the developed country members. Many of these developing countries had taken on new and onerous obligations as a result of the Uruguay Round, in return for little real results in improved market access for their goods in developed economies.

NGOs, as a result of the 18-month campaign of opposition to the MAI, were already organized. The WTO campaign, however, was even broader in scope, both in terms of countries, issues, and types of organizations involved. Opponents' preparations were underway more than a year in advance of the Seattle meeting, and went into high gear once the city had been chosen as the meeting venue (Brecher, Costello & Smith, 2000).

One major difference from the anti-MAI campaign was that this campaign sought to use the meeting venue itself as a site for a public display of opposition. Protests and direct action were designed to disrupt the meeting itself and stop the launch of a round of negotiations.

THE WTO MINISTERIAL AND THE INTERNET

What role did the Internet play in this campaign? The role of the Internet included three aspects: organizing, educating, and mobilizing. The Internet proved invaluable in coordinating and organizing the activities of thousands of groups and individuals. In terms of educating the public, detailed analyses and research were distributed worldwide. In regards to mobilization, many North American organizations also used their sites to encourage and call on citizens to come to Seattle.

In their second analysis of sites, the authors used 40 search engines and identified 4,089 Web sites with material specific to the Seattle round of the WTO. Of these sites 513 were selected to examine and classify.

As Table 3 indicates, those using the Web included a broad range of civil society. However, the significant presence of governments reflected the extent to which they too had learned important lessons and turned to the Internet to get their message out.

The authors also looked at the distribution of sites in terms of origin. What is striking is the fact that the sites included virtually every region of the world. The North still dominated with a majority in the United States. Not surprisingly, most sites contained links to the WTO and the Seattle host organization, the key place for information about the Ministerial, NGO registration, schedules, housing, and the city.

According to public opinion polls, the campaign also had an impact in raising public awareness about the WTO (Agnus Reid, 2002). However, it is debatable whether the civil society campaign can take sole credit for turning Seattle into a fiasco. Differences among member states on key issues, such as agriculture and the discontent of many developing countries with the implementation of the Uruguay round, were also important contributing factors.

FUTURE TRENDS

This examination of the use the Internet to mobilize against the MAI and a new round of trade negotiations in Seattle indicates that the growth of a global civil society has the potential to enhance citizenship globally and domestically. What is particularly striking is the extent to which the use of the Net has leveled the playing field in terms of who can now participate, decentering public discussion away from government agencies and business organizations. Clearly, civil society organizations have become particularly adept at horizontal communications, thus eroding the monopoly of information possessed by traditional economic, broadcast media, and political hierarchies. Indeed, the ability to publicize and disseminate information quickly has made closed-door, secretive trade negotiations difficult, if not impossible.

CONCLUSION

While the use of the Internet enhances the potential for citizenship in a number of respects, those interviewed were perfectly aware of its limitations. A digital divide does exist. Not all information provided is good, accurate, or timely. Often there is too much information, and it is impossible to analyze and respond to all of it. Furthermore, communication on the Net is often intemperate and tangential to the debate. The Net, then, is not a panacea for all that ails citizenship in a global era. It does, however, have the potential to enhance and enrich it.

KEY TERMS

Civil Society: Refers to the sphere of associative activity between the individual and the state. Analysts differ between those who include the economy and those who do not. The authors include the economy.

Global Civil Society: Consists of the myriad groups and networks of action and knowledge that can, but do not necessarily, extend across state borders.

Globalization: Commonly refers to the process whereby the capitalist economy becomes increasingly integrated and organized on a global scale. More broadly, it refers to a social process whereby "the constraints of geography on social and cultural arrangements recede and in which people become increasingly aware that they are receding" (Waters, 1995, p. 3).

Multilateral Agreement on Investment: A draft agreement designed to protect foreign investors by limiting host state regulation. The 30 members of the Organization for Economic Cooperation and Development failed to reach agreement in 1998 after three years, and negotiations ceased.

Networks: Defined by Keck and Sikkink as "forms of organization characterized by voluntary, reciprocal, and horizontal patterns of exchange" (1998, p. 8).

Non-Governmental Organizations (NGOs): Non-profit, self-governing organizations with voluntary membership.

World Trade Organization: Includes 148 member states and was established in 1995 as successor to the General Agreement on Tariffs and Trade. Its primary purpose is to liberalize international trade through rounds of multilateral negotiations and to resolve trade disputes among member countries.

Classification-Rule Discovery with an Ant Colony Algorithm

Rafael S. Parpinelli

Alex A. Freitas
University of Kent, UK

INTRODUCTION

Ant colony optimization (ACO) is a relatively new computational intelligence paradigm inspired by the behaviour of natural ants (Bonabeau, Dorigo & Theraulaz, 1999). The natural behaviour of ants that we are interested in is the following. Ants often find the shortest path between a food source and the nest of the colony without using visual information. In order to exchange information about which path should be followed, ants communicate with each other by means of a chemical substance called pheromone. As ants move, a certain amount of pheromone is dropped on the ground, creating a pheromone trail. The more ants follow a given trail, the more attractive that trail becomes to be followed by other ants. This process involves a loop of positive feedback, in which the probability that an ant chooses a path is proportional to the number of ants that have already passed by that path.

Hence, individual ants, following very simple rules, interact to produce an intelligent behaviour – a solution to a complex problem – at the higher level of the ant colony. In other words, intelligence is an emergent phenomenon; that is, "the whole is more than the sum of the parts".

In this article we present an overview of Ant-Miner, an ACO algorithm for discovering classification rules in data mining (Parpinelli, Lopes & Freitas, 2002a, 2002b). In essence, in the classification task each case (record) of the data being mined consists of two parts: a goal attribute, whose value is to be predicted, and a set of predictor attributes. The aim is to predict the value of the goal attribute for a case, given the values of the predictor attributes for that case.

To the best of our knowledge, the use of ACO algorithms (Bonabeau, Dorigo & Theraulaz, 1999; Dorigo et al., 2002) for discovering classification rules is a very under-explored research area. There are other ant algorithms developed for the data mining task of clustering – see for example Monmarché (1999) – but that task is very different from the classification task addressed in this article. Note that Ant-Miner was designed specifically for discovering classification rules, rather than for solving other kinds of data mining tasks.

In other research areas ACO algorithms have been shown to produce effective solutions to difficult real-world problems. A detailed review about many other ACO algorithms (designed to solve many other different kinds of problems) and a discussion about their performance can be found in Bonabeau, Dorigo and Theraulaz (1999) and Dorigo et al. (2002).

A typical example of application of ACO is network traffic routing, where artificial ants deposit "virtual pheromone" (information) at the network nodes. In essence, the amount of pheromone deposited at each node is inversely proportional to the congestion of traffic in that node. This reinforces paths through uncongested areas. Both British Telecom and France Telecom have explored this application of ACO in telephone networks.

ANT COLONY OPTIMIZATION

An ACO algorithm is essentially a system based on agents that simulate the natural behavior of ants, including mechanisms of cooperation and adaptation.

ACO algorithms are based on the following ideas:

- Each path followed by an ant is associated with a candidate solution for a given problem;
- When an ant follows a path, the amount of pheromone deposited on that path is proportional to the quality of the corresponding candidate solution for the target problem;

- When an ant has to choose between two or more paths, the path(s) with a larger amount of pheromone have a greater probability of being chosen by the ant.

As a result, the ants eventually converge to a short path, hopefully the optimum or a near-optimum solution for the target problem.

In essence, the design of an ACO algorithm involves the specification of (Bonabeau, Dorigo & Theraulaz, 1999):

- An appropriate representation of the problem, which allows the ants to incrementally construct/modify solutions through the use of a probabilistic transition rule, based on the amount of pheromone in the trail and on a local, problem-dependent heuristic;
- A method to enforce the construction of valid solutions;
- A problem-dependent heuristic function (h) that measures the quality of items that can be added to the current partial solution;
- A rule for pheromone updating, which specifies how to modify the pheromone trail (t);
- A probabilistic transition rule based on the value of the heuristic function (h) and on the contents of the pheromone trail (t) that is used to iteratively construct a solution.

Artificial ants have several characteristics similar to real ants, namely:

- Artificial ants have a probabilistic preference for paths with a larger amount of pheromone;
- Shorter paths tend to have larger rates of growth in their amount of pheromone;
- The ants use an indirect communication system based on the amount of pheromone deposited on each path.

MOTIVATIONS FOR USING ACO

ACO possesses a number of features that are important to computational problem solving (Freitas & Johnson, 2003):

- The algorithms are relatively simple to understand and implement, whilst also offering emergent complexity to deal effectively with challenging problems;
- They can be readily hybridized with other techniques and/or problem-dependent heuristics in a synergistic fashion;
- They are compatible with the current trend towards greater decentralization in computing;
- The algorithms are highly adaptive and robust, enabling them to cope well with noisy data.

Two more features of ACO are particularly useful in data mining applications:

- Many projects in the field of data mining were developed using deterministic decision trees or rule induction algorithms. These algorithms are hill climbing like and are susceptible to finding only locally optimal solutions instead of the global optimum. The utilization of ACO to induce classification rules tries to mitigate this problem of premature convergence to local optima, since ACO algorithms have a stochastic component that favors a global search in the problem's search space;
- Unlike classical methods for rule induction, the ACO heuristic is a population-based one. This characteristic has advantages over other methods because it allows the system to search many different points in the search space concurrently and to use the positive feedback between the ants as a search mechanism.

REPRESENTING A CANDIDATE CLASSIFICATION RULE

In Ant-Miner each artificial ant represents a candidate classification rule of the form:

- IF <*term1* AND *term2* AND … > THEN < *class* >.

Each term is a triple <*attribute*, *operator*, *value*>, where *value* is one of the values belonging to the domain of *attribute*. An example of a term is: <*Sex* = *female*>. *Class* is the value of the goal attribute predicted by the rule for any case that satisfies all the terms of the rule antecedent. An example of a rule is:

- IF <*Salary* = *high*> AND <*Mortgage* = *No*> THEN <*Credit* = *good*>.

In the current version of Ant-Miner the *operator* is always "=", so that Ant-Miner can cope only with categorical (discrete) attributes. Continuous attributes would have to be discretized in a preprocessing step.

DESCRIPTION OF ANT-MINER

The pseudocode of Ant-Miner is described, at a very high level of abstraction, in Algorithm 1. Ant-Miner starts by initializing the training set to the set of all training cases, and initializing the discovered rule list to an empty list. Then it performs an outer loop where each iteration discovers a classification rule.

The first step of this outer loop is to initialize all trails with the same amount of pheromone, which means that all terms have the same probability of being chosen by an ant to incrementally construct a rule. This is done by an inner loop, consisting of three steps. First, an ant starts with an empty rule and incrementally constructs a classification rule by adding one term at a time to the current rule. In this step a $term_{ij}$ – representing a triple $<Attribute_i = Value_j>$ – is chosen to be added to the current rule with probability proportional to the product of $h_{ij} \times t_{ij}(t)$, where h_{ij} is the value of a problem-dependent heuristic function for $term_{ij}$ and $t_{ij}(t)$ is the amount of pheromone associated with $term_{ij}$ at iteration (time index) t. More precisely, h_{ij} is essentially the information gain associated with $term_{ij}$ – see Cover and Thomas (1991) for a comprehensive discussion on information gain. The higher the value of h_{ij} the more relevant for classification $term_{ij}$ is and so the higher its probability of being chosen. $t_{ij}(t)$ corresponds to the amount of pheromone currently available in the position i,j of the trail being followed by the current ant. The better the quality of the rule constructed by an ant, the higher the amount of pheromone added to the trail positions ("terms") visited ("used") by the ant. Therefore, as time goes by, the best trail positions to be followed – that is, the best terms to be added to a rule – will have greater and greater amounts of pheromone, increasing their probability of being chosen. Please refer to Algorithm 1.

The second step of the inner loop consists of pruning the just-constructed rule, that is, removing irrelevant terms – terms that do not improve the predictive accuracy of the rule. This is done by using a rule-quality measure, the same one used to update the pheromones of the trails, as defined later. In essence, a term is removed from a rule if this operation does not decrease the quality of the rule. This pruning process helps to avoid the overfitting of the discovered rule to the training set.

The third step of the inner loop consists of updating the pheromone of all trails by increasing the pheromone in the trail followed by the ant, proportionally to the quality of the rule. In other words, the higher the quality of the rule, the higher the increase in the pheromone of the terms occurring in the rule antecedent. The quality (Q) of a rule is measured by the equation:

$$Q = \text{Sensitivity} \times \text{Specificity},$$

where $Sensitivity = TP / (TP + FN)$ and $Specificity = TN / (TN + FP)$. The meaning of the acronyms TP, FN, TN and FP is as follows:

- TP = number of true positives, that is, the number of cases covered by the rule that have the class predicted by the rule;
- FN = number of false negatives, that is, the number of cases that are not covered by the rule but that have the class predicted by the rule;
- TN = number of true negatives, that is, the number of cases that are not covered by the rule and that do not have the class predicted by the rule; and
- FP = number of false positives, that is, the number of cases covered by the rule that have a class different from the class predicted by the rule.

See Lopes (1997) for a discussion about these variables and their use to estimate predictive accuracy.

The inner loop is performed until some stopping criterion(a) is(are) satisfied, for example, until a maximum number of candidate rules have been constructed.

Algorithm 1. High-level pseudocode of Ant-Miner

```
TrainingSet = {all training cases};
DiscoveredRuleList = [];   /* initialized with an empty list */
REPEAT
    Initialize all trails with the same amount of pheromone;
    REPEAT
        An ant incrementally constructs a classification rule;
        Prune the just-constructed rule;
        Update the pheromone of all trails;
    UNTIL (stopping criteria)
    Choose the best rule out of all rules constructed by all the ants;
    Add the chosen rule to DiscoveredRuleList;
    TrainingSet = TrainingSet – {cases correctly covered by the chosen rule};
UNTIL (stopping criteria)
```

Once the inner loop is over, the algorithm chooses the highest-quality rule out of all the rules constructed by all the ants in the inner loop, and then it adds the chosen rule to the discovered rule list. Next, the algorithm removes from the training set all the cases correctly covered by the rule, that is, all cases that satisfy the rule antecedent and have the same class as predicted by the rule consequent. Hence, the next iteration of the outer loop starts with a smaller training set, consisting only of cases that have not been correctly covered by any rule discovered in previous iterations. The outer loop is performed until some stopping criterion(a) is(are) satisfied, for example, until the number of uncovered cases is smaller than a user-specified threshold.

Hence, the output of Ant-Miner is the list of classification rules contained in the discovered rule list.

A SUMMARY OF COMPUTATIONAL RESULTS

We have performed computational experiments comparing Ant-Miner with two well-known rule induction algorithms, namely CN2 (Clark & Niblett, 1989) and C4.5 (Quinlan, 1993) in several public-domain data sets often used as a benchmark in the machine learning literature. More precisely, the data sets used in the experiment are Ljubljana breast cancer, Wisconsin breast cancer, tic-tac-toe, dermatology, hepatitis, and Cleveland heart disease. A detailed description of all these data sets is available online from: *http://www.ics.uci.edu/~mlearn/MLRepository.html*. C4.5 and CN2, as well as many other classification algorithms, are also described in Witten and Frank (2000). C4.5 and CN2 were chosen for comparison because they are, in general, two of the most used algorithms belonging to the rule induction paradigm, where discovered knowledge is expressed by IF-THEN rules. Hence, they are a natural choice to be compared with Ant-Miner, since Ant-Miner also discovers knowledge expressed by IF-THEN rules. The results of the experiments summarized here are described in detail in Parpinelli, Lopes and Freitas (2002a, 2002b).

The results showed that Ant-Miner is competitive with both C4.5 and CN2 concerning predictive accuracy on the test set used to measure the generalization ability of the discovered rules. More precisely, predictive accuracy was measured by the accuracy rate, that is, the ratio of the number of correctly classified test cases divided by the total number of test cases (correctly-classified plus wrongly-classified test cases), as usual in the classification literature (Witten & Frank, 2000). Ant-Miner obtained a considerably better accuracy rate than CN2 in the Ljubljana breast cancer and the dermatology data sets, and a considerably better accuracy rate than C4.5 in the hepatitis data set. However, both CN2 and C4.5 obtained a considerably better accuracy rate than Ant-Miner in the tic-tac-toe data set. In the other data sets the difference in the predictive accuracy of Ant-Miner and the other two algorithms was quite small.

However, concerning rule set simplicity (measured by the number of discovered rules and the number of terms per rule), Ant-Miner discovered rule sets much simpler (i.e., smaller) than the rule sets discovered by both C4.5 and CN2. This is an important advantage in the context of data mining, where discovered knowledge is supposed to be shown to a human user in order to support his/her decision making (Fayyad, Piatetsky-Shapiro & Smyth, 1996).

KEY TERMS

Data Mining: An interdisciplinary research field, whose core is at the intersection of machine learning, statistics, and databases. We emphasize that the goal – unlike, for example, classical statistics – is to discover knowledge that is not only accurate, but also comprehensible for the user.

Overfitting: Term referring to the situation where the discovered rules fit too much to the training set peculiarities. Overfitting usually leads to a reduction of the predictive accuracy rate on the test cases.

Rule List: An ordered list of IF-THEN rules discovered by the algorithm during training. When the rules are applied to classify cases in the test set, they are applied in order. That is, a case is matched with each of the rules in the list in turn. The first rule whose antecedent (conditions in the IF part) matches the attribute values of the case is then used to classify the case; that is, the case is assigned the same class as the class predicted by the first matching rule found in the discovered rule list.

Testing Case: Each of the cases (records) of the test set.

Test Set: A set of cases unseen during the training phase of the algorithm and used to compute the predictive accuracy of the list of rules discovered during the training phase.

Training Case: Each of the cases (records) of the training set.

Training Set: A set of cases used by the algorithm to discover the classification rules. At each iteration of Ant-Miner only one rule is discovered. The training cases that are covered correctly by the discovered rule (i.e., cases satisfying the rule antecedent and having the class predicted by the rule consequent) are removed from the training set. This process is performed iteratively while the number of uncovered training cases is greater than a user-specified threshold.

Classroom Communication on a Different Blackboard

Jennifer Paige Nightingale
Duquesne University, USA

INTRODUCTION

Employing technology that students find enticing and will prepare them well for the future, may be easier than preparing the teachers who will integrate this technology into learning activities. Competition among educational institutions for students is increasing exponentially, which requires a greater sensitivity to student needs (Heckman & Guskey, 1998). Course management systems (CMSs) can build a framework for using technology as a technique of providing this responsiveness to students, predominantly in the form of communication. The aim is to ultimately create an environment conducive to teaching and learning via a technological community where students, faculty, adjunct instructors, staff, and administration can work together to achieve a common goal—produce quality graduates.

BACKGROUND

The Impact of Technology

According to some educational technology resources, technology clearly has had, and will continue to have, a major impact on education. Many institution segments are moving transactions and shared information into online communication channels, such as the Internet. The U.S. Department of Education explained that the development of the National Education Technology Plan is part of a long-range national strategy and guide for using technology effectively to improve student academic achievement—directly or through integration with other approaches to overall reform. The *No Child Left Behind Act* is raising standards for student achievement, giving students more information and more choices, requiring more accountability from schools, and funding education at record levels. The goals of the *No Child Left Behind Act* are as follows (Kozberg, 2002):

1. To improve student achievement using technology in elementary and secondary schools
2. To assist students in becoming technologically literate by the time they finish the eighth grade
3. To ensure that teachers are able to integrate technology into the curriculum to improve student achievement

Rod Paige, U.S. Secretary of Education, believes that "by harnessing technology, we can expand access to learning and close the achievement gap in America."

As stated in Vallone (2000):

Education is the fuel for the New Economy, and demand for online teaching and learning resources has already reached critical mass. Web-based and Web-enhanced courses are…already popular e-learning platforms in higher education today. According to Student Monitor, 90% of college students used the Internet last fall and 66% were connecting once a day or more often. According to Campus Computing, over 53% of college courses used e-mail last year, almost 39% used Internet resources, and almost 28% used Web pages for class materials and resources… (p. 1).

As education and technology continue to merge and evolve at rapid speed, institutions will find an enormous array of effective solutions to augment their educational offerings and build deeper relationships with current and prospective students, alumni, and administrators (Blackboard® Incorporated, 2001). CMSs are modifying the way instructors disseminate information. A growing number of campuses identify CMSs as "very important" in their institutional information technology planning, and approximately one-fifth (20.6%) of all college courses now use course management tools, up from 14.7% in 2000 (Green, 2001). A leading e-learning industry analyst firm projects that the higher education e-learning market will grow from $4 billion today to $11 billion by 2003 (Stokes, 2000).

Choosing the Technology

Tomei (2002, p. 5) explained that to succeed in technology implementation, we need to understand that the technology itself is not the goal. In deciding what technology will support the objectives or if a CMS can satisfy determined needs, consider the following:

- The benefit of a CMS to faculty and an institution is that it should provide instructors with a pre-made course Web template on which they can easily place, especially if they possess the computing skills and knowledge identified above, their course materials and activities.
- A CMS should service the majority of instructors and their curriculum needs and yet be flexible enough to provide advanced users with the basics upon which they can add further functionality and meet the needs of special and unique requests.
- A CMS should be cost-effective for the institution in terms of operating and support costs and resources.
- Not only are developer skills and understanding important, an institution must commit to effective infrastructure and strategic support of the CMS by ensuring that adequate support for users exists and that resources are available for hardware and software improvements and maintenance necessary for reliable operation of the CMS.

Currently, Blackboard has been able to meet the above criteria, and as its increased use by faculty and programs across campus indicates, it has become the preferred CMS at Duquesne University (see Table 1). The fourth column indicates the growing trend of professors who use Blackboard over the previous semester. Furthermore, when SOBA-Net was born, less than 12% of the School of Business faculty was using Blackboard to supplement their face-to-face courses. Now we have 88.4% of faculty participation. Regardless of which technology you choose, you must realize the implementation is an ongoing process that demands time, attention, and dedication.

METHODOLOGY

The History of SOBA-Net

The Duquesne University School of Business (SOBA) in Pittsburgh, Pennsylvania, is bridging the communication gap between students, faculty, and staff with an online community called **SOBA-Net** (School of Business Administration Network). Using the CMS, Blackboard®, as a portal, users find important information, communication, and resources for their programs. SOBA-Net is quickly becoming a tool on which students, faculty, and staff depend.

There is no doubt that technology has had a major impact on our daily lives. In summer 1999, Duquesne University adopted the Blackboard® CMS as a means to provide technological advancements to education. This system traditionally allows for teaching online, where colleges and universities all over the world are diving into the online education arena. For example, an instructor can use a CMS course site simply and easily for increasing the availability of course materials, assignments, resources, and grades. In an effort to meet student demands, this CMS was modified to build human relationships that allow students to take an active role in, and be held accountable for, their academic careers. Ultimately, the creation of SOBA-Net has taken the foundation of a CMS and altered it to become a school management system (SMS).

What is a School Management System and Portal?

A management information system is, according to Ox (2002), a computer-based system that supports managers and their subordinates in their daily work and strategic planning….managerial decisions and daily operations. An SMS manages a school's key functional data, including items such as staff and faculty data, class schedules, school guidelines, special programs, and other school information, and, depending upon the type of SMS implemented and the desired outcomes, the system can range from low-end to high-end capabilities. Many schools depend on integrated information systems to manage their data and provide detailed information that aids in the communication process (Blackboard® Incorporated, 2001).

A portal is not a new concept to the technology industry; in fact, www.yahoo.com and www.msn.com are two of the many organizations that have used portals from the beginning. Building an online community in Blackboard® has made it convenient for students to find the tools and resources they need to be successful in their academic careers. "In the Internet economy, people, process, and technology must be inextricably linked," explained Greg Baroni (1999, [Online]), national partner-in-charge of the KPMG higher education practice. "Portals

Table 1. Statistics for nondistance learning courses

Term	Total Courses	Unique Faculty	Increase
Fall 2003	255	142	15%
Spring 2003	221	121	12%
Fall 2002	197	109	

are the latest iteration of enabling technology that universities can integrate to create strategic advantage."

Why Blackboard®?

Blackboard® makes it relatively easy to provide students with course materials in HTML, PDF, Word, PowerPoint, or Excel formats. It provides student home page creation, built-in chat and online discussion capabilities, e-mail, collaborative or group work facilitation and management areas, assessment creation and automatic grading, grade book distribution, class management features (such as calendaring or tasks), and a digital drop box for students to use to submit assignments. Course sites are password protected and are available only to registered students.

Although DU supports both WebCT® and Blackboard® CMSs, Blackboard® was selected because of its low learning curve, visual appeal, and secured environment, as well as the ability to access information via the Internet. In addition, some of the school's faculty participated in training when Blackboard® was initially implemented campus-wide in summer 1999, bringing a familiarity component into play and encouraging faculty involvement in implementation.

SOBA-Net reinforces both Duquesne University's and SOBA's directive of integrating technology across the curriculum. For many faculty members, the shear thought of integration can be greatly intimidating. By using Blackboard®, faculty members can observe how a CMS is used to aid in disseminating materials and communicating with students; in moving from observing to participating, the intimidation can be significantly reduced.

What were the Initial Objectives?

It was first thought that academic advisors would benefit most, as they constantly searched for a better method of communicating with the students and distributing information relevant to their academic careers. Thus, they embraced and encouraged this improvement and rather than merely adding to the student's knowledge bank, the objective was to set students up for success by requiring them to take an active role in their education. Students and advisors would be able to work smarter and more efficiently, help improve overall communication between faculty, staff, and students, validate concepts taught throughout the curriculum (i.e., teamwork), and greatly reduce the paper trail.

Getting Started

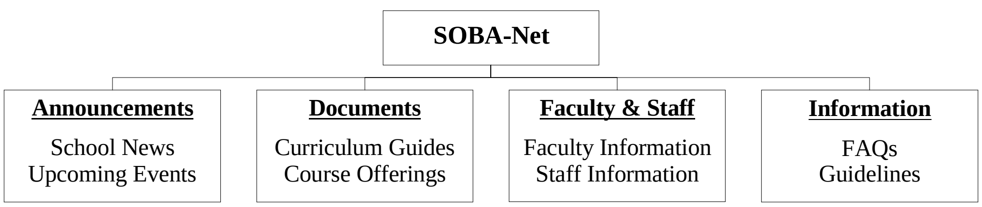
Before documents and information are uploaded, specific objectives and guidelines must be established. White and Weight (2000, p. 185) have used technology as a tool to enable human relationships, and have found that people are the real reason for success in any online learning environment. This environment requires a value-added approach, where technology is used to enhance the complex private and social activities of the learning process (p. vii). In this stage, three factors must be considered:

- Content management: What should be online? Who will provide it? Who will maintain and update it? How will it be organized? Is security an issue? What areas of the CMS should be enabled or disabled?
- Interactivity: What limitations will be imposed? Do all users have the ability to participate in threaded discussions? Should specific guidelines and standards be established and posted?
- User management: Who will manage the users and passwords (if applicable)? Should different security settings exist for different types or classifications of users (e.g., faculty, staff, students, etc.)?

Building the Virtual Community

Once the guidelines are established, the construction can begin. This is the longest part of the process, and obtaining the information can be a challenge. Consider holding CMS training sessions to involve faculty and staff—your colleagues add valuable feedback and offer assistance to feel like a valuable part of the process. After all, the virtual community encompasses the entire school, so demonstrate the need for and value of teamwork from

Figure 1. Snapshot of SOBA-Net's schema



its inception. In addition, draw an initial schema before uploading any content (see Figure 1). It is critical that the content be organized and easy to navigate, or users will not return.

If You Build It, They Will Come

This is not exactly the case. The overall marketing and enthusiasm generated will determine its success, and like the implementation phase, marketing SOBA-Net is an ongoing process that demands time, attention, and dedication. To generate interest and maintain momentum, remember that behavior breeds behavior—if you are excited about it, then others will follow suit. Users must have a reason to log in, so offer incentives or hold contests to create initial excitement. The results indicate that both the faculty and academic advisors proved to be a valuable communication medium and significant marketing resource.

Where are We Now?

At the time of SOBA-Net's initial construction, we did not have the skills or technology needed to develop such a site and host it on our Web server. Its success, along with improved technical resources and knowledge during the past year, has enabled us to centralize the information. Sections now exist for both prospective and current students as well as faculty, staff, administration, alumni, and friends (http://www.business.duq.edu).

Regardless of the technology used, it is important to understand how the fundamental concepts, through the construction and use of such a portal, will aid in building relationships and enhancing communication skills.

CONCLUSION

SOBA-Net provides connectivity via the Internet, preserves the School of Business, Duquesne University, meets President George W. Bush's initiative for technology integration and enhancement, and appeals to the students' desire for online resources.

While it may be too early to determine SOBA-Net's effectiveness in fostering academic success, it has encouraged students to become more self-sufficient and assume some responsibility and accountability for their educational outcomes. In addition, there has been a notable increase in faculty use of Blackboard® in their classes, and students are encouraging those who do not use it to adopt it. The information superhighway transports teachers and students beyond the walls of their classrooms by providing access to an immeasurable quantity of information (Tripathi, 2000). As educators, we must utilize the tools at hand to foster students' communication skills and accountability. The School of Business's experience has had a positive affect not only school-wide, but also throughout campus, and, as a result, several other programs are now developing similar sites for their faculty, staff, students, and administration.

KEY TERMS

Computer-Based Information System (CBIS): A computer-based information system is an information system that uses computer technology to perform input, processing, and output activities. A CBIS consists of people, procedures, data, hardware, and software.

Groupware: This software can be used by a group of people who are working on the same information at separate workstations. It includes features such as e-mail, shared calendar, task list, and address book, and is used for project management, brainstorming, and action planning.

Hypertext Markup Language (HTML): A markup language used to structure text and multimedia objects as well as set up links between documents. This language is used extensively on the Internet and can be viewed in a Web browser.

Internet: A worldwide system of networks that has transformed communications and methods of commerce by allowing various computer networks to interconnect. Sometimes referred to as a "network of networks," the Internet materialized in the United States in the 1970s but did not become overtly visible until the early 1990s.

Portable Document Format (PDF): According to Adobe Systems Incorporated, a PDF is a "universal file format that preserves the fonts, images, graphics, and layout of any source document, regardless of the application and platform used to create it."

Portal: A portal is any Web site considered an entry point to other Web sites, often by being or providing access to a search engine. Some examples include www.Yahoo.com, www.Google.com, and www.MSN.com.

Push Technology: Push technology enables people to subscribe to and have news and information delivered directly to their e-mail, releasing them from having to search the Internet.

Schema: A diagram, outline, or model.

Client/Server and the Knowledge Directory

INTRODUCTION

Data, information, and knowledge are three related but not interchangeable concepts. Data are a set of discrete, objective facts about events. Information is organized data presented in context. Data become information when their creator adds meaning or value. Similarly, knowledge derives from information as information derives from data. Knowledge can be viewed as information in context, together with an understanding of how to use it. Knowledge can be either explicit (knowledge for which a person is able to make available for inspection) or tacit (knowledge for which a person is unable to make available for inspection) (Brooking, 1999; Davenpot & Prusak, 1998). In Table 1, a list of knowledge that is particularly critical for business organizations is given.

Knowledge is an intellectual property that although paid for in part by the employer is a difficult asset to control, as it is fragmented in documents, policies, procedures, and other data storage mediums. Another challenge for management is to retain this knowledge in a form that is easily retrievable. This is not an easy task, since the enterprise must first identify the location of all needed knowledge, and second, determine the easiest way to retrieve it.

There are many definitions of knowledge management, but the Gartner Group (1999) description seems most appropriate for the perspective expressed in our article: "Knowledge management promotes an integrated approach to identifying, capturing, retrieving, sharing, and evaluating an enterprise's information assets. These information assets may include databases, documents, policies and procedures, as well as the un-captured tacit expertise and experience stored in individual workers' heads."

This definition implies that information assets are plentiful and are stored in numerous locations throughout the organization. Storage options include documents, documents in document management systems, groupware such as Lotus Notes, and expert or knowledge-based systems (Brooking, 1999). Physically these information assets can be electronically stored on compact disk, laser disk, mechanical hard drives, microfilm, microfiche, and embedded in computer programs. Further, information assets are also stored in books, documents, and other paper-based medium.

BACKGROUND

In a world of multiple computer languages, database management systems, assorted collaborative and group support software, network technologies, and data storage methods, it can be a difficult and complex problem to

Table 1. Knowledge that is particularly critical (Brooking, 1999)

- Knowledge of a particular job
- Knowledge of who knows what in a company
- Knowledge of how to get things done in a company using the corporate culture
- Knowledge of who is best to perform a particular job or task
- Knowledge of corporate history (how and why)
- Knowledge of business customs
- Knowledge of a particular customer account
- Knowledge of how to put together a team that can achieve a particular task
- Knowledge of how to approach a particular problem which is difficult to solve

locate and retrieve enterprise knowledge. If KM promotes an integrated approach to identifying, capturing, retrieving, sharing, and evaluating an enterprise's information assets, then the challenge is to create a knowledge management system in order to get the right information to the right person at the right time.

"An integrated and integrative technology architecture is a key driver for Knowledge Management Systems (KMS) … KMS seem to require a variety of technologies: database and database management, communication and messaging, and browsing and retrieval. The need for seamless integration of the various technologies may lead to the dominance of the Internet and Internet-based KMS architectures" (Alavi & Leidner, 1999). Alavi and Leidner (1999) also note that "organizational intranets will also play a dominant role in support of internal knowledge management activities due to cost-effective technical capabilities including: access to the legacy systems, platform independence, access to multimedia data formats, a uniform and easy-to-use point-and-click interface, and capability for easy multi-media publication for knowledge sharing."

A CLIENT/SERVER ARCHITECTURE FOR KMS

Computing sources for the first 30 years of the information technology revolution were dominated by isolated hardware and network environments. Mainframes, mini-computers and local area networks were initially set up to support specific business functions. Each computing complex was installed with a separate physical data network. IBM mainframes used coaxial cable and 3270 terminal emulation and the IBM System 38 mini-computer used twin-axial cable and 5250 terminal emulation. Local area networks used their own respective cabling medium and data network architecture. As a result, these environments were isolated and data sharing was almost impossible (Kern et al., 1998).

Information systems written for these monolithic computer complexes contain three basic components: a presentation layer, a processing layer, and a data storage layer (Boar, 1996; Borthick & Roth, 1994). All three layers execute on one hardware platform. During the 1980s and 1990s, multiple protocol support between different platforms across inexpensive connections became more common. This connectivity enhancement helped the development of client/server technologies, which distributed these layers across hardware and operating systems platforms (Boar, 1996; Duchessi & Chengalur-Smith, 1998; Schulte, 1995). A client/server architecture consists of three layers: the presentation layer, the business logic layer, and the data layer. A two-tier client/server architecture places the presentation layer on the client and data layer on the server. The business layer may reside on either the client or server, or both. A three-tier client/server architecture places the presentation layer on the client, the business logic layer on a middle tier, and the data layer on a server. Although there are many variation of the client/server model, two-tier and three-tier are the two basic deployments (Edwards, 1999; Weston, 1998).

The three-tier client/server architecture has many advantages over the two-tier client/server architecture, including less complexity, higher security, higher encapsulation of data, better performance efficiency, excellent scalability, excellent application reuse, a good server-to-server infrastructure (via server-side middleware), legacy application integration (via gateways), excellent internal support, support for heterogeneous databases, rich communication choices, excellent hardware architecture flexibility, and excellent availability. The main disadvantage is the difficulties in development, but these difficulties are getting less and less over time (Orfali et al., 1999). One way around this development problem is to adopt a component-based architecture design.

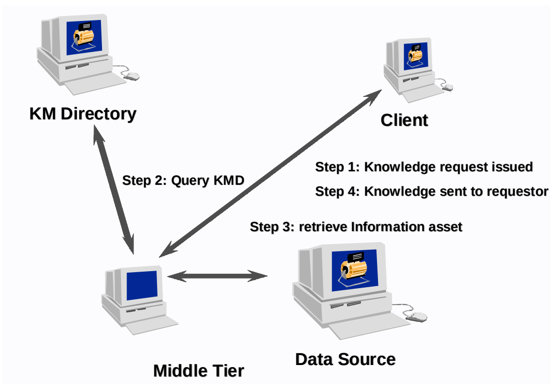
Employing a three-tier client/server architecture would provide a good flexible architecture for KMS. The structure would be very similar to the three-tier client/server architecture detailed by Orfali et al. (1999), except it would also have a knowledge directory (covered in the next section). The client layer would have at least the following: a nice GUI, a Web browser, the client operating system, and any required client-side applications for KM (such as Lotus Notes). The middle layer would contain a network operating system, and transport stack (such as TCP/IP) and service specific middleware for: databases (such as ODBC, JDBC, and SQLJ), internet/intranets (such as HTTP and CGI), e-mail (such as SMTP and POP3), storing and accessing multimedia documents, coordinating group conferencing, linking individuals in group scheduling, and workflow processes. The server layer would contain the server operating system and specific server-based applications such as database management systems, document management systems, server side groupware, and so forth.

KNOWLEDGE MANAGEMENT DIRECTORY

Achieving the connection to numerous data and information sources is a serious challenge for the development of KMS. Organizational knowledge management strives to cultivate, nurture and exploit knowledge at different levels and in different contexts throughout the organization (Handzic & Bewsell, 2001). The demands placed on the

Figure 1. Knowledge management directory process (Galup & Dattero, 2000, 2002)

Step 1: The Client issues an inquiry for knowledge.
Step 2: An inquiry is sent to the Knowledge Management Directory and a summary listing similar to an Internet search is presented to the Client. The KMD presents the Client with an inventory of the KM assets organized by context.
Step 3: When a KM asset is selected, the KMD launches the appropriate software and retrieves the knowledge.
Step 4: The knowledge is sent to the requester.



information technology infrastructure to support an integrated approach to identifying, capturing, retrieving, sharing, and evaluating an enterprise's information assets is a major undertaking; especially since these information assets may include databases, documents, policies and procedures stored in electronic forms.

One of the major requirements of KM is the ability to locate the knowledge and present it to the knowledge requester. The need for a directory of information assets is imperative. A facility, such as the Knowledge Management Directory (KMD), supports the central task of organizational knowledge management and knowledge mapping (Galup, Dattero, & Hicks, 2003). Knowledge mapping provides a continuously evolving organization memory by capturing and integrating knowledge sources and communicating knowledge in an understandable way (Wexler, 2001).

A knowledge directory (some sort of list or picture) points to knowledge (in people, documents, or databases) but does not contain it. The KMD resolves the client request to connect to an information asset by translating the keyword into a data source location, thereby permitting the customer to navigate the numerous information asset resources and locate the best match.

The KMD categorizes the context of the knowledge and provides the computational tools to provide the user with access to the requested knowledge. To use the KMD, a user selects a topic from the user interface screen. When the topic is selected, a list of all resources of each type (expert/practice, decision support systems/warehouse, database, expert, and document) is displayed. The user then selects and evaluates sources until the knowledge is acquired. When multiple knowledge sources exist for a topic, the user will have to choose which knowledge source is most accurate and best suited to his or her needs. The knowledge seeker should be influenced to select the most complete and accurate knowledge available. In the KMD design, this is accomplished by ordering the knowledge sources by their inherent verification characteristics. The most accurate sources are placed at the top of the display, implying their desirability to the user. Expert systems and best practices represent complete, accurate solutions to specific problems, so they are the most desirable knowledge source and are ordered first. Data warehouses and decision support systems applications are the next highest in accuracy, followed by experts and documents (Hicks, Dattero & Galup, 2002, 2003).

CONCLUSION

Our three-tier client/server architecture for KMS has traits of the network model for KMS (Alavi & Leidner, 1999; Bowman, 2002). A network KMS "… focuses on building knowledge directories. This involves defining the knowledge categories that are relevant to the organization, identifying knowledge owners for each category, and creating a searchable directory to help others in the organization identify and locate knowledge owners" (Bowman, 2002). Our three-tier client/server architecture for KMS also has traits of the repository model for KMS (Alavi & Leidner, 1999; Bowman, 2002), because our KMS architecture retrieves explicit organizational knowledge. Therefore, our three-tier client/server architecture for KMS has the traits of the two major models for KMS. Further, it provides a seamless integration of the variety of technologies required for a KMS such as database management, document management, groupware, and e-mail.

KEY TERMS

Client/Server: Client/server technologies distributed these layers across hardware and operating systems platforms.

Knowledge: Knowledge is an intellectual property that although paid for in part by the employer is a difficult asset to control as it is fragmented in documents, policies, procedures, and other data storage mediums. Another challenge for management is to retain this knowledge in a form that is easily retrievable. This is not an easy task, since the enterprise must first identify the location of all needed knowledge, and second, determine the easiest way to retrieve it.

Knowledge Management: Knowledge management promotes an integrated approach to identifying, capturing, retrieving, sharing, and evaluating an enterprise's information assets. These information assets may include databases, documents, policies and procedures, as well as the un-captured tacit expertise and experience stored in individual workers' heads.

Knowledge Management Directory: A knowledge directory points to knowledge (in people, documents, or databases) but does not contain it.

Knowledge Management System: An integrated and integrative technology architecture consisting of a variety of technologies: database and database management, communication and messaging, and browsing and retrieval, that seamlessly integrates knowledge sources in an organization.

Three-Tier Client/Server: Three-tier splits the logic between 1) clients that run the graphical user interface (GUI) logic, 2) the application server running the business logic, and 3) the database and/or legacy application.

Two-Tier Client/Server: Two-tier splits the processing loading in two. The majority of the applications run on the client (often referred to as "fat client"), which typically sends SQL requests to a server-resident database.

Cluster Analysis Using Rough Clustering and k-Means Clustering

C

Kevin E. Voges
University of Canterbury, New Zealand

INTRODUCTION

Cluster analysis is a fundamental data reduction technique used in the physical and social sciences. The technique is of interest to managers in information science because of its potential use in identifying user needs though segmenting users such as Web site visitors. In addition, the theory of rough sets is the subject of intense interest in computational intelligence research. The extension of this theory into rough clustering provides an important and potentially useful addition to the range of cluster analysis techniques available to the manager.

Cluster analysis is defined as the grouping of "individuals or objects into clusters so that objects in the same cluster are more similar to one another than they are to objects in other clusters" (Hair, Anderson, Tatham & Black, 1998, p. 470). There are a number of comprehensive introductions to cluster analysis (Arabie, Hubert & De Soete, 1994; Cramer, 2003; Everitt, Landau & Leese, 2001). Techniques are often classified as hierarchical or nonhierarchical (Hair et al., 1998), and the most commonly used nonhierarchical technique is the *k*-means approach developed by MacQueen (1967). Recently, techniques based on developments in computational intelligence have also been used as clustering algorithms. For example, the theory of fuzzy sets developed by Zadeh (1965), which introduced the concept of partial set membership, has been applied to clustering (Dumitrescu, Lazzerini & Jain, 2000). Another technique receiving considerable attention is the theory of rough sets (Pawlak, 1982), which has led to clustering algorithms referred to as rough clustering (do Prado, Engel & Filho, 2002; Voges, Pope & Brown, 2002).

This article provides brief introductions to *k*-means cluster analysis, rough sets theory, and rough clustering, and compares *k*-means clustering and rough clustering. The article shows that rough clustering provides a more flexible solution to the clustering problem, and can be conceptualized as extracting *concepts* from the data, rather than strictly delineated subgroupings (Pawlak, 1991). Traditional clustering methods generate *extensional* descriptions of groups (i.e., which objects are members of each cluster), whereas clustering techniques based on rough sets theory generate *intensional* descriptions (i.e., what are the main characteristics of each cluster) (do Prado et al., 2002). These different goals suggest that both *k*-means clustering and rough clustering have their place in the data analyst's and the information manager's toolbox.

BACKGROUND

k-Means Cluster Analysis

In the *k*-means approach, the number of clusters (*k*) in each partition of the data set is decided *prior to* the analysis, and data points are randomly selected as the initial estimates of the cluster centres (referred to as centroids). The remaining data points are assigned to the closest centroid on the basis of the distance between them, usually using a Euclidean distance measure. The aim is to obtain maximal homogeneity within clusters (i.e., members of the same cluster are most similar to each other), and maximal heterogeneity between clusters (i.e., members of different clusters are most dissimilar to each other).

K-means cluster analysis has been shown to be quite robust (Punj & Stewart, 1983). Despite this, the approach suffers from many of the problems associated with all traditional multivariate statistical analysis methods. These methods were developed for use with variables that are normally distributed and that have an equal variance-covariance matrix in all groups. In most realistic data sets, neither of these conditions necessarily holds.

Rough Sets

The concept of rough sets (also known as approximation sets) was introduced by Pawlak (1982, 1991), and is based on the assumption that with every record in the information system (the data matrix in traditional data analysis terms), there is associated a certain amount of information. This information is expressed by means of attributes (variables in traditional data analysis terms), used as descriptions of the objects. For example, objects could be individual users in a study of user needs, and attributes could be characteristics of the users such as gender, level of experience, age, or other characteristics considered relevant. See Pawlak (1991) or Munakata (1998) for comprehensive introductions.

In rough set theory, the data matrix is represented as a table, the information system. The complete information system expresses all the knowledge available about the objects being studied. More formally, the information system is a pair, $S = (U, A)$, where U is a non-empty finite set of objects called the universe and $A = \{a1, \ldots, aj\}$ is a non-empty finite set of attributes describing the objects in U. With every attribute $a \in A$ we associate a set Va such that $a : U \rightarrow Va$. The set Va is called the domain or value set of a. In traditional data analysis terms, these are the values that each variable can take (e.g., gender can be male or female; users can have varying levels of experience).

A core concept of rough sets is that of indiscernibility. Two objects in the information system about which we have the same knowledge are indiscernible. Let $S = (U, A)$ be an information system; then with any subset of attributes B, ($B \subseteq A$), there is associated an equivalence relation, $IND_A(B)$, called the B-indiscernibility relation. It is defined as:

$$IND_A(B) = \{ (x, x') \in U^2 \mid \forall\ a \in B\ \ a(x) = a(x') \}$$

In other words, for any two objects (x and x') being considered from the complete data set, if any attribute a, from the subset of attributes B, is the same for both objects, they are indiscernible (on that attribute). If $(x, x') \in IND_A(B)$, then the objects x and x' are indiscernible from each other when considering the subset B of attributes.

Equivalence relations lead to the universe being divided into partitions, which can then be used to build new subsets of the universe. Two of these subsets of particular use in rough sets theory are the lower approximation and the upper approximation. Let $S = (U, A)$ be an information system, and let $B \subseteq A$ and $X \subseteq U$. We can describe the set X using only the information contained in the attribute values from B by constructing the B-lower and B-upper approximations of X, denoted $B_*(X)$ and $B^*(X)$ respectively, where:

$$B_*(X) = \{ x \mid [x]_B \subseteq X \},\ \text{and } B^*(X) = \{ x \mid [x]_B \cap X \neq \emptyset \}$$

The set $BN_B(X)$ is referred to as the boundary region of X, and is defined as the difference between the upper approximation and the lower approximation. That is:

$$BN_B(X) = B^*(X) - B_*(X)$$

If the boundary region of X is the empty set, then X is a crisp (exact) set with respect to B. If the boundary region is not empty, X is referred to as a rough (inexact) set with respect to B. The important insight of Pawlak's work is his definition of a set in terms of these two sets, the lower approximation and the upper approximation. This extends the standard definition of a set in a fundamentally important way.

Rough Clustering

Rough clusters are a simple extension of the notion of rough sets. The value set (Va) is ordered, which allows a measure of the distance between each object to be defined, and clusters of objects are then formed on the basis of their distance from each other. An object can belong to more than one cluster. Clusters can then be defined by a lower approximation (objects exclusive to that cluster) and an upper approximation (all objects in the cluster which are also members of other clusters), in a similar manner to rough sets.

Let $S = (U, A)$ be an information system, where U is a non-empty finite set of M objects $(1 \leq i \leq M)$, and A is a non-empty finite set of N attributes $(1 \leq j \leq N)$ on U. The j^{th} attribute of the i^{th} object has value $R(i, j)$ drawn from the ordered value set Va .

For any pair of objects, p and q, the distance between the objects is defined as:

$$D(p,q) = \sum_{j=1}^{N} | R(p,j) - R(q,j) |$$

That is, the absolute differences between the values for each object pair's attributes are summed. The distance measure ranges from 0 (indicating indiscernible objects) to a maximum determined by the number of attributes and the size of the value set for each attribute.

One algorithm for producing rough clusters is as follows (Voges et al., 2002). Initially, a distance matrix for all paired object comparisons is calculated. All object pairs at interobject distance D, where D steps from 0 to a determined maximum, are identified. Each object pair (a_i, a_j) can be in one of three situations in relation to current cluster membership, with the following consequences:

1. Both objects have not been assigned to any prior cluster. A new cluster is started with a_i and a_j as the first members.
2. Both objects are currently assigned to clusters. Object a_i is assigned to object a_j's earliest cluster, and object a_j is assigned to object a_i's earliest cluster. The earliest cluster is the first cluster the object was assigned to.
3. One object, a_i, is assigned to a cluster and the other object, a_j, is not assigned a cluster. Object a_j is assigned to object a_i's earliest cluster.

Voges and Pope (2004) have developed a new technique for generating rough cluster descriptions using an evolutionary algorithm.

FUTURE TRENDS

The theory of rough sets continues to generate numerous edited books and conferences extending Pawlak's original insight into new areas of application and theory (e.g., Lin & Cercone, 1997; Polkowski & Skowron, 1998; Polkowski, Tsumoto & Lin, 2000; Wang, Liu, Yao & Skowron, 2003; Zhong, Skowron & Ohsuga, 1999).

CONCLUSION

In rough clustering an object can belong to more than one cluster and therefore necessarily produces different solutions to *k*-means clustering, where an object can belong to only one cluster. This section briefly outlines a comparison between rough clustering and *k*-means clustering. A more detailed comparison can be found in Voges et al. (2002).

In business, one of the most common applications of cluster analysis is the segmentation of a market by identifying homogeneous groups of buyers (Punj & Stewart, 1983; Wedel & Kamakura, 2000). Segmentation can also be applied to groups of users to assist in identifying user needs. In a market segmentation study that compared *k*-means and rough clustering analyses of shopping orientations of Internet shoppers, Voges et al. (2002) found that the two clustering techniques resulted in some clusters that were identified by both techniques, and some clusters that were unique to the particular technique used. The rough clustering technique also found clusters that were "refined" sub-clusters of those found by *k*-means clustering, and which identified a more specific sub-segment of the market.

Rough clustering produces more clusters than *k*-means clustering (Voges et al., 2002), with the number of clusters required to describe the data dependent on the interobject distance (D). It was found that the lower approximation of each cluster was dependent on the number of clusters selected for the solution. More clusters means an object has a higher chance of being in more than one cluster, which moves the object from the lower approximation to the boundary region and reduces the size of the lower approximation. This suggested that a number of factors needed to be considered when determining the best maximum value for D and the best number of clusters to include in the solution. A solution with too few clusters does not provide a useful interpretation of the partitioning of the data. On the other hand, too many clusters make interpretation difficult. In addition, the degree of overlap between the clusters needs to be minimised to ensure that each cluster provided information to aid in interpretation. Determining a good rough cluster solution requires a trade-off between these factors.

KEY TERMS

Approximation Set: An alternative (and more technically correct) name for a rough set, which is defined by two sets, the lower approximation and the upper approximation.

Boundary Region: Those objects that may or may not be in the approximation set. It is the difference between the upper approximation and the lower approximation. If the boundary region is empty, the set is said to be crisp. If the boundary region is not empty, the set is rough.

Cluster Analysis: A data analysis technique involving the grouping of objects into sub-groups or clusters so that objects in the same cluster are more similar to one another than they are to objects in other clusters.

k-Means Clustering: A cluster analysis technique in which clusters are formed by randomly selecting k data points as initial seeds or centroids, and the remaining data points are assigned to the closest cluster on the basis of the distance between the data point and the cluster centroid.

Lower Approximation: In rough sets theory, one of the two sets used to define a rough, or approximate set. The lower approximation contains objects that are definitely in the approximation set.

Market Segmentation: Market segmentation is a central concept in marketing theory and practice, and involves identifying homogeneous sub-groups of buyers within a heterogeneous market. It is most commonly conducted using cluster analysis of the measured demographic or psychographic characteristics of consumers. Forming groups that are homogenous with respect to these measured characteristics segments the market.

Rough Classification: Rough classification finds mappings from the partitions induced by the equivalence relations in the condition attributes to the partitions induced by the equivalence relations in the decision attribute(s). These mappings are usually expressed in terms of decision rules. It performs the same type of classification function as discriminant analysis or logistic regression, where there is a known sub-grouping in the data set, which is identified by the decision attribute.

Rough Clustering: Rough clustering is a simple extension of rough sets theory, and is analogous to traditional cluster analysis. The information table has no pre-existing subgroups, and clusters of objects are formed based on a distance measure. Clusters are defined by a lower approximation (objects exclusive to that cluster) and an upper approximation (all objects in the cluster which are also members of other clusters), in a similar manner to rough sets. An object can belong to more than one cluster.

Rough Set: The concept of rough, or approximation, sets was introduced by Pawlak, and is based on the single assumption that information is associated with every object in an information system. This information is expressed through attributes that describe the objects, and objects that cannot be distinguished on the basis of a selected attribute are referred to as indiscernible. A rough set is defined by two sets, the lower approximation and the upper approximation.

Upper Approximation: In rough sets theory, one of the two sets used to define a rough, or approximate set. The upper approximation contains objects that may or may not be in the approximation set. It can be formally defined as the union of the lower approximation and the boundary region. It is the complement of the set of objects definitely not in the set.

Cognitive Research in Information Systems

INTRODUCTION

The existence and significance of cognition in organizations and its influence on patterns of behaviour in organizations and organizational outcomes are increasingly accepted in information systems (IS) research (Barley, 1986; DeSanctis & Poole, 1994; Griffith, 1999; Griffith & Northcraft, 1996; Orlikowski, 1992, 1994 #208). However, assessing the commonality and individuality in cognition and eliciting the subjective understanding of research participants either as individuals or as groups of individuals remain a challenge to IS researchers (Orlikowski & Gash, 1994). Various methods for studying cognition in organizations have been offered - for example, clinical interviewing (Schein, 1987), focus groups (Krueger, 1988), discourse-based interviewing (Odell, Goswami & Herrington, 1983). This article proposes that cognition applied to making sense of IT in organizations can also be explored using Kelly's (1955) Personal Construct Theory and its methodological extension, the Repertory Grid (RepGrid). The RepGrid can be used in IS research for uncovering the constructs research participants use to structure and interpret events relating to the development, implementation, use and management of IS in organizations.

In the context of this article, cognition is considered to be synonymous with subjective understanding: "the everyday common sense and everyday meanings with which the observed human subjects see themselves and which gives rise to the behaviour that they manifest in socially constructed settings" (Lee, 1991, p. 351). Research into cognition in organizations investigates the subjective understanding of individual members within the organization and the similarities and differences in the understandings among groups of individuals (Jelinek & Litterer, 1994; Porac & Thomas, 1989). In IS research, it is the personal constructs managers, users and IS professionals use to interpret and make sense of information technology (IT) and its role in organizations. The discussion here outlines the myriad of ways the RepGrid can be employed to address specific research objectives relating to subjective understanding and cognition in organizations. It illustrates, from a variety of published studies in IS (see Table 1), the flexibility of the RepGrid to support both qualitative and/or quantitative analyses of the subjective understandings of research participants.

BACKGROUND

We propose to use a framework to facilitate this discussion (see Figure 1) that presents a two-dimensional view of the types of research using the repertory grid. The examples in Table 1 are mapped along these two dimensions.

Figure 1. Distinguishing research using the repertory grid

Theory-Focused	Hunter (1997) *	Latta and Swigger (1992) †
Method-focused	Moynihan (1996) *	Phythian and King (1992) †

* Idiographic (i.e. individual interpretations – unique grids)
† Nomothetic (i.e. group interpretations – common grids)

Theory-Focused vs. Method-Focused

On one dimension, we distinguish research that applies Kelly's (1955) personal construct theory (theory-focused) from those applying the repertory grid method, without delving into the conceptual underpinnings of the theory (method-focused). When introduced some 45 years ago, the repertory grid technique served as the methodological extension of the personal construct theory. It operationalizes key aspects of Kelly's fundamental postulate and corollaries. IS researchers interested in the subjective understandings of individuals will find the repertory grid a powerful tool that permits the study of the individual's construct system and provides richer cognitive insights into research findings. For example, Latta and Swigger (1992) validated the use of the repertory grid for representing commonality of construing among participants regarding the design of intelligent user interfaces. The study lent strong support to the commonality corollary in grids, which can be confidently used to represent a consensus of knowledge around a problem domain. Hunter (1997) used the laddering technique to elicit what Kelly termed as super-ordinate constructs – constructs that are core to the individual's system of interpretation.

In contrast, there is research that has accepted Kelly's theory and employed the repertory grid solely as a data gathering technique. These works have employed the utility of the technique purely for its methodological strengths. Stewart and Stewart (1981) suggest, "At its simplest, Grids provide a way of doing research into problems – any problems – in a more precise, less biased way than any other research method" (pp. vii). These authors further contend that the repertory grid "….enables one to interview someone in detail, extracting a good deal of information … and to do this in such a way that the input from the observer is reduced to zero" (p. 5). Two of the examples in Table 1 have taken the method-focused approach to the use of the repertory grid technique. For instance, Moynihan (1996) was purely interested in using the repertory grid technique to collect data and to compare the results with the extant literature. Moynihan argued that the free-ranging responses resulting from the non-prohibitive nature of the technique permitted the participants to apply the "theories-of-action" (theories individuals use to guide their actions) they employ daily – resulting in the identification of themes and issues over and above the extant literature. In the studies by Phythian and King (1992), the repertory grid was used to explore the similarity and differences in the views between individual managers. No direct references were made to Kelly's personal construct theory, as the focus was to identify key factors influencing tender decisions and the relationships among these factors by interviewing two managers closely involved in such tender activities.

Qualitative vs. Quantitative

On the second dimension, we distinguish research that is either qualitative or quantitative. The identification of emerging themes from elicited constructs is common in a qualitative approach using the repertory grid. For example, Hunter (1997), when investigating how certain groups of individuals interpreted the qualities of "excellent" systems analysts, employed content analysis of the data gathered from individual interviews conducted using the repertory grid technique. The numeric component of the grid was only employed to conduct visual focusing at the end of each interview as a means of quickly assessing what had transpired during the interview and whether the research participant agreed with this initial assessment. Similarly, Moynihan (1996) employed the repertory grid technique as a method to elicit interpretations from research participants of what aspects were considered important when deciding upon an approach to adopt for projects to be conducted for external clients. Unique grids were developed for each research participant. Then the data were analyzed from a qualitative perspective via content analysis at the construct level, where emerging themes were identified and categorized. In these examples, the researchers took an open view toward gathering data and allowed themes or categories to emerge from the data as the investigation proceeded.

In contrast, the quantitative approach utilizes mathematical and/or statistical analyses of grid data (Daniels, Markoczy & de Chernatony, 1994). These techniques are commonly used to explore the structure and content of an individual's construct systems or make comparisons between groups of individuals (Ginsberg, 1989). This approach was adopted by two of the examples in Table 1. For instance, in Phythian and King (1992), statistical analyses (specifically, cluster analysis and correlation analysis) were conducted on individual and combined grids. These data were used to support the development of an expert support system. Similarly, Latta and Swigger (1992) applied cluster analysis and Spearman's rank order correlation to analyze the grids. The study revealed an overall correlation between the students' and the instructor's grids, promoting the utility of the repertory grid technique in modeling knowledge relating to the design of information systems.

Idiographic vs. Nomothetic

Within both the qualitative and quantitative perspectives, research using the repertory grid technique is either

Table 1. Examples of IS research using the RepGrid

	Hunter (1997)	Moynihan (1996)	Phythian and King (1992)	Latta and Swigger (1992)
Research Objectives	Explore the qualities of "excellent" systems analysts	Identify the situational factors considered in the planning/running of new systems development projects	Develop rules for an expert system to support customer tender evaluations	Validate the RepGrid in modeling communal knowledge regarding design of system interfaces
Research Perspective	Qualitative	Qualitative	Quantitative	Quantitative
Nature of RepGrid	Idiographic	Idiographic	Nomothetic	Nomothetic
Key Findings	Several themes considered as qualities of "excellent" systems analysts	Identified themes over and above literature. Differences in project managers' construction of project contexts	Identified key factors and rules influencing tender decisions. Expert system improved consistency	Commonality of constructions support the use of the RepGrid to model group knowledge
Research Design:				
Element Selection	Systems analysts with whom participant has interacted	Systems development projects on which participant has worked	Previous customer tender enquiries	Components of online bibliographic retrieval systems
	Elicited	Elicited	Supplied	Supplied
Construct Elicitation	Qualities of "excellent" systems analysts	Situational factors influencing risks in new systems projects	Key factors and rules influencing tender decisions	Attributes of system interface design
	Minimum context form (triadic sort) and laddering	Minimum context form (triadic sort)	Minimum context form (triadic sort) and laddering	Minimum context form (triadic sort) and supplied constructs
Linking	Rating	None	Rating (Grid) Ranking (Elements)	Rating
RepGrid Analysis	Content analysis Visual focusing COPE and VISA	Content analysis	Cluster analysis (FOCUS), correlation, mathematical modeling	Cluster analysis, correlation
Sample and Size	53 (users and IT professionals) from two insurance companies	14 systems development project managers	Two manager-experts involved in assessing tender enquiries	Instructor and students who completed an "information search and retrieval" course

idiographic or nomothetic in nature. The idiographic approach focuses on the subjective experiences of the individual and presents results in expressions and terms used by the individual. The resulting grid is considered unique in that there are no common elements or constructs employed in the elicitation process. For example, in the study of systems analysts, each participant was asked to name up to six systems analysts with whom s/he had interacted. In this project, Hunter (1997) provided a role description (i.e., system analysts interacted with) and asked each participant to specify examples that fit this category. The analysts named were not common among participants and as such the resulting grids were not common in terms of the elements used. Similarly, Moynihan (1988) asked each participating project manager to make a list of systems development projects s/he had worked on as a project manager. If the project manager named more than nine projects, s/he was then asked to choose the three that were most successful, the three that were the least successful, and three in between. Moynihan's research objective was to identify the situational factors project managers regard as important when planning new development projects and not to compare the subjective understandings of different project managers. As such, he did not supply a common set of systems development projects that would have permitted a comparative analysis of individual grids.

In contrast, research comparing the grids of individuals or groups of individuals requires different decisions to be made concerning the elements and constructs in the repertory grid process. This nomothetic approach necessitates the use of a common set of elements and/or constructs to permit comparisons to be made between grids (Easterby-Smith, 1980). Such research also tends to be quantitative in nature. For example, research to identify the similarities and differences in two managers' views on tender enquiry evaluations imposed a common set of tender enquiries as elements in the repertory grid process (Phythian & King, 1992). This permitted the comparison of the construct systems of the two managers based on their personal experiences of similar events. In another example, a set of constructs was elicited from an instructor and then supplied as common constructs for a group of students to evaluate against a prescribed set of elements representing the features of online bibliographic retrieval systems (Latta & Swigger, 1992). This permitted the commonality of construing among students and between students and the instructor to be tested. In these examples, the reason for the use of common components in the repertory grid process was to compare grids.

Finally, none of the examples discussed in this section approached their studies using both qualitative and quantitative approaches. This does not imply that the repertory grid cannot lend itself to both qualitative and quantitative analysis of the collected data.

CONCLUSION

This article has demonstrated the flexibility of the repertory grid technique to support both qualitative and/or quantitative approaches to investigating the subjective understanding of human subjects in complex and socially dynamic organizations. With this technique, both qualitative and quantitative approaches need not be mutually exclusive. For instance, Hunter (1997) approached his study of systems analysts from a grounded theory perspective. The data collected using the repertory grid were analysed to identify themes or qualities of "excellent" systems analysts. In an extension of this investigation, the characteristics of excellent systems analysts were statistically tested to highlight the similarities and differences in the subjective understandings of Canadian and Singaporean research participants (Hunter & Beck, 1996).

We would like to conclude by reiterating two important points. The first is a word of caution. The repertory grid should not be considered a panacea to investigating the subjective understanding of individuals in an organizational setting. It can be used in conjunction with other methods – as a means of validating other techniques or as a preliminary phase to further interpretive or positivist investigations. The second is that the personal construct theory is one of several theories in cognitive science (Berkowitz, 1978). The repertory grid is one of several cognitive mapping methods available to the IS researcher (Huff, 1990). This article was written in an attempt to stimulate interest in the IS research community of the need for more cognitive emphasis in our field. Hopefully, IS researchers will be encouraged to further reflect on the virtues of applied theories and methods that can deliver utilizable and consumable outcomes to research and practice in IS.

KEY TERMS

Cognition: Cognition is considered to be synonymous with subjective understanding, "the everyday common sense and everyday meanings with which the observed human subjects see themselves and which gives rise to the behaviour that they manifest in socially constructed settings" (Lee, 1991, p. 351).

Construct: Constructs represent the research participant's interpretations of the elements. Further understanding of these interpretations may be gained by eliciting contrasts resulting in bi-polar labels. Using the same example, research participants may come up with bi-polar constructs such as "high user involvement – low user involvement" to differentiate the elements (i.e., IS projects). The labels represent the CSFs of IS projects.

Elements: Elements are the objects of attention within the domain of investigation. They define the entities upon which the administration of the RepGrid is based.

For example, to explore the critical success factors (CSFs) of IS projects, IS researchers can use IS projects as elements in the RepGrid.

Idiographic: The idiographic approach focuses on the subjective experiences of the individual and presents results in expressions and terms used by the individual. The resulting RepGrid is considered unique in that there are no common elements or constructs employed in the elicitation process across the sample.

Links: Links are ways of relating the elements and constructs. The links show how the research participants interpret each element relative to each construct. Further, the links reveal the research participant's interpretations of the similarities and differences between the elements and constructs.

Nomothetic: The nomothetic approach permits the comparison of RepGrids of individuals or groups of individuals. It necessitates the use of a common set of elements and/or constructs to permit comparisons to be made between RepGrids.

Repertory Grid (RepGrid): The RepGrid is a cognitive mapping technique that can be used to describe how people think about a phenomenon in their world. The RepGrid technique, for IS, entails a set of procedures for uncovering the personal constructs individuals use to structure and interpret events relating to the development, implementation, use, and management of IT in organizations. The RepGrid contains three components – elements, constructs and links.

Collaborative Learning On–Demand

Giancarlo Fortino
DEIS - Università della Calabria, Italy

INTRODUCTION

Advances in communications and software technology are leading the Internet to become an open and distributed computing platform able to provide diversified services which can be ubiquitously accessed by many users.

Electronic learning-oriented services are well suited to be supported by and delivered through the Internet. They are strategic for enabling virtual universities, enhancing the skills of the employees of a company, and facilitating auto-training.

Nowadays, a multitude of networked e-learning systems and applications, which can be usefully employed to support distance learning, have been developed. They are basically based either on asynchronous learning models or on synchronous learning models (see Table 1). Specifically, "virtual or real" collaborative learning environments are particularly interesting in the education research area since they are aimed at creating computer-based and multimedia-oriented learning processes where learners, that belong to a collaborative and interactive group, cooperatively construct knowledge (Costantini & Toinard, 2001).

In fact, it has been proved that instructional methods promoting interpersonal discourse and social construction of knowledge (i.e., collaborative learning techniques) are more effective than methods which simply rely on the broadcast of information (classroom transmission metaphor) or on the asynchronous, self-paced access to online training materials (Cohen, 1994).

In this article, an overview of the *Collaborative Learning On-Demand (CLOD)* paradigm along with its supporting technology (Fortino & Nigro, 2003) is presented.

In particular, the VICRO^{C} system, which fully supports the CLOD paradigm, is described. Finally, the usability evaluation of VICRO^{C} is shown. The carried out experimentations confirmed that the CLOD paradigm has the potential to improve the learner's productivity.

BACKGROUND

Collaborative Learning on-Demand (CLOD) is a virtual collaborative learning paradigm which enables a self-tutored, interactive and cooperative learning process where a small group of remote students requests, watches and controls the playback of an archived lecture by exchanging questions with each other (Fortino & Nigro, 2003).

CLOD borrows some of the ideas of:

- *Tutored Video Instruction* (TVI), which is a face-to-face collaborative learning methodology in which a small group of students driven by a tutor goes over a videotape of a lecture;
- *Distributed Tutored Video Instruction* (DTVI), which is a fully virtual version of TVI, in which each student has a networked computer equipped with audio (microphone and headset) and video (camera) facilities to communicate within a group.

Table 1. Asynchronous vs. synchronous distance learning

	Synchronous	Asynchronous
Model	The teacher and the student interact with each other in "real time".	The teacher may deliver the instruction via video, computer, or other means, and the students respond at a later time.
Technology	VideoConferencing, AudioConferencing, Internet Chat, Desktop Videoconferencing, Whiteboard	Video Tape, Broadcast Video, E-mail, CD-ROM, WWW-based courses
Example	Using a two-way video conferencing tool, students interact with "live" video of an instructor.	Instruction may be delivered via the Web or videotapes, and the feedback could be sent via e-mail messages.

Table 2. A comparison between CLOD and DTVI

FEATURE	CLOD	DTVI
LEARNING TYPE	SELF-TUTORED	TUTORED
GROUP SIZE	SMALL/MEDIUM (<=20)	SMALL (<=5)
CONTROL OF THE VCR	SHARED AMONG STUDENTS	APPLIED BY THE TUTOR
SUPPORTING TECHNOLOGY	COOPERATIVE PLAYBACK SYSTEMS	CONFERENCING SYSTEMS

TVI and DTVI have proven real effectiveness in that the students involved in their experimentation have been shown to outperform students who physically attended the lectures (Sipusic, Pannoni, Smith, Dutra, Gibbons, & Sutherland, 1999).

The substantial difference between CLOD and DTVI (see Table 2) is that CLOD methodology does not assume the presence of a tutor which guides students to construct knowledge. This fact has a direct impact on the technical implementation of CLOD because, while in DTVI only the tutor has control of the videoconference recorder (VCR), in CLOD each participant to the playback session uses a shared VCR remote controller. In addition, being the learning service on-demand, CLOD needs to be supported by a video on-demand system (VoD).

The CLOD paradigm is supported by the Cooperative Playback Systems (CPS; Fortino & Nigro, 2000) which are media on-demand systems providing cooperative playback sessions. In a cooperative playback session, the participants, who are explicitly grouped, share the vision and the control of a multimedia session streamed by a media server, and interact with each other by means of a question board.

The construction of CPS is efficiently enabled by the IP multicast technology which concurs to save network resources (e.g., bandwidth) and improve scalability (Kumar, 1996). IP multicast allows for the transmission of a packet to a group of hosts which are identified by a multicast address belonging to the class D of IP addresses. The worldwide testbed of IP-multicast is MBone (Multicast Backbone; Kumar, 1996) which, to date, cannot be accessed by all the users of Internet. However, private IP multicast-enabled networks (campus networks or intranets) can be easily set-up. IP multicast has promoted the proliferation of a rich set of multimedia applications, systems and protocols able to support synchronous distance learning over the Internet according to the real/virtual classroom metaphor (Costantini & Toinard, 2001; Crowcroft, Handley, & Wakeman, 1999; Kumar, 1996).

In particular, a CPS can be developed by integrating two enabling MBone-based technologies:

- *VideoConference Recording on-Demand (VCRoD) systems*. They are VoD-like systems which allow a user to connect to a Media Server (MS) and request two kinds of services: recording and playback (Fortino & Nigro, 2003; Holfelder, 1997; MLB, 2001; Parnes, Synnes & Schefstrom, 2000; Shuett, Raman, Chawathe, McCanne & Katz, 1998). Upon requesting a recording service, users can either select a media session being transmitted over an IP-multicast address or send their own media session directly to the MS. This way, the MS archives the media session in a multimedia repository. On the other hand, the playback service allows users to browse the list of the archived media sessions, select a particular media session and control its playback by means of a VCR remote controller. In Table 3, the description of three main VCRoD systems is given.
- *MBone tools*. They are multimedia applications enabling a group of users to interactively and synchronously exchange audio/video "live" streams, text-based messages, and to cooperatively share whiteboards and document editors (MASH Consortium, 2003; MBT, 2003; Parnes, Synnes & Schefstrom, 2000).

To date, a few trials have been devoted to building CPS. The most significant contributions in this direction are the VICRO^C system (Fortino & Nigro, 2003), and the MASH Rover system (MASH Consortium, 2003; Shuett, Raman, Chawathe, McCanne & Katz, 1998).

In particular the VICRO^C system addresses all the features of a CPS whereas the MASH Rover system only provides basic services.

VICRO^C: A COOPERATIVE PLAYBACK SYSTEM FOR CLOD

The main functionalities of the VICRO^C system can be summarized as follows.

C

Table 3. VCRoD systems

SYSTEM	DESCRIPTION
MASH Rover	It consists of two components: the media server and the MASH streaming player. The media server is implemented by using the TACC (Transformation, Aggregation, Customization and Control) toolkit. An RTSP-like protocol is used to remotely control media streams. Mechanisms of advertising and discovering new contents are provided such as rich-description hyperlinks to the archived sessions and automatic detection of significant instants during a session. The client part consists of the MASH streaming player that can operate as media browser or as helper application within a Web browser. It allows the user to bookmark specific sessions and specific instants within a session. The bookmark file can be shared among several participants. The client is implemented in C++ and TCL/TK. It was developed at the University of Berkeley (USA).
mMOD	It consists of three separate parts: the VCR, the data translator and the Web-controller. The VCR is a stand-alone program for recording and playing back IP-packets on either UDP or RTP level. The Data-Translator translates the traffic in various ways (recoding, mixing and switching techniques) to allow users with different bandwidth to access the service. The Web-controller is a program that acts as a Web-interface of mMOD. Using this interface, a new session can be started and controlled and information about running sessions can be listed so that a user can join them. mMOD, which is completely written in Java, was developed at the University of Lulea (SVE).
MVoD	It consists of three basic components: the Manager and the VideoPump, that form the logical unit called MVoD Server, and the MVoD Client. The interaction between the system components is regulated by four protocols: the VCR Service Access Protocol (VCRSAP), the VCR Stream Control Protocol (VCRSCP), the VCR Announcement Protocol (VCRAP), and the VCR Client Message Protocol (VCRCMP). The Manager and the Client are implemented in Java. The VideoPump is implemented in C++. The MVoD Client can be started either as a Java applet within a Java-enabled browser, or as a stand-alone Java application. It was developed at the University of Mannheim (GER).

Group organization, which contains group formation and group management. The former enables the creation of a group of users wishing to work on and control the same playback session. The latter deals with the following issues: (i) how to share the starting time of a playback session for the synchronization of the group members; (ii) how to expel from the group a member who interrupts the others using an improper behavior. To join a cooperative playback session, a Media Client (MC) has to contact the Media Server (MS) in order to authenticate itself and receive the session key (or *Secret Share k*). The scheme adopted is based on asymmetric cryptography and a Certificate Authority (CA; Fortino, Russo & Zimeo, 2003).

Media streaming, which allows for the multicast transmission of encrypted media streams based on the Real-time Transport Protocol (RTP; Schulzrinne, Casner, Frederick & Jacobson, 1996) to the cooperative group which is tuned on a Multicast Media Group (MMG). Encryption of media streams is based on an efficient technique centered on the Blowfish symmetric encryption algorithm (Fortino, Russo & Zimeo, 2003).

Control sharing, which enables a group of users to cooperatively control a media streaming session.

Joint-work, which allows the group participants to collaborate with each other by questioning on the contents of the cooperative session.

The architecture of ViCRO^C is depicted in Figure 1, which shows the basic components along with their protocol-based interactions and highlights the security-enhanced blocks.

Media streaming and playback are respectively supported by the streamer and player components which are based on the Java Media Framework (JMF) in which security was integrated, and are respectively located at the Media Server (MS) and Media Client (MC) sites.

Cooperative playback control is enabled by the Multicast Archive Control Protocol (MACπ) which is a multicast version of the Real Time Streaming Protocol (RTSP; Schulzrinne, Rao & Lanphier, 1998).

Collaboration among users is based on the COllaborative Protocol (COπ) which allows for the multicast-based exchange of questions and annotations. Both MACπ and COπ are based on the Lightweight Reliable Multicast Protocol (LRMP; Liao, 1998).

The Multimedia Archive keeps stored MPEG and RTP-based media files.

The exchange of the secret session keys is enabled by the security-based join tool and the session key dispenser which communicate through SDP/SIP messages (Session Description Protocol/Session Initiation Protocol; Crowcroft, Handley & Wakeman, 1999).

EVALUATION OF VICRO^C

The usability of a CPS is mainly influenced by general factors, which are related to the network and to the desktop hardware and software environment, and by specific factors such as media on-demand service availability, easiness to set up a cooperative playback session, and degree of appeal and simplicity-to-use of the graphical user interface.

The usability evaluation of ViCRO^C was carried out by using three different group of users in different scenarios based on a local cluster of PCs (Fortino & Nigro, 2003). Each user group was small (about four to five persons) and formed by (i) professors and researchers, (ii) graduate students and (iii) students.

In order to have useful feedback by a user, a simple questionnaire was required to be filled out at the end of a cooperative playback session.

The questions were about:

- the perceived *media quality* including video and audio quality, and the quality of the lip synchronization;
- the perceived *interactivity* fluidity when playback control is applied and questions are sent to and received from companions;
- the *friendliness* and *look & feel* attractiveness of the GUI;
- the *degree of breakdown* due to:
  (a) the lack of monitor space to layout all the GUIs;
  (b) the frequent pop-ups of the *Answer* dialog, which allows replying to a question, and the *Voting* dialog, which allows voting a control command.

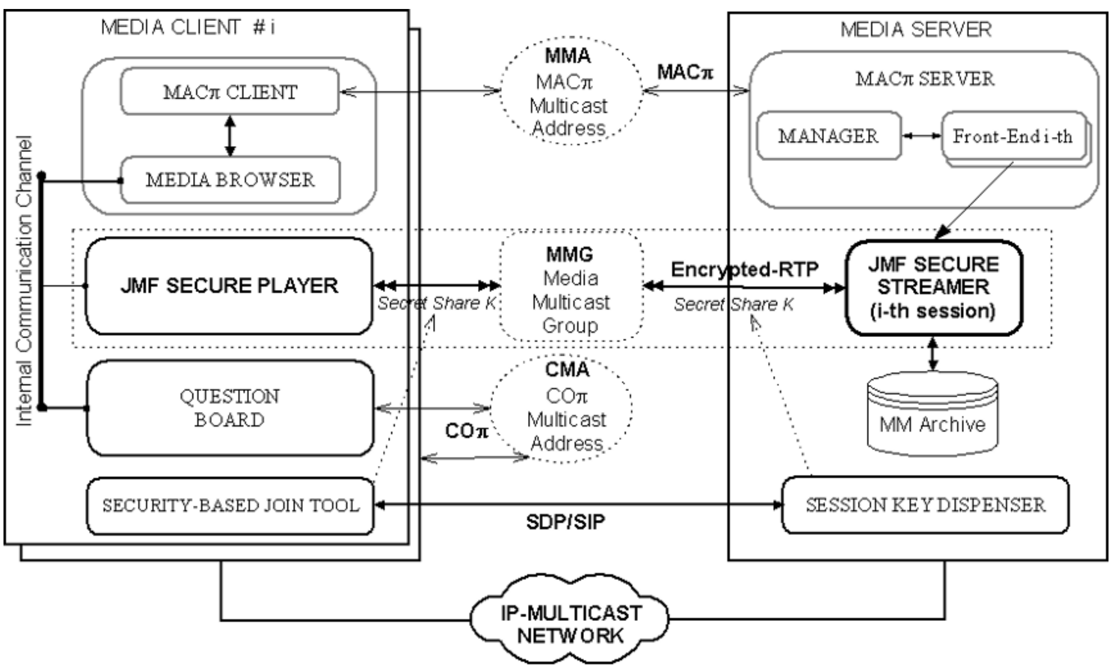
Each question was scored from 1 (lowest) to 5 (highest) points.

The analysis of the results (Table 4) showed that:

- the quality of service of the audio/video streams was considered good by the user;
- the control GUI was considered intuitive and simple to use;
- when the interaction among users increases and the control actions are more frequent, user's attention is taken away from the playback session and focuses on the interaction with the *Answer* and *Voting* dialogs.

The overall evaluation indicated that the CLOD paradigm, featured by the ViCRO^C system, increases the productivity of learners organized in small homogeneous groups.

Figure 1. Architecture of ViCRO^C



C

Table 4. Results of the usability evaluation

Group	Media Quality	Interactivity	Friendliness and Look&Feel	Degree of Breakdown
Professors (mean values)	4.0	3.8	4.2	4.0
Graduate Students (mean values)	3.8	3.6	4.2	4.1
Students (mean values)	3.7	3.4	4.1	4.2

FUTURE TRENDS

The future CPS can greatly benefit from the following advances of the Internet technology: (i) increase of available bandwidth, (ii) "non best effort" guarantees of quality of service and (iii) worldwide exploitation of IP multicast. The first two points can improve usability from a network point of view, whereas the third point can enable geographically distributed cooperative playback sessions. Appealing research opportunities were envisaged as follows: (i) integration of distributed virtual environments with CPS so bringing to life new collaborative distributed virtual environments; (ii) creation of personal and lightweight interfaces to CPS so enabling a client which uses a handheld device (or personal digital assistant) to participate to a cooperative playback session.

CONCLUSION

This article has proposed an overview of the Collaborative Learning On-Demand paradigm and technology. CLOD is an original learning paradigm which enables a group of students to jointly work on and share a playback session. CLOD is fully supported by the Cooperative Playback Systems (CPS); in particular, ViCRO^{C}, a full-fledged CPS developed at University of Calabria which also provides secure cooperative playback sessions, has been described. Usability evaluation of ViCRO^{C} was carried out on the basis of three kinds of tests. Results indicated that media quality is considered good and the GUI easy-to-use. However, under conditions of high transmission frequency of questions and control commands, the attention of the session participants shifts from the view of the playback to coping with frequent pop-ups of the dialog windows. Based on this experience, ViCRO^{C} is being upgraded by using selective filters, which limit undesired questions, and timeouts, which regulate control command transmissions.

KEY TERMS

Certificate Authority: An entity (typically a company) that issues digital certificates to other entities (organizations or individuals) to allow them to prove their identity to others.

CLOD: A virtual collaborative learning paradigm enabling a self-tutored, interactive and cooperative learning process where a small group of remote students requests, watches and controls the playback of an archived lecture by exchanging questions with each other.

Java Media Framework (JMF): A Java library for the development of stand-alone and networked multimedia systems.

MBone: The Virtual Internet Backbone for IP Multicast.

Media Encryption: Any procedure used in cryptography to convert media objects into cipher media objects in order to prevent any but the intended recipient from reading that data.

Multimedia Internetworking: Refers to network infrastructures, protocols, models, applications and techniques which are being currently deployed over the Internet to support multimedia applications such as videoconferencing, VoD, shared workspaces, and so forth.

Usability Evaluation: Can be defined as the act of measuring (or identifying potential issues affecting) usability attributes of a system or device with respect to particular users, performing particular tasks, in particular contexts.

Video On-Demand (VoD): A planned system using compressed video streams to supply programs to viewers when requested, via a network.

VideoConference Recording On-Demand (VCRoD): A VoD system which is also able to dump and archive networked media streams.

Collective Intentional Action in Virtual Communities

Richard P. Bagozzi

Utpal M. Dholakia
Rice University, USA

INTRODUCTION

The Internet is an important innovation in information science and technology and profoundly affects people in their daily lives. To date, these effects have been construed in overly individualistic ways and often all too negatively. For example, the Internet is seen by many as an individual means for obtaining or sending information flexibly and efficiently (e.g., Dreyfus, 2001). Some researchers also claim that participation on the Internet often leads to feelings of isolation and depression and even negatively affects relationships with one's family members and friends (Kraut et al., 1998; cf. Kraut et al., 2002; UCLA Internet Report, 2003). Likewise, Dreyfus (2001) takes a generally pessimistic tone with regard to Internet usage and worries that when we engage the Internet, it "diminishes one's sense of reality and of the meaning in one's life" and "…we might…lose some of our crucial capacities: our ability to make sense of things so as to distinguish the relevant from the irrelevant, our sense of the seriousness of success and failure that is necessary for learning, and our need to get a maximum grip on the world that gives us our sense of the reality of things."

In contrast to individualistic construals of Internet usage, we claim that the Internet often is a medium for group action ("collective intentional action") whereby people function in virtual communities to fulfill not only individual but jointly conceived and mutually beneficial ends (e.g., Bagozzi & Dholakia, 2002). Furthermore, participation on the Internet need not function negatively to harm people and their relationships with others. Instead, participation, particularly in virtual communities, can enhance one's personal well-being and promote positive social values and outcomes.

Our purpose in this article is to consider the emerging ideas and research concerning collective intentional action in virtual communities. We begin with a discussion of collective intentions of virtual community participants, and then study their antecedents and consequences. We conclude with a discussion regarding the importance of studying participants' emotions in enabling collective intentional action in virtual communities. Figure 1 sketches the primary variables and processes under consideration.

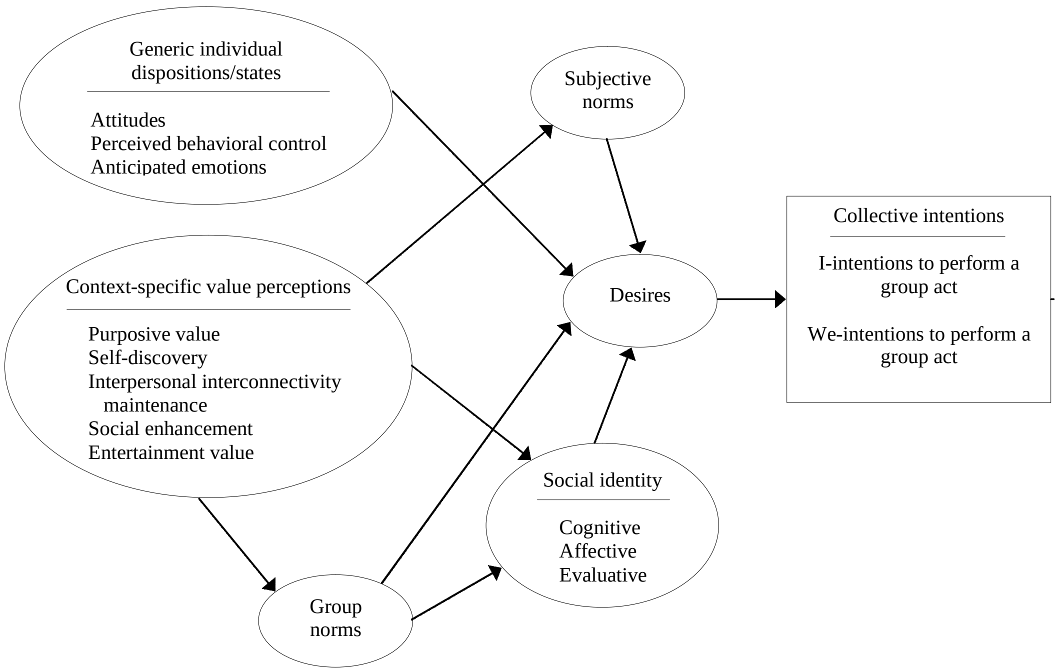
COLLECTIVE INTENTIONS OF VIRTUAL COMMUNITY PARTICIPANTS

Virtual communities are mediated social spaces in the online environment that allow collections of people to form and be sustained through ongoing communication processes. Two kinds of virtual communities are the network-based and small-group-based virtual communities (Dholakia, Bagozzi & Klein Pearo, 2004). The former is a specialized, geographically dispersed virtual community based on a structured, relatively sparse and dynamic pattern of relationships among participants sharing a common focus. Common examples include e-mail lists, Web site bulletin boards, and Usenet newsgroups. Members of network-based virtual communities typically view the community in terms of venue and only superficially identify with particular individuals within the community.

The small-group based virtual community is a handful or so of persons with a dense web of relationships, interacting together online in order to accomplish a wide range of jointly-conceived goals and to maintain the functioning of the group. Common instances of such communities are real-time, online-chat systems, Web-based chat-rooms, multi-player virtual games, and multi-user domains (MUDs). Members of small-group-based virtual communities typically engage often and intensely with the same specific individuals whom they know by name and to a certain extent personally, and they may even on occasion also meet face-to-face in certain communities.

Many behaviors involved in virtual communities, and which form the focus of the present article, are described by their actors through the use of collective concepts, based on a strong sense of "we-ness." Gilbert

Figure 1. Intentional social action and social identity in virtual communities plus key antecedents and consequences



(1992) suggests that "we" can mean the self and one or more others "that share in the action of a verb." Volitionally, we may equate a plural subject with "the concepts of a pool or sum of wills, dedicated, as one, to a certain 'cause'," e.g., promotion of a group goal (Gilbert, 1992). Then, "our wanting X is a reason for me to exercise my will in order to get X" (Gilbert, 1992).

Recently, philosophers have developed elaborate expositions of the logical foundations of collective intentions (Bagozzi, 2000). In abbreviated forms, two formulations of note are Tuomela's (1995) notion of a we-intention ("a commitment of an individual to participate in joint action [that] involves an implicit or explicit agreement between the participants to engage in that joint action" and Bratman's (1999) idea of shared intentions("for you and me to share an intention" means "first, we each recognize the other as a participant whose intentions in favor of the shared activity are partly constitutive of the shared intention. Second, we each intend that the other person's relevant intentions be effective in our joint activity. Third, we each intend that we each fill in and execute each of our individual plans for participating in the joint activity in ways that mesh with and do not thwart each other).

Philosophers have understandably not been concerned with operationalizing collective intentions and developing hypotheses for empirically testing the relationships of collective intentions to antecedents and consequences. Bagozzi and Dholakia (2002) used two measures of collective intentions, which they termed "we-intentions," in their investigation of virtual chat room participation: "We (i.e., I and the group of online friends that I regularly chat with) intend to chat in the virtual chat room together sometime during the next two weeks" and "I intend that our group (i.e., I and the group of online friends that I regularly chat with) chat in the virtual chat room together sometime during the next two weeks." Although not investigated to date in virtual community research, a third operationalization of collective intentions is possible to study: namely, a member's "I-intention" to do his/her part in a joint action of a virtual community. This latter intention might be termed a group-oriented I-intention to contrast it with both the more common I-intention (i.e., an individual person's intention to perform an individual act by him or herself alone and not as part of a group) and we-intentions and shared intentions, as defined above (see Bagozzi & Lee, 2002).

In sum, collective intentions capture a central aspect of purposive social interactions in virtual communities. Members of the community see themselves as either (a) acting as an agent of the group or as an intrinsic part of the whole group which itself acts or (b) acting as a person contributing individually to a group goal or action. We turn now to an analysis of the antecedents of collective intentions.

ANTECEDENTS OF COLLECTIVE INTENTIONS

Research to date has examined virtual community participation as a function of social and individual motives for acting. Consider first the social determinants of participation. Three categories of social factors have been investigated: compliance (subjective norms), group norms, and social identity.

Subjective norms have long been studied within the context of the theory of planned behavior (Ajzen, 1991) but not until recently in virtual communities. As felt expressions from significant others to act, subjective norms are aspects of interpersonal influence and reflect a type of compliance based on the need for approval. Most virtual communities are characterized by little or no opportunities for direct mediation of rewards or punishments, low barriers to exit from the community, and generally inconspicuous participation in the sense that the ability to monitor other people's compliance is relatively low. As a consequence, subjective normative pressure from other members of the virtual community has generally been found to be absent (Bagozzi & Dholakia, 2002; Bagozzi, Dholakia, & Mookerjee, 2005), or modest (Dholakia et al., 2004). Studies to date have examined the indirect effect of subjective norms on intention mediated by desire (see presentation below on individual reasons for acting). A direction for future research would be to study felt normative pressure to participate or not participate in virtual communities, as a function of expectations of significant others outside the virtual community (e.g., family members, authority figures, close friends, coworkers).

Subjective norms function in interpersonal ways but are not group processes *per se*. A more social type of influence on collective intentions can be found through group norms. Group norms consist of shared values or goals among community members with respect to common expectations of group members' conduct and become internalized as a function of developmental processes, socialization, and role modeling (Bagozzi & Lee, 2002). Group norms have been found to influence collective intentions to participate in the virtual community indirectly through desires (Bagozzi, Dholakia, & Klein Pearo, 2004) and directly (Bagozzi et al., 2005; Dholakia et al., 2004). In addition, group norms have been found to influence social identity with one's virtual community (Dholakia et al., 2004).

Social identity in a virtual community refers to one's self-conception based on membership in the community and has three distinct components (Bagozzi & Lee, 2002; Bergami & Bagozzi, 2000; Dholakia & Bagozzi, 2004). The cognitive component captures the degree of self-awareness of membership in the virtual community and is related to the question, "Who am I?" To the extent that one defines him or herself by group membership, he/she can be said to identify with the group. Cognitive social identity is reflected in both the degree of overlap between one's personal identity and the identity of the virtual community, and the extent of perceived congruence between one's attributes and the attributes of the virtual community. A second component of social identity addresses one's affective commitment to the virtual community. This is typically measured by the degree to which one feels attachment and belongingness to the virtual community. The third component of social identity concerns the positive or negative value connotations attributed to virtual community membership. It is manifest frequently by collective or group-based self-esteem and measured by how important or valued one feels as a member of the virtual community. Social identity in the virtual community has been found to strongly influence the desire to participate in network- and small-group-based communities (Bagozzi & Dholakia, 2002; Bagozzi et al., 2004; Dholakia et al., 2004) but not in collaborative browsing groups (Bagozzi et al., 2005).

Collective intentions to participate in virtual communities are driven most directly by the felt desire to participate in the community. Desire is a motivational state that instigates intentions (and in turn, behavior), and is influenced by reasons to act (Bagozzi, 1992). Either deliberative (i.e., volitive) or automatic (i.e., appetitive), desires serve to transform felt plausible bases for acting into actual motivation to act (Perugini & Bagozzi, 2001). Desires are experienced as felt urges to act. A number of studies show that desires strongly influence the commitment and intention to participate in virtual community activities (Bagozzi & Dholakia, 2002; Bagozzi et al., 2004; Dholakia et al., 2004). Future research should explore the possibility that, in addition to personal desires, shared desires might govern intentional social action in virtual communities.

More distal personal reasons for participating in virtual communities can be found in individual dispositions to act, certain mental states or events, and value perceptions (see Figure 1). Actually, such reasons for acting constitute alternative perspectives on how psychological variables function in virtual communities. That is, what we loosely classify here as individual dispositions or mental states/events refers to general psychological reactions from the literature on attitudes and perceived behavioral control (Ajzen, 1991) and anticipated emotions (Bagozzi, Baumgartner, & Pieters, 1998), which are applied to a particular virtual community experience. Attitudes are evaluative reactions toward participating in the virtual community. Perceived behavioral control refers to how easy or difficult it is to participate or how much confidence one has that he/she can participate. Anticipated (positive and negative) emotions are feelings prefactually tied to successfully or unsuccessfully accomplishing a planned goal of participating in a specific virtual community. All three of the above are reasons for acting. Alternatively, reasons for acting might be represented in more context-specific ways. Value perceptions refer to specific attributes of participation in a virtual community that potentially provide reasons for participation. These include purposive value (i.e., informational and instrumental utility), self-discovery, maintenance of interpersonal connectivity, social enhancement (i.e., increase in status), and entertainment value (e.g., fun and relaxation).

Bagozzi and Dholakia (2002) discovered that positive anticipated emotions influenced the desire to participate in virtual communities (chat rooms), and Bagozzi et al. (2004) found that both positive and negative emotions influenced the desire to participate in (small-group- and network-based) virtual communities. The effects of attitudes on desire have been mixed, with one study showing no effect (Bagozzi & Dholakia, 2002), and one study revealing an effect for small-group-based, but not network-based, virtual communities (Bagozzi et al., 2004). Neither of the above mentioned studies examined the effects of attitudes and anticipated emotions on group norms and social identity. Perceived behavioral control has been found to have mixed effects. Bagozzi and Dholakia (2002) discovered no effects for perceived behavioral control on either desires or intentions. Dholakia et al. (2004) revealed that perceived behavioral control influenced desires for network-based virtual communities but not small-group based virtual communities. They also found that perceived behavioral control had direct effects on intentions for both network-based and small-group based virtual communities (not shown in Figure 1). Bagozzi et al. (2005) showed that perceived behavioral control influences intentions to participate in collaborative browsing but not chat-rooms for Americans, while perceived behavioral control influenced intentions to participate in chat-rooms for Indians. In the only study found that examined value perceptions, Dholakia et al. (2004) showed that purposive value affects both group norms and social identity, self-discovery influences group norms, and entertainment value determines social identity. Since group norms and social identity ultimately had effects on desires, the influence of value perceptions on collective intentions is mediated through desires. Dholakia et al. (2004) also found that entertainment value directly affects participation in virtual communities. Finally, within the context of the theory of planned behavior (Ajzen, 1991), Bagozzi et al. (2005) discovered that attitudes influence intentions to participate in collaborative browsing and chat-room groups.

CONSEQUENCES OF COLLECTIVE INTENTIONS

The primary outcome of collective intentions with respect to participation in virtual communities is, of course, actual engagement with the community. Only three studies have investigated participation behavior in virtual communities as a function of collective intentions. Bagozzi et al. (2004) found that collective intentions influence actual participation for both network-based and small-group-based virtual communities. Likewise, Dholakia et al. (2004) showed that collective intentions influence participation behavior in their study of virtual communities, and Bagozzi et al. (2005) found similar results for both collaborative browsing and chat-room groups.

What about second-order effects of involvement with virtual communities? Bagozzi et al. (2004) examined the effects of collective intentions to engage in virtual community activities on off-line behavioral outcomes. For small-group-based virtual communities, the stronger the intention to participate in these communities, the less telephone and radio were used and the more people actually engaged in reading books. For network-based virtual communities, the stronger the collective participation intention, the less television was watched, and the more people interacted with family members, friends, and neighbors, and the more they engaged in such hobbies as sports teams and book clubs.

A neglected area of research is the study of the effects of virtual community participation on general well-being. While some commentators have warned about such negative effects of participation on the Internet as alienation, disembodiment, and depression (e.g., Dreyfus, 2001; Kraut et al., 1998), negative outcomes are not inevitable. Researchers need to focus on what happens in one's personal and social life on and off the Internet and how the two modes of experience relate to each other and one's well-being. The Internet, in general, and participation in virtual communities, in particular, can enhance human well-being under certain conditions. This might happen when social identity and personal identity are fostered and people give and receive in meaningful ways to the relationships within which they are engaged. Moreover, virtual communities and the members within them may even participate in fulfilling outreach activities, altruistic acts, group citizenship behaviors (Bergami & Bagozzi, 2000), and charity work, which also potentially adds to human flourishing.

CONCLUSION

A key to the formation and ongoing vitality of virtual communities is the involvement and commitment of people to the community and the challenge and joy they receive from participation. Human emotion plays an essential part in the life of virtual communities and their relationship to its members. Figure 1 summarizes places in collective intentional action system where this happens. First, positive and negative anticipated emotions are tied to the fulfillment or thwarting of virtual community participation as a personal goal and thus function to orient and motivate the individual to act in a purposive way toward one's virtual community. Second, rational, emotional, and social reasons for participating in virtual communities are integrated and transformed through formation of desires to participate or not. A third way that emotions appear in the collective intentional action system is in affective commitment (i.e., feelings of attachment and belongingness to the community). People potentially receive happiness and satisfaction from identification with and participation in their virtual communities, as well as give back emotion, time, and effort to the communities and people in it. Finally, emotions reside in general well-being that is psychologically and socially constructed as people reflect upon and discuss their experiences in their virtual communities with members and others outside the community. A full range of individual and social emotions are to be expected in virtual communities, depending on the level of involvement and commitment demanded: empathy, trust, affection, pride, joy, happiness, guilt, shame, embarrassment, frustration, disgust, anxiety, envy, and jealousy. Obviously, these positive and negative emotions can make participation in a virtual community a rewarding/punishing or pleasant/unpleasant experience, depending on the nature of the experience and its meaning for the person embedded in it.

KEY TERMS

Collaborative Browsing: Online navigation on the Internet by a group of individuals that assembles in the same physical setting and browses online using the same or adjacent interfaces in the attainment of task-oriented objectives.

Compliance: Social influence process whereby a person conforms to the expectations of others based upon the motivation of a need for approval. Also known as subjective norm.

Collective Intentional Action: Mutual or joint behaviors performed by a group of persons and that are explained by collective intentions (e.g., we-intentions) and such social influence as compliance, group norms, and social identity and such personal mental states as anticipated emotions, desires, and value perceptions (e.g., purposive value, self-discovery, maintenance or personal connectivity, social enhancement, and entertainment value).

Network-Based Virtual Community: A specialized, geographically dispersed virtual community based on a structured, relatively sparse and dynamic pattern of relationships among participants sharing a common focus.

Small-Group-Based Virtual Community: A handful or so of persons with a dense web of relationships, interacting together online in order to accomplish a wide range of jointly conceived goals and to maintain the functioning of the group.

Social Identity: A conception of the self consisting of (a) self-awareness of membership in a specific group, (b) emotional attachment or involvement with the group, and (c) a positive or negative value connotation attached to this group membership (i.e., group-based or collective self-esteem). These are sometimes referred to, respectively, as the cognitive, affective, and evaluative components of social identity.

Subjective Norms: Social influence process whereby a person acts on the basis of internalized values or goals shared with members of a reference or friendship group. Similar to compliance.

Virtual Communities: Mediated social spaces in the online environment that allow collections of people to form and be sustained through ongoing communication processes.

We-Intention: Decision of a person to participate in joint action and which involves an implicit or explicit agreement between the participants to engage in the joint action.

Combining Local and Global Expertise in Services

Hannu Salmela

Juha Pärnistö
Fujitsu Services, Finland

INTRODUCTION

Since the 1990s, services characterized by a considerable geographical distance between the service person and the customer have become increasingly commonplace. Banks and insurance companies are introducing call centers or service centers to complement, or even replace, the old regional service organization. In the information and communication technology (ICT) sector, companies such as Fujitsu and IBM provide part of the end-user support for their clients from a few centralized call centers. Telecommunications operators have established call centers to serve their customers in conducting basic business transactions. To a large extent, the change in the 1990s can be attributed to ICT development. As call centers and local offices have equal access to all the information, many of the services that previously had to be provided locally can now come from a call center. Furthermore, this decade will bring new technologies that will further enhance capabilities to serve customers over long distances. They will, for instance, provide increasingly rich media for interaction between customers and remote service personnel.

This article investigates factors that need to be considered when moving service production from regional offices to service centers. The empirical part of the study comprises a longitudinal analysis of the ways how Fujitsu Invia, a European IS company within Fujitsu Group, has transformed its service organization. The company has moved a long way from local, site-specific service units to national service centers, and ultimately to a few global centers that provide services to thousands of computer users worldwide. In retrospect, it can be said that the decision to centralize service production turned out to be very successful. However, the reasons why Fujitsu Invia decided to return part of the end-user support closer to customer sites illustrates the complexities associated with centralizing services that were previously produced locally.

BACKGROUND

The ability to centralize services appears to provide a cure for some of the traditional problems of service organizations. Managers of distributed service organizations are painfully aware of the difficulties to maintain an equal level of knowledge among all individual service persons in all regional offices. Centralizing the services to a call center or service center seems like an easy solution for ensuring that all customers receive equal service.

The more complex the services are, the more difficult it becomes to maintain equal knowledge in all regional offices. Hence, the analysis of forces for specialization among service staff is one of the key issues when considering the potential advantages of centralizing service production. Because of the special expertise necessary to solve the specific problems they encounter, professional service providers need a high level of specialization (Koelemeijer & Vriens, 1998). Factors that increase service complexity and thus pressure for specialization include (Mäkelin & Vepsäläinen, 1989), for instance,

1. diversity in customer needs and requests,
2. variety in the services available,
3. the number of situational factors that need to be considered,
4. uncertainty related to customer needs and circumstances,
5. the ability of the customer to define the services, and
6. the complexity of contracts used for governing the transactions.

In essence, complexity makes it difficult for a generalist service person to be able to handle all possible inquiries from all customers adequately. While generalists can deal with routine cases, specialists are needed to handle the difficult and unique cases. The main problem for producing complex services in regional offices is that it is difficult to maintain highly specialized knowledge in every regional office. The most forceful argument for establishing a service center is that the customer with a unique problem can talk with a global specialist rather than with a local generalist. In addition, the cost savings that can be achieved in regional offices (office space, service personnel) are often sufficient to make the projects acceptable in terms of financial profitability measures.

In this chapter we suggest, however, that managers should also pay considerable attention to the opposite forces as well, that is, forces for providing local service. An obvious reason for providing services locally is that the service has a physical component and thus requires presence close to the customer. There are, however, many soft issues that may also make the customers prefer a local and personal service. In face-to-face discussions, information can be communicated with multiple cues like the sound of voice, facial expressions, and body language. Thus, the richness of communication media is very high (Daft & Lengel, 1986; Huang, Watson, & Wei, 1998). In this respect, the need to rely on conversations over phone or e-mail may have a negative impact on the quality of service.

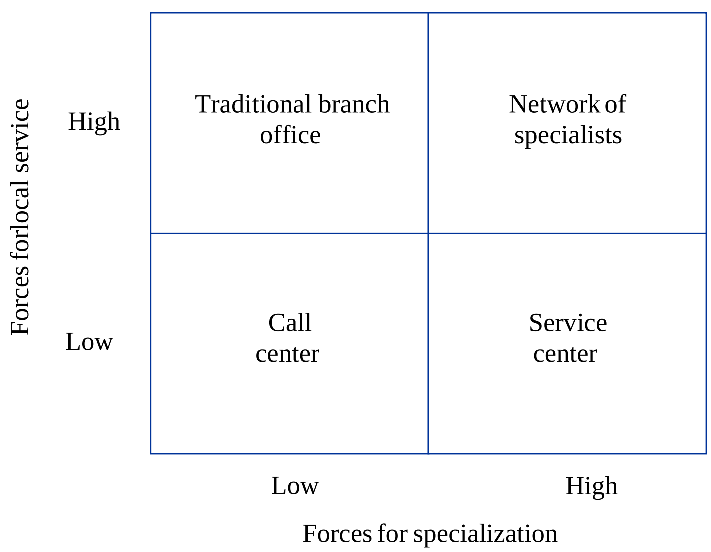
A TYPOLOGY OF SERVICE ORGANIZATIONS

The typology that is suggested in this article is based on forces for providing local service and forces for specialization among service staff. Figure 1 provides a typology of four ideal types of service organizations, each designed to take into account the particular nature of service situations. Each organizational type has its strengths as well as its typical ways of using technology. More often than not, service organizations provide a mix of services for their customers. Some of the services provided may require local presence and some of them specialization. Thus, the objective is not to locate the whole company to a single quadrant. Rather, it is essential to identify all services that are provided to customers and to locate each of them to the right quadrant.

A *traditional branch office* is best suited to relatively simple service situations that require local presence. In simple services, the local generalist service persons are able to provide sufficient service quality. The quality and profitability of service is ensured by replicating and controlling precisely defined activity cycles, personal selling approaches, inventory control patterns, and counter display techniques (Quinn & Paquette, 1990). The possibilities for more stringent specialization are limited because a relatively small number of service personnel in one office have to deal with a full variety of customer inquiries.

In a *call center*, service personnel are centralized to one physical location. Part of the service personnel is moved from regional offices to a physical location to answer a definite set of requests from customers. The change is usually motivated by a managers' observation that some of the simple services are such that customers don't really expect to be served locally. The objectives for

Figure 1. Simple typology of service organizations



establishing a call center are a reduced cost of service, extended contact hours, and standardized quality. As the services provided are fairly simple, there is no need for specialization between service personnel: Any service person can solve any incoming customer inquiry.

A *service center* type of organization takes advantage of the fact that one centralized unit handling inquiries from a large number of customers allows greater specialization of service personnel. Each service person specializes in a particular type of customer problem, and incoming customer inquiries are routed to the best specialist in that area. The assumption is that a specialist with experience in solving similar problems with many companies can provide a more accurate service, particularly with regard to complex customer problems.

A *differentiated network* is the most challenging type of service organization as the service should be simultaneously local and specialized. Neither a local service office nor a centralized service center alone can provide the service. Finding a perfect organization in this quadrant is difficult. Often, organizations in this quadrant rely on a combination of traditional branch offices and centralized service centers (which deal with more complex cases). The potential for using sophisticated information and communication technologies is clearly highest in a differentiated network.

Even if the differentiated network may seem like a less attractive organizational solution, one should keep in mind that in service situations requiring both a local presence and specialization, there may be no alternative. In this situation, a service center may not be able to respond to local needs.

In fact, writings about multinational manufacturing enterprises often favor a differentiated network, which allows local responsiveness in different areas but possesses the control mechanisms to ensure global integration (Bartlett & Ghoshal, 1998; Nohria & Ghoshal, 1997; Prahalad & Doz, 1987). Rather than choosing a fully centralized or decentralized structure, the assets and resources of the company are widely dispersed but mutually supportive to achieve global-scale efficiency, the roles and responsibilities of organizational units are differentiated but interdependent to maximize national flexibility, and its knowledge and initiatives are linked through a worldwide learning capability that assures the efficient development and diffusion of innovations (Bartlett & Ghoshal).

With such practices, the organization provides a context for employees to create and share both tacit and explicit knowledge (Nonaka & Takeuchi, 1995; Polanyi, 1966). The relationships between individual actors are seen as a form of social capital that constitutes a valuable resource (Castells, 1996; Nahapiet & Ghoshal, 1998). In essence, it is asserted that creating and sharing knowledge in a geographically distributed organization is not only possible, but it may even be more effective than knowledge creation in one centralized point.

It seems apparent that many service organizations could benefit from similar practices. In fact, predictions of the impact of IT on service organizations have discussed the “spider’s web” type of organization, where local offices are independent but are also able to use each other’s knowledge resources as and when needed (Quinn & Paquette, 1990). Similarly, a recent study concluded that the competence to do global product development is both collective and distributed (Orlikowski, 2002).

DEVELOPMENT OF SERVICES IN FUJITSU INVIA

Fujitsu Invia (formerly ICL Invia) is a North-European vendor of information technology products and services. It belongs to Fujitsu Group, which operates in more than 100 countries and has almost 200,000 employees. Because the case describes developments mainly in the Fujitsu Invia, this brand name will be used below hereafter. According to a recently launched strategy, Fujitsu Invia has two main businesses: solutions and services. Solutions business refers to consulting, designing, and constructing information systems. Services business mainly involves operating customer’s IT infrastructure as well as business applications. The case description focuses on service business and its evolution during the past few years.

Stage 1: All Services Produced Locally

Only a few years ago, Fujitsu Invia was mainly a hardware vendor. The main service was naturally hardware maintenance, which is typically a local service. The customers were provided with a service number to which they could call and report a hardware failure. The maintenance organization also delivered large installation projects, but not actual end-user support or administrative services (e.g., opening of a new e-mail address). These were typically delivered by the customer’s own IT department. Maintenance was organized in regional business units that were quite independent. Customer-call management and the information system for managing service processes were typically shared by business units on a national level. Service coordination between countries was not really required, although certain issues such as pricing and service levels were negotiated on a corporate level.

Stage 2: Initiation of Centralized Service Production

In the second stage, customers became interested in acquiring relatively large service packages so that one vendor takes responsibility for a relatively large and logical part of the IT services. The change was initiated by customers who found managing IT and particularly the IT infrastructure increasingly difficult. These packages typically include a selection of IS services, for example (Weill & Broadbent, 1998),

- on-site support (i.e., solving end users' problems locally),
- help desk (i.e., a contact point where end users' requests are registered and escalated; also attempts to solve requests),
- hardware maintenance (i.e., fixing broken IT equipment),
- systems management (i.e., monitoring and operating systems typically from a centralized service center), and
- service management (i.e., customer reporting, maintaining contracts, improving service quality).

It was not possible to deliver these services by a maintenance organization, so in order to respond to this request, Fujitsu Invia established new business units. Centralized services (mainly help desk and systems management) are used to support the IT infrastructure. Centralization seemed like an obvious solution because of cost-effectiveness requirements and also because the technical expertise is easier to acquire and maintain in specialized teams. The aim was to minimize local service. Maintenance is the only local service. New technologies, like remote management, further improved the quality of service as end users no longer needed to describe the problems in detail. The help-desk specialist simply opened a remote connection to the end user's workstation, diagnosed the problem, and changed the parameters or trained the end user.

Stage 3: End-User Services Return to be Produced Locally

Although a centralized service center is probably the most cost-effective way to organize this type of services, there are also some problems. Customer organizations are not standardized really well even though the technological solutions are. Information systems can be installed in many ways, a situation that has implications on their operation. The quality of service perceived by end users is an even more significant issue. It seems that people prefer to be served locally. The barrier to call to a distant help desk and to an unknown specialist is rather formidable, even within a single nation. Furthermore, transferring the necessary knowledge about local environments to a help desk is not easy. Therefore, a local service organization is frequently required to manage situations like this. The end user easily feels that he or she has to call a help desk, which mainly escalates problems to a local organization. The added value of the service can be questioned.

Because of the problems described above, the help desk has been reorganized in some customer cases so that the first line is either integrated with a local service organization, or the help-desk first line is actually on the customer site. Some members of the on-site support team receive customer service requests, and other members undertake installations and problem solving. The roles within the team can be changed, which means that the on-site support team knows the local customer environment very well, and also the end users know on-site support people. This makes communication easier and the barrier to calling is lower. The solution rate has improved significantly in the pilot cases (in one case, from a level of 50% to 80%), which makes it possible to deliver the same service with fewer resources. At the same time, customer satisfaction improved (in the example case, from 6.5 to 8.4 when measured on a 1 to 10 scale). Their second-line and third-line support is still delivered from a centralized service center during the night and weekends.

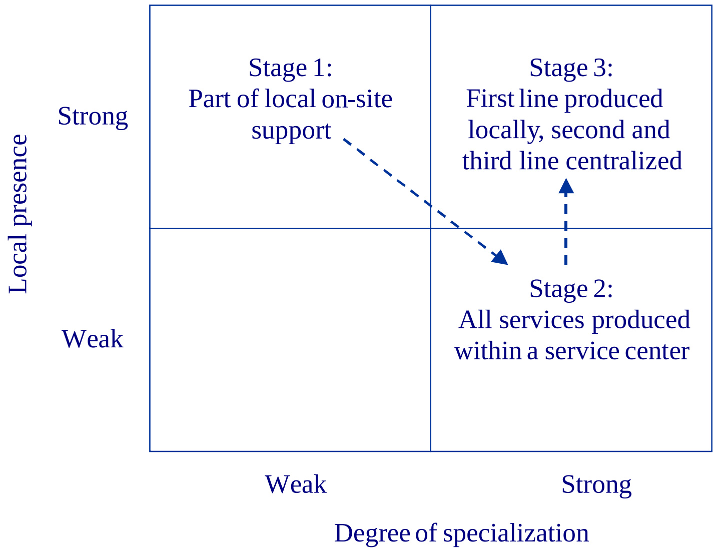
Analysis of the Nature of Services

The most problematic service for Fujitsu Invia has been how help-desk services should be organized. What makes it problematic is that on the one hand, end users in customer companies prefer to contact local service persons instead of a distant call center. On the other hand, solving the problems often requires a specialized knowledge that the local service persons lack. The fact that the service should be both simultaneously local and also specialized has made the service difficult to organize, and the attempt to find the best means of organization has been a trial-and-error process (Figure 2).

In the first stage, the idea of providing help-desk services to end users was more or less informal. While end-user satisfaction for services was probably high, the customers felt that the cost of producing services locally was too high. Outsourcing these services to Fujitsu Invia and simultaneously centralizing them was considered an interesting option. The new technologies appeared to provide excellent tools for centralized production of help-desk services. When the service was centralized, however, more was learned about its nature. Service turned out to be more local than what the customers and Fujitsu

C

Figure 2. Organizational arrangements for help-desk services in different stages



Invia had expected. In the third stage, help-desk services for large-site customers are based on a combination of local and centralized services. While the experiences from this organizational form are highly positive, it is also more costly and can be applied only to customers with relatively large sites.

FUTURE TRENDS

The sociological theory of the postindustrial society was elaborated more than 3 decades ago (Bell, 1973; Touraine, 1969). In essence, the theory combined three postulates (Castells & Aoyama, 1994): (a) The source of productivity and growth lies in the generation of knowledge, (b) economic activity shifts from goods production to services delivery, and (c) the importance of occupations with a high information and knowledge content will increase.

Existing postindustrial societies do not fully reflect all predictions made within this theory (Castells, 1996; Castells & Aoyama, 1994). Nevertheless, the significance of various types of services, for example, capital management services, services produced for industrial companies, and social and health services, is increasing. As firms in advanced economies have off-shored manufacturing jobs, the society as a whole has transformed toward a "service economy" model (Castells & Aoyama). Hence, the significance of services in general and knowledge-intensive services in particular is increasing.

The point raised in this paper is that information and communication technology will also induce a major transformation inside the service sector. Increasing telecommunications bandwidth together with its falling cost will enable new applications that are particularly useful for geographically dispersed production of services. In the future, the possibility to use wide computer screens for face-to-face interaction is likely to have a major impact on the way services are organized. Furthermore, the penetration of innovations such as integrated customer databases, e-services, global scheduling systems, call center technology, and virtual learning environments is likely to continue.

The emergence of call centers and service centers provides first visible evidence that the transformation is already taking place. However, as the Fujitsu Invia case illustrates, a call center can be too remote for providing services that require local presence. Hence, the organizational forms required in many services may be more complex than mere centralization of service production. The pressures for local responsiveness are likely to force service organizations to adopt similar complex network structures as some of the advanced manufacturing companies are already using.

This research was, however, based on only one project in one service organization. As service organizations both in the private and public sector have been slow in adopting new technologies, previous IS research has paid relatively little attention to these sectors. The need for further research about the ways in which organizational structures, processes, and information infrastructures are being transformed is evident.

CONCLUSION

This paper provides a simple typology of service situations that can be used when planning IT investments in service organizations. The use of the typology is illustrated through a longitudinal analysis of the ways in which Fujitsu Invia, a European IS service company, has transformed its service organization to better meet customer expectations and needs. Practicing managers can use the typology to analyze organizations' services, to investigate where services ought to be produced, and how ICT technology should be employed to support customer service situations. The authors hope that this article will be useful for people working in companies either providing a service business or aiming to enter a service business in an international context. For research, the typology, its dimensions, and the background theories identified provide some early steps on the way toward a more comprehensive understanding about the impact of ICT on service organizations.

KEY TERMS

Capabilities: Are repeatable patterns of action in the use of assets to create, produce, and/or offer products to a market (Sanchez et al., 1996).

Competence: An ability to sustain the coordinated deployment of assets in a way that helps a firm to achieve its goals (ability here is used in the ordinary language meaning "of a power to do something"; Sanchez, Heene, & Thomas, 1996).

Information: Refers to data that give meaning by reducing ambiguity, equivocality, or uncertainty, or data that indicate that conditions are not presupposed (Huber, 1991).

Knowledge: Refers to interpretations of information, know-how, and beliefs about cause-effect relationships (Huber, 1991).

An entity **learns:** If, through its processing of information, the range of its potential behaviors is changed. The information processing can involve acquiring, distributing, or interpreting information (Huber, 1991).

Perceived Service Quality: Refers to customers' cognitive evaluation of the service across episodes compared with some explicit or implicit comparison standard (Storbacka, Strandvik, & Grönroos, 1994).

Skill: Understood as a special form of capability, with the connotation of a rather specific capability useful in a specialized situation or related to the use of a specialized asset (Sanchez et al., 1996).

Communication Management for Large Modules

Elayne Coakes
University of Westminster, UK

Dianne Willis
Leeds Metropolitan University, UK

INTRODUCTION

This article addresses issues concerning the suitability of particular media as mass communication tools in an UK higher education setting. It looks firstly at the use of e-mail as a communication method whilst managing large modules. The article then goes on to examine the use of a Virtual Learning Environment (VLE) to provide a mass communication method more suited to the needs of both the staff and the students.

An in-depth case study will look at how a large module is managed through the use of a Virtual Learning Environment, discussing the pros and cons of using such technology. For the purposes of this article, distance learning will not be considered, as the university in question has no plans to follow or adopt such an approach for the courses that undertake these modules.

BACKGROUND TO THE STUDY

The University of Westminster is a large, modern university operating on four sites across the centre of London and West London. It was Britain's first polytechnic, established in 1838 in Regent Street, and it still uses these original buildings for lectures and seminars. It became a university in 1992 and is now recognised in the *Financial Times* annual survey as the top English 'new' university.

The university has a population of both full-time and part-time students drawn from the local surrounding areas, but also has a large population of international students. Many of these students are studying post-graduate or post-experience/professional updating courses.

The Westminster Business School operates out of the Marylebone campus, which is situated close to Regents Park and is thus a very popular location for students to attend courses, as not only is it in the centre of London, but is also easily accessible by public transport.

COMMUNICATION MEDIA

This section discusses the theoretical background to communication studies looking at 'fitness for purpose' for the media.

To begin, a brief overview of the communication process and its constituents would be useful. A basic theoretical model of the communication process states that messages are 'sent' and 'received', confirmation of receipt and interpretation of the message indicates that it is a two-way communication process (Warner, 1996). The efficiency of this process is subject to a variety of issues such as:

- *Effectiveness:* How do we measure this when using e-mail or a Web site?
- *Simultaneous reception of information by recipients:* The information is available simultaneously, but how do we measure if students have accessed it?
- *Acknowledgement of receipt:* With e-mail, a receipt can be provided, but how is this addressed using a Web site?
- *Speed:* How quickly does the information reach the recipients?
- *Cost of the process:* Is it cost effective?

All of these factors will be considered in the case study section of the article.

It can be said that one of the major benefits of the growth in the use of the Internet has been the ability to communicate using e-mail as a medium. E-mail is still the most regularly used aspect of the Internet, and the level of usage is growing. Sands (2003) argues that e-mail is now as accepted a communication method as the telephone within just a few years of its introduction. E-mail has become a common mode of communication for many people, though exceptions must be made for those who do not have easy and regular access to the technology required. Adequate access to the technology is assumed in this article. However, communications theorists argue there are problems with the use of e-mail as the sole communication medium. Culnan and Markus (1987) suggested that a lack of face-to-face communication changes the intra- and interpersonal variables because of a lack of social context. Sproull and Kiesler (1986) argued that e-mail was devoid of social cues, and this would seriously affect communication patterns. E-mail provides neither audible nor visible cues to the communication process and as such can be seen as a relatively impoverished communication style. Hirschheim (1985) argued that one of the major benefits of using e-mail is to support communication between people who are geographically distant. This leads us to the initial premise that although widely utilised, there are significant problems with the use of e-mail as the sole communication medium.

There are further problems with an e-mail system in that it is not always possible to ensure that the recipient has received and read the message in an appropriate timeframe. This may be caused by a variety of problems, both technical and human. These issues are discussed in more detail and possible solutions posited in Willis and Coakes (2000).

Further analysis of the current situation indicates that e-mail lacks the collaborative dimension that is needed in today's world. In an academic setting, the ability to discuss matters in 'real time', rather than waiting for a reply from a tutor via an e-mail system, may be of great importance.

IS E-MAIL A SUITABLE MASS COMMUNICATION MEDIUM?

A traditional view of the mass communication process would have the university providing content and it passing to the students via the e-mail medium as shown in Figure 1.

This model allows no interaction. We posit that what is required in the modern communication environment is a more interactive model which allows students to influence the content, as well as be recipients of, information. In our article, the aim of mass communication is to provide information simultaneously to a large number of students. We have to seriously question whether e-mail is the correct option given the problems outlined.

Further analysis leads us to the model suggested below which, while offering limited interaction, we feel is likely to be more effective and more satisfactory than the traditional model outlined above.

The model outlined as Figure 2 gives students the option of simply gaining information via the medium, or engaging and interacting with it by influencing the content. From the preceding arguments, it is doubtful that e-mail can fulfil the role of the appropriate medium in the new model, so an alternative has to be found.

The ability to interact is an aspect that has acquired great importance in the communication process, and a method must be found that does not have the weaknesses of e-mail. What is required is a medium that can have input from both staff and students, and which can change rapidly to respond to these needs. As the staff and students are already familiar with e-mail and the Internet, a move to a more directly Web-based approach using a VLE is likely to provide a viable solution. This is supported by the fact that students have better access to Web sites and are more used to using this medium now than in the past. Additionally, many organisations limit the size of e-mails that can be sent across the network, which can cause real problems when disseminating large amounts of information, which can cause issues with part-time students who use their workplace e-mail systems for their prime communication access. The authors feel the use of a Web site accessible from any location and requiring only a browser offers a realistic alternative.

In terms of the ability to interact, asking students to access a Web site is not necessarily more effective than the simple use of e-mail - it is the add-ons of lecture notes, seminar notes, and feedback that will make the medium more successful.

Figure 1. A traditional mass communication model

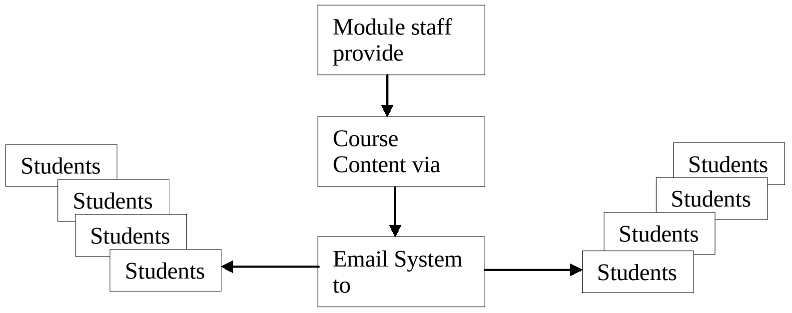

Figure 2. An interactive mass communication model (Adapted from Hoffman, Novak & Chatterjee, 2000)

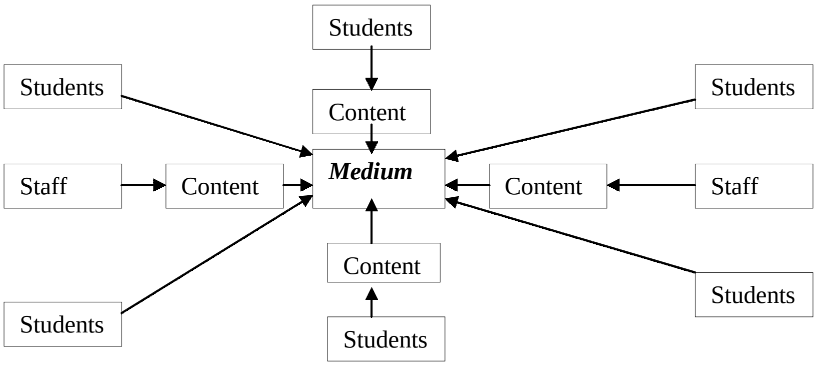

Kling (1996) looked at the benefits of electronic newsgroups, bulletin boards, conferences, and distribution lists, and the ways in which these change the communication model. There is some evidence to suggest that electronic communities help to foster a sense of community amongst geographically isolated people, and this would be of obvious benefit to the groups

being studied, as they are unable to meet physically, but may wish to feel part of a group (Kling, 1996). Therefore, it can be seen that in order to provide a sense of community for the large numbers involved in the case study, some communication medium needs to be added to foster a sense of group identity. As described below the VLE provides these capabilities.

ARE VLEs SUITABLE AS A MASS COMMUNICATION MEDIUM?

Much of the literature on VLEs is written from the point of view of their use as a teaching tool, considering what adjustments need to be made in order to present material in an online environment (Collins, 2000; Johnson, Aragon, Shatk & Palma-Rivas, 2000; Mishra, 2002). In most cases, the use of a VLE as an educational tool is not separated from its use as a communication tool; communication is one aspect of the range of options provided. This study comments on the use of a VLE as the definitive source of information for a particular module, and contrasts the capabilities for communication and tracking of student engagement. Work by Kekkonen-Moneta and Moneta (2002) indicates results that are better than traditional classroom teaching when a VLE is used. However, Mishra's (2002) work indicates that new possibilities in terms of the learning experience online are not being addressed in most cases.

This study focuses on the benefits to students of having one source for all information and the advantages this gives over multiple source enquiry points. According to Barbera (2004) the main issue is quality and how this is addressed in a virtual learning environment. VLEs tend to focus on technological and aesthetic criteria over educational ones, and there is often confusion between their use as a mere supply of information and their capabilities for knowledge-building processes. Quality will be seen as not merely offering Web pages full of information, but in establishing filters to ensure materials are reliable and worthy.

A further dimension of VLEs is their humanism (McFazdean, 2001). The instructor is no longer the orator of information, but needs to encourage learners to feed their own curiosity—that is, 'spoon-feeding' is inappropriate in this environment. Guidelines for a productive VLE include maintaining a non-authoritarian style and explicitly stating what is required of the students at all times. A further issue raised by McFazdean (2001) is that of the capability of the technology to support the demands of the group; aspects such as not owning a powerful enough computer to run the software and poor levels of computer literacy form technical barriers to the successful use of the learning environment.

A similar use of VLEs was undertaken at the University of Hull (Pennie, Barnett, Chin & Dolphin, 2001) which focuses on the experiences there of migrating two modules to a VLE, in response to increasing numbers of full-time and part-time students. The VLE approach was selected to cope with rapid change in online information resources, coupled with the need to make students more aware of what resources are best for them and how to use them effectively.

THE CASE STUDY

Strategies for Information Management Module

This is a large postgraduate module that is compulsory for students on two master's programmes and available for students on other master's programmes as an option.

Originally this module had a Web site that was used as a method of ensuring that communication is kept consistent and constantly available, but was in addition used to provide additional teaching materials around and between formal lectures and seminars (Coakes & Willis, 2002). Students on this module are assertive about what they want from a Web site, and have been instrumental in suggesting changes and additions to content and layout; as a result the standard Web site was recently replaced by a Virtual Learning Environment.

The VLE (BlackBoard™ is a standard, pre-programmed Web site brought in from a commercial supplier. It is a Web-based server software platform for course management that is gradually replacing lecturer-built Web sites across the university, and has a number of advantages and disadvantages over the standard (FrontPage) designed Web site. These are listed below.

A 2004 survey of 1,000 students at the university showed that modules using a VLE produced a more positive view (of the module) from the students; in particular, enhanced communication was considered a positive outcome as was the ability to retrieve information and announcements.

PROS AND CONS OF USING A WEB SITE FOR DISSEMINATING INFORMATION

The major pro in the use of this type of communication is the secure knowledge that you have done your best to make all the necessary information available, to all the stakeholders — staff and students — in one place that can be accessed by all. It makes it much harder for students to claim 'but x told me something else', as all students are automatically referred to the Web site when querying something. In addition, having the information provided in written form, rather than verbal, attempts to provide some security that, for those students for whom English is not their first language, consistency of interpretation of instructions is provided. The issue of closure and understanding that what has been achieved is complete and unambiguous is discussed in Coakes and Willis (2000), and also the potential for misinterpretation, misunderstanding, and misinformation through the written word in Willis and Coakes (2000), where we also discuss the often slap-dash, and haphazard way that e-mails are written. Responses to communications are 'dashed off' without due care, or at least the care required of a written, paper-based reply that a Web site environment can provide. A particular issue with using only e-mail as a means of communication is the lack of guarantee of delivery. Not just physical delivery through the technology, but also a guarantee that the e-mail has been accessed and acted upon by the recipient. As an experiment a number of e-mails with read receipts were sent over a period of months to a selected population of IT-oriented students. The read receipts were often returned up to six weeks after the e-mail was sent!

The cons are threefold: firstly the time involved in developing and managing the site can be considerable, especially at the beginning of a semester, and is a constant drain as the site has to be updated regularly; secondly, students cannot be forced to use to the Web site, although we can make it very difficult for them if they don't; and thirdly the technology—in order to rely on such technology for student support, it is essential that it is reliable and easily available. Additionally, many staff members will be reluctant to use the new technology and may take some time to adjust.

FUTURE TRENDS

It is clear from the literature that the use of VLEs will increase over time as pressure on both lecturers and students increases for flexible forms of course delivery. This may in time be supplemented by a financial pressure to increase staff/student ratios in times of falling student numbers. The new debate in the use of VLEs is not around using such environments for giving lectures, but for creating online learning environments with support groups and group-work, fostering a different type of learning environment from that encountered in standard lectures and seminars.

As lecturers become more familiar with the use of this type of technology, it can become increasingly integrated into 'normal' courses through use of the discussion facility to encourage critical thinking and debate amongst students and as a supplement to the face-to-face seminars. Group-work can also be facilitated through these environments, which can overcome the distance issue between part-time and full-time students working together on group projects for instance. Indeed, we are currently considering how students who are undertaking the same module, but in universities sited across the world

Table 1. The VLE and students

Students	*Advantages*	*Disadvantages*
	The provided interface is the same across all modules.	As the area titles are largely pre-programmed, lecturers have to be creative as to where they place the items for their modules. Thus some students 'lose' material or fail to access it appropriately or at the correct time.
	The inbuilt e-mail facility allows easy communication with all students on the module.	The e-mail addresses listed are those given by the students when they register at the university. Unfortunately many students do not use the standard university e-mail, but a Yahoo account or similar, and forget to check their university account!
	The announcements page permits students to see any urgent messages that the lecturer needs to bring to their notice.	
	The site is hosted on the university intranet, but is accessible on the Internet with the student's standard password.	
	The Web site actually develops interactively with the student comments; it is enhanced with new references, updates to materials, answers to questions raised in seminars, and through student e-mails. This interactive aspect is considered by students to be an important point in the Web site's favour, in particular, as it shows that lecturers are listening to them and are involved in the teaching of the modules.	
	The Web sites are available to potential and forthcoming students (entering as guests if the lecturer permits) as a 'taster' of what will be coming.	
	Ensuring essential materials such as assessments are on the Web site reduces student stress, as they know they always have access to vital details should they lose the originals.	Printing issues especially with Adobe files.
	Students can compare their work against posted assessment comments and see where they may have fallen short without talking to lecturers.	
	The use of a Web site also provides a learning experience for students in Web navigation and the utilisation of essential 21st century skills such as file downloading. These may be new skills for some international students.	
	Forums are available for students to discuss issues relating to seminars and lectures.	Students are reluctant to use the discussion areas due to the *time* factor involved and also perhaps due to the exposure (of what they might see as their weakness if they ask questions).
	Group work is able to be performed, as the site permits group areas to be created for joint working. The discussion areas additionally have chat rooms.	
	A link to the university's electronic resources is provided.	

Table 2. The VLE and lecturers

Lecturers	*Advantages*	*Disadvantages*
	As the interface is pre-programmed, the lecturer is not required to know any programming skills or to make any decisions on layout.	There is no opportunity to provide the information in a unique manner, and many of the section titles are inappropriate but cannot be customised.
	The e-mail facility allows easy communication with all students on the module.	The e-mail addresses listed are those given by the students when they register at the university.
	The announcements page permits students to see urgent messages.	
	As the material is contained within the intranet, intellectual property issues are no longer such a worry as when Internet access permitted anyone access to all module materials.	
	All module teaching staff also access this material and thus can ensure that they all talk with 'one voice' in relation to queries; also ensures that they have all the vital module information readily available in good time for preparation of seminars and are kept informed of what has been covered in lectures and so forth.	
	Putting answers to student queries on the Web sites saves lecturer time; it can also be shown that using such Web sites saves staff time in other ways. For instance, by ensuring that all essential information such as assessment details are on the site, duplicate copies do not have to provided in office hours to students who have lost their originals.	The time issues with updating and monitoring the Web site and providing the additional items such as tests.
	Another saving in staff time has been provided through posting a set of generic comments as feedback on formative assessments.	
	The Web also permits lecturers to monitor student activity on the site, and to see which areas have been accessed and when by individual students. Students who have not been accessing materials can be followed up.	
	Online assessments (tests of various types) are able to be created for assessment or reinforcement of seminar activities.	

(Europe and South East Asia for instance), can undertake group-work supported in just such a way.

The capability of the VLEs to enable online assessment and automated marking may additionally provide both lecturers and students with quick assessment and results for those topic areas which are suitable. One issue that needs careful consideration is that of engagement with modules. Unless students are required to access the VLE on a regular basis, there may be difficulty in getting all students assessed at any one time. It is particularly useful in those subjects where online collaboration forms part of the assessment regime.

In a recent course undertaken on e-tutoring by one of the authors (on BlackBoard), it was noted that:

"…the power of online learning is the potential to put experiences together that otherwise would never encounter one another, i.e., on this course we have a number of people across a relatively small 'world' (the university) who would probably never had had the opportunity to share experiences and therefore create better understanding (or knowledge)." (Gunter, 2004)

It is this power that may provide the boost to VLEs and their future use.

CONCLUSION AND PLANS FOR THE FUTURE

As discussed earlier, these Web sites are not static. We have talked about the need for interactivity, and this is a factor for future development. Issues such as speed of response and download time are important considerations if moving towards a multimedia approach, and this may negate some of the positives of the change to a Web-based solution. There are always issues and enhancements, however, now that the basics are working, that could be provided.

Hit counters have proved not to work successfully in FrontPage, however the new VLE can be monitored for students accessing selected pages. However, these are not a good measure of the extent to which participation is leading to learning. This is better monitored by feedback from the students on the effectiveness of the sites and the future development needs.

Enhancements will be provided as time and software capabilities permit and as the students suggest. The obvious development is to move towards a multimedia-based Web site with enhanced capabilities, but there are issues with media storage facilities here, as well as copyright.

In conclusion, it has to be said that the use of a VLE has been very successful and has the potential to allow delivery of such large modules on other courses with the ability to manage the process—a truly enabling technology.

KEY TERMS

Bulletin Board: An electronic message database where people can log in and leave messages.

Conferences: Virtual synchronised communication across multiple sites.

Distribution Lists: E-mail lists of all participants in the virtual environment who can be contacted as a totality or divided into specified sub-groups.

Electronic Communities: Online forums to discuss topics of mutual interest.

Electronic Newsgroup: A collection of messages posted online by individuals on a specified subject matter.

Module: A discrete educational item that covers a topic such as Statistics. It would typically consist of a set number of weeks of learning material delivered through lectures and seminars.

Virtual Learning Environment: Technology-mediated venue for learning; typically includes asynchronous as well as synchronous facilities.

Comparing Conventional and Non–Parametric Option Pricing

Paul Lajbcygier
Monash University, Australia

INTRODUCTION

Once, the seminal Black–Scholes (Black & Scholes, 1973) model was thought to be the last word on option pricing: all that was needed, it was thought, was some adjustments and it could be applied to price options on any financial instrument.

In the past two decades, increases in the bias of these Black–Scholes style models (Rubinstein, 1985) have led researchers to develop new models, coined modern parametric option pricing models. The underlying logic of this modern parametric option pricing program is that by loosening the "unrealistic" assumptions of the conventional Black–Scholes style option pricing models (e.g., including jumps in stochastic processes describing underlying asset prices (Merton, 1973); incorporating skewness and/or kurtosis describing the underlying asset distribution (Corrado & Su, 1996); considering the effects on demand and/or supply (Follmer & Sondermann, 1986); and the effects of tax (Scholes, 1976)), it is possible to mitigate the bias associated with them.

However, recently, many authors (e.g., Bakshi, Cao & Chen, 1997; Bakshi & Chen, 1997) have found that the modern parametric models are found to:

- be too complex;
- have poor out of sample performance;
- have implausible/inconsistent implied parameters.

Perhaps the final word on modern parametric models should be left to Fischer Black (Black, 1998): "The Black–Scholes formula is still around, even though it depends on at least 10 unrealistic assumptions. Making the assumptions more realistic hasn't produced a formula that works better across a wide range of circumstances".

FUTURE TRENDS: NON-PARAMETRIC OPTION PRICING

If we concede that the modern parametric option pricing program has failed, where does this leave us? There remains significant, persistent and systematic bias in modern parametric option pricing models (Rubinstein, 1985). The ideal option pricing model would not only provide unbiased option prices, be consistent with the underlying process and distributions of asset returns, and have minimal assumptions and parameters to estimate, it would also incorporate a statistical estimate of option pricing error. This ideal model may never be found by generalizing the unrealistic assumptions of the conventional option pricing models. What alternative is left?

Either we must accommodate option pricing model error explicitly and surrender any notion of improvement, or some new, alternative approach must be used. Non-parametric techniques represent such an alternative approach.

There are three scenarios where non-parametric approaches are particularly useful:

- when conventional/modern parametric solutions lead to bias in pricing;
- when conventional/modern parametric solutions exist but are too complex to use;
- and, when conventional/modern parametric solutions do not exist.

Non-parametric option pricing models can be divided into two separate strands: the model free and the semi-parametric. These two strands can be characterized by their dependence on finance theory. Model free non-parametric techniques have no reliance on finance theory whatsoever; semi-parametric approaches have a high reliance on finance theory (e.g., approaches that augment parametric option pricing models with non- parametric techniques).

Numerous technologies have been used to estimate model free non-parametric option pricing, including: genetic programming (Chen, Yeh & Lee, 1998), kernel regression (Ait-Sahalia & Lo, 1995; Broadie, Detemple, Ghysels & Torres, 1996) and artificial neural networks (Malliaris & Salchenberger, 1993).

The fundamental problem of non-parametric model free option pricing models lies with their greatest strength: their independence from the assumptions of finance theory. On the one hand, this independence is a great strength because being free of these assumptions means that the persistent, systematic and significant bias found in parametric option prices may be eliminated. On the other hand, this independence is a great weakness. The fact that non-parametric model free option pricing approaches do not rely on any finance theory for their derivation means that there is no guarantee that the prices obtained from these models will not conform to rational pricing[1].

So, the cost of the complete flexibility of the model free non-parametric option pricing approaches is that there can be no guarantee of rational pricing. Ghysels et al. (Ghysels, Patilea, Renault & Torres, 1997) state:

"non parametric model free option pricing becomes quickly infeasible since it is not able to capture a large set of crucial restrictions implied by arbitrage."

The aim of semi-parametric option pricing models is to estimate a portion of the option pricing model non-parametrically while retaining the conventional option pricing model framework to guarantee rational pricing.

There are three main branches of semi-parametric option pricing. Hybrid approaches model conventional option pricing residual error in the hope of reducing this error (Lajbcygier, 2003). General volatility models use non- parametric techniques to estimate the volatility used in conventional parametric option pricing (Dumas, Fleming & Whaley, 1996). Finally, equivalent martingale measures (or risk neutral pricing) (Campbell, Lo & Mackinlay, 1997) use non- parametric techniques to estimate the risk neutral probability distribution, which in turn can be used to price options.

CRITICAL ISSUES

Despite all its promise, non-parametric option pricing approaches are considered an emerging technology with the potential to help improve option pricing. There are still many open critical issues (some of which are discussed in Table 1).

CONCLUSION

The ideal option pricing model would not only provide unbiased option prices, be consistent with the underlying process and distributions, and have minimal assumptions and parameters to estimate, it would also incorporate a statistical estimate of option pricing error. No such model exists today. It is interesting to speculate as to whether such a model will exist in the future, and if the model will be parametric, non-parametric, or a mixture of the two.

As Campbell, Lo and Mackinlay (1997) have stated, non-parametric option pricing approaches hold promise:

"Although it is still too early to tell if these non parametric and highly data intensive methods will offer improvements over their parametric counterparts, the preliminary evidence is quite promising."

Table 1. Summary of critical issues of non- parametric option pricing

Elimination of Option Pricing Bias To eliminate persistent, systematic and significant bias in option pricing is a critical requirement of any model.
Poor out of sample fit of modern parametric option pricing models The fact that many modern parametric models provide inaccurate pricing out of sample (i.e., for data which were not used for parameter estimation) presents a major flaw.
Implausible Implied Parameters Some parameters implied by a modern parametric model fitted to a data set (e.g., skewness) may be nonsensical.
Arbitrage and Option Pricing The process by which "riskless profit" can be earned when certain pricing conditions do not hold.

KEY TERMS

Call Option: The right but not the obligation to purchase a stock (or financial instrument) at a pre-determined price at some time in the future.

Financial Future: The right and obligation to purchase an underlying financial instrument at a pre-determined price at some time in the future.

Modern Parametric Option Pricing Models: Those models that extend the Black–Scholes work and relax some of their assumptions in the hope of eliminating bias.

Non-Parametric Option Pricing Models: Pricing options using inductive or statistically oriented techniques.

Put Option: The right but not the obligation to sell a stock (or financial instrument) at a pre-determined price at some time in the future.

Stochastic Process: A mathematical description of the random movement of a stock or financial instrument such as a future.

Volatility: The most important input to the Black–Scholes model (a.k.a. standard deviation of the underlying asset price returns).

ENDNOTES

[1] Rational pricing refers to option pricing constraints that must be obeyed.

Complex Adaptive Enterprises

INTRODUCTION

In a world where the market, customer profiles and demands change constantly and the events in the global marketplace are unpredictable, it becomes increasingly difficult for an enterprise to sustain its competitive advantage. Under these conditions of uncertainty, complexity and constant change, it becomes very important for an enterprise to be able to learn from its experience and to adapt its behavior in order to constantly outperform its competitors. An enterprise that has these characteristics is a complex adaptive enterprise.

The interrelationships between resources in a complex adaptive enterprise and its global behavior within the marketplace can be numerous and mostly hidden, and can affect many different resources throughout the enterprise. One of the main challenges of the modern enterprise is to understand this complex web of interrelationships and to integrate this understanding into its business processes and strategies in such a way that it can sustain its competitive advantage.

BACKGROUND

The Chain of Sustainability

According to the resource-based theory, there are dynamic relationships between enterprise resources, the capabilities of the enterprise and the competitive advantage of the enterprise. The complex adaptive enterprise maintains a chain of sustainability that constantly evolves from the interactions between the individual resources and the interactions between the resources and the dynamically changing marketplace.

Resources or assets are the basic components in the chain of sustainability. Example resources are products, employee skills, knowledge, and so forth. These resources are combined into complementary resource combinations (CRCs) according to the functionality that these resources collectively achieve. CRCs are the unique inter-relationships between resources and are the source of competitive advantage in an enterprise, as these relationships cannot be duplicated by competitors. The behaviors of the CRCs define the strategic architecture of an enterprise, which is defined as the capabilities of an enterprise, when applied in the marketplace.

Social complexity refers to the complex behavior exhibited by a complex adaptive enterprise, when its CRCs are embedded in a complex web of social interactions. These CRCs are referred to as socially complex resource combinations (SRCs). In social complexity, the source of competitive advantage is known, but the method of replicating the advantage is unclear. Examples include corporate culture, the interpersonal relations among managers or employees in an enterprise and trust between management and employees. SRCs depend upon large numbers of people or teams engaged in coordinated action such that few individuals, if any, have sufficient breadth of knowledge to grasp the overall phenomenon.

Casual ambiguity refers to uncertainty regarding the causes of efficiency and effectiveness of an enterprise, when it is unclear which resource combinations are enabling specific capabilities that are earning the profits.

The Complex Adaptive Enterprise

A complex adaptive enterprise is an enterprise that can function as a complex adaptive system. A complex adaptive system can learn from and adapt to its constantly changing environment. Such a system is characterized by complex behaviors that emerge as a result of interactions among individual system components and among system components and the environment. Through interacting with and learning from its environment, a complex adaptive enterprise modifies its behavior in order to maintain its chain of sustainability.

It is impossible for an enterprise that cannot learn from experience to maintain its chain of sustainability. The learning process involves perception of environmental inputs, understanding the perceived inputs (making meaning out of these inputs), and turning this understanding into effective action (Senge, Kleiner, Roberts, Ross & Smith, 1994). The Soft Systems Methodology (Checkland, 2004) is a methodology that was developed that involves perception, understanding and acting in an enterprise.

Understanding Emergence

Self-awareness in a complex adaptive enterprise is instrumental in the maintenance of the chain of sustainability. Enterprises need to understand the interrelationships between the individual behaviors of the resources and the emergent behaviors of the CRCs and SRCs. This will enable the enterprise to understand its own social complexity and causal ambiguity.

Emergence, the most important characteristic of a complex adaptive enterprise, is the collective behavior of interacting resources in the CRCs. Emergence is the same as holism (Baas & Emmeche, 1997). Holism in a complex adaptive system means that the collective behaviour of the system components is more than the sum of the behaviours of the individual system components, for example, a flock is more than a collection of birds and a traffic jam is more than a collection of cars (Odell, 1998).

What does it mean to understand something? According to Baas & Emmeche (1997), understanding is related to the notion of explanation. All complex adaptive systems maintain internal models (Holland, 1995). These mechanisms are used for explanation and understanding.

The human mind is self-aware and capable of self-observation and self-interaction. Consciousness may be seen as an internal model maintained by the mind. In Minsky's *Society of Mind*, internal observation mechanisms called A-Brains and B-Brains maintain internal models consisting of hyperstructures called K-Lines. Each K-Line is a wire-like structure that attaches itself to whichever mental agents are active when a problem is solved or a good idea is formed (Minsky, 1988). Minsky describes how a system can watch itself, using its B-Brain.

Gell-Mann (1994) refers to the information about the environment of a complex adaptive system and the system's interaction with the environment as the "input stream" of the system. A complex adaptive system creates and maintains its internal model by separating "regularities from randomness" in its input stream (Gell-Mann, 1994). These regularities are represented using hyperstructures, which in turn constitute the internal model of the complex adaptive system. The observation mechanism of a complex adaptive system is responsible for the identification of regularities in its input stream, as well as for the progressive adaptation of the hyperstructures to include these regularities.

In the complex adaptive enterprise, the hyperstructures encode the knowledge of the enterprise, and are distributed throughout the enterprise. This knowledge belongs to one of the following component knowledge types:

- knowledge related to internal relationships within the company;
- knowledge related to products and services;
- knowledge related to business processes and business units;
- knowledge related to specific projects and project implementations;
- knowledge related to customers;
- knowledge related to the marketplace.

Component knowledge consists of both tacit and explicit knowledge. Tacit knowledge is usually defined as that which cannot be written down or specified. This knowledge is embedded within the interrelationships between the local behaviors of resources within the CRCs and the emergent behaviors of the CRCs. Knowledge, particularly tacit knowledge, is the most important strategic resource in an enterprise (April, 2002).

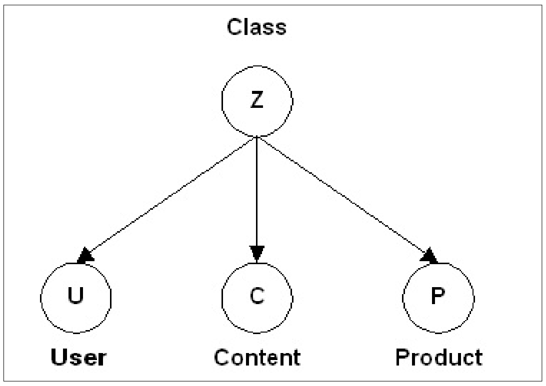
Bayesian Hyperstructures

Bayesian networks provide the ideal formalism to be used as hyperstructures in the complex adaptive enterprise. These networks can be used to encode beliefs and causal relationships between beliefs and provide a formalism for reasoning about partial beliefs under conditions of uncertainty (Pearl, 1988). These networks can be used to learn a probabilistic model of what the emergent effects are of certain interactions and behaviors in response to certain environmental states (the causes). Such a causal model can then be queried by an arbitration process to decide which action(s) are most relevant given a certain state of the environment.

A Bayesian network is a directed acyclic graph (DAG) that consists of a set of nodes that are linked together by directional links. Each node represents a random variable or uncertain quantity. Each variable has a finite set of mutually exclusive propositions, called states. The links represent informational or causal dependencies among the variables, where a parent node is the cause and a child node, the effect. The dependencies are given in terms of conditional probabilities of states that a node can have given the values of the parent nodes (Pearl, 1988). Each node has a conditional probability matrix to store these conditional probabilities, accumulated over time.

Figure 1 illustrates a simple Bayesian network, which we adapted from the user-words aspect model proposed by Popescul, Ungar, Pennock & Lawrence (2001). Our

Figure 1. A simple Bayesian network



network models the relationship between three observable variables, namely users (U), the contents of browsed web pages characterized in terms of concepts (C), products bought from these pages (P) and one hidden variable, namely the class variable (Z).

In Figure 1 above, the states of the hidden class variable Z are mined from historical data (observations of U, P and C). The class variable Z is the single cause influencing multiple effects (U, P and C). This probability distribution is called a naïve Bayes model or sometimes called a Bayesian classifier (Russell & Norvig, 2003).

Bayesian learning can be described as the "mining" of the structure of a Bayesian network and the calculation of the conditional probability matrices from history data. The data may be incomplete and the structure of the Bayesian network can be unknown.

Bayesian inference is the process of calculating the posterior probability of a hypothesis H (involving a set of query variables) given some observed event e (assignments of values to a set of evidence variables),

$$P(H \mid e) = \frac{P(e \mid H)P(H)}{P(e)}, \text{ where}$$

$P(H \mid e)$ represents the belief in H given e,

$P(e \mid H)$ represents the belief in e given H, and

$P(H)$ and $P(e)$ represent the beliefs in H and e respectively.

Bayesian inference is NP-hard (Pearl, 1988; Dechter, 1996). In order to simplify inference, Bayesian networks are simplified to trees or singly-connected polytrees. A tree is a DAG in which each node has only one parent (Pearl, 1988). A singly-connected polytree is a DAG in which the nodes can have multiple parents, but with the restriction that there is only one path, along arcs in either direction, between any two nodes in the DAG (Nilsson, 1998; Pearl, 1988).

SELF-AWARENESS AND SUSTAINABLE COMPETITIVE ADVANTAGE USING BAYESIAN AGENCIES

Adaptive agents are the basic building blocks of a complex adaptive system. The collective behavior of the agents, the interactions between the agents and the environment as well as the interactions between the agents themselves comprise a complex set of causal relationships.

We implement complex adaptive systems using Bayesian agencies that collectively implement Bayesian behavior networks. These networks are Bayesian networks that model the regularities in the input stream of a complex adaptive system. The nodes in a Bayesian behavior network are grouped into what we call competence sets, where each competence set has an associated set of actions that must be performed by the Bayesian agencies depending on the states of the nodes in the competence set. These actions are usually part of a business process or workflow in the enterprise.

Complex adaptive systems generate their internal models from re-usable building blocks (Holland, 1995). As an example, the quarks of Gell-Mann (1994) are combined into nucleons, nucleons are combined into atoms, atoms are combined into molecules, and so forth. It is essential that the knowledge in the internal model of the enterprise be represented using re-usable building blocks, in order for the enterprise to be able to function as a complex adaptive system.

Our Bayesian agencies consist of simple re-usable software components, distributed throughout the enterprise. There are two types of Bayesian agencies, namely belief propagation agencies and competence agencies. Belief propagation agencies consist of a collection of components, where each component can be one of three re-usable components, namely node components, link components and belief propagation agents. Collectively these simple components capture the knowledge throughout the enterprise by collectively implementing distributed Bayesian behavior networks. Each node component implements a Bayesian behavior network node. Each network link is implemented by a queue, together with a link component that participates in the synchronization of messages flowing to the child, or to the parent node via the queue. For each queue, a belief propagation agent is deployed that listens on that queue for messages from the child or parent node of the associated network link.

The belief propagation agents collectively perform Bayesian inference by localized message passing in response to the environmental evidence in order to update the beliefs of network nodes. The competence agencies use the beliefs of selected network nodes to determine if certain business components must be activated or not. Business components are re-usable components containing parts of business processes or workflow processes. Each competence agency monitors a set of constraints on the beliefs of a subset of nodes – the constraint set. If all the constraints in a constraint set are met, the competence agency can activate its associated business component.

Node components are deployed throughout the enterprise to collect evidence from disparate data sources within the enterprise or from external data sources. The Bayesian agencies incrementally learn from this experience.

The Bayesian agencies are observation mechanisms that enable the enterprise to be self-aware. Belief propagation agencies are connected to the real world. As soon as evidence is received from the environment, the belief propagation agents collectively perform Bayesian inference by using local message passing. The competence agencies inspect the beliefs of nodes and act upon these beliefs and possibly change the state of the environment, influencing the collective Bayesian inference of the belief propagation agencies.

The flexibility, adaptability and reusability of automated business processes (enterprise software) determine the ability of an enterprise to evolve and survive in the marketplace (Sutherland & van den Heuvel, 2002). The belief propagation agencies enable the re-usable business components in the competence agencies to be flexible and adaptable.

We have successfully implemented prototype Bayesian agencies using Sun's Enterprise JavaBeans™ component architecture. We developed prototype node and link components and belief propagation agents that are assembled into distributed Bayesian behavior networks, collectively performing Bayesian learning and Bayesian inference in singly-connected Bayesian behavior networks with known structure and no hidden variables.

FUTURE TRENDS

Future research will involve a full implementation of Bayesian learning, where Bayesian agents collectively and incrementally discover structure from data in the presence of known values for variables as well as in the presence of missing data. We will also complete the collective belief propagation capabilities of the Bayesian agencies in order to cope with multiply-connected Bayesian behaviour networks.

CONCLUSION

Our Bayesian agencies can be distributed throughout an enterprise, enabling it to function as a complex adaptive enterprise. These agencies will assist the enterprise to be self-aware by collectively modeling the complex interrelatedness of local behaviors of resources and emergent behaviors of CRCs, from which the enterprise's tacit knowledge, social complexity and causal ambiguity emerges – the source of its competitive advantage. The enterprise can then use this self-understanding to adapt its business processes and to formulate new knowledge or business strategies in response to the ever-changing marketplace in order to sustain its competitive advantage.

KEY TERMS

Bayesian Agencies: Agencies consisting of simple agents that collectively implement distributed Bayesian behavior networks. The agents are organized into agencies, where each agency activates one or more component behaviour depending on the inference in the underlying Bayesian behaviour network.

Bayesian Behavior Networks: Specialized Bayesian networks, used by the Bayesian agents to collectively mine and model relationships between emergent behaviours and the interactions that caused them to emerge, in order to adapt the behaviour of the system.

Bayesian Hyperstructures: Bayesian Behavior Networks are Bayesian hyperstructures that in turn constitute the internal model of the complex adaptive system.

Causal Ambiguity: Refers to uncertainty, by competitors, regarding the causes of efficiency and effectiveness of a company, when it is unclear which resource combinations are enabling specific competitive capabilities that are earning the company profits.

Chain of Sustainability: An evolving, dynamic and matched mix between company resources (arranged in value-generating combinations) and the changing marketplace that gives the company a competitive edge.

Competence Sets: The nodes in a Bayesian behavior network are grouped into competence sets, where each competence set has an associated set of actions that must be performed by the Bayesian agencies depending on the states of the nodes in the competence set.

Competitive Advantage: A company is said to have a competitive advantage when, based on its strategic architecture and complementary resource combinations (CRCs), it is able to implement a strategy that generates returns and benefits in excess of those of its current competitors – who simultaneously are implementing strategies, similar or otherwise – because of the perceived value in the marketplace. The definition therefore also depends on what the company, its management and its stakeholders, define as what the required returns and benefits should be (because even though many would list it as financial, clearly this does not apply to all companies, i.e., an advantage could be something other than financial). One could reasonably expect, though, that companies within similar industries would define similar variables as the required returns and benefits. A company is said to have a sustained competitive advantage when it is implementing a value-creating strategy, which generates returns and benefits at a level not enjoyed by current competitors and when these other companies are unable to reach an "equilibrium level" with the company enjoying the advantage. In this sense, the definition of sustained competitive advantage adopted here does not imply that it will "last forever," and does not depend upon the period of time during which a company enjoys a competitive advantage (rather, the equilibrium level is critical in this definition).

Complementary Resource Combinations (CRCs): Are not factor inputs, but are complex combinations of interrelated configurations, or networks of assets, people, and processes that companies use to transform inputs to outputs. Many of these configurations are a blend of "hard" tangible resources and "soft" intangible resources which simply cannot be recreated by another company. Finely honed CRCs can be a source of competitive advantage.

Resources: Also known as "assets", come in many forms, from common factor inputs that are widely available and easily purchased in arms-length transactions, to highly differentiated resources, like brand names, that are developed over many years and are very difficult to replicate. Resources come in two main forms: "tangible resources", which are the easiest to value, and often are the only resources that appear on a company's balance sheet. They include real estate, production facilities and raw materials, among others. Although tangible resources may be essential to a company's strategy, because of their standard nature they rarely constitute a source of competitive advantage; and "intangible resources" - include such things as company reputations, brand names, cultures, technological knowledge, know-how shared among employees, patented process and design, trademarks, accumulated learning and/or knowledge, as well as experience. These resources often play important roles in competitive advantage (or disadvantage) and company value. Intangible resources also have the important property of not being consumed in usage.

Social Complex Resource Combinations (SRCs): Depend upon large numbers of people, or teams, engaged in coordinated action such that few individuals, if any (both outside the company, as well as inside the company), have sufficient breadth of knowledge to grasp the overall phenomenon.

Social Complexity: Is when the source of advantage is known, but the method of replicating the advantage is unclear, e.g., corporate culture, the interpersonal relations among managers in a company, or trust between management and labor.

Strategic Architecture: Refers to a company's capabilities, when applied in the marketplace.

Component-Oriented Approach for Designing Enterprise Architecture

Ajantha Dahanayake
Delft University of Technology, The Netherlands

INTRODUCTION

One of the main challenges enterprises face today is how to manage complexity of systems being developed, effectively utilize the power of the Internet, and be able to rapidly adapt to changes in both technology and business. The new paradigm of component-based development (CBD) has been introduced as an excellent solution for building complex Internet-enabled enterprise information systems (Brown, 2000; Szyperski, 2002). The basic idea of CBD originates from the strategy successfully applied in other engineering disciplines that a system developed from components is more flexible and easier to develop. CBD provides higher productivity in system development through reusability, more effective system maintenance, higher quality of solutions and the possibility for parallel work. Moreover, it provides better system adaptability through replaceability of parts, localization and better control of changes, system scalability, and the possibility of using legacy assets.

CBD has often been presented as a new silver bullet for complex, enterprise-scale system development in the Internet age (Udell, 1994). However CBD inherits many concepts and ideas from the earlier encapsulation and modularization, "divide-and-conquer" initiatives in information technology (IT). The NATO Conference in 1968 recognized that producing software systems should be treated as an engineering discipline providing system assembling from software components (McIlroy, 1968). Parnas (1972) defines concepts and requirements for decomposing system into modules. These principles of separation of concerns, encapsulation, and plug-and-play building blocks have been applied in different ways through the concepts of functions, subroutines, modules, units, packages, subsystems, objects, and now components.

The CBD paradigm has been first introduced at the level of implementation and deployment. CBD middleware technologies, such as CORBA Components (Siegel, 2000), Sun's Enterprise Java Beans and Microsoft's COM+/.NET, are now used as standards for the development of complex enterprise distributed systems. While the technology solutions are necessary in building the system, one cannot simply program and deploy components using a component middleware without any prior plan to follow from business requirements towards implementation. For the effective use of the CBD paradigm and in order to gain real benefits of it, the component way of thinking must be applied in earlier phases of the development lifecycle, such as system analysis and design. CBD methods and approaches proposed so far do not provide a complete and consistent support for various component concepts. Components are often treated as implementation concepts—packages of binary or source code that can be deployed over the network nodes. During the system analysis and design, components, if used, are often represented as larger-grained business objects. This suggests using components mainly at the system implementation and deployment as software code packages, while still following the principles of object-oriented modeling, analysis and design. At the same time, the role and usefulness of the component concept as a bridge between business and technology issues have not been truly recognized yet. Components can be identified very early in the system lifecycle, namely derived from business requirements, and then used as central artifacts of the whole development process. In this way, the whole process would be structured and organized around the same set of component concepts. That can provide a necessary alignment and traceability from business services to implementation assets. The benefit from the separation of concerns using components will be gained at all levels of system development.

BACKGROUND

Component technologies are now widely used in the development of complex Internet-enabled systems. First, VBX controls, DCOM/COM, CORBA and Java Beans, and now COM+/.NET, CORBA Components and Enterprise Java Beans (EJB) represent the standard component-based implementation solutions. The physical perspective on components as binary packages of software is still predominant. The standard unified modeling language (UML) treats components as packages of binary code and uses them in describing system implementation through component and deployment diagrams (Booch, Rumbaugh, & Jacobson, 1999). Components in UML represent physical things that can be deployed over network nodes. The Catalysis approach defines a component as a package of software code as well as other software artifacts (D'Souza & Wills, 1999). According to Szyperski, a software component is a unit of composition with contractually specified interfaces and explicit context dependencies (Szyperski, 2002). A software component can be deployed independently and is subject to composition by third parties. Gartner Group (1997) defines a runtime software component as a dynamically bindable package of one or more programs managed as a unit and accessed through documented interfaces that can be discovered at runtime. Definition of a business-oriented component concept can be found in Herzum and Sims (2000), where a business component is the software implementation of an autonomous business concept or business process, and in Andersen Consulting (1998), where a business component is a means for modeling real-world concepts in the business domain. When introducing components, the question about similarities and differences between objects and components are naturally arising. According to Udell (1994), components represent a new silver bullet for system development in the Internet age, while objects have failed to provide higher level of reusability. In the UML, components are nothing else than larger-grained objects deployed on the network nodes. In Szyperski (2002), a component comes to life through objects, and therefore, it would normally contain one or more classes, as well as traditional procedures and even global variables. In a debate over this topic (Henderson-Sellers, Szyperski, Taivalsaari, & Wills, 1999) granularity has been seen as the main issue in distinguishing components and objects. According to Catalysis, components are often larger-grained than traditional objects, and can be implemented as multiple objects of different classes.

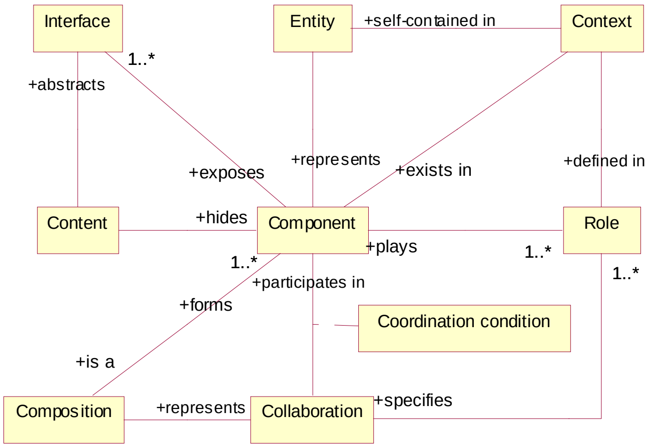
The academia and industry have just started to recognize the importance of new CBD methods, processes, techniques and guidelines. The methods and approaches are often greatly influenced by the object-oriented concepts, constructs and principles, dictated by the use of the standard UML. The Rational Unified Process (RUP) (Jacobson, Booch, & Rumbaugh, 1999), Catalysis, and the Select Perspective (Allen & Frost, 1998) can be considered as the first generation of the CBD methods. The business component factory (BCF) (Herzum & Sims, 2000), the UML components approach (Cheesman & Daniels, 2000), and the KobrA approach (Atkinson et al., 2002) represent the second generation of the CBD methods. These methods are more focused on components concepts than previous ones. They provide a comprehensive support to CBD throughout the system lifecycle, and represent remarkable achievements in the field. On the other hand, there are certain shortcomings. The analysis and evaluation of CBD methods can be found in Dahanayake, Sol, and Stojanovic (2003).

SERVICE-BASED COMPONENT CONCEPT

Components have been so far used mainly as implementation artifacts. However, the components are equally useful and important if used as modeling and design artifacts for building the logical architecture of the system (Stojanovic & Dahanayake, 2002). The essence of the component approach is the explicit separation between the outside and the inside of the component. This means that only the question WHAT is considered (what useful services are provided by the particular building block to the context of its existence?) not the HOW (how are these services actually implemented?). A component fulfills a particular role in the context, by providing and requiring services to/from it. A component has a hidden interior and exposed interface. It participates in a composition with other components to form a higher-level behavior. At the same time, every component can be represented as a composition of lower-level components. Well-defined behavioral dependencies and coordination of activities between components are of a great importance in achieving the common goal. The metamodel of the core component concepts is shown in Figure 1.

According to the role(s) a component plays in the given context, it exposes corresponding behavior by providing and requiring services to/from its context, or by emitting and receiving events. The services a component provides and requires form the basic part of its contract. Services can be of different types such as performing computation, providing information, communication with the user, and so forth. They are fully specified in a contract-based manner using pre-conditions, post-conditions and other types of constraints. A component must handle, use, create or simply be aware of certain information to provide its services properly. In order to be used in a different context or to be adaptable to the changes in its context, a component can possess configuration parameters that can adapt the component according to new requirements coming from the outside. A component can possess a set of non-functional parameters that characterize the "quality" of its behavior. Figure 2 shows the component specification concepts.

Figure 1. Core component concepts



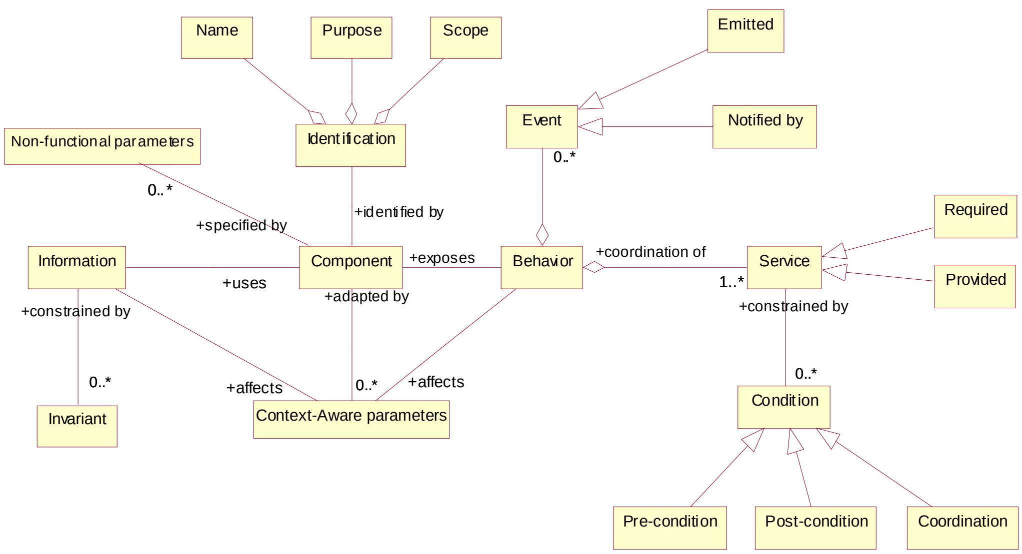
BUSINESS-DRIVEN COMPONENT ARCHITECTURE

In order to manage complexity and ensure completeness in the specification of components and component-oriented system architecture we use the ISO standard reference model of open distributed processing (RM-ODP) as an underlying idea (ODP, 1996). RM-ODP defines a framework for specifying architectures for distribution, interoperability and portability of applications based on object-oriented technology. The RM-ODP specification of a system consists of five different specifications, corresponding to five separate, but related and consistent viewpoints – enterprise, information, computational, engineering, and technology. Based on ODP viewpoints, we propose the following three architectural models:

- business architecture model (BAM);
- system architecture model (SAM); and
- distribution architecture model (DAM).

These different but consistent and correlated architectural models provide us a way of separation of concerns through different architectural views (Stojanovic, Dahanayake, & Sol, 2001). The relation between our architectural models and the RM-ODP viewpoints, as well

Figure 2. Component specification concepts

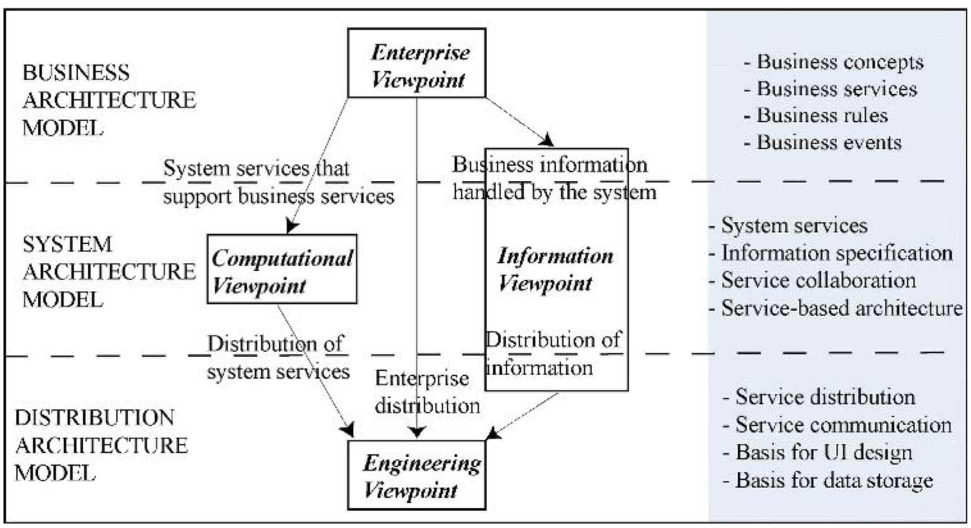


as the main relations between the models are shown in Figure 3. Our main idea is to incorporate the component concept into each of the RM-ODP viewpoints. In this way, we can define component-oriented viewpoints on the system, completely focused on the component concept and organized around it, as powerful means for specifying component architecture. The same consistent set of component concepts used in different viewpoints represents the point of consistency and integration between them.

Proposed models are defined as following:

- *Business architecture model (BAM)* specifies the behavior of the system in the context of the business for which it is implemented. It represents business context and processes in which the system should participate, services that must be offered by the system to fulfill business purposes, business domain concepts and information that must be handled by the system, and business rules that must be satisfied and supported by the system. Defined services are the basis for identification of higher-level business components as we have seen in the previous section. Each business component, as well as their collaboration, must be specified in the business architecture model, through the common set of component properties. Business domain conceptual information should be defined and cross-referenced by the specification of business services offered by components. This shows how conceptual information types are used and handled by particular business components in providing services. Each business component is typically a collaboration of several system components. This means that identified business components are used as an entry for defining business-driven system architecture and correspondent system components.
- *System architecture model (SAM)* defines the structure of the system in terms of configurations of system services and the interactions among them to provide necessary business services related to the business requirements on the system. This model defines information that should be handled by the system, rules for information dynamics, and information processing that should be performed by the system. SAM takes higher-level components identified in the previous model as an input. This model further specifies system components that in collaboration realize required business services. Components of different granularity are defined and fully specified. This model specifies also information managed by the system, that is, by each of its components. Collaboration of components inside the system architecture is specified as a potential for future distribution of components. System components provide lower grained services that in collaboration actually realize business services. Each system service component actually represents one or a collaboration of several distributed components.
- *Distribution architecture model (DAM)* specifies a distributed infrastructure of the system in terms of distribution of system services, their allocation and communication over the tiers in the n-tier architecture. This model defines in what way information is distributed over the network nodes, as a basis for future data storage and user interface design. It

Figure 3. Proposed architecture models and RM-ODP viewpoints



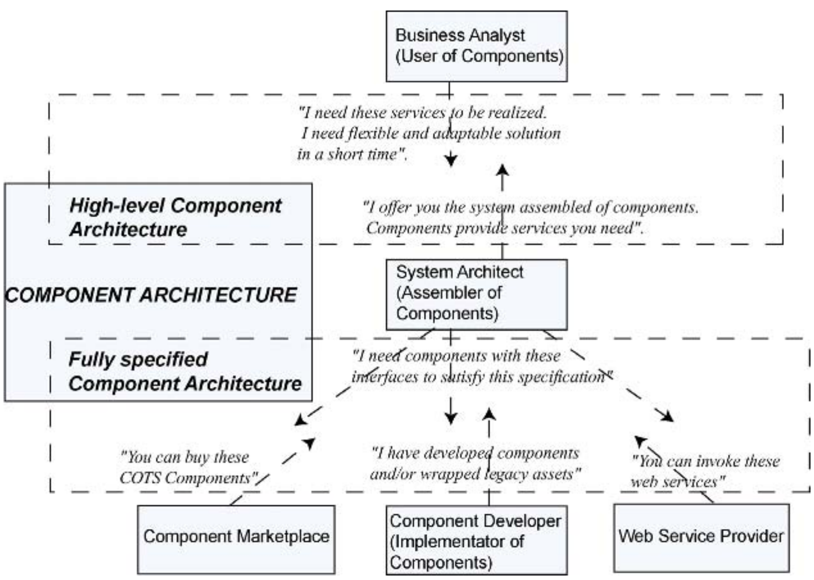
describes also the way of eventual distribution of the enterprise, for example in the case of so-called virtual enterprises. DAM uses collaboration of components inside the specified architecture as a starting point, and uses particular distributed settings to precisely define complete component-based multi-tier system architecture. Distributed components are actually system components in the distribution context. Typically business and system components can have user-interface, business logic, and permanent storage facets (one, two or all three of them), so that they can be represented as a collaboration of their subcomponents (i.e., distributed components) attached to different architecture tiers.

FUTURE TRENDS

The approach presented in this article is in line with the current OMG strategy in establishing the model driven architecture (MDA) (OMG-MDA, 2004). The MDA suggests first creating a high-level UML description of how applications will be structured and integrated, independently of any implementation details (Platform Independent Model"PIM), then moving toward more constrained UML design according to a chosen platform (Platform Specific Model"PSM), and, finally, converted into language code for a specific platform. Our service-based component approach actually aims at fully specified component-oriented PIM that can be easily mapped first to component-oriented PSM and then to a particular component middleware. In this way, components are not only implementation units but also the main artifacts in system analysis and design. The component concept is the focus of the whole development process and the point of integration and consistency between different perspectives, viewpoints and abstraction levels of the system.

The approach presented here represents a paradigm shift from components as objects to components as services. Defining components as basically service managers provides both business and IT people with a powerful and easily understandable concept for representing their views on the enterprise distributed system. Thus, a business analyst represents a system through the set of collaborating business-oriented services, a system architect specifies this service assembly in the form of the component system architecture, while a software developer provides a realization of these services using lower-level software artifacts. The approach can be effectively applied for modeling, analysis and design of systems using a new paradigm of Web services (W3C, 2004). Web services are self-contained, self-describing, modular units providing a location independent business or technical service that can be published, located and invoked across the Web. From a technical perspective, a Web service is essentially an extended and enhanced component interface constructs. Web services are natural extension of component thinking and further convergence of business and tech-

Figure 4. A role of component architecture in a dialog between actor roles



nology. By using the approach presented here, Web services become just one way of possible realization of the service-based component specification. In this way, the approach provides a smooth transition from the standard object-oriented way of thinking to the advanced Web-service paradigm.

CONCLUSION

Defined component architecture actually represents a point of negotiation between different actors in component-based system development (Figure 4). It provides a clear connection to the business processes and business domain that are the basis for the requirements of the system being developed. At the same time, this architecture provides an easy and effective mapping into appropriate implementation architecture of the system.

The higher-level component architecture, not overloaded with unnecessary details, can be used for the purpose of negotiation between the business user as the user of component system and the system architect as the assembler of components. At this level, it should be decided how business requirements should be mapped into the system solution in the best and most effective manner. It is possible to exactly determine what system parts are responsible for satisfying particular business needs, and therefore be able to replace/improve/change those parts if business is changed. Business users can easily recognize and articulate their needs through the business component architecture that hides implementation details from them.

On the other hand, the completely specified component architecture can serve as a point of negotiation between a system architect on one side, and a component developer, a provider of COTS components, or a provider of Web services, on the other side. At this level, the decision about an appropriate implementation solutions for components specified in the architecture should be made. The way of concrete realization of the component specification is not important as long as the contract between the component and its context is completely fulfilled.

KEY TERMS

Architecture: The fundamental organization of a system, embodied in its components, their relationships to each other and the environment, and the principles governing its design and evolution (ANSI/IEEE Standard 1471-2000).

Architecture Viewpoint: An abstraction of a set of concerns on a system derived by using a set of concepts and rules of structure (RM-ODP).

Component: An encapsulated, autonomous, service-based software unit that delivers useful services through the well-specified interface to its environment.

Component-Based Development: A software development approach where all aspects and phases of the development lifecycle are based on components.

Component Interface: The behavior of a component along with constraints at a subset of component's interactions, data types used in exposing the behavior, configuration and quality parameters of the behavior.

Component Middleware: A commercially available component technology and its associated connectivity capabilities; includes, for example, CORBA components, EJB and COM+/.NET.

Model: Represents the system from a set of concerns. A model can be informal, semi-formal and formal. A system is typically represented by a set of models, each addressing some particular area of concern.

Composition in Object-Relational Database

J. Wenny Rahayu
La Trobe University, Australia

INTRODUCTION

Object-Relational Database (ORDB) is increasingly popular as the database storage. Its popularity is based on its ability to capture the object-oriented modeling semantic and the maturity of relational implementation.

Many works have proposed the design method for ORDB. The design includes different data structures and relationships. One type of relationship is *composition*. It is not the same as aggregation. While aggregation is identified as a relationship in which a composite object ("whole") consists of other component objects ("parts") (Rumbaugh et al., 1991), composition has two additional constraints mentioned below.

- *Non-shareable*. This is the case when one class can only be the part of one and only one other class. Treating this type as aggregation enables other classes to own the "part" class and thus, violate the conceptual semantic.
- *Existence-dependent*. This is the case when one class can only exist with the existence of another class. Treating this as aggregation will enable a "part" class to remain in existence even though the "whole" class has been removed.

These reasons have motivated us to differentiate between the composition and the aggregation. This work will focus to preserve the composition hierarchy.

In ORDB, composition can be implemented as the attribute of row type. Row type is the constructed data type that contains a sequence of attribute names and their data types (Fortier, 1999; Melton, 2002). Row type attribute will be fully dependent and exclusive to the object that owns it.

This article aims to propose models for preserving a composition in ORDB, and in particular, we introduce the use of row type. We also propose the main queries required for the composition hierarchy.

BACKGROUND

In this section, we show a brief overview on SQL row type. We also show the related work on composition relationship mapping in object-relational database.

Row Type: An Overview

Before we start using row type in ORDB, we will briefly discuss this data type. Row type is one data type available in the Structured Query Language (SQL). This language was introduced in 1970 and has emerged as the standard language for Relational Database (RDB) (Melton, Simon, & Gray, 2001). It is used for database definition and manipulation.

Along with the establishment of RDB and the emergence of ORDB, SQL has undergone many changes, one of which is the additional data types. It is required to accommodate complex data structures. One of the data type is Row Type.

Fortier (1999) and Melton (2002) define row type as constructed type that contains a sequence of attribute names and their data types. This type is actually not a new data type in the database system. It has been used even since the legacy data model era (CODASYL Database Task Group, 1971).

After the emergence of relational model, there is also a data model that is aimed at capturing the nested structure such as row type in relations. The model is called Nested Relational Model (Jaeschke & Schek, 1982; Roth & Korth, 1987). Nevertheless, traditional relational model still dominates the database community. Even until recently there is no commercial DBMS which has chosen to implement the Nested Relational Model even in its original form (Elmasri & Navathe, 2002).

Not until the release of SQL 1999, relational model recognizes row type as one data type that can enrich its data structure (Fortier, 1999). In SQL4, it is even possible to have varying levels of row type (Melton, 2002). It has become a powerful means to capture real world problems that can rarely be represented by a simple flat table. General syntax for the SQL4 row type is shown as follows:

SQL4 Row Type

CREATE TABLE <table schema>
($attr_1$ data type
CONSTRAINT $attr_1$ **PRIMARY KEY**, ...,
$attr_i$ **ROW** ($attr_{i1}$ data type,...,
$attr_{ij}$ data type));

Existing Mapping Methods for Composition in ORDB

Mapping method can be defined as a formal process of transforming a schema level (such as conceptual schema) to another schema level (such as logical schema) in a database system. A mapping method works effectively if the schema result is complied with the requests. If the result schema does not preserve all semantics of the requests, the mapping method is not effective.

Some works on mapping methods have tried to preserve composition hierarchy in ORDB. However, no work utilizes the row data types that were introduced by SQL 1999 (Fortier, 1999) and is enriched in SQL4 (Melton, 2002). Very often the "part-of" relationship is either flattened or split into an entirely separate table (see Figure 1).

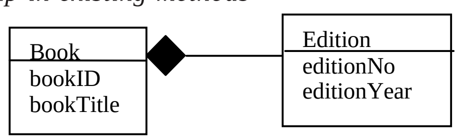
The most common practice of implementing composition relationship is by separating the "part" component in another table with composite PKs. This practice only uses object-oriented paradigm for conceptual modeling. The implementation is purely relational (Ambler, 1997; Hsieh & Chang, 1993).

Marcos, Vela, Cavero and Caceres (2001) propose a design of aggregation and composition in ORDB. In the logical and the implementation level, they use the nested table for the "part" component. Two problems arise. Firstly, nested table is a vendor-specific feature. It is not recognized in SQL standard. Secondly, the implementation of nested table cannot represent the composition type because actually the "part" component is stored in a separate table.

Rahayu and Taniar (2002) use two different ways of preserving this type of relationship. It uses index clustering for relationships that requires ordering semantics, and nested tables for the one which does not. However, this work can only be applicable for regular aggregation relationship.

We find that the existing works either have not preserved the composition semantic or have preserved it as

Figure 1. Composition relationship in existing methods



Composition flattened into separate tables

a usual aggregation. Therefore, we aim to propose new methods that can preserve the composition hierarchy in ORDB.

PROPOSED MAPPING METHODS

We propose the mapping methods of composition relationship into ORDB using row type. Our mapping method aims to transform the composition relationship into ORDB tables.

To model the conceptual schema, we use the Unified Modeling Language (UML) notation (Booch, Rumbaugh & Jacobson, 1999). It is a powerful notation to specify, visualize, and construct conceptual schema. Using UML, we can distinguish aggregation and composition easily. For example, in Figure 2a, composition is shown by a full diamond shape symbol. If it is an aggregation relationship, the diamond shape symbol will not be filled.

We map the "whole" class as the table and the "part" class as the row type attribute. For multiple-row, we use multiset data types (Melton, 2002). Other types of collection are also possible depending on the requirements for ordering and duplication semantic.

This work has increased the usage of ORDB for different database domains. In Pardede, Rahayu, and Taniar (2004), a subset of our proposed mapping methods has been used to accommodate XML data storage. It shows the utility and the practical importance of the work.

Single Row Composition

If the "part" class of the composition is single, we can map the class as a single row (see Figure 2a).

Rule1: For two classes namely C_1 and C_2 with elements/attributes (A,B) and (M,N) respectively, if C_1 is composed by at most one C_2, implement C_2 as a single row attribute of table C_1. Transformation result is:

$$\text{Table } C_1 \, (A, B, \overset{1}{\underset{0}{Row}} \; C_2 \, (M, N)).$$

Example 1: Class AUTHOR is composed by at most one type ADDRESS (see Figure 2b). The composition type will be mapped into a single row attribute in ORDB table. The transformation into ORDB is shown in the following:

```
CREATE TABLE Author
(AuthorID CHARACTER VARYING(20)
 CONSTRAINT authorid_pk PRIMARY KEY,
 AuthorName CHARACTER VARYING(2),
 Address ROW (Street CHARACTER VARYING(50),
City CHARACTER VARYING(30),
Country CHARACTER VARYING(5)));
```

The proposed method has captured the real semantic of composition hierarchy. In ORDB, the "part" class is physically implemented inside the "whole" class. By doing this, we avoid another class sharing the particular "part" class (non-shareable constraint). We also ensure that on removal of the "whole" class, we remove all "part" classes that are defined inside it (existence-dependent constraint).

In Example 1, the *address* data has a composition relationship to the *author*. It means that the *address* can only be attached within the *author* data and its existence is dependent on the *author* data.

Multiple Row Composition

If the "whole" class can have more than one "part" class of the same type, we use a multiple row (see Figure 3a).

Figure 2. Composition for single row

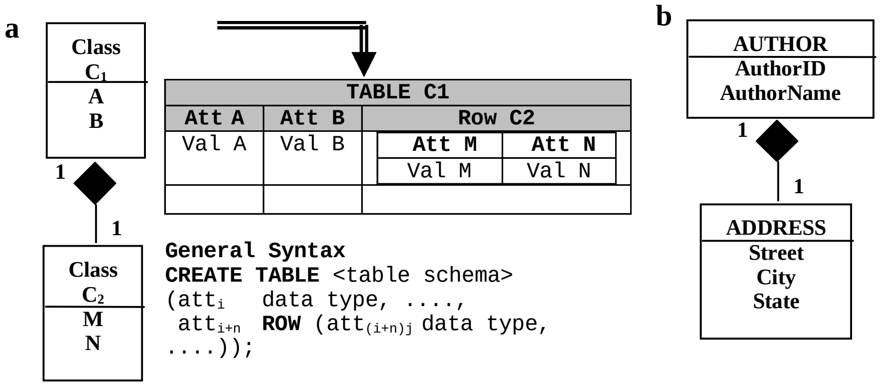

Figure 3. Composition for multiple row

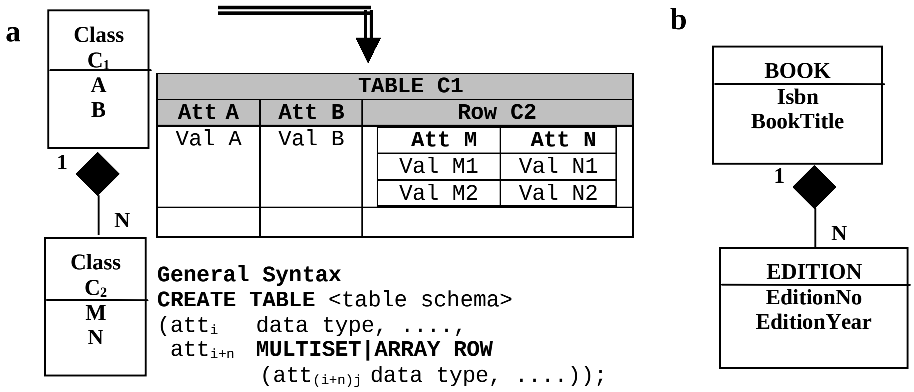

Figure 4. Composition for multilevel row

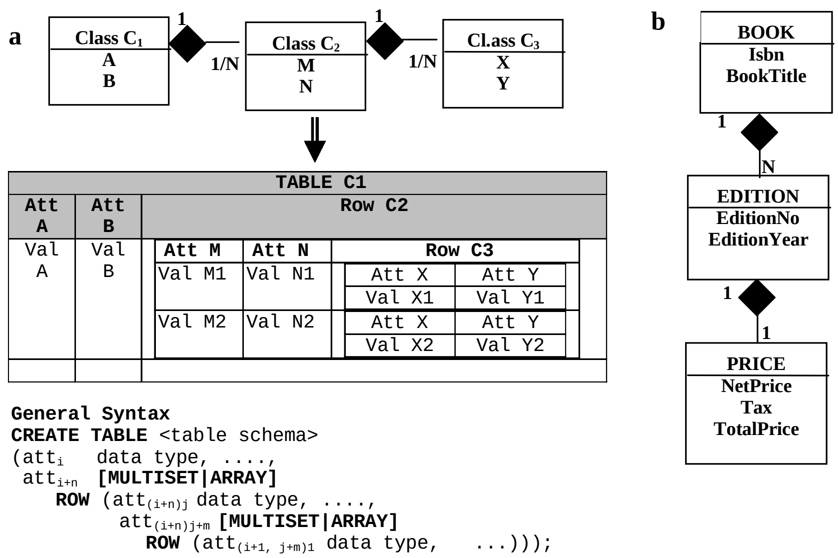

Rule 2: For two classes namely C_1 and C_2 with elements/attributes (A,B) and (M,N) respectively, if C_1 can be composed by more than one C_2, implement C_2 as a multiple row attribute of table C_1. Transformation result is:

$$Table\ C_1\ (A, B, \overset{n}{\underset{0}{Row}}\ C_2\ (M, N))$$

Example 2: Class BOOK can be composed by more than one class EDITION (see Figure 3b). The composition class will be mapped into a multiple-row attribute in ORDB table. The transformation into ORDB is shown in the following:

CREATE TABLE Book
(Isbn CHARACTER VARYING(5)
CONSTRAINT isbn_pk PRIMARY KEY,
BookTitle CHARACTER VARYING(50),
Edition MULTISET (**ROW** (EditionNo NUMBER,
EditionYear NUMBER)));

This example shows that EDITION class is mapped as a collection of row attribute in table *Book*. If we remove a *book* details, all details of the book *edition* will also be removed.

Multilevel Row Composition

In ORDB, supported by SQL4, we can have a row inside another row attribute. The data structure will be more complex than the flat relationship in a conventional model, but sometimes it resembles the real world problem.

If the "part" class of the composition can be composed by other "part" class, we use multi-level row (see Figure 4a).

Rule 3: For three classes namely C_1, C_2 and C_3, with elements/attributes (A,B), (M,N), and (X, Y) respectively, if C_1 is composed by C_2 and C_2 is composed by C_3, implement the last two types as a multi-level row attribute of C_1. Transformation result is *Table* $C_1(A, B, \underset{0}{\overset{1/n}{Row}}\ C_2(M, N, \underset{0}{\overset{1/n}{Row}}\ C_3\ (X, Y)))$

Example 3: Continuing Example 2, now class EDITION can be composed by at most one class PRICE (see Figure 4b). The composition class will be mapped into a multi-level row attribute in ORDB table.

```
CREATE TABLE Book
(Isbn CHARACTER VARYING(5)
 CONSTRAINT isbn_pk PRIMARY KEY,
 BookTitle CHARACTER VARYING(50),
 Edition MULTISET
(ROW (EditionNo NUMBER,
EditionYear NUMBER,
Price ROW (NetPrice DECIMAL(3,2),
Tax DECIMAL(3,2),
TotalPrice DECIMAL(3,2)))));
```

In this example, the class PRICE is mapped as *price* row attribute inside *edition* row attribute. And we have *edition* as the row attribute of *Book* table. If we remove a *book,* all details of the *book edition* and its price will also be removed.

COMPOSITION QUERIES

Our previous section describes the proposed methods for preserving composition in ORDB using row types. This section shows how the queries can be performed in the data structures.

We describe two type of queries namely *part queries* and *whole queries*. Part query is a query used to retrieve the information of "part" classes with selection predicates originated at the "whole" class. Whole query is a query used to retrieve information of "whole" class with selection predicates originated at the "part" classes.

Single Row Composition Query

Part query and whole query general syntax for single row composition is shown as follows. SQL 1999 provides double dot notation (Fortier, 1999) to specify a subpart of a table such as row type element.

Part Query:

```
SELECT <alias1..”part”_class_attributes>
FROM <“whole”_class_table alias1>
WHERE <alias1.”whole”_class_attribute = &input_class_selection_predicates>
```

Whole Query:

```
SELECT <alias1.”whole”_class_attributes>
FROM <“whole”_class_table> alias1
WHERE <alias1..”part”_class_attribute = &input_class_selection_predicates>
```

An example of a part query is to retrieve the street and the city of a given author id (e.g., AuthorID = 'RE01'). The SQL statement for this query is shown in the following:

```
SELECT A..street, A..city
FROM Author A
WHERE A.AuthorID = ‘RE01’;
```

An example of a whole query is to retrieve an author name who lives in Melbourne, Australia. The SQL statement for this query is shown in the following:

```
SELECT A.AuthorName
FROM Author A
WHERE A..city = ‘Melbourne’
AND A..country = ‘Australia’;
```

Multiple Row Composition Query

Part query and whole query general syntax for multiple row composition is shown as follows. TABLE keyword is used to treat collection types such as multiset as a table, allowing querying in the same way that any base table is accessed.

Part Query:

```
SELECT <alias2..”part”_class_attributes>
FROM <“whole”_class_table alias1, TABLE(alias1.”part”_class_name) alias2>
WHERE <alias1.”whole”_class_attribute = &input_class_selection_predicates>
```

Whole Query:

```
SELECT <alias1.”whole”_class_attributes>
FROM <“whole”_class_table alias1,
```

TABLE(alias1.”part”_class_name) alias2>
WHERE <alias2..”part”_class_attribute = &input_class_selection_predicates>

An example of a part query is to retrieve the edition details of a given book title (e.g., BookTitle = ‘Database Systems’). The SQL statement for this query is shown in the following:

SELECT E..EditionNo, E..EditionYear
FROM Book B, TABLE(b.edition) E
WHERE B.BookTitle = ‘Database Systems’;

An example of a whole query is to retrieve the book title of given edition (e.g., EditionNo = ‘5’) and published after 2002. The SQL statement for this query is shown in the following:

SELECT B.BookTitle
FROM Book B, TABLE(b.edition) E
WHERE E..EditionNo = 5
AND E..EditionYear > 2002;

Multilevel Row Composition Query

As we know, multi-level row is formed by more than one single row and/or multiple row attribute. Therefore, the general syntax is really dependent on the combination of the row in different levels. For example, if the first level of row is multiple and the second level is a single row, the general syntax is as follows.

Part Query:
SELECT <alias2..”part2"_class_attributes>
FROM <“whole”_class_table alias1, **TABLE**(alias1.”part1"_class_name) alias2>
WHERE <alias1.”whole”_class_attribute = &input_class_selection_predicates>
AND <alias2..”part1"_class_attribute = &input_class_selection_predicates>

Whole Query:
SELECT <alias1.”whole”_class_attributes>
FROM <“whole”_class_table alias1, **TABLE**(alias1.”part2"_class_name) alias2>
WHERE <alias2..”part1"_class_attribute = &input_class_selection_predicates>
AND <alias2..”part2"_class_attribute = &input_class_selection_predicates>

An example of a part query is to retrieve the total price of a given book title (e.g., BookTitle = ‘Database Systems’) and a specific edition number (e.g., EditionNo = 5). The SQL statement for this query is shown in the following:

SELECT E..TotalPrice
FROM Book B, TABLE(b.edition) E
WHERE B.BookTitle = ‘Database Systems’
AND E..EditionNo = 5;

An example of a whole query is to retrieve the book title of given maximum price $50 and oldest edition accepted (e.g., Edition No = 3) and published after 2002. The SQL statement for this query is shown in the following:

SELECT B.BookTitle
FROM Book B, TABLE(b.edition) E
WHERE E..EditionNo > 2
AND E..TotalPrice < 50;

FUTURE TRENDS

In the future, we will require database storage that can capture the semantic of the applications with a high level of correctness. This article demonstrates how composition semantics should be distinguished from the aggregation semantic. We expect future works utilizing many new SQL data types to accommodate different semantic constraints.

At the time of writing, the queries for row components are not sophisticated since we have to treat the row components as a table. In the future, the SQL standardization body will need to enable users to perform a direct query of the row components.

Finally, more applications are expected to use row data type. So far, row data type is typically used for single row composition (such as address attribute). This article has demonstrated how this data type can be applicable for more complex structures.

CONCLUSION

It is evident that the previous works on ORDB transformation have not captured the semantic of composition in their mapping results. It has limited the usage of ORDB in some database problems, especially those that require specific relationship constraints to be met.

In this article, we have shown how the composition relationship can be preserved in the implementation using ORDB. We propose the usage of single-row, multiple-row, and multi-level rows for different cardinality and different levels in the composition hierarchy. We also provide two main important queries for the composition hierarchy, the part queries and the whole queries.

Unlike other works in composition transformation, our method preserves the "part" component as the part of the "whole" component. By doing this, we maintain the non-shareable and existence dependent constraints from the conceptual level.

Finally, this work provides general methods for ORDB. It can be used for any database domain that uses ORDB for its storage solution. A subset of this work has been implemented for XML documents storage.

KEY TERMS

Aggregation: A relationship in which a composite object ("whole") consists of other component objects ("parts").

Composition: A specific form of an aggregation. It is a relationship in which a composite object consists of non-shareable objects, and the latter are existence-dependent to the former.

Mapping Method: A formal process of transforming a schema level (such as conceptual schema) to another schema level (such as logical schema) in a database system.

Object-Relational Database: Database that is developed using object-oriented concept and is implemented in relational environment. This database was introduced in the 90s and since then has been widely used for database applications.

Part Query: Query to retrieve the information of "part" classes with selection predicates originated at the "whole" class.

Row Type: Constructed data type that contains a sequence of attribute names and their data types.

Structured Query Language (SQL): A standard interactive and programming language for getting information from and updating a database. It was developed by IBM in the mid-1970s for relational database management systems.

Unified Modeling Language (UML): A notation to specify, visualize, construct real-world objects. It is a standard modeling technique for object-oriented design methodology. It is also frequently used for object-relational database since this data model has object-oriented features.

Whole Query: Query to retrieve information of "whole" class with selection predicates originated at the "part" classes.

INTRODUCTION

Computers in the workplace are a given. Although the advantages of computers are well-known and proven, many people still try to avoid using them. It is extremely important to find out which factors influence the success of end-user computing. What are the reasons that some people excel on a computer while others have problems and even build up a resistance toward the use of computers?

This chapter provides a literature-based overview of computer attitude and computer anxiety as factors that influence a user's resistance, commitment, and achievement. A graphic model, according to which the interactions between computer attitude and anxiety, their causes, indicators, and impacts may be understood, is proposed. It is put forth that external strategies to deal with anxiety and a negative attitude are imperative to break down a snowballing effect of cause and effect and to ensure effective end-user computing.

BACKGROUND

Computer Attitude

Gordon Allport (1935) defined the concept of attitude, in general, as follows: "An attitude is a mental and neural state of readiness, organized through *experience*, exerting a directive or dynamic *influence* upon the individual's *response* to all objects and situations with which it is related" (p. 810). In other words, attitude is determined by experience and impacts upon the individual's behavior.
